Methods: In 42 patients with SSc, presence of NP was assessed using the PainDetect questionnaire and subsequently confirmed by neurological evaluation. Patients with previously diagnosed neurological disorders and diabetes were excluded. Relationship between NP and disease status, symptoms of depression and quality of life was investigated. Index of disease status (IDS) was assessed using the Scleroderma Assessment Questionnaire (SAQ), occurrence of depressive symptoms using the Beck’s Inventory (BDI), and quality of life was evaluated using the EQ-SD index. In order to evaluate possible causes of NP in SSc, all patients with NP, except one (who did not agree with further assessments) underwent detailed neurological and electroneurography (ENG) examination, as well as HgbA1C and vitamin B12 level testing.

Results: 12/42 (28.6%) of patients were found to have NP. Patients with and without NP were similar in age and disease duration. NP was found more frequently in patients with IcSSc (32.3%), than in dcSSc (18.2%), as well as in patients with ACA (46.7%) compared to patients with ATA (17.6%) and both ACA and Anti-RNA polymerase antibodies, but the differences were not statistically significant. Patients with NP had significantly higher mean values of IDS (1.28 vs 0.66) and BDI (18.3 vs 9.9) than patients without NP (p<0.01). Mean value of the EQ-SD index was significantly lower in patients with NP (0.39 vs 0.79, p<0.01).

Conclusion: The presence of NP was significantly associated with the presence of SSc. There was a significant decrease in EQ-SD and scores of Beck’s Inventory and present higher level of depression in patients with NP. The findings are consistent with previous studies. Further studies are needed to better understand the complex mechanisms underlying the development of this frequently occurring NP.
MORTALITY PROFILE IN SYSTEMIC SCLEROSIS: A LARGE RETROSPUNCTIVE POPULATION-BASED STUDY FROM BRAZIL

R.P. Rezende 1, R. Gismondi 1, H. Maleh 1, M.L. Rosa 2, R. Ramos 1, L.O. Mocarzel 1.

Background: Systemic sclerosis (SSc) is an uncommon autoimmune multisystem disease associated with reduced life expectancy compared with the general population.1 In order to prolong survival of this patient population, clear information on the most important death-related conditions is undoubtedly necessary. No mortality data in SSc, however, are available from Latin America, as well as few large series studies have been done at the mortality profile in SSc.

Objectives: We aimed to describe the causes of death in SSc occurred in the state of Rio de Janeiro, Brazil, from 2006–2015, and also to compare the data gathered with the general population mortality.

Methods: All death certificates issued in the state of Rio de Janeiro, Brazil, from 2006–2015 were screened for the code attributed to SSc according to the tenth revision of the International Classification of Diseases (ICD-10), either as an underlying (UD) cause of death (also referred to as basic cause of death) or a non-underlying (non-UD) cause. In addition to compiling the causes of death in both settings, we also non-adjusted as well as the age bracket-adjusted (age at death ≤50 years and ≥50 years) mortality ratio against the general population for each cause of death when SSc was listed as a non-UD cause.

Results: Of 1,294.491 fatalities recorded over the study period, ICD-10 code for SSc was listed on 374 (0.02%) death certificates, being a basic cause of death on 223 occasions and a non-UD cause on 151 occasions. The overall mean (SD) age at death in SSc was 58.7 (15.6) years, with men (n=56) having an earlier mean age at death than women (n=318) [53.5 vs 59.6 years, respectively; p<0.004]. For SSc as a basic cause of death, the main non-UD causes were respiratory system diseases had a strong impact on mortality, as evidenced by previous publications.1 Although microvascular and macrovascular abnormalities frequently coexist in disease such as diabetes mellitus and other vascular diseases, the possible association between microvascular failure and macrovascularopathy in SSc patients have been only recently described.2

Objective: The aim of the study was to estimate in SSc patients the relationship between the function by serum enzyme-linked immunosorbent assay. We serially measured serum anti-MDA5 antibody, and neopterin and IL-18 as markers of activated macrophage by serum enzyme-linked immunosorbent assay. We tracked them at three points in each patients: before treatment, soon after a series of intravenous cyclophosphamide pulse therapy (about 3 months later after onset) and the remission status (about one year later after onset).

Methods: Thirteen anti-MDA5 positive CADM patients were enrolled. We measured serum anti-MDA5 antibody, and neopterin and IL-18 as markers of activated macrophage by serum enzyme-linked immunosorbent assay. We tracked them at three points in each patients: before treatment, soon after a series of intravenous cyclophosphamide pulse therapy (about 3 months later after onset) and the remission status (about one year later after onset).

Results: Four patients died soon after the initial treatment because of the deterioration of RPILD. At onset of the disease, the levels of serum anti-MDA5 antibody and neopterin were extremely high (169.75±24.3 index and 27.6±24.1 nmol/l) in all patients. However serum IL-18 level was almost normal (479.3±501.4 pg/ml). Among the 9 surviving patients, it took about one year for anti-MDA5 antibody level to decrease to the normal range. On the other hand, neopterin level decreased quickly after the initial treatment. The level of anti-MDA5 antibody transitioned from 169.75±24.3 index to 93.1±50.1 index, and then to 44.8±54.5 index (P<0.003). Neopterin level transitioned from 27.6±24.1 nmol/l to 9.1±6.5 nmol/l, and then to 6.4±5.0 nmol/l (P<0.006). IL-18 level transitioned from 479.3±501.4 pg/ml to 246.0±175.8 pg/ml, and then to 233.2±180.1 pg/ml (P<0.02). The level of anti-MDA5 didn’t correlate with the level of ferritin (r=0.28), neopterin (r=-0.16), IL-18 (r<0.08) and soluble IL-2 receptor (r<0.27), but the level of anti-MDA5 antibody decreased quickly after the initial treatment.
of neopterin was well correlated with the level of ferritin (r=0.95), IL-18 (r=0.77) and soluble IL-2 receptor (r=0.75).

Conclusions: Anti-MDA5 antibody titer is useful if the patients could reach and maintain the remission or not. Serum neopterin level is useful to predict the clinical status at present for therapeutic indication.

Osteonecrosis of the Lunate Bone Associated to Systemic Sclerosis

M. Uop Vitalletta, S. Zegarra Mondragón, W.A.A. Sifuentes Giraldo, C. de la Puente Bujidos, M. Vázquez Diaz. Rheumatology, Ramon y Cajal University Hospital, Madrid, Spain

Background: Osteonecrosis of the lunate bone (OLB), also known as Kienböck’s disease, is a rare disorder that has been recently reported in several patients with systemic sclerosis (SSc).1, but still it is not clear if this is only a coincidence of 2 rare disorders or whether OLB is a potentially under-recognized manifestation of SSc.

Objectives: To describe the clinical features of patients with SSc seen in a Spanish tertiary care center, who develop OLB.

Methods: We performed a retrospective observational study that included patients followed in our center between January 2010 to December 2015. Demographic data, clinical and laboratory features, risk factors for osteonecrosis, imaging, treatment and outcome were collected.

Results: A total of 115 SSc patients were identified and 4 of them (3.47%) developed OLB. Mean age of these patients was 58.5 (range: 52–73), being all women. 2 cases were limited cutaneous SSc ( lcSSc) and 2 cutaneous diffuse SSc. 3 cases showed antitopoisomerase I antibodies, but none presented anticitodiolipin antibodies nor had previous thrombotic events. Mean disease duration was 13.5 years (range: 7–17). One patient was ex-smoker, but none had alcohol consumption, and one case was hypertensive. All patients had vascular manifestations (severe Raynaud phenomenon, digital ulcers in treatment with endothelin antagonists and perfusion of iv prostaglandins, and one case had critical digital ischemia); all the patients showed calcinosis in the upper limbs, and they also had joint involvement (50%), gastrointestinal (100%), and pulmonary (50%) manifestations. History of reloged corticosteroid therapy at low doses (prednisone 5–10 mg/day) was present in all cases and was discontinued one year before the onset of osteonecrosis in one case. OLB was unilateral right in 3 cases and bilateral in one case. The patients presented with clinical pain and/or swelling in the affected wrist in the months prior to diagnosis of OLB, which was evidenced by simple radiography, MRI and bone scintigraphy. One of the cases also showed extensive synovitis in the affected wrist and another one developed collapse of the lunate bone with displaced fragment and edema. Treatment was surgical in 25% of the cases (proximal carpectomy), and conservativin in the rest. Among the total SSc population studied there was another case of lcSSc presenting osteonecrosis of the left talar scaphoid bone.

Conclusions: A total of 15 cases of OLB associated to SSc have been reported to date, so it could be an underestimated disease-associated feature of SSc. It has been suggested that its etiology is linked to SSc-related vasculopathy and all our cases had evidence of severe vasculopathy. The location and vascularization of the lunate bone should be taken into account, since no case developed osteonecrosis in other common locations despite corticotherapy, and complete occlusion of the distal ulnar artery has been reported in 3 cases of the literature. The presence of pain, with or without wrist inflammation in SSc patients should make us consider OLB, which is probably more frequent than expected, especially when there is evidence of severe SSc-related vasculopathy.

Predictors of Morbidity and Mortality in Patients with Early Systemic Sclerosis: Long-Term Follow-Up from a Single Centre Inception Cohort Study

S. Panopoulos, V.K. Bourina, G. Konstantonis, K. Fragiadaki, P.P. Sfikakis, M.G. Tektontidou. First Department of Propedeutic and Internal Medicine and Joint Academic Rheumatology Program, National and Kapodistrian University, Medical School, Athens, Greece

Background: Several studies have investigated the predictors of morbidity and mortality in Systemic sclerosis (SSc). However long-term follow-up data from inception cohorts of early SSc patients are limited.

Objectives: To identify predictors of morbidity and mortality in a single centre inception cohort of early SSc patients at long-term follow-up.

Methods: Our inception cohort comprised SSc patients who fulfilled the American College of Rheumatology criteria, were recruited within 12 months of disease onset and followed prospectively for at least 3 years. Clinical manifestations, laboratory and lung function tests were recorded for each patient at baseline and at 3rd and 6th years of follow up. Multivariate regression analysis and Cox proportional hazard models were used to identify predictors (clinical manifestations, laboratory and lung function tests at baseline) of morbidity and mortality in SSc, respectively.

Results: A total of 114 patients (96 female, mean age at diagnosis 48.1±13.5 years, 53 diffuse SSc subtype) were included in the study, from January 1997 to December 2012. All patients were followed for at least 3 years and 84 patients for at least 6 years. Twenty (17.5%) of 114 patients died during a mean follow up of 101.8±48.5 months. In multivariate regression analysis predictors for major SSc manifestations at 6 years were: diffuse subtype (OR: 6.2, p=0.015); anti-Scl-70 positivity (OR: 3.9, p=0.05), esophageal involvement (OR: 6.5, p=0.017) and digital ulcers (OR: 8.6, p=0.003) at baseline for the development of pulmonary fibrosis (PF). The presence of digital ulcers at baseline was a predictor for the development of arthritisms (OR: 3.7, p=0.05) and the presence of arthritisms at baseline for the development of pulmonary hypertension (PH) (OR: 5.4, p=0.039). Cox proportional hazard models multivariate analysis revealed that independent predictors of mortality were: male gender (HR: 3.3, p=0.023), diffuse type (HR: 8.7, p=0.004), PF at baseline (HR: 2.7, p=0.05), PH based on echocardiography at baseline (HR: 12.7, p=0.001) FVC <80% (HR: 2.74, p=0.042) and DLCO <60% of predicted value at baseline (HR: 2.97, p=0.016).

Conclusions: Results from long-term follow-up data from a single centre inception cohort indicate that diffuse SSc subtype, anti-Scl-70 positivity, esophageal involvement and digital ulcers at baseline are independent predictors for the development of PF. Male gender, diffuse subtype, PF, PH and decreased FVC and DLCO at baseline are prognostic factors of mortality.

Coadministration of Bosentan Has No Effect on the Pharmacokinetics of Nintedanib

S. Wind1, G. Simons1, J. Bertulys1, C. Coeck2. 1Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; 2SCS Boehringer Ingelheim Comm.v., Brussels, Belgium

Background: Nintedanib is a potent intracellular inhibitor of tyrosine kinases that has been approved for the treatment of idiopathic pulmonary fibrosis and is being investigated as a treatment for interstitial lung disease associated with systemic sclerosis (SSc-ILD). Bosentan is a dual endothelin receptor antagonist used in the treatment of pulmonary arterional hypertension, which is a common comorbidity of SSc-ILD.

Objectives: To ascertain the effect of bosentan on the pharmacokinetics of nintedanib.

Methods: In an open-label, single-centre study, healthy male subjects aged ≥18 and ≤56 years with a body mass index (BMI) =18.5 and ≤29.9 kg/m2 received a single dose of nintedanib 150 mg alone (period 1) followed by bosentan 125 mg twice daily (bid) for 8 days (bosentan loading dose phase on days 1–6) with a single dose of nintedanib 150 mg on day 7 (period 2). The primary endpoints were the maximum plasma concentration (Cmax) of nintedanib and the area under the plasma concentration-time curve from time 0 to the last quantifiable concentration (AUC0-∞) of nintedanib. The secondary endpoint was the AUC from time 0 extrapolated to infinity (AUC0-∞) for nintedanib.

Results: Thirteen subjects (12 White; mean [SD] age 35.0 [9.8] years and BMI 24.5 [2.5] kg/m2) were treated. All subjects completed the planned observation period. Based on Cmax, AUC0-∞ and AUC0-∞ exposure to nintedanib was similar after a single dose of nintedanib given alone or in combination with multiple doses of bosentan 125 mg bid (Table). Adverse events were reported in 4 subjects (30.8%) on nintedanib alone (period 1), 4 subjects (30.8%) on bosentan 125 mg bid (period 1–6 of period 2) and 2 subjects (15.4%) after administration of bosentan with nintedanib (days 7 and 8 of period 2). All adverse events were mild in intensity.

Conclusions: Coadministration of bosentan 125 mg bid had no effect on the pharmacokinetics of a single dose of nintedanib 150 mg.

**FR0412 THE POSITIVE EFFECT OF RITUXIMAB IN PULMONARY FIBROSIS OF SYSTEMIC SCLEROSIS**

P. Kiryttopoulos1, T. Michailidis1, E. Papchianou1, M. Charalampidis2, P. Dimitriadis2, A. Agorastos2, 1Department of Internal Medicine, General Hospital of Veria, Veria; 2Gastroenterology Department, Thaegeneio Hospital of Thessaloniki, Thessaloniki; 3Health Center of Alexandria, Alexandria, Greece; 4Oncology Department, St. Thomas Hospital, London, United Kingdom

**Background:** Pulmonary fibrosis is one of the graven manifestations of Systemic Sclerosis (SSc) and conventional DMARDs therapy has not shown any particular positive effect.

**Objectives:** Our goal was to see whether the elimination of B - lymphocytes through use of anti – CD20 Mab, Rituximab (RTX) would offer to the improvement of the pulmonary function of SSc patients.

**Methods:** We studied 23 SSc patients with pulmonary fibrosis, who received treatment with RTX (n=12) or DMARDs treatment (n=11) for 1 to 3 years (1.9 years). Conventional therapy included azathioprine (n=4), mycophenolate mofetil (n=5), and DMARDs treatment was recorded with FVC improvement in the first year of treatment (FVC 81.3 +/- 12.6 vs FVC 87.4 +/- 11.3 out on the onset of the study and at the first year respectively, p=0.02) when on the other hand DMARDs treated patients didn’t show any FVC improvement at all.

**Results:** All RTX – treated patients did not present any lung HRCT deterioration imaging, in contrast to DMARDS – treated patients who were also submitted to lung HRCT each year of the study, all showing signs of CT imaging deterioration. Similar findings, as far as FVC was concerned, were recorded at the 3rd year of the study (RTX patients, n=6 and DMARDs patients, n=11). 3rd year RTX FVC deterioration of the interstitial pulmonary fibrosis of Systemic Sclerosis. The pathophysiology of this particular fibrosis and the possible molecular role of B-lymphocytes in the inversion of this procedure need yet to be furtherly explored.

**FR0413 ACUTE EFFECT OF ILOPROST ON PERIPHERAL CIRCULATION AS ASSESSED BY VIDEOCAPILLAROSCOPY AND 22-MHZ POWER DOPPLER ULTRASONOGRAPHY**

T. Schioppo1,2, A. Orenti1,3, B. Poracchi1,3, O. De Lucia2, A. Mugro2, P.L. Meroni1,2, F. Ingegnoli1,2 on behalf of OPERA study group. 1Università degli Studi di Milano; 2ASST Pini-CTO; 3Lab of Medical Statistics, Epidemiology and Biometry GA Maccarone, Milano, Italy

**Background:** Vascular involvement is a hallmark of systemic sclerosis (SSc) and it is responsible for some of the most common complications of the disease such as Raynaud’s phenomenon (Rp), digital ulcers (DUs) and pulmonary arterial hypertension. I.V. iloprost (ILO), a prostacyclin analogue, has been shown to be effective in reducing Rp severity, DUs healing and preventing [1].

**Objectives:** To assess the acute effect of ILO on acral circulation as assessed by videocephaloscopy and 22-MHz Power Doppler ultrasonography (PDUS).

**Methods:** 44 SSc consecutive patients fulfilling the 2013 EULAR classification criteria were enrolled. Each patient was evaluated before and immediately after I.V. ILO administration (0.5–2.0 ng/Kg/min for 6 consecutive hours). PDUS was performed at the 3rd and 4th finger of the dominant hand after exclusion of ulnar artery occlusion (UAO). In case of UAO non-dominant hand was examined. Ultrasound investigation was performed with Esaote MyLab 70 VVG by means of linear array transducer (10–22 MHz). Power Doppler settings were standardized (Doppler frequency 14.3 MHz, Gain 55%, PRF 750 Hz). PDUS measurements included sagittal scan of nailbed and fingertip perfusion score of sagittal scan of nailbed and fingertip pre- and post-therapy are shown in Table 1.

**Results:** The study population included 44 SSc patients, 40 (90.9%) women, 35 (79.5%) limited cutaneous SSc, median age 60.2 years old and median disease duration 8 years. 19 (43.2%) had history of DUs, among them 15 had experienced more than one DUs and 1 had active DU at the moment of evaluation. In a study where operator-dependent methodological errors are limited we found that the majority of connective tissue disease patients with PAH showed no difference between baseline RHC-derived PASP or PVR could be predicted by the corresponding changes from baseline in follow-up TTE. RHC and TTE were always performed, each, by the same examiner.

**Conclusions:** In a study where operator-dependent methodological errors are limited we found that the majority of connective tissue disease patients with PAH showed no difference between baseline RHC-derived PASP or PVR could be predicted by the corresponding changes from baseline in follow-up TTE. RHC and TTE were always performed, each, by the same examiner.

**FR0414 CAN ECHOCARDIOGRAPHY REPLACE FOLLOW-UP CARDIAC CATHETERIZATION IN RE-EVALUATION OF PULMONARY ARTERIAL HYPERTENSION? A LONGITUDINAL SINGLE-CENTER STUDY OF 30 CONNECTIVE TISSUE DISEASE PATIENTS**

V.-K. Bourna1, I. Tsaligaris2, L. Raillidis2, D. Konstantonis2, A. Anthi2, S. Orfanos2, S. Panopoulos1, P.P. Sfikakis1. 1First Department of Propedeutic Internal Medicine and Jointed Rheumatology Program; 2Pulmonary Hypertension Clinic, Attikon University General Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece

**Background:** Transthoracic echocardiography (TTE) is well validated for initial assessment of connective tissue disease patients with suspected pulmonary arterial hypertension (PAH). However, in patients with PAH confirmed by the gold-standard method of right heart catheterization (RHC) the role of TTE in their follow-up is less known.

**Objectives:** To test the hypothesis that TTE can replace follow-up RHC in connective tissue disease-associated PAH.

**Methods:** This retrospective study included 30 consecutive patients with systemic sclerosis (n=24) and mixed connective tissue disease (n=6) (mean age±SD: 60±12 years, 87% women), in whom PAH was suggested by TTE and further confirmed by a baseline RHC (pulmonary artery systolic pressure (PASP): 56±19.1, range 25–90mmHg; pulmonary vascular resistance (PVR): 5.9±3.6, range 0.7–14.5). The cohort excluded patients: diabetic cardiopathy (n=4), range 2–7 (L/m²/m²). All 30 patients underwent a second RHC and TTE at follow-up, after 11±6 (range 4–29) months. Ten patients had a 3rd follow-up RHC and TTE 22±7 (range 15–37) months from baseline, thus producing in all 50 pairs of baseline and follow-up measurements. By considering follow-up RHC as the gold-standard, we examined whether clinically meaningful hemodynamic changes (i.e.<15% change from baseline) in either RHC-derived PASP or PVR could be predicted by the corresponding changes from baseline in follow-up TTE. RHC and TTE were always performed, each, by the same examiner.

**Results:** In 68% of comparisons between baseline and follow-up, the latter TTE measurements could safely replace RHC in terms of PASP estimation. Using McNemars test we confirmed that the two methods did not differ significantly (Table 1). When in addition to changes in PASP, PVR changes were also considered, follow-up TTE could again safely replace the second RHC in 70% patient retests (Table 2). Of note, baseline hemodynamic values or TTE measurements did not differ between patients in whom TTE could replace RHC and those in whom the results of the two methods at follow-up were divergent.

**Table 1. McNemars test comparing PASP estimated by repeat TTE to that measured by repeat RHC shows no difference between the two methods**

capillary abnormalities correlate with organ damage in Chinese patients with systemic sclerosis

W.Y. Yeung1, C.C. Mok2, K.L. Lee1. 1Department of Medicine, Pamela Youde Nethersole Eastern Hospital; 2Department of Medicine, Tuen Mun Hospital, Hong Kong, -

Objectives: To study the nailfold capillaroscopic patterns and microangiopathy evolution score (MES) and correlate with the severity of organ damage in Chinese patients with systemic sclerosis (SSc).

Methods: Patients who fulfilled the 2013 ACR criteria for SSC were studied. A full physical examination was performed. Blood was taken for SSC autoantibodies, along with a full lung function test and echocardiogram. The extent of skin involvement was assessed by the modified Rodnan skin score (mRSS). Organ damage of SSc was assessed by the Medsger disease severity scale. A Nailfold capillaroscopic examination was performed by a trained nurse blinded to the medical history of the patients. The following parameters were obtained: (1) capillaroscopic patterns (early, active and late); (2) Degree of enlarged capillaries, giant capillaries, capillary haemorrhages, capillary density, disorganization of vascular array and capillary ramification assessed by a semi-quantitative method; and (3) MES score (sum of capillary density, disorganization of vascular array and capillary ramification). Correlation among the capillaroscopic patterns, individual capillaroscopic parameters and the MES with organ damage was performed by the Spearman’s rank correlation test.

Results: A total of 138 Chinese patients were studied (91.3% women; age 58.36±11.81 years). The median disease duration was 8.14±6.21 years. 39 (28.3%) patients had DcSSc and 99 (71.7%) had LcSSc. Anti-centromere, anti-Scl 70 and anti-RNA polymerase III antibodies were present in 28.6%, 28.5% and 5.6% of the patients respectively. Organ damage was present in all patients, most common being skin (84%), lung (79%), peripheral vascular (74%) and GI tract (46%). The median mRSS was 6 (ICR 2–12). A total of 27 patients (19.7%) had early SSc pattern on capillaroscopy, 40 (29.2%) had active pattern and 68 (49.6%) had late pattern. The median MES score was 3.02 (ICR 1.76–5.25). Patients with late SSc pattern on capillaroscopy had significantly longer disease duration and were more likely to have organ damage in the general, peripheral vascular and lung domains compared to those not having late SSc patterns. The total MES score correlated significantly with organ damage scores in the muscle (Rho 0.188; p=0.029), GI tract (Rho 0.189; p=0.048) and lung (Rho 0.265; p=0.006) domains. Regarding individual components of the MES score, capillary density correlated significantly with scores in the peripheral vascular (Rho 0.460; p<0.001), skin (Rho 0.343; p<0.001), joint/tendon (Rho 0.290; p<0.01), muscle (Rho 0.295; p<0.001) and GI tract (Rho 0.188; p=0.028) and lung (Rho 0.238; p=0.015) damage domains. Enlarged capillaries correlated significantly with scores in the muscles (Rho -0.205; p=0.017) and lung (Rho -0.213; p=0.029) damage domains. Giant capillaries and microhaemorrhages correlated significantly with scores in the peripheral vascular (Rho 0.239; p<0.005 and Rho 0.228; p=0.007) respectively damage domains. Disorganization of capillary array correlated significantly with scores in the lung (Rho 0.253; p=0.009) damage domain. Capillary ramifications correlated significantly with the scores in the kidney (Rho 0.171; p=0.048) damage domains.

Conclusions: In Chinese patients with SSC, capillaroscopic patterns and components of the microangiopathy evolution score were associated with severity of organ damage.

DOI: 10.1136/annrheumdis-2017-eular.5548
Hg. For transcriptome analysis, total RNAs from whole peripheral blood cells were extracted with using PAXgene miRNA kit. After constructing single-stranded, strand-specific libraries, multiplex sequencing was done. After quantifying the expressions of transcripts, differentially expressed genes (DEGs) between exPH and exN group were selected by paired T-test (P < 0.05). And then, hierarchical clustering analysis and pathway enrichment analysis (PathVisio) were performed.

Results: There were no significant differences between exPH and exN group in the result of total skin score, serum BNP, tests of pulmonary function and thermography after 0°C-stress. Positive SSc-related autoantibody was a risk factor for exPH (odds ratio, 1.41); especially, positive anti-RNP seemed to be prominent (odds ratio, 3.21). Based on the 817 DEGs between exPH and exN group, the hierarchical clustering showed major 4 clusters, and one of them consisted of only cases in exPH group. When we focused on 117 genes reported to be for exPH, it is noteworthy that 4 of them including TGF-β induced protein were differentially expressed. Pathway analysis of transcriptome revealed that 22 pathways, such as the hypertrophy model, lung fibrosis and Wnt/B-catenin signaling, were differentially enriched between exPH and exN group.

Conclusions: The paradigm of SSc-PAH management should ideally be aimed at detecting early PVD and starting treatment prior to fulfilling the criteria for PAH. Although detection of early PVD in SSc patients remains a major challenge, exercise DE seemed to be a good, non-invasive method for screening. It is noteworthy that expression changes in some of known PAH-related genes were detected from peripheral blood of exPH patients. It shows the possibility that the therapeutic intervention at early stage of the disease may alter the clinical course.

FRI0419 FACTORS ASSOCIATED WITH STEROID-FREE REMISSION IN PATIENTS WITH INFLAMMATORY MYOPATHIES. A RETROSPECTIVE ANALYSIS OF A SINGLE-CENTER COHORT

Y. Sato1, K. Kobayashi1, K. Minegishi1, S. Ohno1, H. Nakajima2, 1Center for Rheumatic Diseases, Yokohama City University Medical Center; 2Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background: The inflammatory myopathies are a heterogeneous group of connective tissue diseases characterized by muscle weakness and inflammation. Corticosteroids are the standard main treatment for inflammatory myopathies. However, steroid therapy often causes a wide range of side effects. Although immunosuppressive drugs are used as steroid-sparing agents in an effort to prevent disease recurrence, the appropriate duration of steroid use remains unclear.

Objectives: We investigated whether steroid therapy can be safely withdrawn in patients with inflammatory myopathies followed in a single center.

Methods: We retrospectively reviewed clinical charts of 71 consecutive patients (age 51±15.7 y.o., female 69%) who met Bohan and Peter criteria for polymyositis (PM)/dermatomyositis (DM) and modified Sontheimer’s criteria for clinically amyopathic dermatomyositis (ADM), respectively. Steroid-free remission was defined as a 3-month consecutive period of no disease activity without corticosteroid treatment. Factors associated with steroid-free remission were examined.

Results: Of 71 identified patients, 29 patients (40%) were DM, 15 patients (21%) were PM, 9 patients (13%) were overlap myositis, and 18 patients (25%) were ADM. Thirty-seven patients (52%) had muscle weakness, 5 patients (7%) had malignancies and 43 patients (61%) had signs of interstitial lung disease. With a mean follow-up of 6.6±5.0 years, 9 patients (13%) died during follow-up period. The remaining 62 patients were treated with corticosteroids alone or in combination with immunosuppressants. Steroid-free remission was achieved in 21 of 62 patients (34%) patients with a mean time to steroid withdrawal of 5.5±4.0 years. Six of 21 patients (29%) relapsed 1.7±1.7 years after steroid withdrawal. There were no differences in onset of age, disease duration, positive ANA, positive Anti-Jo-1 antibodies, serum creatine kinase levels, maximum dose of corticosteroids, skin, joint and lung involvement between steroid-free group and non-steroid-free group. Elevated inflammatory markers were associated with long-term steroid use (p < 0.038). Concomitant immunosuppressants were more frequently used in non-steroid-free group than steroid-free group (p < 0.002).

Conclusions: Steroid-free remission might be achieved in some patients with inflammatory myopathies.

FRI0418 THE PREDICTIVE PROGNOSTIC FACTORS FOR CLINICAL COURSE OF POLYMYSITIS/DERMATOMYOSITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

Y. Sugiyama1, R. Yoshimi1, M. Tamura1, N. Hamada1, H. Nagai1, N. Tsushida1, Y. Soejima1, Y. Kunishita1, D. Kishimoto1, H. Nakano1, R. Kaniyama1, K. Minegishi2, Y. Asami1, Y. Kirino1, S. Ohno2, H. Nakajima1 on behalf of Y-CURD Study Group. 1Department of Stern Cell and Immune Regulation, Yokohama City University Graduate School of Medicine; 2Center for Rheumatic Diseases, Yokohama City University Medical Center, Yokohama, Japan

Background: Interstitial lung disease (ILD) and concomitant infectious diseases are the predominant causes of death in polymyositis/dermatomyositis (PM/DM). We have already reported that hypocapnea and ILD lesion in upper lung fields are independent prognostic factors. Micro RNA is a non-coding RNA, which has a certain function such as transcriptional regulation. miR-1 has been reported to be associated with myocyte differentiation and to decrease in muscle tissue from patients with inflammatory myopathies.

Objectives: Here we investigated the association of serum miR-1 level with clinical course of PM/DM-associated ILD (PM/DM-ILD).

Methods: We retrospectively analyzed clinical baseline, serum miR-1 level, initial therapeutic regimens, total amounts of PSL, clinical outcomes, and episode of infection of patient with PM/DM-ILD who had received initial treatment at six hospitals associated with Yokohama City University from 2003 to 2016. The serum miR-1 level was measured by quantitative real-time PCR.

Results: One hundred sixty patients (PM 22, DM 51, and clinically amyopathic DM 43) patients were included. The mean age was 56±15 years and 83 were female. As initial therapies, oral PSL, methylprednisolone (mPSL) pulse, intravenous cyclophosphamide (IVCY), and oral calcineurin inhibitor therapies were performed in 113 (97%), 80 (69%), 48 (41%), and 58 (48%) patients, respectively. Forty-one patients had a serious infection at 51±38 days from initiation of immunosuppressants and 10 died of infections. Old age, low PaCO2 and albumin, high LDH and K, high score of ILD, high initial dose of PSL, mPSL pulse, IVCY, calcineurin inhibitor and combination therapy were extracted as risk factors for infection by univariate analyses. A multivariate logistic regression analysis revealed that combination therapy (p = 0.012, OR 2.83), old age (p = 0.024, OR 2.12), high initial dose of PSL (p = 0.024, OR 2.69), low albumin (p = 0.031, OR 3.56), and low PaCO2 (p = 0.038, OR 2.67) were independent risk factors for infection. Serum samples were obtained from total of 14 patients and 13 healthy controls. Serum miR-1 levels in PM/DM-ILD patients before treatment were significantly higher than those in healthy controls (p = 0.047). Also serum miR-1 levels were significantly higher in PM/DM-ILD patients with concomitant infectious diseases as compared to patients without infectious diseases (p = 0.043). We further divided the PM/DM-ILD cases into two groups by the serum miR-1 level. The higher miR-1 group showed poorer effectiveness of ILD treatment (p = 0.040), and lower lymphocyte count (p = 0.013) as compared to the lower miR-1 group.

Conclusions: Appropriate monitoring is important for PM/DM-ILD, especially in older patients with malnutrition or decreased respiratory function. miR-1 can be a new biomarker for predicting treatment response and concomitant infectious diseases during treatment for PM/DM-ILD.

Spondyloarthropathy - etiology, pathogenesis and animal models

FRI0420 ASSOCIATION OF SUPPRESSOR OF CYTOKINE SIGNALING -3 (SOCS-3) EXPRESSION WITH INTERLEUKIN-23 RECEPTOR (IL-23R) SINGLE NUCLEOTIDE POLYMORPHISMS (SNPS) IN ANKYLOSING SPONDYLITIS (AS)

M.A. Sánchez1, R. Villareas2, J. Polo y La Borda3, J. Campos3, J.M. Rodríguez-Grande1, J. Sanz2, B.J. Robles Flores2, A. Royuela1, P. Lucas2, M. Mellado1, J. Mulelo1, 1Rheumatology, Instituto de Investigación Biomédica Hospital Universitario Puerta de Hierro Majadahonda; 2Clinical Biostatistics Unit, Instituto de Investigación Biomédica Hospital Universitario Puerta de Hierro Majadahonda; 3Immunology and Oncology Department, Centro Nacional de Biotecnología. CNIC. Madrid; 2Rheumatology; 3Clinical Biostatistics Unit, Instituto de Investigación Biomédica Hospital Universitario Puerta de Hierro Majadahonda; 4Clinical Biostatistics Unit, Instituto de Investigación Biomédica Hospital Universitario Puerta de Hierro Majadahonda. Madrid (Spain); 1Immunology and Oncology Department, Centro Nacional de Biotecnología. CNIC. Madrid; 2Rheumatology; 3Clinical Biostatistics Unit, Instituto de Investigación Biomédica Hospital Universitario Puerta de Hierro Majadahonda; 4Clinical Biostatistics Unit, Instituto de Investigación Biomédica Hospital Universitario Puerta de Hierro Majadahonda. Madrid (Spain)

Background: Nowadays genetic-association studies have discovered new genes, other than HLA-B27, as IL-23R associated with AS. The signalling pathway through IL-23R is negatively regulated by the SOCS proteins. However, the reports regarding the roles of SOCS in AS are very rare at present.1,2

Objectives: The aim of this study is to assess the gene expression of SOCS-1,
Dysregulated miR-125 promotes joint angiogenesis

Methods: We studied 74 patients (64.8% males) recruited from the Rheumatology Unit of the Puerta de Hierro Hospital diagnosed of AS following the Modified New York Criteria. The study cohort included patients with a mean age of 55.2±11, 2 years of follow-up (Statistical analysis: Kruskal-Wallis and reverse transcribed into cDNA. mRNA expression was assessed by real-time quantitative RT-PCR using specific primers and Power SYBR Green PCR Master Mix (Applied Biosystems). SNP genotyping [rs1129026 (G/A), rs10489629 (T/C), rs1343151 (G/A) rs2201841 (C/T), rs1004819 (C/T) y rs11209032 (A/G)] was performed using the Sequenom MassARRAY platform. In 17 cases there were two samples from the same patient. These samples were obtained from two scheduled visits and 99 samples were analyzed. To determine the effect of independent variables on levels of SOCS genes expression, we fitted population-averaged mixed-effects linear regression models, nested in a random intercept, using the xtgee command of Stata v12. P-values of <0.05 were considered statistically significant.

Results: Cellular SOCS-1, -2 and -6 expression did not show significant differences between the risk alleles carriers and the protective alleles carriers in any of the IL-23R SNP studied. SOCS-3 increased significantly in protective alleles carriers of the IL-23R intronic SNP rs10489629-G (CC-CT-CT, P=0.029), the IL-23R non-synonymous SNP (Arg381Gln) rs11209026-A (AA-GG-GG, P=0.047) and the IL-23R intronic SNP rs1343151-1 (AA-AG-GG, P=0.005).

Conclusions: Higher SOCS-3 expression levels for AS patients carriers of protective alleles of the IL-23R rs10489629-G, rs11209026-A and rs1343151-1 as compared to carriers of risk genotypes could influence the pathogenesis of this disease.

FRI0421 | DYSREGULATED MIR-125 PROMOTES JOINT ANGIOGENESIS IN PSA THROUGH ALTERED BIOENERGETICS

S. Wade 1, N. Ohnesorge 2, M. Biniecka 3, S. Merrigan 2, T. McGarry 1, M. Canavan 1, D.J. Veale 4, B. Kennedy 5, U. Fearon 1, 1Molecular Rheumatology, Trinity Biomedical Sciences Centre, Conway Way, University College Dublin; 2St Vincent’s University Hospital, Dublin, Ireland

Background: Psoriatic arthritis (PsA) is characterised by an early vascular phase which is essential in perpetuating pannus growth, immune responses and disease progression. Recently, numerous studies have highlighted the emerging importance of endothelial cell metabolism in controlling angiogenesis. Herein, we propose microRNA, miR-125, modulates EC bioenergetics and orchestrates joint angiogenesis as characterised using ex vivo and in vivo tissue/cell assays and a novel in vivo model.

Objectives: To examine the relationship between miR-125, angiogenesis and cellular metabolism in the PsA synovium.

Methods: Primary PsA synovial fibroblasts (PsA FLS) and microvascular endothelial cells (HMVEC) were transfected with anti-miR-125a. Angiogenic mechanisms were quantified using tube formation assays, invasion by Transwell Matrigel chambers, migration by wound repair and metabolic gene expression by RT-PCR. Real-time analysis of extracellular acidification rates (ECAR) and oxygen consumption rates (OCR) of anti-125 treated HMVEC was assessed using the XF-24 Flux Analyzer (Seahorse Bioscience). To determine if altered metabolic gene expression was associated with microRNA expression, the IL-23R and the IL-23R gene expression levels were assessed in early undifferentiated arthritis (EUA) and PsA patients.

Results: In vivo angiogenic effects of miR-125 were assessed using the Zebrafish model. A significant increase in tube formation, cellular invasion and/or migration was observed in anti-miR-125a morpholinos treated Zebrafish as compared to control. miR-125 significantly decreased basal, maximal and stimulated glycolysis as characterised using the XF-24 Flux Analyzer (Seahorse Bioscience).

Conclusions: Our data demonstrates decreased expression of miR-125 in PsA synovium and in vivo models was strongly associated pro-angiogenic mechanisms. Elevated glycolysis following miR-125 inhibition may enables endothelial cells to meet the increased energy and biosynthetic demands for new vessel formation. Correcting these deficiencies and their resulting metabolic shift, either by using a novel drug target, may provide therapeutic benefit, especially in early disease.

FRI0422 | ESTROGEN ATTENUATES THE DISEASE ACTIVITY OF SPONDYLOARTHRITIS IN SKG MICE

H. Jeong 1, E.-K. Baek 2, Y.H. Eun 1, I.Y. Kim 1, E.-J. Park 3, J. Lee 1, E.-M. Koh 1, H.-S. Cha 1, 1Samsung Medical Center; 2Samsung Biomedical Research Institute, Seoul; 3Jeju National University Hospital, Jeju, Korea, Republic Of

Background: Ankylosing spondylitis is a male-predominant disease, and the male gender is also associated with more severe radiographic damage. Estrogen modulates immune-related processes such as T cell differentiation and cytokine production.

Objectives: This study aimed to evaluate the role of estrogen in the disease activity of spondyloarthritis (SpA).

Methods: The effects of estrogen on the development of arthritis were evaluated by performing an ovariectomy and E2 pellet implantation in the zymosan-treated SKG mouse. Clinical arthritis scores were measured and PET-CT was performed to quantify joint inflammation. Total RNA was extracted from the hindpaws and perepaws and the expression of TNFα, IL-6, IFNγ, IL-4, IL-17A, IL-23, Dkk1, and SOST was measured by Quantigenie 2.0 plex assay. Results: Zymosan exposure triggered SpA-like diseases in SKG mice, including peripheral arthritis, spondylitis, dactylitis, enthesitis, and psoriatic skin lesions. E2-treated mice showed remarkable suppression of arthritis clinically and little infiltration of inflammatory cells in the Achilles tendon and intervertebral disc.

Conclusion: Estrogen suppressed arthritis development in SpA model of SKG mouse. Results of the study suggest that estrogen may have an anti-inflammatory effect on the disease activity of SpA.

FRI0423 | ANTIBODIES TO TYPE II COLLAGEN: A NOVEL TOOL FOR THE SPONDYLOARTHRITIS DIAGNOSIS?

C. Vinci 1,2, M. Infantino 3, P. Pozzilli 1, V. Grossi 1, M. Manfredi 2, F. Bandinelli 4, F. Li Gibbo 1, A. Damian 5, R. Strollo 6, M. Benucocci 7, A. Nissim 8, 1Bioclinical Pharmacology, Queen Mary University of London, London, United Kingdom; 2Endocrinology and Diabetes, Campus Biomedico, Rome; 3Immunology and Allergology Laboratory Unit; 4Rheumatology Unit, San Giovanni di Dio Hospital, Florence, Italy

Background: Spondyloarthritis (SpA) is an inflammatory joint disease with chronic, progressive, axial inflammation of the spine and the sacroiliac joints. Diagnosis of SpA is done criteria by clinical symptoms, radiology and MRI or ultrasound following ASAS criteria. AS is similar to rheumatoid arthritis (RA) and psoriatic arthritis (PsA) as they are all inflammatory joint disease. Nevertheless they show considerable different pathology.

Objectives: The aim of our study is to test whether a novel assay that we developed for RA can be used for SpA diagnosis. We have previously showed that antibodies to oxidative post-translational modified collagen type II (oxPTM-CII) are present specifically in RA patients whether ACPA positive or negative. [2] Our study intends to investigate the reactivity to oxPTM-CII in SpA patients in comparison to other inflammatory diseases (PsA, EUA) and newly diagnosed SpA.

Methods: oxPTM-CII were generated using ribose and various reactive oxidants, and then they were analysed by SDS-PAGE. Binding to native and oxPTM-CII was evaluated by ELISA and Western Blotting. We used a cohort of sera from 67 patients with SpA, 54 patients with PsA, 49 patients with EUA. As control we used 80 patients with fibromyalgia (FM) and 70 healthy subjects. The specificity of the binding was further assessed by competitive ELISA and western blot.

Results: We detected stronger reactivity to SpA compared to PsA and even EUA serum samples. Hence specific binding to oxPTM-CII was seen in the 52% of SpA sera compared to 12% in PsA and 10% in EUA. There was no binding in samples from FM and healthy individuals. A group of the most reactive SpA samples was evaluated by western blot confirming a strong binding to several fragments or aggregates of oxPTM-CII.

Conclusion: For the first time we demonstrated that anti-ROS-CII may become a novel biomarker for SpA diagnosis.

References:
Background: Previous studies indicated a potential role for mucosal-associated invariant T (MAIT) cells in the pathogenesis of ankylosing spondylitis (AS)\(^1\),\(^2\). Active peripheral arthritis and extra-articular manifestations may influence the presence of circulating MAIT cells in AS.

Objectives: To investigate circulating MAIT cells in a homogeneous group of axial spondyloarthritis (SpA) patients with only axial involvement in comparison to age- and sex-matched healthy controls (HC). Secondly, to explore the association of MAIT cells with symptom duration and disease activity.

Methods: Consecutive axial SpA patients from the Groningen Leeuwarden axial SpA (GLAS) cohort without active peripheral arthritis, inflammatory bowel disease, psoriasis or uveitis were included. Patients with active infections or current use of biologics were excluded to rule out possible influence on the presence of circulating MAIT cells. Disease activity was assessed using ASDAS, BASDAI, and serum CRP levels.

The frequencies and absolute numbers of circulating MAIT cells were examined in peripheral blood of all studied patients by 5-color flow cytometry. Immediately after sampling, EDTA-blood was stained with anti-CD3, anti-CD8, anti-TCRVa7.2, anti-CD161, and anti-TCR\(\gamma\)\(\delta\). After staining, the cells were washed, fixed, and analyzes immediately on FACS. MAIT cells were identified phenotypically as CD3\(^+\)CD8\(^+\)TCRVa7.2\(^+\)CD161\(^{high}\) cells.

Results: Of the 41 included axial SpA patients, mean age was 46±16 years, 73% were male, mean symptom duration was 23±14 years, and 78% were HLA-B27 positive. Mean ASDAS was 2.6±1.0, mean BASDAI was 4.4±2.5, and median CRP was 3 (range 2–30). 70%, 54% and 37% of axial SpA patients had ASDAS ≥2.1, BASDAI≥4 or CRP≥5, respectively. HC had exactly the same age and sex distribution.

Both the percentages and absolute numbers of circulating MAIT cells were comparable between axial SpA patients and HC (Figure 1). In axial SpA patients, absolute numbers of MAIT cells correlated negatively (rho=-0.339) with symptom duration. No significant associations were found between MAIT cells and disease activity, except for a negative correlation (rho=-0.332) between frequency of MAIT cells and BASDAI (Table 1).

<table>
<thead>
<tr>
<th>Table 1. Association of percentages and absolute numbers of MAIT cells with symptom duration and assessments of disease activity in axial SpA patients (n=41), Spearman correlation coefficients</th>

regarding IL23 (276 vs 262 pg/ml, p<0.05) and IL17 levels (184 vs 223 pg/ml, p<0.02). Only 22 (6.6%) AS patients carried the protective rs11209026 A allele, while 206 (61.7%) carried the rs11209023 A risk allele (p=0.003). There was no demonstrable influence of individual genotypes (A vs G, AA vs AG vs GG) or haplotypic combinations on BASFI, spinal function tests, CRP, ESR, IL-23 or IL-17 levels (all p>0.05).

Conclusions: While there is a high prevalence of the IL-23R rs11209023 A risk allele in Caucasian AS patients, this has no demonstrable bearing on clinical disease measures or serum IL-23 and IL-17 levels.

Collantes-Estevez 2, 1IMIBIC/Reina Sofia University Hospital/Cordoba University; 1IMIBIC/Reina Sofia University Hospital Cordoba University; CIBERObn and ca13; Cordoba, Spain

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease, of unknown aetiology, associated to the development of several comorbidities such as atherosclerosis. Splicing is a post-transcriptional process involved in the RNA maturation. Recent studies have revealed that a pathological dysregulation of the splicing machinery or splicosome is associated to several human diseases. Yet, the splicing alterations have not been described in AS.

Objectives: To analyze the dysregulation of the splicing machinery in patients with AS. To evaluate the association between the alteration of this process and the clinical, inflammatory, oxidative, and atherogenic profiles present in this pathology.

Methods: Fourteen AS patients and 14 healthy donors (HDs) were included in the study. Disease function and activity status were analyzed using the BASFI and BASDAI. The expression of selected components of the major (n=12) and minor-spoolosome (n=4), and splicing factors (n=28) was evaluated in purified monocytes, lymphocytes and neutrophils from patients and HDs (n=14 each) by Fluidigm methodology. Oxidative stress, inflammation and atherogenicity were evaluated by flow cytometry and ELISA. Endothelial function was determined by the post occlusive hyperaemia test using Laser-Doppler.

Results: Compared to HDs, a significant dysregulation in the expression of relevant splicing factors and splicosome components was found in all the leukocyte subtypes from AS patients, being neutrophils which displayed higher numerical differences, particularly in a specific subset of monocytes and minor-spoolosome members, and splicing factors was observed when compared lymphocytes (U4, U6, NOA1, RMB17), monocytes (PRP8, SF3B2 TV2, CELF4, ESRR2, RBM3, SAM68 TV1, SRSF10, TIA1) and neutrophils (U11, U2, U2AF2, U11, CA 150, ESRR1, PSF, PTB, SRM160).

**THE JAK1-SELECTIVE INHIBITOR, FILGOTINIB, INHIBITS INFLAMMATION PATHWAYS OBSERVED IN AN IL-23-INDUCED PSORIATIC ARTHRITIS MURINE MODEL**

R. Blancañez 1, R. Blanqué 1, C. López-Pedraza 1, S. Pedraza-Arévalo 2, M. del Rosario Gil de Río-Moreno 1, M.C. Ábalos-Aguilera 1, P. Ruiz-Llimón 1, C. Pérez-Sánchez 1, J. P. Castaño 2, M. C. Castro 1, N. Barja-Rosa 1, I. Arias-de la Rosa 1, P. Font 1, A. Escudero 1, J. P. Cañedo 2, R. M. Luque 2, E. Collantes-Estevez 2, 1IMIBIC/Reina Sofia University Hospital/Cordoba University; 1IMIBIC/Reina Sofia University Hospital Cordoba University; CIBERObn and ca13; Cordoba, Spain

Background: JAK1-selective inhibitor filgotinib (GLPG0634, GS-6034) has shown efficacy in PsA but not in Psoriasis, and it has no impact on psoriatic lesions. In this study, we demonstrate the anti-inflammatory activity of filgotinib (4 mg/kg) in an IL-23-induced murine CIA model, which is significant over placebo and results in a significant improvement of the clinical, inflammatory, oxidative, and atherogenic profiles present in this pathology.

Objectives: To evaluate the efficacy of filgotinib in an IL-23-induced murine CIA model.

Methods: Three-week-old C57BL/6 male mice were injected intradermally with 50μg of IL-23 enhanced Episomal Expression Vector (EVE) and treated with filgotinib or vehicle from day 10 (therapeutic mode) and sacrificed after 16 days of treatment. TNFα, IL-19, Mip1 and Tnf were used to determine the proportion of B-cells (CD45+, CD19+) NK cells (CD11b+, CD3+, CD19+) among CD3+ T-cells and T-cells expressing CCR6, a functional marker for IL-17 production, as was observed in mice (2). This is the first report of filgotinib targeting IL-23, as was observed in previous studies.

Results: Sixteen days after treatment, the proportion of T-cells was 26% and 34% in PEB and peripheral blood respectively.

Conclusions: Systemic expression of IL-23 in mice generated a PsA phenotype that was associated with altered gene expression in diseases. A strong interferon signature was reversed by filgotinib as were several inflammatory and disease markers. Together with the stage 2 clinical results in RA and CD, these data support the study of filgotinib for the treatment of PsA patients.
Correlation studies revealed that disease activity (CRP, ESR, BASDAI) was associated to the alteration of a vast number of spliceosome components in the three subtypes of analyzed leukocytes. In addition, the BASFI index correlated with the expression of splicing factors ESPR1, SRSF1 and TRA2B in neutrophils. The inflammatory, athrogenic and oxidative profile of AS leukocytes was related to the expression of a number of spliceosome molecules in the three leukocyte subsets, although neutrophils exhibited the highest number of deregulated spliceosome components related to inflammation (STAT3, TNF-α, IL-1α, IL-1β, IL-5) and cell adhesion (ICAM-1, SELLS, THBS4, CD45). Finally, endothelial dysfunction correlated with the expression of several components of the spliceosome-generating factors in monocytes and neutrophils.

Conclusions: 1) AS patients display a dysregulation of the splicing machinery components associated to disease function and activity. 2) The expression of spliceosome members in the different leukocyte subsets is related to the inflammatory, oxidative and proatherogenic profile of AS patients.

Alteration of the spliceosome may provide new biomarkers for diagnosis and clinical monitoring of AS.

FRIO430 | DUAL TREATMENT OF DISEASE ACTIVITY AND HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. van Tubergen1, M. Imkamp1,2, A. Boonen1, S. Arends3,4, M. Dougados5, R. Landewe5, S. Ramiro2, F. van den Bosch6, D. van der Heijde6, F. Wink4, A. Spoorenberg3,4, V. Lima Passos2, M. Imkamp1,2, A. Boonen1, S. Arends3,4, M. Dougados5, R. Landewe5, S. Ramiro2, F. van den Bosch6, D. van der Heijde6, F. Wink4, A. Spoorenberg3,4, V. Lima Passos2.

Background: The ultimate goal of managing Ankylosing Spondylitis (AS) is to improve and maintain the patient’s health-related quality of life (HRQoL). To reach this goal, rheumatologists target towards low disease activity, as this is the main modifiable factor. To date, there is insufficient insight into (1) the co-evolution of disease activity and HRQoL, and (2) the heterogeneity in such trajectories among patients.

Objectives: To explore the heterogeneity of AS by identifying different temporal patterns of co-dependence between disease activity and HRQoL over 8 years follow-up.

Methods: Data from Outcome in AS International Study (OASIS; n=161) and Groningen Leeuwarden AS (GLAS; n=264) cohorts were used. All patients had an established diagnosis of AS. In GLAS, all patients started a biological. HRQoL and disease activity were measured bi-annually using ASQoL and ASDAS-CRP
respectively. Patients were classified into latent groups with individuals following a similar course of disease activity and HRQoL. These trajectories were estimated by Group-Based Trajectory Modelling. Next, the trajectories were profiled by Group-Based Trajectory Modelling. Finally, multivariate linear regression showed that 61.1% of the variability of HRQoL was mainly characterized by male gender and HLA-B27; improving impact by higher age, younger age, short symptom duration, and biological intake; high impact by higher age, long symptom duration, and (bridging) syndesmophytes (Table). 

Conclusions: We identified five dual trajectories of disease activity and HRQoL, each demonstrating a clear mutual relationship. These trajectories and their profiles provide insight into the heterogeneity of the impact of AS on patients’ health and overall functioning.

CLINICAL WORSENING ACCORDING TO THE PATIENT IS INFLUENCED BY AXIAL SPONDYLOARTHRITIS: RESULTS OF THE ASAS-FLARE STUDY IN 1169 PATIENTS
A. Moltó1, B. Meghnathi1, L. Gossec2, R. Landewé3, D. van der Heijde4
1Observatorio de Enfisema, Madrid, Spain; 2Sorbonne Universités, UPMC Univ Paris 06; AP-HP, Pitié Salpêtrière Hospital; 3Department of Rheumatology, Universiteit Medical Center Groningen, Groningen, Netherlands; 4Rheumatology, University Medical Center Groningen, Groningen, Netherlands

Methods:
Prevalence of flares/worsening of the disease in axSpA is not well known, with prevalences ranging from 10 to 40%.

Objectives:
To evaluate the prevalence of disease worsening according to the patient’s perception in an axSpA population with stable disease and its correlation with disease activity parameters.

Methods: Study: International multicentric (20 countries) longitudinal (2 visits: 1 week – 6 months) observational in 2016, under the guidance of ASAS. Patients: axSpA patients with stable disease according to the rheumatologist. Data on disease characteristics were collected at baseline, and data on disease activity were collected at both visits. Disease worsening was defined at the follow-up visit by the patient using the MCID question (“Think about all the ways your spondyloarthritis has affected you during the last 48 hours. Compared to the last visit how did you feel during the last 48 hours? Improved/No change/Worse”). If patients answered “worse”, they marked if they considered themselves in an acceptable symptoms state (PASS) and whether they considered treatment intensification was necessary. Analyses were descriptive and changes in disease activity were calculated according to patient-reported worsening.

Results: Among the 191 patients included, 1169 patients had complete data. Patients were predominantly males (64.8%), had a mean age and disease duration of 41.7 (SD 12.4) and 12.6 (9.9) years, respectively. History of X-ray sacroiliitis, MRI sacroiliitis and HLAB27+ were present in 944 (80.6%), 471 (40.6%) and 807 (69.0%) patients, respectively. 56% (n=655) patients were receiving a biologic treatment. At the baseline visit, mean BASDAI (0–10) was 1.2, and CRP significantly increased in patients considering themselves worsening, not changed and worsened, respectively. Among the 1639 patients included, 1169 patients had complete data.

Results:
Among the 1169 patients with complete data, 116 patients had stable disease according to the rheumatologist. Data on disease-related factors and disease activity. Univariate logistic regressions and a logistic regression (with a categorical variable respectively) were performed to relate QoL with the studied covariates.

Background: Axial spondyloarthritis (SpA) is associated with several extra-articular manifestations such as the skin disease psoriasis. On the other hand, SpA was found to be more prevalent (3–4%) in patients with another skin disease: hidradenitis suppurativa (HS). HS is a chronic, recurrent, debilitating inflammatory skin disease that involves deep-seated painful nodules in the inverse body regions, with an average prevalence of 1% in the European population and a female predominance (ratio 3:1). Thus far, the prevalence of HS in axial SpA is not exactly known.

Objectives: To investigate the prevalence of HS in patients with axial SpA.

Methods: A self-screening questionnaire with validated questions concerning HS symptoms and signs including prototypical pictures was send to all participating patients from the Groningen Leeuwarden axial SpA (GLAS) cohort in 2016. All patients fulfilled the ASAS axial SpA criteria. Self-reported HS symptoms were verified by checking medical records and/or verification by phone, as defined by HS of a dermatologist.

Results: In total, 588 questionnaires were send to the GLAS patients, of which 459 were returned and could be included in the final analysis (response rate 78%). Of the included patients, mean age was 42±13 years, 63% were male, mean symptom duration was 23±13 years, and 78% were HLA-B27 positive. The questionnaire data showed a high self-reported HS prevalence of 11%. HS symptoms were confirmed by doctor’s diagnosis in the large majority of these patients (45% (51/225), respectively. The next step will be the comparison of patient characteristics and clinical assessments between axial SpA patients with and without HS.

Conclusions: The present observational cohort study shows that HS is a common skin disease in patients with axial SpA.

FRIO0434

POOR QUALITY OF LIFE IN PATIENTS WITH SPONDYLOARTHRITIS IS NOT EXPLAINED BY STRUCTURAL DAMAGE. DATA FROM REGISPONSER

Rheumatology, Hospital Universitario Reina Sofia de Córdoba/ Imibic/ Universidad de Córdoba, Córdoba, Spain

Background: In recent years it has become increasingly important the evaluation of the global impact of the disease in patients with Spondyloarthritides (SpA) through the use of the Patient-reported Outcomes (PROs) (1). One of the most used PROs is the Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire, which refers to Health-Related Quality of Life (HRQoL). Since this is a subjective and multifactorial outcome (2), our goal is to detail the most important factors which are related in these patients.

Objectives: To evaluate QoL in patients with SpA and to define its association with disease-related factors and patient’s features.

Methods: A cross-sectional multicenter study which includes 2229 patients with SpA selected from the national Spondyloarthritides Spanish Registry (REGISPONSER). The main outcome was the assessment of QoL performed through the ASQoL questionnaire. Subsequently, we studied its relation with different factors organized into 5 groups: sociodemographics, emotional, functionality, disease-related factors and disease activity. Univariate logistic regressions and a multiple linear regression (considering ASQoL as a qualitative variable and quantitative variable respectively) were performed to relate QoL with the studied covariates.

Results: The mean ASQoL score in the entire population studied was 6.09±5.12. The average age was 47.7±13.26 years old and 698 (31.31%) were women. In univariate logistic regressions, significant differences (p<0.05) were seen in many variables included in the 5 groups: poor QoL (ASQoL<9) is related with gender (female), age, mental and physical component from SF-12 questionnaire, disease duration, inflammatory back pain (IBP), alternating buttock pain, BASFI (Bath Ankylosing Spondylitis Functional Index), BASDAI (Bath Ankylosing Spondylitis Functional Index), BASDI (Bath Ankylosing Spondylitis Disease Activity Index), ESR (Erythrocyte Sedimentation Rate) and global patient’s VAS (Visual Analogue Scale), among others.

Finally, multivariate linear regression showed that 61.1% of the variability of ASQoL (R² =0.611, p<0.001) is explained by sex (female), physical component and 2nd item form SF-12 questionnaire (related to functionality), 6th and 7th items form SF-12 (both related to mental status), global patient’s VAS, BASFI and BASDAI.

Conclusions: Poor QoL in SpA patients can be explained by high disease activity
and by a deterioration in functionality and mental status. However, clinical form of SpA, disease duration and structural damage in spine do not explain this decrease of QoL.

COMPARISON BETWEEN CENTRAL AND LOCAL ASSESSMENT OF RADIOGRAPHIC SACROILIACITIS IN PATIENTS WITH RECENTLY DIAGNOSED AXIAL SPONDYLODIRARTHROPATHY IN PROOF STUDY
D. Poddubnyy1, R.D. Inman2, J. Sieper3, H. Haibel1, M. Hoijnik1, 1Charité Universitätsspitze Berlin, Berlin, Germany; 2Toronto Western Hospital, Toronto, Canada; 3AbbVie, Ljubljana, Slovenia

Background: High inter-reader variability of radiographic sacroiliitis assessment has been reported in a number of previous studies, suggesting its low reliability for the diagnosing and classification of axial spondylodirarthropathy (axSpA).

Objectives: To compare the results of local versus central scoring of radiographic sacroiliitis in a large multinational cohort of patients (pts) with recently diagnosed axSpA.

Methods: PROOF is a prospective observational study evaluating clinical and radiographic outcomes in axSpA pts in rheumatology clinical practice in 29 countries. Pts with axSpA fulfilling ASAS classification criteria were eligible if diagnosed ≤1 year prior to study enrolment. Radiographs of sacroiliac joints (SJ) collected at baseline were graded according to the modified New York (mNY) criteria (0–4 for each SJ). Pts with sacroiliitis of grade ≥2 bilaterally or grade ≥3 unilaterally were classified as ankylosing spondylitis (AS); otherwise pts were classified as non-radiographic axSpA (nr-axSpA). All available radiographs were assessed first by a local reader (LR) and then by a central reader (CR1), who was blinded to the results of the LR. In the case of a disagreement in the classification (AS or nr-axSpA), the radiograph was evaluated by the 2nd central reader (CR2), who was blinded to the previous assessments and the final classification was made based on the decision of 2 out of 3 readers.

Results: Of the 2126 pts enrolled in PROOF, 1583 were included in this analysis based on available radiographs of the SJ. Based on the LR judgment, 987 pts were classified as AS and 596 as nr-axSpA, while 1158 were classified as AS and 425 as nr-axSpA according to CR1. Following CR1 assessment, 1146 (72.4%) pts retained their LR classification, while 437 (27.6%) pts were classified differently. Of the 437 pts with discrepant classification assessed by CR2, 175 (72.4%) pts retained their LR classification, while 437 (27.6%) pts were classified as non-radiographic axSpA (nr-axSpA). All available radiographs were assessed first by a local reader (LR) and then by a central reader (CR1), who was blinded to the previous assessments and the final classification was made based on the decision of 2 out of 3 readers.

Conclusions: In the PROOF study, the agreement between local and central classification of pts with nr-axSpA vs AS was significant. Pts classified as nr-axSpA by LR were three times more likely to be re-classified compared with AS pts, which may be related to difficulty in the assessment of less advanced structural changes.

FR0436 | CHRONIC PAIN IN PATIENTS WITH ESTABLISHED AXIAL SPONDYLODIRARTHROPATHY AND ASSESSMENT OF PAIN SENSITIVITY BY COMPUTERIZED PNEUMATIC CUFF PRESSURE ALGOMETRY: RESULTS FROM THE SPARTAKUS COHORT
E. Mogard1, T. Olofsson1, A. Breemander2, S. Bergman3, L. E. Kristensen4, J. Kvistgaard Olsen5, J.K. Wallman1, E. Lindqvist1, 1IKVL, Department of Rheumatology, Lund University, Lund; 2School of Business, Engineering and Medicine, Halmstad University, Halmstad; 3Primary health care unit, Department of Public Health and Community Medicine, Institute of Public Health and Community Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 4The Parker Institute Department of Rheumatology, Copenhagen University Hospital Fredriksberg and Bispebjerg, Copenhagen, Denmark

Background: Pain is a common symptom in all arthritides, and remains a problem also with better treatment options. In axial spondylodirarthropathy (axSpA), data on chronic pain remain scarce.

Objectives: To study pain distribution, duration and intensity in axSpA, and relate this to disease status and measurement of pressure pain sensitivity.

Methods: Consecutive patients (n=115) with clinical axSpA diagnoses (ankylosing spondylitis (AS) or undifferentiated axial spondylodirarthropathy (USpA)) were examined and answered a questionnaire. Patients were categorised as having no chronic pain (NCP), chronic regional pain (CRP) or chronic widespread pain (CWP). Pressure pain sensitivity was assessed by computerized pneumatic cuff pressure algometry (CPA) on the dominant lower leg, and pain threshold, pain tolerance and temporal summation (assessed by the temporal summation index, TSI) were recorded. Differences in disease status and pressure pain sensitivity between patients with CWP versus NCP were assessed (Chi-square or Mann-Whitney U-test).

Results: Fifty percent of patients reported CWP, irrespective of clinical diagnosis (AS 47%, USpA 53%), and more men than women reported CWP (59% versus 37%, p<0.001). Only 18% of all patients reported NCP. Overall, higher disease

AS = ankylosing spondylitis; nr-axSpA = non-radiographic axial spondylodirarthropathy.
activity, pain intensity, worse fatigue, global health and function were observed among patients with CWP compared to those with NCP. There was a trend towards lower pain tolerance in patients with CWP compared to NCP (Table). Lower pain tolerance and higher TSI scores were observed among patients reportingVAS pain >40 versus those with VAS pain scores <40 (mean (SD) 51.9 (21.2) versus 68.1 (28.1), p=0.007; 0.73 (0.60) versus 0.55 (0.59), p<0.045).

Conclusions: In this population-based, cross-sectional study of established axSpA, chronic widespread pain was common, affecting 50% of the patients and generally associated with higher disease activity and worse function. CPA shows promising results regarding assessment of pain sensitivity, although larger studies are needed for more conclusive results.

FRIO437 EFFECTS OF ANKYLOSING SPONDYLITIS ON PLANTAR PRESSURE DISTRIBUTION

E. Mesci 1, N. Mesci 2, A. İlçaşoğu 1. 
1Physical Therapy and Rehabilitation, İstanbul Medeniyet University Göztepe Education and Research Hospital; 2Physical Therapy and Rehabilitation, Haydarpaşa Numune Education and Research Hospital, İstanbul, Turkey

Background: It is considered that postural changes that occur in patients with ankylosing spondylitis (AS) are biomechanically compensated for by contribution from movements of hip, knee and ankle joints [1]. The effects of this phenomenon on the foot, the most distant segment of the kinetic chain, have not been fully elucidated.

Objectives: In the present study, our aim was to investigate possible changes in plantar load distribution in AS patients.

Methods: The study enrolled 30 AS patients diagnosed as per modified New York criteria and 30 healthy controls matched for age, gender and body mass index. Bath Ankylosing Spondylitis Metrorolgy Index (BASMI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional Index (BASFI) scores were obtained for all patients. Using a foot pressure platform, the distance from the center of pressure (CoP) to the posterior heel line was measured in centimeters (cm) in both groups (DCoP) (figure 1). Percent total plantar load distribution over the proximal half and distal half of the foot was calculated.

Results: Mean DCoP distance was significantly shorter in AS patients 9.65±0.96 cm in comparison to that of control group (10.41±0.89 cm) (p=0.011). While the percent total plantar pressure applied on proximal half of the foot was 60.46±7.82% in AS patients, it was only 55.96±6.21% in the control group (p=0.031). However, AS patients had less percent pressure applied on the distal half of the foot (39.53±7.62%) versus control patients (44.04±6.21%) (p=0.031), The mean ratio of the percent pressure distribution over the proximal half of the foot, the most distal segment of the kinetic chain, have not been fully elucidated.

Conclusions: Plantar pressure distribution seems to be displaced towards the hindfoot in sagittal plane due to biomechanical changes in patients with ankylosing spondylitis. This points out to the significance of the lower extremities in the compensation of postural changes in AS patients.

FRIO438 RISK FACTORS FOR UVEITIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A RETROSPECTIVE COHORT STUDY

E.E. Lee, M.J. Kim, E.Y. Lee, Y.W. Song, E.B. Lee. Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of

Background: The uveitis is one of the most common extra-articular manifestation of ankylosing spondylitis (AS), occurring in 20–30% of the patients with AS. But it is not clear which factors are associated with the occurrence of uveitis in patients with AS.

Objectives: To evaluate the risk factors for uveitis in patients with AS.

Methods: A total of 1061 Korean patients who were diagnosed with AS at Seoul National University Hospital between January 2004 and December 2015 were evaluated in this study. Using electronic medical record review, the information on the occurrence of uveitis after AS diagnosis and the other demographic and clinical characteristic were obtained, which included, age, gender, disease duration, previous history of uveitis, smoking status, Bath ankylosing spondylitis activity index, HLA-B27 positivity and level of serum inflammatory markers. After dividing the patients into those who experienced uveitis after AS diagnosis (uveitis group) and those who did not (non-uveitis group), the potential risk factors for the occurrence of uveitis were evaluated using univariable and multivariable logistic regression analysis. Receiver operating curve analysis was performed.

Results: Among the 1061 patients, 837 (78.9%) were male and their mean (SD) age was 27.9 (6.2) years. During the observation of 4231 patient-year, uveitis occurred in 142 (13.4%) patients (uveitis group). Patients in the uveitis group had longer disease duration than those in the non-uveitis group (10.0±6.6 vs. 8.2±6.2 years, p=0.003). The proportion of the patients with prior uveitis before diagnosis of AS or HLA-B27 positivity were higher in the uveitis group than those in the non-uveitis group. (58.5% vs. 12.1%, 95.7% vs.83.7%, respectively) There were no significant differences in ESR and CRP between the two groups. In the multivariable analysis, two most significant risk factors for new-onset uveitis was the prior uveitis before the diagnosis of AS (OR=11.18 [95% confidence interval (CI): 7.09–17.63]) and HLA-B27 positivity (OR=9.15 [95% CI: 1.23–68.41]). The area under the curve (AUC) of the final multivariable model was 0.809 (95% CI: 0.77–0.85).

FRIO439 PSYCHIATRIC DISORDERS ASSOCIATED WITH ANKYLOSING SPONDYLITIS

Background: Ankylosing spondylitis (AS) is an inflammatory rheumatic disease characterized by spinal and/or peripheral involvement, enthesitis, dactylitis, and several extra-articular manifestations. Chronic inflammation often leads to reduced spinal mobility and functional disability. The frequency of fatigue, sleep disturbances, and psychological problems has increased in patients with AS.1

Objectives: Although there are studies investigating depression and anxiety frequency in AS patients, different psychiatric disorders such as impulsivity, alexithymia and eating disorders have not been evaluated. The aim of this study is to investigate the frequency of different psychiatric disorders in AS patients, and to evaluate the relationship between these disorders with disease activity and functional status.

Methods: Patients with AS (n=70) and healthy controls (n=56) were included in the study. The Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Functional Index, Bath Ankylosing Spondylitis Metrology

Index (BASMI), pain visual analog scale, Beck depression scale, Beck anxiety scale, Barratt impulsiveness scale, Toronto alexithymia scale, Eating attitude test, fatigue, Ankylosing spondylitis quality of life, and Nothingam health profile were administered.

Results: The frequency of depression, anxiety and non planning impulsiveness were higher in patients with AS than in healthy controls (p<0.05), although no difference was found in terms of alexithymia, fatigue, and eating attitude. Depression and anxiety were correlated with high disease activity, fatigue, impaired physical functioning, and lower quality of life in the patients with AS. Non planning impulsiveness was correlated with fatigue and lower quality of life while there was no correlation with disease activity and functional impairment. BASMI scores were not associated with psychiatric disorders.

<td>21.7±31.18</td>
<td>22.0±13.24</td>
</tr>
</tbody>
</table>

Conclusions: Depression and anxiety were associated with disease activation, while impulsivity frequency was increased independently of disease activity. Reducing in the quality of life and functional competence due to the psychiatric disorders indicates that, AS patients may require a psychological care approach during the follow up.

FR0441 | NECK PAIN IN ANKYLOSING SPONDYLITIS: FOCUS ON ACTIVE INFLAMMATORY AT THE CRANIOCEWAL JUNCTION ON MRI

G. Slobodin 1, I. Rosner 1, A. Avisiat 1, D. Rimar 1, A. Shigpelman 2, D. Militianu 3, 1Rheumatology; 2Orthopedic Surgery, Bni Zon Medical Center; 3Radiology/Musculoskeletal Imaging, Rambam Medical Center, hails, Israel

Background: A wide spectrum of structural changes in the elements of cranio cervical junction in patients with ankylosing spondylitis (AS) has been recently described in a retrospective study using computed tomography [1]. The clinical significance of those findings requires further elaboration.

Objectives: To explore and describe inflammatory MR imaging findings in the cranio cervical junction in patients with AS and neck pain.

Methods: Eighteen patients with AS and continuing neck pain, as well as 9 patients with fibromyalgia of the same age and similar level of severity of neck pain, were recruited as a control group, underwent relevant rheumatologic examination. X-ray of cervical spine and MRI study, which included STIR, CUBE T2, FSE and FSE FAT SAT sequences before and after administration of gadolinium.

Results: In the AS group, 12 males and 6 females diagnosed by 1984 New York criteria, of median age 40.5 years (range 31–61 years) and median disease duration of 8 (range 1–35) years, with 13 under treatment with anti-TNF agents were studied. All patients suffered from neck pain, with median VAS of 7 (range 2.5–10). Range of neck spine motion was limited in all but 3 patients. Seven of 18 patients had evidence of cervical syndesmophytes on X-Ray. In addition to expected findings of syndesmophytes, active inflammatory phenomena were seen in MR imaging in two of 18 patients with AS and in none with fibromyalgia (Fig. 1). Both AS patients with positive MRI were on anti-TNF therapy during the study and did not have syndesmophytes at the cervical spine as also by X-ray films.

Conclusions: Active inflammation of both entheses and joints of the cranio cervical junction was demonstrated by MRI in some patients with AS and persistent neck pain. Active lesions at the cranio cervical junction should be included in the differential diagnosis of neck pain in AS.

FR0440 | PRESENCE OF BONE MARROW EDEMA ON MAGNETIC RESONANCE IMAGING OF THE SACROLIAC JOINTS IN MILITARY RECRUITS BEFORE AND AFTER 6 WEEKS OF INTENSIVE PHYSICAL TRAINING

G. Varkas 1,2, M. de Hooge 1, T. Renson 1,2, F. Van den Bosch 1,2, M. de Hooge 1, T. Renson 1,2, P. Carron 1,2, S. De Mits 3, M. de Hooge 1, T. Renson 1,2, P. Carron 1,2, S. De Mits 3, I. Sung 4, S.-J. Kim. 1Department of Rheumatology, Ghent University Hospital; 2VIB Inflammation Research Centre; 3Department of Rehabilitation Sciences and Physical Therapy, Ghent University, Gent; 4Department of Radiology, Jessa ziekenhuis, Hasselt, Belgium

Background: Studies have shown an increase of bone marrow edema (BME) on magnetic resonance imaging (MRI), especially in feet and ankles of professional athletes and in minimally active healthy controls after mechanical stress [1]. Although this has been described for several joints and across different sport activities, information concerning BME in the sacroiliac joints (SIJ) has not been studied. In axial spondyloarthritis (AxSpA), the presence of 1 BME lesion is expected findings of syndesmophytes, active inflammatory phenomena were seen in MR imaging in two of 18 patients with AS and in none with fibromyalgia (Fig. 1). Both AS patients with positive MRI were on anti-TNF therapy during the study and did not have syndesmophytes at the cervical spine as also by X-ray films.

Objectives: To explore and describe inflammatory MR imaging findings in the cranio cervical junction in patients with AS and neck pain.

Methods: Eighteen patients with AS and continuing neck pain, as well as 9 patients with fibromyalgia of the same age and similar level of severity of neck pain, were recruited as a control group, underwent relevant rheumatologic examination. FR0442 | IDENTIFICATION OF ENTHESITIS AT THE ACHILLES TENDON INSERTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS USING DIGITAL RADIOGRAPHY

I. Sung, S.-J. Kim. Orthopedic Department, Hanyang University Medical Center, SEOUL, KOREA, Seoul, Korea, Republic Of

Background: Posterior heel pain is a common symptom in the foot and ankle region, with many different causes that need to be distinguished by differential diagnosis. Among them is ankylosing spondylitis (AS), in which enthesitis of
the heel is common and occasionally is responsible for their initial symptom to seek clinics. An early or timely recognition of active enthesitis of AS from simple radiographs comes to be relevant issue.

**Objectives:** The purpose of current study is to assess measurement reliability and diagnostic validity for detecting the digital radiographic findings of enthesitis at the Achilles tendon insertion in patients with AS.

**Methods:** Current study is a blinded, matched, cross-sectional study with 44 patients (65 feet) having clinical enthesitis at the Achilles tendon insertion (Group I), and 44 healthy controls (65 feet) (Group II). Suggested findings of enthesitis including retrocalcaneal recess obliterations from retrocalcaneal bursitis, increased thickening in shadow of the Achilles tendon and posterior soft tissue at its insertion from the swellings of those soft tissues were assessed on digital radiographs of standing hindfoot lateral view, and their measurement reliabilities were determined. To investigate diagnostic validities, diagnostic odds ratios (DOR), positive likelihood ratio (PLR), and negative likelihood ratio (NLR) were estimated for radiographic findings of retrocalcaneal recess obliterations (RRO). For the thickness of the Achilles at its insertion (TAI) and swollen posterior soft tissue, the receiver operating characteristic (ROC) curve analysis was done.

**Results:** There were no significant differences between two groups in mean age, BMI and sex ratio. Intra- and inter-observer reliability of all measurements showed high degree of agreements (0.786 to 0.941). The diagnostic odds ratio of RRO for detecting enthesitis was 66.0. The sensitivity, specificity were 92.7%, 66.9%, and PLR, NLR were 8.00, 2.33, respectively. The mean TAI of Group I and II were 4.57mm±2.29, 3.87mm±1.57, respectively (p-value < 0.001). An under the ROC curve of TAI was 0.806, and the optimal cut-off value predicting enthesitis was 5.47mm, and its sensitivity and specificity were both 72.3%

**Conclusions:** Retrocalcaneal recess obliteration and thickened shadow of Achilles tendon at its insertion and swollen posterior soft tissue on digital radiographs of standing hindfoot lateral view are regarded as the easy and useful findings for enthesitis of the posterior heel. For searching enthesitis at the Achilles insertion in patients with AS, such findings from simple radiographs showed high measurement reliability and validity.

**Disclosure of Interest:**
[3] Freedman M, Steller D. Digital radiography of the musculoskeletal system: the radiographs of standing hindfoot lateral view are regarded as the easy and useful tool to both scores was higher in patients with AS+FM. According to the BASDAI in this analysis was 0.1/100PY (Table). The rates of IBD events varied across trials in early ankylosing spondylitis: do we need new criteria? Arthritis and Rheumatism 2005;52(4):1000–1008.

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease that affects the axial skeleton and characterized by pain, stiffness and fatigue [4]. One of the frequent concomitant condition in patients with AS is fibromyalgia (FM), FM shares some common symptoms with AS. According to the many reports concurrent FM in patients with AS has been found in 5.7 - 41.3% cases [1, 2, 3, 5]. Due to the fact that pain is a major component of the disease activity scores of the AS (Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS)), concomitant FM can significantly modify the disease activity in patients with AS.

**Objectives:** The aim of this study was to evaluate the effect of FM on disease activity in patients with AS.

**Methods:** Diagnosis of AS was identified according to the modified New York criteria (1984). FM was diagnosed by ACR criteria (1990). Disease activity was assessed by BASDAI and ASDAS.

**Results:** 80 patients with AS were included into study (15 females and 65 males), age (M ± SD) 41.64±11.4 years. Nineteen patients (23.8%) met the criteria for FM. In both groups, ESR (37.7±18.8 and 39.00±19.6 mm/h) was comparable, while CRP in Group I and II were 4.52±2.11, 3.07±1.56, respectively (p-value < 0.001). Ankylosing spondylitis functional and activity indices in clinical practice. Alan G. MacDonald et al. Rheumatology 2014;53:650–657.

**Introduction**

**Background:** The incidence rates of IBD AEs in ADA clinical trials were generally low (12.7/100 pt-years). The rates of IBD events in patients with AS+FM (patients (pts) who are at higher risk of IBD as a feature of SpA).

**Objectives:** The purpose of this analysis was to determine the rates of IBD adverse events (AEs) in ADA clinical trials, particularly in spondyloarthritis (SpA) patients (pts) who are at higher risk of IBD as a feature of SpA.

**Methods:** The rates of IBD AEs in 73 phase 2–4 interventional ADA clinical trials in rheumatoid arthritis (RA), polyarticular juvenile idiopathic arthritis (pJIA), pediatric enthesitis-related arthritis, uveitis (non-infectious intermediate, posterior, or pan-uveitis), hidradenitis suppurativa (HS), adult and pediatric psoriasis (Ps), psoriatic arthritis (PsA), non-PsA peripheral SpA, non-IBD indications.

**Results:** ADA was administered to 23735 pts, representing 36404.6 PY of exposure. Overall, the IR for IBD events in all interventional ADA trials included in this analysis was 0.1/100PY (Table). The rates of IBD events varied across therapeutic interventions from <0.1 to 0.8/100PY. There were no reports of IBD events in pediatric pts. The IR for IBD events in RA, uveitis, HS, and PsA were <0.1, 0.2, 0.4, and <0.1/100 PY. In SpA, the overall rates of IBD were 0.5/100 PY, while the rates were 0.8, 0.5, and 0.7/100 PY in PsA, non-PsA pSpA, nr-axSpA, and AS, respectively. 2216 pts with axSpA (AS: 2026, nr-axSpA: 190) were exposed to ADA: in AS, 14 IBD events (7 new onset and 7 flares) were reported in 12 pts (7 new onset and 5 flares), while in nr-axSpA, 2 IBD events were reported in 1 pt (2 flares).

**Table. Incidence of IBD events in patients from ADA clinical trials.**

**Table. Incidence of IBD events in patients from ADA clinical trials.**

**No IBD events were reported in pediatric patients.**

| Age | ARA Adult and pediatric patients in all interventional studies excluding Crohn's disease, ulcerative colitis, and intestinal Behcet's disease.
|---|---|
| All ARA patients in all interventional studies of nr-axSpA, psA, non-PsA pSpA, nr-axSpA, and AS.
| All ARA patients in all interventional studies of nr-axSpA and AS.

**Abbreviations:** IBD = inflammatory bowel disease; ADA = adalimumab; PY = patient-years; SpA = spondyloarthritis; Wm = weight; CFRD = concomitant FM and AS.

**Conclusions:** The rates of IBD AEs in ADA clinical trials were generally low across all indications, with all events occurring in adult pts. In AS pts, who are at increased risk of manifesting IBD, the rates of IBD for pts treated with ADA (0.7/100 PY [95% CI, 0.4–1.1]) were similar to published placebo rates pooled
FAecal calprotectin, but not anti-saccharomyces cerevisiae antibodies, is linked to worse disease status in axial spondyloarthritis patients without inflammatory bowel disease: results from the spartakus cohort

T. Olofsson 1, E. Mogard 1, K. Andréasson 1, J. Marsal 2, M. Geijer 2, L.-E. Kristensen 1,4, E. Lindqvist 1, J.K. Wallman 1, Department of clinical sciences Lund, Rheumatology; 2Department of clinical sciences Lund, Gastroenterology, Lund University, Lund; 3Department of Radiology, Faculty of Medicine and Health, Örebro University, Örebro, Sweden;
4The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Frederiksberg and Bispebjerg, Copenhagen, Denmark

Background: Inflammatory bowel disease (IBD) is a common comorbidity in axial spondyloarthritis.

Objectives: To study faecal calprotectin (F-calprotectin) levels and anti-Saccharomyces cerevisiae antibodies (ASCA) and their associations with disease status and gastrointestinal (GI) symptoms in axial spondyloarthritis.

Methods: Consecutive patients with a clinical axial spondyloarthritis diagnosis were examined and classified as non-radiographic axial spondyloarthritis (nr-axSpA) or ankylosing spondylitis (AS; modified New York criteria; n=48). Only patients without known IBD were included. F-calprotectin and ASCA IgA and IgG antibodies in serum were measured by commercially available enzyme-linked immunosorbent assay kits (Calpro AS; ORGENTEC Diagnostika).

Results: Elevated levels of F-calprotectin (>50 mg/kg) were observed in 15% of nr-axSpA and 40% of AS patients (non-significant difference, with reservation for small groups). Overall, worse mean disease activity/disability scores were observed among patients with elevated versus normal F-calprotectin levels (Table), whereas no association was seen between F-calprotectin and GI symptoms. Similar results remained after exclusion of patients with mononuclear type anti-tissue transglutaminase IgA. Elevated levels of ASCA IgA were observed in 8%/2% of nr-axSpA/AS patients, and IgG in 28%/26%. Only 2 subjects were ASCA double positive. Neither disease activity/disability measures nor GI symptoms were associated with ASCA status.

Areya 2, J. Rech 1, M.F. Neurath 1, G. Schett 1, Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany; 2Medical Department 2, St. Vincent Hospital, The VINFORCE Study Group, Vienna, Austria; 3Department of Internal Medicine 1, University of Erlangen-Nuremberg, Erlangen, Germany; 4Div. of Rheumatology, Facultade de Medicina da Universidade de São Paulo, São Paulo, Brazil

Background: Musculoskeletal symptoms are considered as one of the most frequent extra-intestinal manifestation in Inflammatory Bowel Disease (IBD) patients with a prevalence of up to 40% involving axial and/or peripheral joints. Data on the prevalence of musculoskeletal disease, in particular of SpA are limited and vary considerably due to different criteria the studies have used to define musculoskeletal disease in IBD patients.

Objectives: To define the prevalence of axial and peripheral spondyloarthritides (SpA) according to Assessment of Spondyloarthritis International Society (ASAS) criteria in patients with Crohn’s disease (CD) and ulcerative colitis (UC).

Methods: The SPICE cohort (Spondyloarthritis in IBD patients) enrolled 102 IBD patients (62 with CD and 40 with UC) with a median (IQR) disease of 11.0 (18.0) years were assessed. 38.2% fulfilled ASAS criteria for SpA with no difference between CD and UC. ASAS axial SpA criteria were fulfilled by 12%, ASAS peripheral SpA criteria by 31.4% of the IBD patients. Inflammatory back pain was present in 24.5% with MRI signs of sacroiliitis in 48% of IBD patients with inflammatory back pain. Disease activity according to ASDAS-CRP was moderate to high in 91% of the patients with axial SpA. Peripheral arthritis was present in 71.6%, while arthritis was found in 71.6% of the IBD patients.

Conclusions: Both major forms of IBD show a similar burden of musculoskeletal disease. More than one third of inflammatory bowel disease patients show axial or peripheral SpA according to ASAS criteria. Peripheral SpA is more commonly found than axial SpA.

EVALUATION OF SUPPURATIVE HIDRADENITIS IN PATIENTS WITH CHRONIC ARTHRITIS TREATED WITH FULL AND TAPERED BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

Background: Suppurative Hidradenitis (SH) is an inflammatory skin disease which often presents a poor prognosis to treatment. It is a disorder of the apocrine glands (axillary, inguinal and analgenial regions) that can result in infection, inflamed nodules, cysts, abscesses and sinus tracts. There is a 1–4% incidence of SH in patients with spondyloarthropathies and inflammatory bowel disease, possibly due to innate immune system deregulation. The use of biological disease-modifying anti-rheumatic drugs (bDMARD), specifically tumor necrosis factor inhibitors, has been useful in cases when other therapies fail.

Objectives: To evaluate the prevalence of SH using the SH-questionnaire in bDMARD-treated chronic arthritis patients.

Methods: This cross-sectional study included 325 patients diagnosed with chronic arthritis. Patients were recruited consecutively from the Biological Therapy Unit of the Hospital General Universitario Gregorio Marañon and evaluated from January to March of 2015. All patients had been undergoing full or tapered bDMARD treatment for at least 1 year and none had any history of SH. Those patients deemed to be in clinical remission were on tapered bDMARD dosage. All patients self-selected the validated SH-questionnaire (1) which was considered positive when one answer was affirmative and when lesions presented in >1 anatomical location. Patient pathologies were subclassified into 2 groups: i) peripheral arthritis (PerAR) which includes rheumatoid arthritis (RA), psoriatic arthritis (PsA) and peripheral spondyloarthropathies (PerSpA); ii) axial spondyloarthopathies (AxSpA). Clinical evaluation was performed by the same physician for all patients. Demographic, clinical and laboratory variables were recorded and disease status was assessed through the relevant clinical index, i.e.DAS28-ESR, DAS28-CRP, SDAI, CDAI, BASDAI, BASFI, ASDAS-CRP.

Results: SH-positive was observed in 25/325 (7.7% vs. 92.3%) patients. Of these 25 patients, 12 (48%) were female and 13 (52%) male. Mean age was 52 years (SD±12.9) and mean time since diagnosis was 14 years (SD±9.3). Twenty-four out of 25 patients were undergoing anti-TNF treatment (ETN=10, GOL=7, ADL=4, CTZ=1). Eighty-four percent of patients were undergoing full bDMARD dosage with the remaining 16% tapered. By subset pathology, 13 SH positives were PerAR type and 12 were AxSpA (5.8% vs. 11.8%, p=0.062). On analysis of PerAR subtypes, we found 6 patients had PsA and 9 RA. Evaluating clinical disease activity, we found 9/13 patients in the PerAR group to be in clinical remission according to DAS28-ESR and CDAI (p=0.02 for both). Additionally, we found only 4/12 patients in remission in the AxSpA group as defined under BASDAI, BASFI and ASDAS-CRP (p=0.006, p=0.005, p=0.004, respectively).

Conclusions: SH-positive was more common in the AxSpA than in the PerAR group, which is consistent with published data. A bDMARD tapered dosage was related to SH-positive which might be linked to persistent and undetectable chronic inflammation.

Sex differences in disease activity according to composite indices in spondyloarthritis: a systematic review and meta-analysis

M. Blasco-Blasco1, L. Castrojén2, V. Jovani3, E. Eliseo4, M. Ruiz-Cantero1,5

1Public Health, University of Alicante, Alicante, Spain; 2Rheumatology, Rush University Medical Center, Chicago, United States; 3Rheumatology, Alicante University General Hospital; 4Rheumatology, Miguel Hernández University; 5Clinical Epidemiology, University of Alicante, Spain

Background: The Bath Ankylosing Spondylitis (AS) Disease Activity Index (BASDAI), an index of only patient-self-report measures, and AS Disease Activity Score (ASDAS)1, which adds patient global estimate and laboratory tests to BASDAI elements are widely used in Spondyloarthritis (SpA). Both indices are specifically designed to evaluate disease activity AS patients. Some studies have shown worse BASDAI in women, but sex-related differences by ASDAS remain unclear2,3.

Objectives: To analyze reports of sex-stratified disease activity measures -BASDAI and ASDAS- in patients with SpA.

Methods: Data sources included PubMed (1950 to December 2016), Embase, Web Of Science, and manual searches of references lists. We included observational studies and randomized trials comparing disease activity scores, specifically BASDAI and ASDAS, between men and women with SpA. Studies quality was determined in line with the STROBE statement for observational studies and CONSORT statement for RCT, considering ≥50% positive items as low quality. Randomized effects were performed to report the mean difference (95% confidence interval) by gender, and heterogeneity was measured via I2 statistic in order to check the results robustness.

Results: From 672 identified studies 18 cross-sectional studies, 3 cohort, 2 case-control studies, and 1 RTC reported sex-stratified BASDAI and ASDAS. ASDAS was evaluated in 3,758 patients (36.5% women) in 9 studies, and BASDAI included 12,329 patients (34.3% women) in 24 studies. In a meta-analysis of mean difference BASDAI including 19 studies the mean difference was 0.56 (95% CI: 0.47, 0.66) and I2=43%, indicating a significantly higher disease activity in women (Figure). In a meta-analysis of 7 studies ASDAS the mean difference was 0.06 (95% CI: -0.04, 0.16) and I2=41%, not showing statistically significant differences.

Conclusions: We identified relevant sex differences in disease activity according to BASDAI with higher disease activity in women, but not according to ASDAS. In SpA, women present more peripheral arthritis and higher pain, which may influence the BASDAI score, mainly based on patient-self-report measures. It is important to recognize these differences that may influence management decisions based on disease activity measures.

**FR0452** IMPACT OF A TRAINING PROGRAM AND EARLY REFERRAL ON DIAGNOSTIC DELAY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbraa1, D. Galvez-Ruiza1, J. Gratacos-Masmiglia1, C. Blanch Mur1, E. Collantes-Estevez1, P. Zarcoc-Montejo1, O. Braco1, I. Universidad de Sevilla, Seville, Spain; 2. La Paz, Madrid; 3. Par Tauli, Sabadell; 4. L'Hospitalet de Llobregat, Barcelona; 5. Universidad de Cordoba, Cordova; 6. Fundación Alarcón, Madrid, Spain

**Background:** In patients with axial spondyloarthritis (axSpA), diagnosis delay (DD) postpones the initiation of the most appropriate treatment with irreversible consequences on physical function, mobility and quality of life of patients. DD is also responsible for increased health costs resulting from incorrect referrals, visits to inappropriate health professionals and poorly planned diagnostic tests. Many initiatives have been undertaken in recent years in an attempt to reduce DD but their influence is still unknown.

**Objectives:** i) To determine diagnosis delay in patients with axSpA in Spain; ii) To assess the pre-diagnosis care process; iii) To analyse the possible beneficial effects on DD of a training programme for primary care physicians and early referral to rheumatology units.

**Methods:** A sample of 680 patients diagnosed with axSpA was interviewed during 2016 as part of the SPANISH ATLAS in Spain. This project aims to improve early diagnosis and to promote the use of effective treatments in axSpA patients. Collected data included: socio-demographics, medical visits prior to diagnosis, date for first symptoms and diagnosis and disease characteristics. This information was used to determine the DD and the possible beneficial effects on DD of a training programme, in terms of health care visits and early referral to rheumatology units. A descriptive analysis was performed, stratifying the results according to the start of the symptoms (before and after 2009). The ESPERanza Program (a Spanish prospective multicenter national health programme aimed at facilitating early diagnosis of patients with axSpA) started in 2009.

**Results:** 53% of the patients included were females. Mean scores (standard deviation) were 45.7 (10.8) years for age and 12.4 (11.2) for disease duration. 77.1% were HLA-B27+. Visits to health professionals prior to diagnosis included: primary care physicians (88.5%), orthopaedic surgeons (71.7%), rheumatologists (70.4%), and physiotherapists (47.6%). The mean number of consultations prior to diagnosis was 2.6; 3.0; 2.0 and 3.4, respectively. Patients stated the onset of the first ax-SpA symptoms was at mean 24.4 years of age, with diagnosis at mean 32.9 years of age, translating into a mean DD of 8.5 years. For 25% of patients DD was >12 years, whereas a DD of >2 years was found in only 25% of respondents. Mean DD for patients whose first symptoms appeared before 2009 was 9.5 years, whereas for patients whose first symptoms appeared after that date it was significantly reduced to 2.5 years.

**Conclusions:** The mean delay in diagnosis axSpA in Spain is above 8 years. Patients make a longer number of visits to a wider variety of specialist physicians before they are diagnosed, which could point to proof of wrong referrals by primary care. However, DD has fallen drastically (to a mean 2.5 years) since the implementation of the ESPERanza Program in 2009, suggesting that training primary care physicians has substantial beneficial effects on patients with axSpA and the care process.

**FR0454** M-SASSS AND CERVICAL SEGMENT C7-D1. SHOULD THE ORIGINAL SCORE BE MODIFIED?

M.J. Moreno-Martinez1, M.J. Moreno-Ramos2, L.F. Linares-Ferrando2, J. Gratacos-Masmiglia1, C. Blanch Mur1, E. Collantes-Estevez1, P. Zarcoc-Montejo1, O. Braco1, 1. Universidad de Sevilla, Seville, Spain; 2. School of Statistics, Faculty of Sciences, National University of Colombia, Medellin, Colombia

**Background:** Spondyloarthritis (SpA) is considered a chronic inflammatory condition. Spondylitis affects the junction of vertebrae, but with x-rays in special positions. Theoretically, the C7-D1 intervertebral segment should not be evaluated through a simple lateral radiograph, but with x-rays in special positions.

**Objectives:** To evaluate the importance of the assessment of the C7-D1 intervertebral segment in patients with Ankylosing Spondylitis.

**Methods:** The patients come from a Spondyloarthropathies Unit (Hospital Virgen of the Arrixaca, Murcia, Spain). All patients are diagnosed with Ankylosing Spondylitis (New York Modified Criteria)

The usual radiographic study was performed to calculate the m-SASSS (lateral cervical and lumbar) at level C7-D1 of patients with axSpA and control patients.

**Results:** We included 47 patients (81% male and 19% female) with a mean age of 48 (± 8) years and a mean duration of symptoms of 18 (± 5) years. The mean time between the two radiographic studies was 3 (± 1) years. The control group was made up of 61 people (40, 7% men) with a mean age of 50 years (± 11).

The mean age of the control group was higher than patients (p < 0.001).

The C6-C7 intervertebral level could be assessed radiographically with the lateral cervical radiograph in 93% of the patients and in 85, 2% of controls, and the C7-D1 level was only assessed in 22, 7% of the patients and 50% of the controls.

We analyzed whether the assessment of intervertebral level C7-D1 could be influenced by other variables such as sex, age or duration from the symptoms without finding a statistical result.

The 88, 5% of patients had a lower border of C7 normal or with squaring, erosion or sclerosis. Only 1 patient had syndesmophyte and 2 patients had a bridge between vertebrae. On the upper border of D1, 85, 5% of patients had normal or type-1 lesions (squaring, sclerosis or erosion), there wasn’t syndesmophytes and 2 patients had a bridge (Table)
Conclusions:

- The cervical segment C7-D1 is not usually valuable through a lateral cervical radiograph.
- Most of our patients with Spondylitis have no significant lesions in this segment.
- It is recommended to modify the m-SASSS index by removing the assessment of the cervical segment C7-D1.

FR0455 | RADIOGRAPHIC PROGRESSION OF HIP ARTHRITIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH TNF INHIBITORS

M. Konsta1,2, M.T. Nurmohamed3, A. Iliopoulos1, J.C. van Denderen2, I. Visman2, P.P. Stilkas3, I.E. van der Horst-Bruinisma2.1 First Department of Propaedeutic Internal Medicine, Rheumatology Department, Joined Rheumatology Program, National and Kapodistrian University of Athens, Medical School, Athens, Greece;2 Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands

Background: Although there is debate whether treatment with TNF inhibitors (TNFi) in AS may not inhibit spinal radiographic progression, the effect on hip involvement may be different (1,2).

Objectives: To estimate the impact of long-term TNFi treatment on radiographic progression of hip arthritis in AS, by adding a quantitative scoring method, previously applied in hip osteoarthritis, to the BASRI-hip score.

Methods: Consecutive TNFi-naïve AS patients (fulfilling the modified New York criteria) who were eligible for TNFi treatment were included. Hip involvement was assessed clinically (pain, reduced range of motion and intermalleolar distance) and radiographically. X-rays of the pelvis and lateral cervical and lumbar spine were obtained at 3 time points: at baseline two and seven years after the start of TNFi. Both hips were scored using: a) BASRI-hip score (BASRI-h score ≥2 is classified as definitive hip involvement), b) mean joint space width (MJSW), c) vertical span of bridging syndesmophyte.

Results: 262 AS patients (188 men, age: 49.6±12 years, disease duration: 24.4±12 years) under TNFi treatment were included. Definite hip involvement at baseline was detected in 95/262 (36%) patients, who had significantly higher BASRI-hip score [2 (2-2.5) median (IQR) vs. 0.5 (0-1) p<0.0001] and lower MJSW (3.6±0.7 vs. 4.5±0.7, p<0.0001), compared to those without. In patients with hip arthritis at baseline, both BASRI-h score and MJSW remained unchanged during follow up. In patients without hip arthritis, the BASRI-hip score remained unchanged after 2.5±0.7 years, but increased significantly after 7±2.3 years compared to baseline. In contrast, the MJSW in patients without hip arthritis remained unchanged at the three time points. The MJSASSS raised significantly during the follow-up period, regardless of hip involvement (see table).

Conclusions: One third of the AS patients suffer from radiographic hip involvement, which seems to stabilize during long-term anti-TNF treatment. Assessment of MJSW may contribute to detect minor changes in contrast to BASRI-hip score’ rough estimation.

FR0456 | AGE AT SPONDYLOARTHRITIS DIAGNOSIS AND RISK OF CARDIOVASCULAR COMORBIDITY: RESULTS FROM THE COMOSPA STUDY

M.H. Derakhshan1, N.J. Goodson2, J. Packham3, R. Sengupta4, H. Marzo-Ortega5, A. Molto6, S. Siebert7 on behalf of BRITSpA and COMOSPA investigators.1 Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow;2 Academic Rheumatology Department, University of Liverpool, Liverpool;3Haywood Rheumatology Centre, Keele University, Keele; 4Royal National Hospital for Rheumatic Diseases, Bath;5NIHR, Leeds Teaching Hospitals Trust and LiRRM, University of Leeds, Leeds, United Kingdom;6Parisi Descartes University, Hôpital Cochin, Paris, France

Background: Spondyloarthritis (SpA) and chronic inflammatory diseases are associated with a number of cardiovascular comorbidities. It is unknown whether age at SpA diagnosis is associated with cardiovascular outcomes in later life.

Objectives: To examine the relationship between “younger age at SpA diagnosis” and risk of various cardiovascular comorbidities.

Methods: COMOSPA is a large worldwide cross-sectional study comprising 3984 patients from 23 countries evaluating comorbidities in patients with SpA (1). We evaluated the association between “younger age at SpA diagnosis” (defined in 5-year blocks) and cardiovascular comorbidities using uni-variable and multi-variable logistic regression. Each model comprised one cardiovascular co-morbidity as dependent and “age at SpA diagnosis” as predictor adjusted for age, sex, BMI, history of smoking, alcohol, NSAIDs, DMARDs, biologics, steroids and other relevant factors.

Results: The data of 3923 patients (64% male) were available for analysis. Current age ranged from 18 to 100 with median (IQR) of 42 (32–53) years. The median (IQR) age at SpA diagnosis was 33 (25–43) years. Main reported cardiovascular-related comorbidities were hypertension (22.4%), ischemic heart disease (IHD) (6.2%), stroke (1.3%) and diabetes mellitus (5.5%). The risk of hypertension, after adjustment for potential confounding factors was associated with younger age at SpA diagnosis (OR=1.10, 95% CI: 1.05 -1.16), indicating 10% higher risk of hypertension for each 5 year younger age at time of SpA diagnosis (Table). Confounding variables showing significant association with hypertension were current smoking (OR=1.12, 95% CI: 1.10–1.13, p<0.001), male gender (OR=1.47, 95% CI: 1.20–1.80, p<0.001), current BMI (OR=1.09, 95% CI: 1.07–1.11, p<0.001), ever use of steroids (OR=1.24, 95% CI: 1.03–1.50, p=0.027) and ever use of synthetic DMARDs (OR=1.28, 95% CI: 1.05–1.57, p=0.017), but not ever use of NSAIDs or biologic DMARDs.

Conclusions: Younger age of SpA diagnosis is associated with increased risk of developing hypertension but not other cardiovascular comorbidities in this study. The explanation for this association is not clear and does not appear to be due to increased NSAID exposure.

FR0457 | THE ROLE OF SERUM HMBG1 IN BONE REMODELING AND OSTEOPOOROSIS IN A GROUP OF ANKYLOSING SPONDYLITIS PATIENTS

M. Calis1, I. Cuce2, I. Gunturk3, E. Cuce1, C. Yazıcı4, 1Department of Physical Medicine and Rehabilitation, Er耶ves University, Faculty of Medicine, Kayseri; 2Department of Physical Medicine and Rehabilitation, Adiyaman University Training and Education Hospital, Adiyaman; 3Institute of Health Sciences, Biochemistry, Er耶ves University; 4Department of Medical Biochemistry, Er耶ves University, School of Medicine, Kayseri, Turkey

Background: Ankylosing spondylitis is characterized by new bone formation and bone loss, associated with inflammation, which are mediated by cytokine-signaling pathways. High mobility group box 1 (HMBG1) protein, is a nonhistone nuclear protein, which is secreted by inflammatory cells, is also defined as a bone-active

References:

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.6733
cytokine. Recent studies have shown that RANKL induces HMGB1 release and it is required for RANKL-induced osteoclastogenesis in vitro and in vivo.

**Objectives:** To investigate the relationship of serum HMGB1 levels with RANKL/Osteoprotegerin (OPG) axis and clinical and radiographic parameters in patients with AS.

**Methods:** In this cross-sectional study, serum samples for total HMGB1, sRANKL and OPG were detected from 54 tumour necrosis factor (TNF) inhibitor naive patients with AS according to the modified New York criteria [mean age 34.9 years (S.D. 7.1); duration of symptoms 8.6 years (S.D. 4.2); male gender 38 patients (70.4%) and 26 healthy controls. ESR, CRP, Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASI) were assessed for each patient.

**Results:** Baseline HMGB1 levels were relatively higher in patients with AS than HC, however no statistically significant in other. Serum HMGB1 levels correlated with CRP (rho=0.368 and P=0.006), ASDAS-CRP (rho=0.358 and P=0.008) and BASDAI (rho=0.334 and P=0.014) and BASFI (rho=0.355 and P=0.014) in patients with AS. CRP and ASDAS-CRP showed more correlation to HMGB1 levels than BASDAI. There was no significant correlation between HMGB1 levels with sRANKL, OPG, mSASSS and spine or femur BMD values. In addition, serum OPG levels and the ratio of sRANKL to OPG from AS patients were significantly higher than those of HC.

**Conclusions:** The studied levels of HMGB1 in the sera of AS patients, are increased compared to healthy controls. Serum HMGB1 levels are related to BASDAI, ASDAS-CRP BASFI and CRP in patients with AS. Different results in the literature on serum HMGB1 levels as well as our results support the hypothesis that HMGB1 plays a role in the pathogenesis of AS. According to our knowledge, it is the first trial evaluating association between serum HMGB1 levels with sRANKL-OPG axis, bone mineral density and new bone formation in AS patients and it seems not to be related for these conditions.

**ASSESSMENT OF BONE MINERAL DENSITY IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHROPSIS FROM CORSOR COHORT: 2 YEARS FOLLOW UP**

**Background:** Bone loss in patients (pts) with early axial spondylarthropathy (axSpA) is insufficiently studied and may be associated with disease activity. Objective: To assess the bone mineral density (BMD) in pts with early axSpA base on data from 2 years follow up of CORSAR cohort.

**Methods:** The research included 65 pts with axSpA (criteria ASAS 2009) with disease duration <5 years and age at onset <45 years. Pts at least 2 years follow up, 32 (49.2%) male, pts mean age was 25.8 (5.6) y., average disease duration 2.1 (15.4) mo, 60 (92.3%) pts were HLA-B27 positive. At baseline all pts were NSAID-naive, DMARD-naive, anti-TNF-naive. For 2 years all pts taking NSAIDs at therapeutic doses, part of the pts received sulfasalazine and anti-TNF. BMD was measured using dual energy x-ray absorptiometry (DXA) of the femoral neck (FN) and lumbar spine (LS) (L2–4) at baseline and after 1 year, and 2 years follow up. BMD reduction was defined as Z score < -2 (at least one site).

**Results:** Low BMD at baseline followed in 9 (13.8%) pts, in 10 (15.3%) pts after 1 year and in 5 (7.7%) pts after 2 years follow up. There were no significantly differences between the mean values of BMD at baseline and after 2 year, data are shown in the Table.

**Conclusions:** Low BMD was quite rare (14%) in patients with early axSpA. Small frequency of BMD reduction in the Russian cohort of axSpA patients after 2 years of study is probably due to disease activity decrease on anti-inflammatory therapy.

**DEVELOPMENT AND VALIDATION OF A SPANISH TOOL FOR SEMI-AUTOGRAPHIC QUANTIFICATION OF SACRIOCILIAC INFLAMMATION BY MAGNETIC RESONANCE IN SPONDYLOARTHROPSIS (SCAIS)**

P. Zarco 1, R. Almodovar 1, A. Bueno 2, L.M. Molinero 3. 1 Unit Rheumatology, 2Unit Radiology, Hospital Universitario Fundación Alcorcón; 3Ingeniera ALCE, Madrid, Spain

**Background:** Different systems to quantify inflammatory changes in sacroiliac MRI have been developed [1, 2] These systems include the Spondyloarthropathy Research Consortium of Canada (SPARCC), the Berlin, the Aarhus-Puhakka, and Aarhus-Madsen, the Leeds, the MR Imaging of Seronegative SpA (MSS), Leeds, Sieper/Rudwaleit and Hermann/Bollow scoring systems. In addition, the use of these quantification methods is restricted to clinical trials, since their use in clinical practice is limited due to their complexity, need for trained personnel, and prolonged procedural time. The development of computer-aided systems that make it closer to the developed technique, the authors modified the SPARCC method by using a single coronal section instead of the standard six consecutive ones.

**Results:** The interobserver reliability was high, with intraclass correlation coefficients for global score of 0.81 (95% CI: 0.59–0.94). Convergent validity was good, with high correlation with the Berlin (rho between 0.797 and 0.913) and the SPARCC methods (rho between 0.566 and 0.897). Mean time employed in the reading procedure was 30 seconds.

**Conclusions:** The developed semi-automatic technique permits a fast and valid calculation of overall BME lesion at the SI joint on MRI images.

**EXTRA-ARTICULAR MANIFESTATIONS IN PATIENTS WITH AXIAL SPONDYLOARTHROPSIS: A CROSS SECTIONAL STUDY FROM SOUTHERN DENMARK**

R.A. Andreasen 1, 2, R. Christensen 1, L.E. Kristensen 1, T. Ellingsen 3, 4, H.C. Horn 3, I.M.J. Hansen 2, 5.

1Unit Rheumatology; 2Department of Clinical Research, Odense University Hospital, Svendborg; 3Rheumatology; 4Patient data Explorative Network, H.C. Horn 3, I.M.J. Hansen2,5.

**Objectives:** To compare patients with AS and articular symptoms, many patients with SpA also have extra-articular manifestations (EAM) which contribute to reduced quality of life. SpA appears to the prototype of the disorder, AS, three male cases are documented for every female case.

**Background:** Axial (ax) spondylarthropathy (SpA) is a heterogeneous group of chronic inflammatory diseases. In SpA, extra-articular disease is subdivided into two groups referred to as nonradiographic and radiographic (i.e. AS) respectively. Next to the spinal and articular symptoms, many patients with SpA also have extra-articular manifestations (EAM) which contribute to reduced quality of life. SpA appears to be more frequent in men than women in its axial presentations, and in reference to the differential expression of the disorder, AS, three male cases are documented for every female case. However, since the introduction of the new ASAS criteria for axSpA these differences are no longer so apparent. Nevertheless, little is known of the differential clinical expression of SpA between males and females.

**Objectives:** The objective of this study was to compare patients with AS and...
nr-axSpA stratified by gender, using standardized clinical tools (including patient-reported outcomes (P-ROs)) and C-reactive protein (CRP) level as a biomarker for inflammation.

**Methods:** AxSpA patients were included prospectively and underwent an examination program at one visit. We used ASAS criteria and the modified New York criteria for classification. Information on demography and P-ROs was obtained. A trained physician performed a clinical examination, and BASMI and the Spondyloarthropathy Research Consortium of Canada Enthesitis Index (SPARCC) was used to enthesis count. Chi-square and t-tests were used for categorical and continuous variables respectively to test the null hypothesis.

**Results:** Eighty patients with axSpA were included. Table 1 shows the results (mean ± SD or relative frequency) for the comparison of demographic and disease characteristics between clinical subgroups.

**Conclusions:** For the P-ROs, BASDAI and pain were higher in females diagnosed with nr-axSpA, and the CRP was significantly lower in this group. Peripheral and EAMs were slightly equally prevalent in AS and nr-axSpA in men and women except for uveitis, which is slightly more prevalent in AS. Our data show that AS patients were more frequently male than nr-axSpA patients. These results are in line with previous studies showing that male patients with axial SpA have more structural damage on radiographs than female patients. Among women, this study indicate that pain is more pronounced in non-radiographic axSpA than in AS, potentially revealing that chronic widespread pain (e.g. fibromyalgia) might interfere with the diagnostic accuracy of the non-radiographic axSpA subgroup. However, despite the absence of radiographic changes, patients with nr-axSpA have a burden of illness, with self-reported disease activity and functional impairments comparable with those of patients with structural changes consistent with AS.

**FRI0461 MUSCLE WASTING IN MALE TNF-α BLOCKER NAÏVE ANKYLOSING SPONDYLITIS PATIENTS: A COMPARISON OF GENDER DIFFERENCES IN BODY COMPOSITION WITH DUAL-ENERGY X-RAY ABSORPTIOMETRY**

Background: Ankylosing Spondylitis (AS) patients have different disease characteristics compared to males. This might be explained by differences in body composition (BC), as women have higher total body fat mass, and adipose tissue can produce adipokines and participate in inflammatory and immunological processes.

**Objectives:** To assess gender differences in BC measured by Dual-Energy X-ray Absorptiometry (DXA) in a cohort of AS patients naïve to TNF-α blockers, and compare the BC with the reference population.

**Methods:** AS patients (Modified New York Criteria), 18 years old or older, who had a whole body DXA analysis before TNF-α blockers were included. Demographic information and disease activity measures (ASDAS and BASDAI) were reported. Fat Mass (FM) was reported as total FM (sum of trunk, arms, legs, and head), BF% (ratio FM/Total body Mass), and Fat Mass Index (FM/M2 kg/m2).

**Fat Free Mass (FFM), calculated as lean mass + bone mineral content, and its index (FFMI kg/m2) were reported. BF%, FMI, and FFMI percentiles, according to the reference population tables, stratified by age and gender, were also reported.

**Results:** Seventy consecutive patients were included, 60% were men. Baseline demographic characteristics were similar in men and women. Women had significantly higher BF% and FMI, and lower FFMI as absolute values (table 1). The FFMI percentile was markedly low in men (31.7%) (Figure 1). After multivariate analysis, an ASDAS-CRP > 3.5 was related with lower FFM in the whole group (β-coefficient -5.1, 95% CI -10.2 to -0.1, P=0.047). ASDAS > 3.5 was related to lower fat content in men and to higher fat content in women. The same relationships were found for BASDAI > 4.

**Conclusions:** Muscle wasting, measured as low FFM compared to the reference population, was found in male TNF-α blocker naïve AS patients, especially in those with active disease. Women had higher volumes of body fat than men, but near the median of the reference population. The relationships between fat content and disease activity support the complex association between adipose tissue and inflammation.

**Acknowledgements:** This study was endorsed by an ASAS (Assessment of SpondyloArthritis international Society) Fellowship.

**FRI0462 THE PISTOL-GRIP DEFORMITY IS MORE FREquent IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

O. Tosun1, D. Solmaz2, O. Gercik3, G. Karaca4, A. Tosun5, M. Ozmen3, F.E. Topal6, S. Akar7, R. Radiology, Katip Celebi University Faculty of Medicine, Izmir; 2Rheumatology, Katip Celebi University Faculty of Medicine, Izmir; 3Rheumatology, Katip Celebi University Faculty of Medicine, Izmir; 4Radiology, Katip Celebi University Faculty of Medicine, Izmir; 5Emergency Medicine, Katip Celebi University Faculty of Medicine, Izmir; 6Physical Medicine and Rehabilitation, Katip Celebi University Faculty of Medicine, Izmir; 7Emergency Medicine, Katip Celebi University Faculty of Medicine, Izmir, Turkey

**Background:** Femoroacetabular impingement (FAI) is characterized by early pathologic contact of the proximal femur with the acetabulum. Finker impingement is the anterior acetabular cause of FAI. Whereas cam deformity seems like a flattening of the anterior contour of the head/neck junction or an osseous hump leading a decreased femoral head/neck offset. Patient with FAI present with a hip or a trochanteric painnously in the sitting position or during or after activity. It might also be an important cause of hip osteoarthritis (OA).

**Objectives:** Therefore in this study we evaluated the frequency of pistol-grip deformity (PGD), described as the most characteristic feature of cam-type FAI, in axial spondyloarthritis (axSpA) patients as a potential alternative cause of hip or trochanteric pain.

**Methods:** A total 180 patients (107 [59%] male, mean age 41.9±12.8 years) with axSpA according to ASAS criteria and 198 patients (120 [61%] male, mean age 40.5±14.8 years) admitted to the emergency department (mostly due to trauma) and who had pelvic X-ray were included in the study. Patients with hip OA, hip prosthesis, acetabular protrusion or who have radiographs taken improper technique were excluded. An experienced radiologist assessed all anteroposterior pelvic radiographs. PGD was determined by demonstration of spherical or non-spherical shape of femur head on AP pelvic radiograph.

**Results:** The axSpA group consists 135 ankylosing spondylitis and 45 non-radiographic axSpA patients. The mean duration of symptoms was 13.8±11.3
years in axSpA patients. Radiographic findings of cam abnormality (figure) were significantly more frequent in axSpA patients in comparison with control subjects (30/150 [20%] vs 17/193 [9%] and P=0.004). Cam-type radiographic abnormality was only present in 2 female control subjects and none of female axSpA patients. FAI was significantly correlated with the presence of HLA-B27 (r=0.213 and P=0.048), smoking (r=0.184 and P=0.018), height (r=0.283 and P=0.001) and gender (r=0.443 and P<0.001).

Conclusions: Our results showed that radiographic findings compatible with PGD were frequent in axSpA patients. In addition to repetitive injury to the proximal femoral physis, new bone formation may be responsible for increased FAI in axSpA. In axSpA patients with hip or trochanteric pain, FAI may be kept in mind as an alternative explanation of the symptoms.

FRIO464 ARTERIAL WALL INFLAMMATION IS NOT AFFECTED BY ANTI-IL17 TREATMENT IN PATIENTS WITH PERIPHERAL SPONDYLOARTHROSIS
L.J.J. Van Mens 1, S.L. Verweij 2, A.W.R. van Kuik 3, E.S.G. Stroes 2, D.L. Baeten 1, 4.
1AMC, Amsterdam Immunology and Rheumatology Center; 2Vascular medicine, Academisch Medisch Centrum; 3Reade, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands; 4UCB, Brussels, Belgium

Background: Patients with spondyloarthritis (SpA), a chronic inflammatory disease, have an increased cardiovascular risk which is partly due to increased inflammatory activity in the arterial wall. IL-17A blockade with secukinumab is an effective treatment for SpA. The role of IL-17A in atherogenesis is controversial, some studies suggest that IL-17A is pro-atherogenic, while others indicate that IL-17A is athero-protective. So, it is not known what the effect is of treatment with IL-17A blockade on inflammatory activity in the arterial wall.

Objectives: To assess the effect of 3 months treatment with secukinumab on arterial wall inflammation in SpA patients with peripheral disease (pSpA).

Methods: We included 20 patients with clinical pSpA in a 12 week open-label trial. Treatment consisted of 300 mg secukinumab once a week during the first 4 weeks and then every 4 weeks thereafter. EULAR DAS response was used to define a responder/non responder state. To measure arterial wall inflammation we performed a 18-fluorodeoxyglucose positron emission tomography with computed tomography (18F-FDG PET/CT) imaging in 18 patients at week 12, which is a validated method to quantify arterial wall inflammation. Arterial wall inflammation is measured in both the ascending aorta and carotids, maximal FDG uptake is shown as the maximal target-to-background ratio (TBRmax).

Results: 18 patients with pSpA (age 44±12, 72% male) and without a previous cardiovascular event underwent imaging. Overall, three months treatment with secukinumab resulted in a significant improvement of disease activity with 17/18 patients achieving a EULAR DAS response (9 good and 8 moderate responders). Correspondingly, CRP levels decreased significantly (baseline: 3.2 [1.2–2.4] mg/dl v.s wk 12: 2.0 [1.0–3.5] mg/dl, p=0.011). Additionally, arterial wall inflammation as measured by PET-CT did not change over the course of the 12 weeks treatment with secukinumab (aorta TBRmax baseline: 3.3±0.9 vs. wk 12: 3.3±0.7, p=0.861; carotid TBRmax baseline: 1.88±0.6 vs. wk 12: 1.76±0.4, p=0.067).

Conclusions: This pilot study in 18 patients with pSpA without any preexisting CV events showed that treatment with secukinumab for 3 months has no effect on arterial wall inflammation as measured by PET-CT. Further research in larger patient groups, over a longer period of treatment, and with different measurements remains warranted to fully elucidate the effect of IL-17A blockade on vascular inflammation.

FRIO465 ANGLES OF SACRUM INCLINATION EFFECT ON RADIOLOGIC IMAGING READING IN SPONDYLOARTHROSIS (THE ANTELOPE-DESIR STUDY)
M. Herbette 1, L. Deloix 2, F. Garrigue 1, L. Gossec 3, A. Simon 1, A. Feydi 1, F. de Bruin 1, M. Reijnierse 4, D. van de Heijde 1, D. Loëille 5, P. Claudepierre 6, T. Marhadour 1, A. Saraux 1 on behalf of DESIR cohort. 1Rheumatology; 2Radiology; CHU Brest and Université Bretagne Occidentale, Brest; 3Rheumatology, Pitié -Salpétrière, Paris; 4Neurosurgery, CHU Brest and Université Bretagne Occidentale, Brest; 5Radiology, CHU Cochin, Paris, France; 6Radiology, 7Rheumatology, Leiden, Leiden, Netherlands; 8Rheumatology, CHU, Nancy, France; 9Rheumatology, CHU Creteil, Paris, France

Objectives: To assess the impact of spinal angles on clinical and imaging features of suspicion of axial spondyloarthritids (axSpA).

Methods: The DESIR cohort is a prospective longitudinal cohort study of adults aged ≥18 years with inflammatory back pain (IBP) ≥3 months, <3 years. Baseline lateral lumbar radiography of patients included in DESIR cohort were read by two central blinded fellow readers (and a rheumatologist spine specialist in case of discrepancy) for Sacral Horizontal Angle (SHA), Lumbosacral angle (LSA) and total Lordotic Angle (TLA) measures. On the basis of literature, patients were classified depending on whether they had TLA more or less than 50°, SHA more or less than 40° or LSA more or less than 15°. Associations between angles and baseline clinical variables, presence of X-Rays (New York) and MRI (ASAS and MORPHO proposal definition) sacroiliitis, presence of spinal signs of spondyloarthritids (mSASSS, BASRI-total, SPARCC scores), presence
of spinal degenerative MRI signs on X-rays (yes or no) and MRI (presence of Modic abnormalities, Pfirrmann score, Canal stenosis, Extrusion). High intensity zone Facet osteoarthritis according to central reading (two readers) and axSpA diagnostic confidence (according to local clinician’s confidence on a 0–10 visual analog scale) were assessed by univariate analysis using the chi-square test (or Fisher’s exact test where appropriate) and the Mann-Whitney test. Adjustment for multiple testing was performed according to Bonferroni method.

**Results:** Of 708 patients, data were available for 677, 675 and 672 for SHA, LSA and TLA, measures with a mean value of 39.2°, 14.5° and 51.5° respectively. Clinical features and diagnostic confidence did not differ between the SHA, LSA and TLA groups. More sacrolilits imaging, according to ASAS (41.4% versus 32.0%) and MORPHO definition (48.6% versus 39.3%), were reported in TLA group but the differences did not reach statistical significance. Radiological scores were low with a mean value of 0.49 (±1.83), 0.30 (±0.78) and 4.9 (±9.0) for mSASSS, BASRI-total and SPARCC score, respectively, and no inter-group difference was found. In LSS1, more grade 3 and 4 Pfirrmann class and MDCiscophy (types 1 and 2) were observed for SHA <40°, and TLA <50° (p<0.001) whereas the difference did not reach the significance level for LSA<15° (p<0.05) (table).

**Conclusions:** Lumbar spine morphology is not associated with any clinical variable, presence on X-Rays or MRI of spinal signs of spondyloarthritis or sacroilits. At the LSS1 level, a more horizontal SHA and a reduction of TLA is associated with more degenerative radiological lumbar spine manifestations.

**FR0467 DEVELOPMENT AND PRELIMINARY VALIDATION OF THE COMPUTED TOMOGRAPHY SACROIACIAL STRUCTURAL SCORE (CT-SSS) FOR ASSESSMENT OF STRUCTURAL LESIONS IN AXIAL SPONDYLOARTHRITIS**

W.P. Maksymowych1,2, M. Raynal2, D. Loeuille3, M.-A. D’Agostino4, J. Pascio5, R.G. Lambert5, 1Medicine, University of Alberta; 2CalEArthritis, Edmonton, Canada; 3Rheumatology, CHRU de Nancy, Vandoeuvre-lès-Nancy; 4Rheumatologie, Université Paris Ouest, Paris, France; 5Radiology, University of Alberta, Canada

**Background:** Computed tomography (CT) is considered the imaging benchmark for the assessment of certain structural lesions in the sacroiliac joints (SIJ) of patients with axial spondyloarthritis (axSpA). Availability of low dose radiation techniques may lead to more widespread use, potentially as a structural endpoint in clinical trials research.

**Objectives:** We aimed to validate a new CT-based scoring method, the CT Sacroiliac Structural Score (CT-SSS), for assessing structural lesions in the SIJ.

**Methods:** CT scans of the SIJ from 44 patients (26 females, mean age 49.4 years, mean symptom duration 9.1 years) were reconstructed in the semicoronal plane parallel to the superior border of the sacrum and scoring of lesions was confined to this plane. Structural lesions were scored in consecutive slices in SIJ quadrants (erosion, sclerosis) or SIJ halves (ankylosis) on a dichotomous basis (present/absent) using the same anatomical principles as developed for the SPARCC MRI SIJ inflammation and structural scores. The most anterior slice is defined as visible joint >1cm vertical height and when <3 cm is defined as having only upper iliac and sacral quadrants. A visible joint >3cm vertical height is defined as having 4 quadrants. At the posterior aspect of the SIJ, there is a natural separation of iliac and sacral cortical bone by structures in the ligamentary portion. Scoring is terminated when <1cm of iliac and sacral bone is appositional. Two readers independently scored CT scans without a prior calibration exercise and using direct online data entry onto a schematic of the SIJ. Reliability was assessed by kappa statistics, intra-class correlation coefficient (ICC), and Bland-Altman limits of agreement.

**Results:** Scoring was feasible (5–10 minutes per scan) and both ankylosis (ICC=0.95) and erosion (ICC=0.81) were reliably scored (Table). Scoring was less reliably scored (ICC=0.89). Presence/absence of ankylosis was reliably determined irrespective of whether this was based on a single slice (κ=0.77) or 3 consecutive slices (κ=0.81). Reliable detection was lower for erosion (κ=0.50 for 1 or 3 slices) and sclerosis (κ=0.44 and 0.48 for 1 and 3 slices, respectively). Bland-Altman graph illustrates reliability across the range of scores for ankylosis and erosion.

**Conclusions:** The CT-SSS method is feasible and reliable for scoring ankylosis and erosion with minimal calibration. Scoring requires further standardization and calibration.

**FR0468 RADIOGRAPHIC HIP INVOLVEMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A STUDY OF ITS PREVALENCE AND DETERMINING FACTORS**

X. Michelenola, M. López de Recalde, H. Borrell, L. Lluch, P. Juárez, I. Morales, M. Pascual, J.-M. Nolla, X. Juanola, Department of Rheumatology, Hospital Universitari de Bellvitge, L’Hospitalet de Llobregat, Barcelona, Spain

**Background:** Hip involvement in Ankylosing Spondylitis (AS) is the most frequent extraspinal manifestation and a common cause of disability and limited mobility, often ending with hip replacement. There are few studies analysing the radiographic changes of the hip and their relationship with other disease variables.
Objectives: To determine the factors associated with radiographic hip involvement and its prevalence.

Methods: A cross-sectional study was performed based on patients with AS, excluding the patients with associated psoriasis or inflammatory bowel disease. To assess radiographic hip involvement, we scored the last anteroposterior pelvic radiograph performed using the Bath Ankylosing Spondylitis Radiology Index (BASRI). Demographic, clinical, laboratory, and radiographic data were collected and analysed. We considered the presence of hip disease with a BASRI hip score of at least 2.5. The statistical analyses were done using SPSS 24.0. p < 0.05 was considered statistically significant.

Results: 215 patients were identified, with a mean age of 52±13.6 years and 76.7% of the patients were male. The age at onset was 25.29±8.22 years. 86.4% of the patients were HLA-B27-positive. Regarding their treatment, 27.9% were observed in the age, age at onset and presence of peripheral arthritis. Patients with hip involvement had higher scores in BASRI score, ASDAS CRP and ESR. Axial radiographic involvement assessed with axial BASRI score and total SASSS was associated with hip disease and a significant association was seen between hip involvement and metatropic parameters.

Conclusions: Compared to AS patients without hip involvement, the radiographic hip-involved group are younger at disease onset, more frequently men and complaining of typical inguinal pain, have lower BMI and longer disease duration. AS patients having these concomitant risk factors should undergo further hip assessment in clinical practice.

FR0470 CIGARETTE SMOKING HAS A DOSE-DEPENDENT RELATIONSHIP WITH DISEASE ACTIVITY AND CORRELATES WITH MORE FUNCTIONAL LIMITATION AND WORSE HEALTH ASSESSMENT IN THE PATIENTS WITH ANKYLOSING SPONDYLITIS
Y. Jiang, Z. Liao, Z. Lin, M. Yang, Y. Zhang, Q. Li, J. Gu. Rheumatology, the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease that mainly affects the axial skeleton by causing inflammatory and osteoporiferative changes in the sacroiliac joints and spinal structures [1]. Cigarette smoking is associated with poor outcome in patients with established early AS [2].

Objectives: Our study was to investigate the relationship between cigarette smoking and pain, disease activity, functional limitation, and health assessment in Chinese patients with AS.

Methods: Patients with AS (n=683) from China took part in a cross-sectional survey. Smoking status was obtained by a standardized questionnaire, including smoking status (non-smokers, exsmokers, current smokers), the age when starting smoking, cigarette numbers a day and smoking status of family numbers. The Bath AS Disease Activity Index (BASDAI), the Bath AS Functional Index (BASI), visual Analog scale of pain, Health Assessment Questionnaire for Spondyloarthritis (HAQ-S) were analyzed in terms of smoking status and relationship with pack-year history.

FR0469 DIFFERENCES BETWEEN ANKYLOSING SPONDYLITIS PATIENTS WITH AND WITHOUT RADIOGRAPHIC HIP INVOLVEMENT IN CHINA
X. Zheng, Q. Wei, J. Gu. Department of Rheumatology and Immunology, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Hip involvement, defined by clinical examination or imaging techniques, is a problem of great concern in Ankylosing Spondylitis (AS) patients as it affects joint functional impairment and poor outcome. It has been shown that early age at disease onset, peripheral manifestation and severe axial disease are risk factors, but other characteristics do not show consistency through studies and data is scarce so far.

Objectives: We aim to describe the phenotype differences between AS patients with and without radiographic hip involvement and to identify potential risk factors for hip involvement.

Methods: AS patients fulfilling the Modified New York Criteria and whose pelvic X-rays have been assessed by at least one radiologist and one rheumatologist were included. Radiographic hip involvement was defined by features of osteophytes around the femoral neck, erosions of the acetabulum, axial migration of the femoral head or hip joint space narrowing. The medical records were retrospectively reviewed and collected. Demographic and disease characteristics were compared by descriptive and bivariate statistics using SPSS v19.0 and stata v12.1 package.

Results: Totally 621 AS patients with hip involvement and 420 patients without hip involvement were analyzed. Statistical significance were found between these 2 groups regarding age at disease onset, gender, BMI, disease duration and presence of peripheral arthritis, with all p value<0.001. Male patients showed strong risk effect on hip involvement with the odds ratio (OR) around 3.27.

Meanwhile, the hip-involved group had lower body mass index (BMI), which may relate to long disease duration or high inflammation level. No significant difference of HLA-B27 positivity, family history and other factors were observed (Table 1). Binary logistic regression results showed that age at disease onset, gender, BMI and disease duration were associated with hip involvement in AS (p<0.001). For the symptoms, among 69 hip-involved and 75 non-hip-involved AS with corresponding records, 83% hip-involved and 35% non-hip-involved patients complained of typical inguinal pain (OR=8.95, 95% CI=3.85–21.37, p<0.001).

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.4375
Results: Of the all 683 patients, 168 are current smokers, while 108 were significant associated with age, age onset, SDS scores, SRRS scores positively and years of education negatively (P<0.01). SDS scores were associated with age, age onset, SDS scores, SRRS scores positively and years of education negatively (P<0.01). SRRS scores were associated with age, age onset, SDS scores, SRRS scores positively and years of education negatively (P<0.01).

Conclusions: A large number of AS patients were found to have anxiety, depression, sleep disturbance and stressful life events. These problems correlated with each other. Clinicians should pay more attention to psychological disorders and sleep problems in AS patients.

DOES AXIAL SPONDYLOARTHRITIS PHENOTYPE CORRELATE WITH IMAGING MORPHOTYPE?

X. Baraliakos 1, A. Szumski 2, H.E. Jones 3, L. Gensler 4, 1Ruhr University, Bochum, Germany; 2Inventiv Health, Princeton; 3Pfizer, Collegeville; 4University of California, San Francisco, United States

Background: Traditionally, radiographic imaging was used to describe morphological differences between various types of axial SpA (axSpA). The advent of MRI has improved understanding of disease activity and facilitated the identification of non-radiographic spinal changes, and enabled earlier diagnosis and visualization of structural changes, and facilitated the identification of non-radiographic axial SpA (nr-axSpA). The magnitude of the pathologic changes in the axial skeleton is used to quantify inflammatory and structural outcomes of clinical trials and treatment of patients with axSpA.

Objectives: To examine the MRI morphology of sacroiliitis (SI) and vertebral corner lesions in patients with primary (1°, no psoriasis) and secondary (2°, with psoriasis) axSpA.

Methods: This posthoc analysis was performed on data from patients with axSpA enrolled in the EMBARK trial (NCT01258738). Only patients with baseline MRI were included. Symmetric and asymmetric SI, structural lesions, and corner inflammatory lesions were analyzed in 1° axSpA vs 2° axSpA patients. Data were analyzed using one-way analysis of variance for continuous parameters, and Fisher's exact tests for categorical parameters.

Results: The baseline demographics and disease characteristics between the 122 patients with 1° axSpA and 19 with 2° axSpA were similar. Asymmetric sacroiliitis was seen in significantly fewer 1° (43%) vs 2° (68%) axSpA patients. There were no differences in mean SpondyloArthritis Research Consortium of Canada (SPARCC) scores between 1° and 2° axSpA for any of the 4 SI joint (SJ) quadrants. However, the lower iliac quadrants had the highest SPARCC SJ score and the upper iliac quadrants had the lowest SPARCC SJ scores. When analyzing the 4 spine quadrants (lower/upper anterior and lower/upper posterior), 1° patients had higher total SPARCC spine scores than 2° patients for all 4 quadrants at baseline. Collapsing the 4 quadrants shows that 1° axSpA patients had higher SPARCC MRI of the entire spine (23 discovertebral units [DVU]; mean=5.7) compared with 2° axSpA patients (mean=2.7).

Conclusions: We found 1° axSpA patients had more symmetric sacroiliitis and extensive spinal bone marrow edema compared with 2° axSpA patients. In addition, patients appeared to have more asymmetric sacroiliitis. These data may help physicians accurately diagnose patients and decide best treatment options.

FR0474

ANTI-CD74 ANTIBODIES AS DIAGNOSTIC BIOMARKER FOR EARLY AXIAL SPONDYLOARTHRITIS: DATA FROM THE SPONDYLOARTHRITIS CAUGHT EARLY (SPACE) COHORT STUDY

J.J. de Winter 1, M.G. van de Sande 1, N. Baerlecken 2, I.J. Berg 3, R. Ramonda 4, D. van der Heijde 5, M. van der Heijde 5, A.F. van Gaalen 5, T. Witte 5, D.L. Baeten 5, 1AMC, Amsterdam, Netherlands; 2MHH, Hannover, Germany; 3Diakonhjemmet Hospital, Oslo, Norway; 4UnivPD, Padua, Italy; 5LUMC, Leiden, Netherlands

Background: Diagnosis of axSpA is often delayed with 5–10 years. A robust biological disease marker had not been detected and could decrease the current diagnostic delay. Two studies showed that serum anti-CD74 IgA antibodies are increased in SpA 1.2.

Objectives: To explore the value of anti-CD74 antibodies as diagnostic biomarker for axSpA patients in early, chronic back pain.

Methods: We tested the prevalence of anti-CD74 IgG and IgA antibodies in patients from the SPONDyOArtRitis Caught Early (SPACE) cohort by enzyme-linked immunosorbent assay (ELISA). Patients from the SPACE cohort have chronic back pain for ≥3 months and ≤2 years with an onset ≥6 months. Results: We included 560 patients of the SPACE cohort, of whom 274 patients were diagnosed with axSpA by a rheumatologist at baseline. Anti-CD74 IgG levels did not differ between patients with and without axSpA (p=0.152, Table 1). Median anti-CD74 IgA levels (tested with either casein or BSA as a blocking buffer) were higher in patients with axSpA (p<0.0001). Despite these differences at the group level, the diagnostic value of the anti-CD74 IgA antibodies was limited as shown by ROC analysis. The optimal cut off according to ROC analysis was an optical density (OD) of 0.875, providing a sensitivity of 38.3% and a specificity of 77.6%. In line with previous reports, further analysis revealed that total IgA levels were elevated in early axSpA patients vs. non-SpA early back pain patients (p=0.008). When correcting the level of anti-CD74 IgA for the total level of IgA, the differentiating capacity of anti-CD74 disappeared for casein but remained intact for BSA (casein: p=0.731, BSA: p=0.038). Additional analyses using the ASAS classification criteria rather than a clinical diagnosis of axSpA, a strict combination of disease diagnosis and radiological criteria (exclusion of patients without 77.6% of 77.6% and 0.875 optical density (OD) of 0.875, providing a sensitivity of 38.3% and a specificity of 77.6%.

Conclusions: Serum anti-CD74 IgA antibody levels, but not serum anti-CD74 IgG levels, are elevated in patients with axSpA versus non-SpA with back pain <2 years duration. However, ROC analyses revealed that these numerical differences of are limited diagnostic value in these patients with early back pain.

Abstract FR0474 – Table 1

| Parameter | Total (n=141) | 1° axSpA with axSpA enrolled in the EMBARK trial (NCT01258738). Only patients with baseline MRI were included. Symmetric and asymmetric SI, structural lesions, and corner inflammatory lesions were analyzed in 1° axSpA vs 2° axSpA patients. Data were analyzed using one-way analysis of variance for continuous parameters, and Fisher's exact tests for categorical parameters.

Results: The baseline demographics and disease characteristics between the 122 patients with 1° axSpA and 19 with 2° axSpA were similar. Asymmetric sacroiliitis was seen in significantly fewer 1° (43%) vs 2° (68%) axSpA patients. There were no differences in mean SpondyloArthritis Research Consortium of Canada (SPARCC) scores between 1° and 2° axSpA for any of the 4 SI joint (SJ) quadrants. However, the lower iliac quadrants had the highest SPARCC SJ score and the upper iliac quadrants had the lowest SPARCC SJ scores. When analyzing the 4 spine quadrants (lower/upper anterior and lower/upper posterior), 1° patients had higher total SPARCC spine scores than 2° patients for all 4 quadrants at baseline. Collapsing the 4 quadrants shows that 1° axSpA patients had higher SPARCC MRI of the entire spine (23 discovertebral units [DVU]; mean=5.7) compared with 2° axSpA patients (mean=2.7).

Conclusions: We found 1° axSpA patients had more symmetric sacroiliitis and extensive spinal bone marrow edema compared with 2° axSpA patients. In addition, patients appeared to have more asymmetric sacroiliitis. These data may help physicians accurately diagnose patients and decide best treatment options.

DOI: 10.1136/annrheumdis-2017-eular.5381
Background: Axial spondyloarthritis (AxSpA) is a severe and potentially debilitating disease, where earlier diagnosis leads to a better prognosis. Although HLA-B27 antigen is strongly associated with AxSpA, this marker may have a low sensitivity in some Middle-Eastern countries. Recent European studies showed a strong association between antibodies against CD74 and AxSpA with a sensitivity of 85.1%, specificity of 92.2%, and positive likelihood ratio (LR) of 10.8. The diagnostic properties of anti-CD74 may have a particular interest in non-European countries with low HLA-B27 prevalence such as Lebanon.

Objectives: In this prospective study, we tested the diagnostic properties of IgG and IgA anti-CD74 as an early diagnostic marker for AxSpA, compared with HLA-B27, in Lebanon, which is known as one of the countries with the lowest HLA-B27 prevalence ever reported.

Methods: Sera of AxSpA patients and healthy blood donors (HBD) were analyzed for HLA-B27 genes (PCP) and for IgG and IgA anti-CD74 (ELISA). The patients were recruited from rheumatology clinics across Lebanon. Clinical assessment and sera sample collection were performed at a center specialized in AxSpA (Hotel-Dieu de France University hospital, Beirut). Inclusion criteria were: age 18–45 years, Lebanese, symptom duration <3 years, AxSpA as per ASAS criteria (imaging arm), no prior biologic therapy. Interpretation of the radiographic images was performed centrally and blindly. Clinical and laboratory assessments of the disease were performed in all AxSpA patients. Comparison between groups was performed with the Fisher exact test and Student’s t-test. For the diagnostic properties of HLA-B27 and anti-CD74, ROC curves were calculated.

Results: 10 AxSpA patients and in 2 HBD (Sensitivity 34.5%, Specificity 97.2%, Positive LR 10.8) and 18–45 years, Lebanese, symptom duration <3 years, AxSpA as per ASAS criteria (imaging arm), no prior biologic therapy. Interpretation of the radiographic images was performed centrally and blindly. Clinical and laboratory assessments of the disease were performed in all AxSpA patients. Comparison between groups was performed with the Fisher exact test and Student’s t-test. For the diagnostic properties of HLA-B27 and anti-CD74, ROC curves were calculated.

Conclusions: In this study in a population with low HLA-B27 prevalence, IgG anti-CD74 antibodies showed higher diagnostic value than HLA-B27 for AxSpA. This is of special interest in populations with low HLA-B27 prevalence, especially on the background of diagnosing AxSpA when using the clinical arm of the ASAS classification criteria.

FR0477 PROSPECTIVE OBSERVATIONAL STUDY ON THE EVALUATION OF QUALITY OF LIFE IN PATIENTS AFFECTED BY ENTEROPATHIC SPONDYLOARTHRITIS

M.S. Chimienti1, P. Coniglio1, B. Polistena2, P. Triggianese1, A. Ruffa3, C. Canofri1, F. Cereda1, S. Onali3, M. Balan1, E. Calabrese1, C. Petruzelli2, F. Spandonaro2, G. Monteleone1, L. Biancone4, R. Perricone1, 1Department of system medicine, Rheumatology, Allergology and Clinical Immunology; 2Department of Economic and Finance; 3Department of system medicine, Gi Unit, Dpt. University of Rome Tor Vergata, Rome, Italy

Background: Enteropathtic Spondyloarthropathy (ESpA) belongs to the group of Spondyloarthropathy (SpA) typically associated with inflammatory bowel disease (IBD) as Cohn’s Disease (CD) and Ulcerative Colitis (UC). Joint pain is the most common (22–33%) and significant extra-intestinal manifestation in patients with IBD and its management requires rheumatological and gastroenterological competence in collaboration. No data concerning the Health-related quality of life (HRQoL) have been evaluated in patients affected by ESpA.

Objectives: Prospective study was performed in a combined GastroIntestinal and Rheumatologic “GI-Rhe” clinic, in order to evaluate: 1) prevalence and characteristics of articular manifestations in a group of IBD patients; 2) quality of life, state of health and well-being in ESpA patients.

Methods: Patients affected by IBD who presented musculo-skeletal pain between February 2013 and September 2016 (CD 264 and UC 142) were enrolled. New diagnosis, disease management, adverse events as well as laboratory evaluations were assessed every 3 months during the follow-up. Disease activity, function and quality of life in ESpA patients were assessed by ASDAS-CRP, HAQ-S and EuroQol questionnaire.

A total of 427 patients were evaluated for joint involvement (Table 1). The prevalence of SpA in IBD patients was 49.6% (n=212; UC 71 (43.3%), CD 141 (53.4%)), suggesting that the majority of patients with IBD who complain arthritis may have a concomitant SpA. Other rheumatologic diseases were detected in the study population in 215 patients defined as IBD non-SpA. There was a significantly higher prevalence of active intestinal disease in patients with SpA with respect to IBD-non SpA (CD: CDAI>150 in 18.4% vs 8.2% p=0.004; UC: Mayo score >3 in 15.5% vs 0%, p=0.0004). The evaluation of the EuroQol demonstrated a mean value of 0.59 in IBD-SpA patients and of 0.55 in IBD non-SpA (Figure 1A). In IBD-SpA, the health related status was: decent 69.8%, good 17.9% and bad 9.4%. In IBD-non SpA, the health related status was: decent in 74.8%, good in 17.7% and bad in 7% of patients. In both groups, none of the patients had a neither exceptional nor great perception of QoL. No significant differences were observed between the two groups (Figure 1B).

Conclusions: The joint clinic facilitates diagnosis and management of SpA and IBD. Although IBD-SpA patients showed higher IBD disease activity than IBD-non SpA one, both groups of patients have a good health related QL.

SUBCHONDRAL BONE SCLEROSIS ON COMPUTED TOMOGRAPHY – DOES IT HAVE ANY VALUE IN THE DIAGNOSIS OF INFLAMMATORY SACRILIITIS OR IS IT A NON-SPECIFIC FINDING?

O. Azmat1, R.G. Lambert1, Z. Jibri1, W.P. Maksymowych1, 2

1Radiology; 2Medicine, University of Alberta, Edmonton, Canada

Background: Sclerosis in the sacroiliac joints (SIJ) on radiography and computed tomography (CT) is common but widely considered a non-specific finding. Sclerosis due to degeneration and ostearthrosis is a known cause, however, the extent of sclerosis seen in inflammatory sacroiliitis is unknown.

Objectives: We aimed to determine whether this lesion could be reliably detected and its diagnostic utility.

Methods: 215 CT scans were obtained from patients with a history of low back pain. 107 patients had a clinical diagnosis of spondyloarthritides (SpA) and 108 patients were clinically proven not to have SpA. Groups were age and gender matched (140 males, 75 females, mean age was 45 years). Three musculoskeletal radiologists, blinded to patient demographics and diagnosis, scored the CTs after standardization of lesion definitions and calibration. Erosions, sclerosis, and ankylosis were graded by size and number of articular surfaces/joints involved. Sclerosis was considered definite if located along the cartilaginous compartment, measured >5mm in all 3 planes, and present >5mm from the joint surface. Discrepant scores were arbitrated and inter-reader reliability calculated by intra-class correlation coefficient (ICC). Diagnostic utility of CT lesions was determined by calculating sensitivity and specificity for the clinical diagnosis and by logistic regression.

Results: ICC for sclerosis and erosion for each articular surface ranged from 0.65–0.76 and 0.71–0.78, respectively. ICC for ankylosis was 0.87–0.89. Sclerosis occurred in 87 (81%) cases with SpA and 25 (23%) controls. For a single articular surface the specificity for sacroiliitis between 88–94%, for any two articular surfaces 95–100%, for all 4 articular surfaces 100%. Sensitivity ranged from 14% (4 articular surfaces) to 55% (either ilium). Erosion and ankylosis had a similar specificity range of 91–100% and 92–93%. The odds ratio was 4.9 for presence of definite erosions, and 12.6 for bilateral joint involvement. The odds ratio increased to 84.2 for bilateral erosion and 22.8 for bilateral ankylosis.

Conclusions: When sclerosis measures >5mm in three planes and is located >5mm from a joint perimeter, it has high specificity for sacroiliitis, regardless of how many articular surfaces are involved, with similar specificity to erosion and ankylosis.

PREDICTORS OF LONG-TERM MODIFIED MINIMAL DISEASE ACTIVITY RESPONSE IN PERIPHERAL SPONDYLOARTHITIS PATIENTS TREATED WITH ADALIMUMAB

L.C. Coates1, S. Abraham2, W. Tillett3, P.J. Mease4, S. Ramiro5, T. Wu6, X. Wang7, A.L. Pangan8, I.-H. Song9, 1University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds; 2NIHR/Wellcome CRF, Imperial College Healthcare NHS Trust, London; 3Royal National Hospital for Rheumatic Diseases and University of Bath, Bath, United Kingdom; 4Swedish Medical Center and University of Washington, Seattle, United States; 5Leiden University Medical Center, Leiden, Netherlands; 6AbbVie Inc., N Chicago, United States

Background: There is a lack of validated outcome measures in non-psoriatic peripheral spondyloarthritis (pSpA). Therefore, a modified version of the minimal disease activity (mMDA)1 was developed and validated. Identification of factors that predict long-term mMDA response in pSpA patients (pts) can facilitate decisions regarding treatment initiation and maintenance.

Objectives: The purpose of this analysis was to determine predictors of long-term mMDA response following adalimumab (ADA) treatment in pSpA pts from the ABILITY-2 study.

Methods: ABILITY-2 was a phase 3 randomized, double-blind trial evaluating the efficacy and safety of 40 mg ADA every other week versus placebo (PBO) over 12 wks followed by open-label (OL) ADA for 64 wks in pSpA pts. This post-hoc analysis included pts who received at least one dose of ADA during the PBO-controlled period or OL extension. The mMDA for pSpA was defined as achieving at least 5 out of the following 6 criteria: 1) TJC78 ≤1; 2) SJC76 ≤1; 3) pain visual analog scale (VAS) ≤15 of 100 mm; 4) pt global activity (PtGA) VAS ≤20 of 100 mm; 5) HAQ-DI ≤0.5; and 6) tender entheseal points <1 (Leeds Enthesitis Index [LEI] or Spondyloarthritis Research Consortium of Canada [SPARCC] Enthesitis Index). In this post hoc analysis, multiple logistic regression with stepwise variable selection was used to determine predictors of long-term (yrs 1–3) and sustained (defined as mMDA for at least 24 consecutive wks) mMDA responses. Variable selection of baseline (BL) pt demographics and disease characteristics were performed with and without mMDA response at wk 16 (mMDA16) as a candidate. In pts achieving mMDA at wk 16, ADA exposure ranged between 4 and 16 wks.

Results: In pSpA pts treated with ADA, mMDA (5/6 LEI or SPARCC) was achieved by almost 41%, 49%, and 50% of pts at yrs 1, 2, and 3, respectively and sustained mMDA response was achieved by 42% of pts. Regardless of mMDA definition, achieving mMDA response at wk 16 (up to 16 wks of ADA) was a robust positive predictor of attaining both long-term mMDA at yrs 1–3 and sustained mMDA (Figure). In the model examining the BL predictors (model without mMDA16), age, BL enthesitis and BL BASDAI scores were most commonly selected as negative predictors for achieving long-term and sustained mMDA. Other selected predictors included BL dactylitis, physician’s global assessment, hsCRP, and male sex; however, these predictors were not consistently selected for all time points or sustained mMDA.

Conclusions: Early mMDA response is a stronger and more consistent predictor of long-term mMDA, whether at 1, 2, or 3 yrs or sustained over time, than BL.

pain vs. PaG1: -35.7 and 23.3 [-6.3, 1]. LLAo and ULoa remained constant over the whole range of the VISSCALES.

Conclusions: In patients with SpA, fatigue, pain and PaG1 scores were poorly associated and only poorly explained by other potential explanatory variables.

On the individual level, disagreements between the scores were substantial. The finding of a high degree of interrater emmance, which could indicate understanding patient-reported outcome measures and their diverging interplay across individuals.

Psoriatic arthritis

FR0482 INSULIN RESISTANCE IN PATIENTS WITH PSORIATIC ARTHRITIS
A. Abogamal1, E. Mahmoud2, S. Abdullah3, S. Abdelatif4, A. Abdelaziz5, T. Rheumatology; 2Enocrinology; 3Clinical Pathology, Alazhar Faculty of Medicine, Cairo, Egypt

Background: Inflammation and, levels of inflammatory markers, CRP and other cytokines are important for enhancing insulin resistance in PaS patients. Inflammation and, levels of inflammatory markers, CRP and other inflammatory cytokines are important players for enhancement and development of insulin resistance in psoriatic arthritis patients.

Objectives: To investigate the relation between insulin resistance and psoriatic arthritis presence and disease activity. To investigate the relation between insulin resistance and disease activity in patients with psoriatic arthritis.

Methods: Patients Inclusion criteria: all patients in this study had psoriatic arthritis with disease duration 5 years or more. All under conventional DMARDs treatment in the form of methotrexate 12.5 mg/wk, hydrochloroquine 400mg/day. With no treatment with glucocorticoids, 3 months prior to enrollment in the study and no previous treatment with biologics. All patients were Postmenopausal females with 3 or more years since menopause.

Exclusion Criteria: DM, ischemic heart disease, hypertension, or any other chronic diseases. Smoking, on medications Medications that affect blood lipids, or body composition and metabolic functions. Postmenopausal females who were on hormone replacement therapy.

Grouping: G I: Included 50 postmenopausal females with psoriatic arthritis. G II: Included 25 normal postmenopausal females, as a control group.

Methods: 1. Full medical history and Complete clinical examination 2. Anthropometric measurements: Body mass index (BMI), Waist-hip ratio (WHR). 3. The following laboratory investigations were done: C-reactive protein (CRP), Fibrinogen, Fasting insulin. 4. Measures of insulin resistance: Homeostasis model assessment of insulin resistance (HOMA-IR): (a) HOMA 1-IR: It is calculated according to the following equation: Fasting insulin (µU/ml) X FBS (mg/dl)/405.

(2). Insulin resistance was defined as HOMA-IR > 2.67 as cut-off.

Results: Comparing means of age, BMI, and WHR of both groups’ shows no significant difference. This indicates that both groups were matched and valid for comparison. G I have significantly higher values than the control group in the paired fasting glucose and insulin values, were calculated using the computer it is the updated (or computer) model with nonlinear solutions, which also uses the NHWS was a self-administered, web-based, voluntary, confidential questionnaire. Stratified randomised sampling provided a representative sample of EU adults in France, Germany, Italy, Spain and UK. Respondents completing the arthritis module and reporting PaS diagnosis were stratified on a range of demographic and disease-related parameters and randomised to one of two self-reporting surveys: the National Health and Wellness Survey (NHWS) and determine the impact of treatment, or no treatment, on pt-reported outcomes.

FR0484 IMPACT OF PSORIATIC ARTHRITIS ON PATIENT-REPORTED OUTCOMES IN 5 EUROPEAN UNION COUNTRIES
A. B. Ortíz1, J. Gratacos2, A. Dikranian3, L. Fallon4, B. Emir5, T. Smith6, L. Azkm6, L. Chen7, 1Department of Dermatology, New York Medical College, Valhalla, NY, United States; 2Hospital Padre Fatima, Barcelona, Spain; 3Cabrillo Center for Rheumatic Diseases, San Diego, CA, United States; 4Pfizer Canada, Montreal, QC, Canada; 5Pfizer Inc, New York, NY, United States; 6Pfizer Ltd, Sandwich, United Kingdom

Objectives: This non-interventional, cross-sectional, descriptive, exploratory analysis aimed to characterise patients (pts) with psoriatic arthritis (PsA) in the 2016 National Health and Wellness Survey (NHWS) and determine the impact of treatment, or no treatment, on pt-reported outcomes.

Methods: The NHWS was a self-administered, web-based, voluntary, confidential questionnaire. Stratified randomised sampling provided a representative sample of EU adults in France, Germany, Italy, Spain and UK. Respondents completing the arthritis module and reporting PaS diagnosis were stratified on a range of demographic and disease-related parameters and randomised to one of two self-reporting surveys: the National Health and Wellness Survey (SF-36); Work Productivity and Activity Impairment questionnaire and Patient Health Questionnaire-9 (PHQ-9) responses were summarised descriptively.

Results: NHWS was completed by 80,600 adults; 947 completed the arthritis module and self-reported PsA diagnosis. Of these, 65 (7%) reported receiving advanced therapies, 274 (29%) other therapies and 608 (64%) no current treatment. Age and gender were generally balanced between the groups (mean 51–56 years; 51–64% female). More patients on advanced therapies had a body mass index ≥30 (41%) vs other therapies (34%) and no current treatment (28%). Pts on advanced therapies reported more comorbidities (moderate to intense vs other therapies (mean 1.8) and pts with no current treatment (mean 1.7). More pts on advanced therapies were current smokers (49%) vs pts on other therapies (30%) and pts with no current treatment (32%). Prior to treatment with advanced or other therapies, 94% and 74% were self-reported moderate or severe PsA, falling to 58% and 39% respectively, after treatment, compared with 36% and 11% for pts with no current treatment. SF-36 scores and PHQ-9 scores did not widely vary across groups (Table 1). Regardless of treatment groups, pts reported >20% work loss, >45% overall work impairment and >45% activity impairment (Table). More than 60% of pts reporting PaS diagnosis reported no current treatment.

Disclosures: None declared.
In peripheral psoriatic arthritis DKK-1 and PTH are intravenous golimumab in adult patients with PsA.

Methods: This is a multi-center, randomized, double-blind, placebo-controlled trial. Biologic-naive active PsA pts were randomized (1:1) to IV GLM 2mg/kg at weeks (wk) 0, 4, and every 8 wks thereafter or PBO at wk0, 0, 4, 12, and 20 with crossover to GLM at wk24. The primary endpoint was ACR20 response at wk14. Multiplicity-controlled endpoints were ACR50, ACR70, PASI 75, change from baseline in HAQ-DI, enthesitis, dactylitis, SF-36 PCS/MCS scores at wk14; and ACR50 and change from baseline in total modified vdH-S scores at wk14. Efficacy analyses were based on randomized treatment. Adverse events (AE) through wk24 are reported here. Investigators remained blinded through wk60.

Results: the PsA group showed significantly lower Dkk-1 levels when compared to the HC and RA groups. Dkk-1 in the RA group was also significantly higher than in the HC group. A similar trend was documented also for PTH, however a statistically significant difference was observed only when we comparing the PsA vs RA group (table 1, figure 1). No other statistically significant differences in the other markers were found.

Table 1. Values of bone turnover markers (CTX-I, PINP), DKK-1 and sclerostin of PsA, RA patients and control group (mean ± SD).

Conclusions: This study demonstrated for the first time that Dkk-1 levels in PsA are lower than in HC, in contrast with RA where they are higher. These results might contribute to explain the different bone involvement of the two different diseases.

Apremilast is associated with long-term (4-year) DAS-28 (CRP) remission and improvements in skin disease: results from a phase III study in DMARD/biologic-experienced patients with active psoriatic arthritis

1University Hospital Southampton, Southampton, United Kingdom; 2INIBIC-Universitat Autonoma de Coruña, Galicia, Spain; 3Bakerfield Dermatology, Bakerfield; 4Celgene Corporation, Summit; 5University of Massachusetts Medical School, Worcester, United States

Background: Treatment goals for long-term control of skin and joint symptoms in active psoriatic arthritis (PsA) include clinically important changes in DAS-28 (CRP) and improvements in skin disease. PsA can lead to significant physical and associated psoriasis, among patients continuing the study. Apremilast was generally well tolerated with an acceptable safety profile.

Conclusions: Over 208 weeks, Apremilast demonstrated sustained and clinically important improvements in PsA signs and symptoms, including physical function and associated psoriasis, among patients continuing the study. Apremilast was generally well tolerated with an acceptable safety profile.

Background: Psoriatic arthritis (PsA) is a rare disease, with an estimated prevalence of 0.02–0.42% in Europe and US (1). PsA is often regarded as a mild disease, but recent data suggest an increase in comorbidities and mortality, possibly related to systemic inflammation (1).

Objectives: To study all-cause hospitalizations in patients with PsA in the United States (US) from 1993 to 2014.

Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. We examined all inpatient hospitalizations in NIS from 1993 to 2014 with a primary or secondary diagnosis of PsA, and compared them to total all-cause US hospitalizations during the same period. US population estimates and projections for the resident US population were obtained from the US Census Bureau.

Results: There were 789.8 million all-cause hospitalizations in 6.4 billion person-years of observation from 1993 to 2014 (123.4 hospitalizations per 1,000 person-years). During this time period, 332,496 hospitalizations occurred in patients with PsA (5.2 per 100,000 person-years). All-cause US hospitalizations increased from 33.7 million in 1993 to 35.4 million in 2014, an increase of 4.8% over 22 years (Figure, dotted blue line). All-cause hospitalizations in PsA patients increased from 6,866 in 1993 (2.6 per 100,000 person-year) to 33,875 in 2014 (10.6 per 100,000 person-years), a dramatic increase of over 393% (p < 0.0001, Figure solid red line). In 2014, hospitalizations in PsA patients accounted for 163,630 hospital days at a total national cost of over US$1.66 billion.

Conclusions: All-cause hospitalizations in patients with PsA in the US have significantly increased by 393% in the last 22 years, almost 80-fold of the 4.8% increase in US population all-cause hospitalization rate in the same time-period. This calls for an increase need for identification and management of serious and co-morbid conditions in patients with PsA.
CERTOLIZUMAB PEGOL IS ASSOCIATED WITH LONG-TERM IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES IN PSORIATIC ARTHRITIS: 4-YEAR OUTCOMES FROM THE RAPID-PSA STUDY

D. Gladman1, R. Fleischmann2, K. Harris3, L. Peterson4, P.J. Mease5.
1University of Toronto and Krembil Research Institute, Toronto Western Hospital, Toronto, Canada; 2UT Southwestern Medical Center and Dallas Metropolis Clinical Research Center, Dallas, United States; 3UCB Pharma, Brussels, Belgium; 4UCB Pharma, Raleigh; 5Swedish Medical Center and University of Washington, Seattle, United States

Background: Psoriatic arthritis (PsA) is a heterogeneous inflammatory disease that has a substantial impact on patients’ (pts) physical and emotional wellbeing.1 Certolizumab pegol (CZP) is an Fc-free, PEGylated anti-TNF that has been shown to improve patient-reported outcomes (PROs) in pts with PsA over 96 weeks (wk) of treatment in the RAPID-PSA study (NCT01087788).2

Objectives: To investigate whether initial improvements in PROs observed with CZP treatment were maintained over 4 years in the RAPID-PSA study.

Methods: RAPID-PSA was double-blind and placebo-controlled to Wk24, dose-blind to Wk48, and open-label to Wk216. Pts were aged ≥ 18 years, with a ≥ 3% body surface area affected by psoriasis of prior anti-TNF exposure (Table). Similar improvements were observed in both CZP dose regimens for all PROs examined, including PtAAP (CFB at Wk216 in ≥ 3% body surface area affected by psoriasis at baseline (BL)]. Data are reported as the mean change from BL (CFB) for pts randomized to CZP at Wk0, with last observation carried forward (LOCF) imputation for Wk24, and LOCF imputation and observed case (OC) values for Wk216.

Results: Of 273 pts randomized to CZP at Wk0, 248 (91%) completed Wk24 and 183 (67%) completed Wk216. Improvements observed to Wk24 of treatment were generally maintained over 4 years (to Wk216) in all PROs assessed, regardless of prior anti-TNF exposure (Table). Similar improvements were observed in both CZP dose regimens for all PROs examined, including PtAAP (CFB at Wk216 in ≥ 3% body surface area affected by psoriasis at baseline (BL)]. Data are reported as the mean change from BL (CFB) for pts randomized to CZP at Wk0, with last observation carried forward (LOCF) imputation for Wk24, and LOCF imputation and observed case (OC) values for Wk216.

EFFECT OF THE TIGHT CONTROL TREAT-TO-TARGET STRATEGY ON THE DYNAMICS OF ACTIVE MRI SACROIILITIS IN THE RUSSIAN COHORT OF EARLY PERIPHERAL PSORIATIC ARTHRITIS PATIENTS (PRELIMINARY RESULTS OF AN ONGOING OPEN-LABEL REMARC STUDY)

E.E. Gubarev, E.V. Logina, T.V. Korotaeva, D.E. Karateev, V.A. Nasonova
Research Institute of Rheumatology, Moscow, Russian Federation

Background: Axial involvement in early psoriatic arthritis (pSpA) patients is often poorly diagnosed. Magnetic resonance imaging (MRI) of sacroiliac joints (SIJs) helps to better define spinal involvement and is used as an outcome measure to evaluate treatment of axial disease with TNF blockers. Treat-to-target (T2T) strategy was studied in various manifestations of pSpA except axial involvement.

Objectives: To assess the effect of tight control T2T strategy on the 12-months dynamics of active MRI sacroiliitis (MRI-SI) in peripheral pSpA pts.

Methods: 89 treatment-naive pts (MF=42/47) with active peripheral pSpA, according to CASPAR criteria were included; mean age 36.5±10.9 yrs., disease duration 12.1±10.1 mo., disease activity index (DAS) 5.2±2.8, C-RP 16.1 [6.6; 31.0] mg/l, ESR 22.5±19.2 mm/h. At baseline and every 3 mo. of therapy all pts underwent standard clinical examination of PsA activity. All patients were evaluated for the presence of inflammatory back pain (IBP) by ASAS criteria. In pts having IBP, disease activity was also measured by BASDAI. At baseline MRI of SIJs was performed in 79 pts, both with and without IBP, on Signa Ovation of Gothenburg; 2Department of Medicine; 3Department of Gastroenterology and Hepatology, Sahlgrenska University Hospital, Göteborg, Sweden

Background: Patients with psoriatic arthritis (PsA) are at increased risk of developing cardiovascular disease.

Objectives: To determine the prevalence of cardiovascular risk factors among patients with PsA followed at a Swedish Rheumatology Clinic in comparison with the general population (GP).

Methods: A questionnaire including weight, height, smoking habits, hypertension, diabetes and hyperlipidaemia was sent to all PsA patients registered at the Rheumatology Clinic at Sahlgrenska University Hospital, Gothenburg (N=962). Obesity was defined as body mass index (BMI) ≥30 kg/m² and overweight as BMI 25–29.9 kg/m². Comparison with the Swedish GP was made using data from the national population health survey, “Health on equal terms”, which is sent yearly to 20 000 citizens by the Public Health Agency of Sweden.

Results: 666 (70%) of the PsA patients with mean age 56±11yrs (mean: ∼52) women, responded. Higher prevalence of self-reported obesity and several cardiovascular risk factors was found in the PsA patients compared with the GP: Obesity 28.7% [GP 15% (95% CI 1.45–15.9%)], current smoking 10.5% [GP 9% (8.2–9.3%)], former smoking 43.4% [GP 23% (22.3–24.0%)], never smoking 48.8% [GP 63% (61.9–63.8%)], treatment of hypertension 32.1% [GP 20% (19.6–21.2%)] and diabetes 8.3% [GP 6% (5.4–6.3%)]. Treatment of hyperlipidaemia was reported by 15.0% [GP no data] and overweight by 36.2% [GP 36% (34.5–36.5%)]. Data stratified by age and sex is shown in the table. (Numbers are % and 95% CI.)

Conclusions: Obesity was highly overrepresented among the PsA patients. It is imperative to take action against weight gain in overweight patients and promote weight loss in obese patients with PsA, since obesity may be involved in the pathogenesis of the disease and may fuel disease activity.

DISEASE ACTIVITY TOGETHER WITH DEPRESSION CONTRIBUTES TO WORK DISABILITY IN PSORIATIC ARTHRITIS

F. Farkas 1, N. Ikumi 1, A. Szempetey 1, B. Kirby 2, O. FitzGerald 1, 3. Department of Rheumatology, 3Department of Dermatology, St. Vincent's University Hospital, Dublin, Ireland, Dublin, Ireland

Background: Work disability (WD) is an important functional outcome measure in inflammatory arthritis, which has been studied comprehensively in rheumatoid arthritis and anklyosing spondylitis, however limited data are available in psoriatic arthritis (PsA).

Objectives: The aim of this study was to compare 1) patient-reported outcomes (PROs), including depression/anxiety scores; 2) physician-assessed measures and 2) disease activity using minimal disease activity (MDA) and Composite Psoriatic Arthritis Disease Activity Index (CPDAI) in PsA patients with and without WD.

Methods: Consecutive patients with PsA fulfilling the CASPAR criteria were enrolled. Patients on disability pension, those with early retirement due to arthritis, those unemployed, away from work due to sick leave were considered as having WD. Patients have completed questionnaires on physical function and health-related quality of life and they were assessed for depression/anxiety using the Hospital Anxiety and Depression Scale (HADS-A and HADS-D) and Penn State Worry Questionnaire (PSWQ). Patients underwent musculoskeletal and skin assessments. Disease activity was compared between work-disabled and employed patients using MDA and CPDAI. Mann-Whitney, Chi-square tests and linear regression model were used to perform statistical analysis.

Results: 100 PsA patients were recruited, 18 were retired, leaving 82 patients available for analysis. Thirty-one (17 male, age 50.9±9.7 years) patients had work disability versus fifty-nine (29 male, age 49.1±8.8 years) employed patients. Work-disabled patients had significantly higher HADS-D score (5.07±3.01 vs. 2.57±2.64; P<0.001) and significantly worse PROMs, including HADS-D, EQ-5D, BASDAI, BASFI, ASQoL, BAI, BFR-A, PSWQ and pain levels. The proportion of pts reporting improvements ≥ 20% was assessed. Results are significant relationship was revealed between depression and CPDAI, the relationship between depression and disease activity using CPDAI in PsA patients with and without WD. Significant relationship was revealed between depression and CPDAI, which suggests that disease activity together with depression contributes to work disability in PsA.

CONTRIBUTES TO WORK DISABILITY IN PSORIATIC ARTHRITIS

1O. Rebrova, 2N. Bludova, 3O. Volman. Department of Rheumatology, St. Vincent’s University Hospital, Dublin, Ireland, Dublin, Ireland

Background: Work disability (WD) is an important functional outcome measure in inflammatory arthritis, which has been studied comprehensively in rheumatoid arthritis and anklyosing spondylitis, however limited data are available in psoriatic arthritis (PsA).

Objectives: The aim of this study was to compare 1) patient-reported outcomes (PROs), including depression/anxiety scores; 2) physician-assessed measures and 2) disease activity using minimal disease activity (MDA) and Composite Psoriatic Arthritis Disease Activity Index (CPDAI) in PsA patients with and without WD.

SECUKINUMAB PROVIDES RAPID AND SUSTAINED PAIN REDUCTION IN PATIENTS WITH PSORIATIC ARTHRITIS

J.B. McInnes 1, P.J. Mease 2, G. Schett 3, B. Kirkham 4, V. Strand 5, N. Williams 6, T. Fox 7, L. Fricio 8, S. Jügi 9, K.K. Gandhi 10 on behalf of the FUTURE 2 study group. 1University of Glasgow, Glasgow, United Kingdom; 2Swedish Medical Center and University of Washington, Seattle, United States; 3University of Erlangen-Nuremberg, Erlangen, Germany; 4Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom; 5Stanford University School of Medicine, Palo Alto; 6RTI Health Solutions, Durham, United States; 7Novartis Pharma AG, Basel, Switzerland; 8Novartis Pharmaceuticals Corp., East Hanover, United States

Background: Pain remains a major clinical challenge in the treatment of psoriatic arthritis (PsA). Secukinumab (SEC) has demonstrated significant efficacy in PsA patients (pts) across a range of quality of life related outcome measures.1,2

Objectives: This post-hoc analysis evaluated change in pain scores from baseline (BL) to Week (Wk) 104 in PsA pts receiving SEC in the FUTURE 2 study.

Methods: FUTURE 2 study design has been reported.2 Mean change from BL to Wk 104 in PsA pts receiving SEC was evaluated using mixed-effects models for repeated measures (MMRM) through Wk 16 and as observed through Wk 104. Proportion of pts reporting improvements ≥ 20% in mean change from BL were assessed. Results are significant relationship was revealed between depression and CPDAI, the relationship between depression and disease activity using CPDAI in PsA patients with and without WD. Significant relationship was revealed between depression and CPDAI, which suggests that disease activity together with depression contributes to work disability in PsA.

EQUIPMENT OF MELANOTIN IN PATIENTS WITH PSORIATIC ARTHRITIS VIOLATIONS OF EMOTIONAL STATUS

I. Blaginina 1, O. Rebrova 1, N. Bludova 2, O. Volman 2. 1Internal Medicine, St. Lukas State Medical University; 2Lugan's Clinical Regional Hospital, Lugansk, Ukraine

Background: The ability of melatonin to reduce the activity of the sympathetic nervous system tone and of putatory-adrnal system ensures its anti-stress properties. It can be used to reduce psycho-emotional manifestations of chronic pain in patients with psoriatic arthritis (PsA).

Objectives: To evaluate the effect of combined therapy with the use of melatonin in the expression of psycho-emotional disorders as a pain in patients with PsA.

Methods: High levels of anxiety and depressive disorders were established in the survey on Spillerberger Anxiety Scale and on Hamilton Rating Scale for Depression (HRDS) in 43 patients with PsA (≥5 SJC & ≥ 5 TJC; CRP >0.3 mg/dL). The quality of life was studied by questionnaire Medical Outcomes Study Short Form (SF-36). The severity of morning stiffness, pain, patient's health status (EWS) - using the 100-mm visual analog scale (VAS). All patients were receiving a stable dose of MTX for at least 6 months. They were divided into two groups; 1 group (n=22) additionally received 3 mg of melatonin at bedtime for 2 months of observation.

Results: At the end of the observation period the frequency and the level of
severity of depression by HRDS (p=0.0098), and the index of personal anxiety (P=0.009) in group 1 decreased. In the 2nd group above mentioned parameters have not changed. On the 1 group data of SF-36 evaluation: the physical health component has improved - the increase of RP and BP 57.4% and 37.8% from the baseline; vitality and role functioning due to emotional state, have also been increased by 34.3% and 43.5%, respectively. In the 2nd group, investigated parameters have not undergone significant changes in dynamics. In the 1 receiving melatonin group TJC and SJC have decreased by 15% and 22% (p=0.0079, p=0.0022, respectively) and their dynamics in the 2nd group was less significant (p=0.013 and p=0.017, respectively). Also, patients in group 1 have had a more significant reduction in the severity of morning stiffness and joint pain, and in the 2nd group the changes were less significant (respectively, p=0.043, p=0.016). Positive dynamics of CRP in group 1 was more significant (p=0.003), than it was in 2 patients' group (p=0.033).

Conclusions: In the group of patients treated with melatonin was noted improvement in general condition (a significant improvement in the parameters of the physical components of health, reduction of depressive and psycho-vegetative disorders) and also more significant decrease of the intensity of pain and of morning stiffness duration, of TJC and SJC, than in not treated with melatonin patients. Inclusion of Melatonin in the comprehensive PsA therapy promotes not only reduction of depression symptoms and sleep disorders, but also reduces the severity of the chronic pain manifestations and, consequently, improves the quality of life of patients with this disease.

**FRI0496** COMPARING TOFACITINIB SAFETY PROFILE IN PATIENTS WITH PSORIATIC ARTHRITIS IN CLINICAL STUDIES WITH REAL-WORLD DATA

*University of California at San Francisco, San Francisco, CA, United States; 2University of California at San Diego, La Jolla, CA, United States; 3Oregon Health and Science University, Portland, OR, United States; 4Universidade Federal do Paraná, Curitiba, Brazil; 5Charité – Universitätsmedizin Berlin, Berlin, Germany; 6Geisel School of Medicine at Dartmouth, Lebanon, NH; 7Pfizer Inc, Groton, CT; 8Pfizer Inc, New York, NY; 9Pfizer Inc, Collegeville, PA, United States*

**Background:** Tofacitinib is an oral Janus kinase inhibitor under investigation for the treatment of psoriatic arthritis (PsA). Two Phase 3 studies have been completed (NCT01877688; NCT01882438) and a long-term extension (LTE) study is ongoing (database not locked; NCT01976364).

**Objectives:** To compare incidence rates (IR) for adverse events (AEs) of special interest in a tofacitinib cohort from the Phase 3 PsA trials with real-world experience in a comparison cohort from the US Truven MarketScan database.

**Methods:** The tofacitinib cohort included adult patients (pts) from 2 Phase 3 studies with ≥6 months PsA diagnosis who met ClASsification of Psoriatic Arthritis (CASPAR) criteria, had active plaque psoriasis, and active arthritis (≥3 swollen joints, ≥3 tender/painful joints) and who were treated with tofacitinib. Pts were grouped by those who received tofacitinib 5 (N=238) or 10 mg (N=236) twice daily (BID) in the 2 Phase 3 studies, and all pts who received ≥1 dose of tofacitinib in the 2 Phase 3 studies or the LTE (tofacitinib all doses, N=783). The comparison cohort (N=774) comprised pts with moderate to severe PsA, defined by ≥3 swollen joints, ≥3 tender joints, ≥2 diagnosis codes on 2 unique calendar days (≥1 by a rheumatologist) between Oct 2010 and Sep 2015, initiating therapy with a systemic agent for PsA. Key Phase 3 study exclusion criteria were applied to the comparison cohort. IRs for serious infection events (SIEs), herpes zoster (HZ), malignancies (excluding non-melanoma skin cancer [NMSC]), NMSC and major adverse cardiovascular events (MACE) were compared.

**Results:** Mean age, gender and diabetes history were generally similar between the tofacitinib and comparison cohorts (48.7–49.5 years, 42.4–49.2% male, 12.2–15.7% with diabetes history). Overall more pts treated with tofacitinib had prior experience with corticosteroids (15.7–28.2%), conventional synthetic disease-modifying antirheumatic drugs (100%) and tumour necrosis factor inhibitors (48.1–55.9%) vs the comparison cohort (11.9%, 46.6% and 36.6%, respectively). IRs for SIEs were lower for the tofacitinib vs the comparison cohort (Table 1). The tofacitinib cohort had a higher rate of HZ vs the comparison cohort (Table 1). IRs for malignancies and MACE were similar between cohorts (Table 1).

**Conclusions:** IRs of AEs of special interest reported in tofacitinib PsA Phase 3 studies were generally comparable to those in a general PsA population comprising pts receiving a range of biologic agents, except HZ, which was higher for pts treated with tofacitinib but similar to the incidence observed with tofacitinib treatment in other indications.

**FRI0497** WHAT CHOICES DO RHEUMATOLOGIST MAKE IN ESCALATING DMARD THERAPY IN EARLY PSA?

J. Luime, I. Tchetverikov, A. Wervers, A. Gerards, M. Kok, C. Appels, H. van Groenendael, W. vd Graaff, L.-A. Korswagen, J. Veris, M. Hazes, M. Visi on behalf of Cicero. 1 Rheumatology, ErasmusMC, Rotterdam; 2 Data, Analytics and BI, Maxima Medisch Centrum, Veldhoven; 3 Rheumatology, ASZ, Dordrecht; 4 Rheumatology, Fransciscus - Vlietland, Schiedam; 5 Rheumatology, Maassstadziekenhuis, Rotterdam; 6 Rheumatology, Amphia, Breda; 7 Rheumatology, Reumazorg zuidwest Nederland, Roosendaal; 8 Rheumatology, Beatrix ziekenhuis, Gorinchem, Netherlands; 9 Rheumatology, Reumazorg zuidwest Nederland, Goes, Netherlands

**Background:** Psoriatic arthritis (PsA) is a multifaceted disease.

**Objectives:** To newly diagnose PsA patients were included in the Dutch Early south-west Psoriatic Arthritis cohort (DEEPAR) study between August 2013 and March 2016. Initial drug treatment and escalation of therapy were described for all patients. Drivers of treatment changes in the first year were evaluated by mixed

ordered ordinal regression with outcome treatment change and variables joints (66/68 count), skin (PASI), enthesis (LEI and MASES), dactylitis (LDI) and axial disease (BASDAI).

Results: 323 patients had had baseline assessment in March 2016. Their average age was 50.0 years (SD 13.8) and 49% were male. 80% patients had arthritis disease (MDA >30%) and 76% LDA demonstrated that patients with psoriatic arthritis had higher enthesis subtype, 2% axial disease and 9% dactylitis. Initial treatment consisted of methotrexate (MTX) (52%), in 7% of other synthetic disease modifying antirheumatic drugs (sDMARDS) and due to treatment of psoriasis 3% biologicals. Within the different phenotypes MTX was most frequently started in polyarthritis (93%) followed oligoarthritis (83%), monarticular (53%) and other phenotypes (5%). At 12 months 70% (n=148) stayed on the initial drug. Of those switched, 9 started MTX, within the initial MTX users (n=74) almost equal percentages stopped, switched to metotrex (4%). A smaller percentage (2%) switch to lefunomide in medication were driven by swollen joint count and the presence of dactylitis (Table 1).

Conclusions: MTX was initiated in about half of the early PsA patients. The majority of patients were kept on the initial treatment strategy in first year. Failure on initial drug led to variation in subsequent drugs with additional start of other sdmards, switch subcutaneous MTX, to other sdmards or to biological dmards. Treatment change was driven by Swollen Joint Count and presence of Dactylitis. Skin, Enthesis and Axial disease did not play a role in escalating treatment.

FR10498 | OUTCOMES ASSOCIATED WITH ACHIEVEMENT OF VARIOUS REAL-WORLD STUDY ON THE PATTERNS AND COST OF TREATMENT TARGETS IN PATIENTS WITH PSORIATIC ARTHRITIS RECEIVING ADA

J. Smolen1, D. Aletaha1, D.D. Gladman2, Y. Zhou1, P. F. Ganz1, 1Medical University of Vienna, Vienna, Austria; 2University of Toronto Western Hospital, Toronto, Canada; 3AbbVie, Inc., North Chicago, United States; 4AbbVie, Inc., Baar, Switzerland

Background: Various instruments are currently used for disease activity and outcome assessment in psoriatic arthritis (PsA). Some measures attempt to incorporate the total spectrum of psoriatic disease manifestations [eg, minimal disease activity index for PsA (DAPSA)]. Whether in patients (pts) with PsA it is sufficient to primarily consider joint disease aspects remains unclear.

Objectives: To compare DAPSA remission and low disease activity (LDA) with MDA and very low disease activity (VLDA) for the presence of residual abnormalities of the respective composing variables.

Methods: This post hoc analysis included pts with PsA receiving adalimumab (ADA) in one of two multicenter studies: ADEPT was a 24-week (wk), randomized, double-blind, placebo-controlled trial; ACCLAIM was a 12-wk, open-label study conducted in Canada in care settings that reflected usual practice. Frequencies of DAPSA remission/LDA and MDA/VLDA were summarized, and the individual PsA manifestations within these states were assessed. ADA was summarized from the following continuous variables: swollen (66) and tender (68) joints, pt pain (PP), cm), and C-reactive protein (CRP, mg/dL). DAPSA remission was defined as ≤ 20mm, HAQ ≤ 0.5, and PASI ≤ 1 swollen joint, ≤ 1 entheseal point, ≤ 4 and DAPSA LDA as > 20mm, HAQ ≤ 0.5, and PASI ≤ 1 swollen joint, ≤ 1 entheseal point, ≤ 4 and 1 joint overlap, and ≤ 14.

MDA was calculated as ≤ 4 for PsA disease activity for joints and ≤ 14 for psoriatic arthritis, with the exception of experiencing numerically higher PP, PtGA, and PASI scores. Whether in patients (pts) with PsA it is sufficient to primarily consider joint disease aspects remains unclear.

Results: Among 151 pts receiving ADA in ADEPT, 33 (22%) each achieved DAPSA remission and LDA at wk 24, and 10 (14%) and 11 (7%) achieved MDA and VLDA, respectively. Pts achieving DAPSA LDA appeared to mirror those in the remaining pts, with 7892 (42.14%) discontinuing, and 1630 (8.75%; overlap ≤ 30 days) and 17,334 (93.03%) prevalent. Almost half (n=8994; 48.27%) of the pts continued treatment change was driven by Swollen Joint Count and presence of Dactylitis. Skin, Enthesis and Axial disease did not play a role in escalating treatment.

FR10499 | REAL-WORLD STUDY ON THE PATTERNS AND COST OF TREATMENT FAILURE IN PATIENTS WITH PSORIATIC ARTHRITIS USING US CLAIMS DATA

K. Price1, E. Alemao1, L. Burns1, Z. Guo2, V. Anupindi2, S. Goday2, 1Bristol-Myers Squibb; 2Mu Sigma, Princeton, United States; 3Mu Sigma, Bangalore, India

Background: Current treatments for psoriatic arthritis (PsA) are associated with a range of limitations, e.g. side effects, safety concerns and inadequate efficacy. The economic burden of biologic (bDMARD) failure among patients (pts) with PsA is thought to be substantial, but there is a need to quantify this formally.

Objectives: To evaluate PsA treatment failure (i.e. discontinuation and switching rates) in a US managed care setting and its economic consequences.

Methods: Pts aged ≥ 18 years with 2 diagnosis codes for PsA and 1 claim for a bDMARD from 1 Jan 2007 to 31 Mar 2015 in the Truven Health MarketScan® Database (Commercial and Supplemental Medicare) were eligible for the study. Pts were considered incident if they did not have a PsA diagnosis or a bDMARD prescription during 1 year prior to first PsA diagnosis in the study period, and as prevalent otherwise. Pts had a 1-year follow-up from first PsA diagnosis in the study period. The percentages of pts discontinuing a drug, switching to another drug or continuing on the same drug for 1 year from first date of treatment were reported. Healthcare costs for 1 year from initiation of the first bDMARD, (medical and drug costs associated with treatment failures) were reported as cost per-pt-per-month (PPPM), and a generalized linear model was used to analyse the cost after controlling for various demographic variables.

Results: Of the 18,632 pts treated with a bDMARD, 1298 (6.97%) were incident and 17,334 (93.03%) prevalent. Almost half (n=8994; 48.27%) of the pts continued treatment failure was high. Follow-up costs for pts who switched discontinuing, and 1630 (8.75%; overlap ≤ 30 days) switched to another drug. Among incident pts, only 240 (18.49%) continued, 809 (62.33%) discontinued, and 231 (17.80%; overlap ≤ 30 days) and 18 (1.38%; overlap ≥ 30 days) switched to another drug. Pts with an overlap > 30 days were excluded from the analysis. Overall, pts who switched had a higher PPPM total cost ($3217) than those who discontinued ($2650; p < 0.0001) or continued ($2868; p < 0.0001). Similar results were observed in the prevalent and incident groups, respectively, with pts who switched continuing a higher PPPM total cost ($3241 and $3779) compared with those who discontinued ($2583 and $2327; both p < 0.0001) or continued ($2700 and $2600; both p < 0.0001). Increasing age, and increasing ineffectiveness score predicted a higher cost (p = 0.002) and with a 0.49% higher cost in the prevalent group (p = 0.001). Among prevalent pts, females had a 3.08% higher cost than males (p = 0.0068). The Charlson Co-morbidity Index score predicted a higher cost (p = 0.001) and cost of treatment failure as defined by switching or discontinuation were high. Follow-up costs for pts who switched were higher than for pts who continued or discontinued their medication. Baseline age, female sex and comorbidities were associated with higher treatment costs.

AVOIDANCE OF PHYSICAL ACTIVITY LEADS TO REDUCED INFLAMMATORY ENTHESITIS ON ULTRASOUND

K. Wervers1, I. Herrings1, J.J. Luime1, M. Moed1, I. Tchetverikov2, A.H. Gerards3, J.M.W. Hazes1, L. Vis1, 1Rheumatology, Erasmus MC, Rotterdam; 2Rheumatology, Albert Schweitzer Hospital, Dordrecht; 3Rheumatology, Vlietland Hospital, Schiedam, Netherlands

Background: Enthesitis is one of the manifestations of psoriatic arthritis (PsA), but no clear definition for the diagnosis exists. To further evaluate the added value of sonographic evaluation of entheses in diagnosing enthesis, more knowledge on factors associated with sonographic enthesis is needed.

Objectives: We aim to evaluate which clinical characteristics are associated with sonographic enthesis changes in a cross-sectional PsA population.

Methods: established PsA patients were asked to participate, irrespective of enthesitis complaints. Patients were interviewed on history of musculoskeletal complaints (MSC), more specifically if they had complaints during activities and whether they avoided physical activities (during exercise, work, household tasks, hobbies, chores). Tenderness was determined in the MASEI entheses and those in the Leeds Enthesitis Index (LEI) and Maastricht Ankylosing Spondylitis Enthesitis Score (MASES). Previously we showed that a modified Madrid Sonographic Enthesitis Index (MASEI, i.e. excluding knee enthesis thickness and scoring PD-signal semi-quantitatively) distinguishes entheses of PsA patients from those of healthy volunteers (1). A sonographist unaware of clinical findings scored the modified MASEI. Multivariable linear regressions of structural (erosions, calcifications, structure and inflammatory (thickness, bursitis and PD) modified MASEI scores were performed (transformed for a better distribution). Variables included age, gender, PsA duration, medication use (non/NSAIDs vs. sDMARDs vs. bDMARDs), LEI + MASES and avoidance (no vs. yes).

Results: 84 PsA patients participated (45 males, mean age 55, median disease duration 8 years). Median modified MASEI was 12 (IQR 7.25–17), with a structural component score of 7 (3–10) and inflammatory component score of 6 (3.5–8). 8 patients used no medication of NSAIDs only, 36 used sDMARDs and 40 used bDMARDs. 45 patients reported avoiding activities. In a multivariable analysis, inflammatory modified MASEI was negatively associated with avoidance (i.e. fewer inflammatory changes in patients reporting avoidance) and positively associated with age, BMI and use of biologics. Structural MASEI was positively associated with age only.

Conclusions: Avoiding physical activities is associated with fewer inflammatory changes of the entheses. More inflammatory changes are seen in older or overweight patients and patients on biologicals, in the latter possibly due to more active disease.

REAL-WORLD USE OF SECUKINUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS IN THE UNITED STATES: PATIENT PROFILE AND DOSING REGIMEN USE

K. Oelke1, G. Chun2, Y. Li2, X. Liu2, J.B. Palmer2, 1Rheumatic Disease Center, Glendale; 2Novartis Pharmaceuticals Corporation, East Hanover; 3KMK Consulting, Inc, Morristown, United States

Background: As of January 15, 2016, secukinumab became the first fully human anti-interleukin-17 monoclonal antibody approved for the treatment of active disease with psoriatic arthritis (PsA) in the United States. Secukinumab may be administered with or without loading of 150 mg or 300 mg (patients with concomitant moderate to severe psoriasis only) at weeks 0, 1, 2, 3 and 4 followed by maintenance dosing every 4 weeks. The use of a loading regimen of secukinumab in a real-world setting of patients with PsA has not been evaluated since its approval in the United States.

Objectives: To better understand the real-world use of secukinumab by describing the demographic, clinical and treatment characteristics (loading vs no loading) of secukinumab-treated patients with PsA.

Methods: Retrospective data from the Symmetry Health Solutions Lx commercial claims database were used to identify patients who had ≥ 1 secukinumab claim between 01/15/2016 and 06/30/2016. Patients who were included in the analysis were aged ≥ 18 years, had ≥ 1 ICD-9 code of 696.0 or ICD-10 code of L40.5 for PsA and had ≥ 1 pharmacy or medical claim in the 12 months prior to their first secukinumab claim (index date). Patient demographics and secukinumab dosages were examined at the index date. Clinical characteristics, comorbidities and treatment history in the 12 months prior to the index date were identified and presented by use vs no use of loading.

Results: A total of 764 patients met the inclusion criteria. The mean (SD) age was 50.7 (11.6) years, 58.5% of patients were female and 39.8% of patients were from the south. The most common specialties prescribing secukinumab to patients with PsA were rheumatologists (52.1%) and dermatologists (30.0%). A total of 608 patients (79.6%) received loading and 156 (20.4%) did not; at the index date, the majority of patients received secukinumab at the 300-mg dose (73.2%) and the loading (70.2%) and no loading (68.6%) groups. Patient demographics, clinical characteristics and treatment history were generally comparable between groups (Table 1). However, more patients with loading had prior oral corticosteroid (OCS; 30.9% vs 20.5%), targeted synthetic disease-modifying antirheumatic drug (tsDMARD; 24.7% vs 17.3%) and biologic (64.3% vs 59.6%) use compared with those without loading. The most prevalent comorbidities were psoriasis (58.6%), hypertension (34.4%) and hyperlipidemia (26.8%). A higher proportion of patients with loading had hypertension (35.2% vs 31.2%), rheumatoid arthritis (RA; 15.3% vs 10.9%), fatigue (13.5% vs 9.0%) and anxiety (13.3% vs 8.3%) and a lower proportion had psoriasis (57.4% vs 64.1%) compared with those without loading.

Conclusions: This US claims-based study found the majority (≈ 73%) of secukinumab-treated patients with PsA were initiated with a loading regimen. Most patients initiated the 300-mg dose regardless of loading. A higher proportion of patients with loading had prior OCS, tsDMARD and biologic use, as well as hypertension, RA, fatigue and anxiety compared with those without loading, suggesting patients who initiated with loading had more refractory disease. These results provide the first insights into real-world use of secukinumab with and without loading in patients with PsA in the United States.

IXEKIZUMAB REDUCES DISEASE ACTIVITY IN ACTIVE PSORIATIC ARTHRITIS PATIENTS WHO HAD PREVIOUS INADEQUATE RESPONSE TO TUMOUR NECROSIS FACTOR-INHIBITORS

L.C. Coates1, P. Mease2, M.E. Husni3, E. Lespessailles4,5, D.H. Adams6, Ö. Benichou6, L. Kerr7, P. Hellwell1, 1University of Leeds, United Kingdom; 2Swedish Medical Center and University of Washington, Seattle; 3Cleveland Clinic, Cleveland, United States; 4Orlés University; 5Department of Rheumatology, C.H.R. Orlés, Orlés, France; 6Eli Lilly and Company, Indianapolis, United States

Background: Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory disease associated with psoriasis, peripheral arthritis, enthesitis, dactylitis, and spondylitis. Ixekizumab (IXE), a monoclonal high affinity antibody that selectively targets interleukin-17A, has improved disease activity and physical function in bDMARD-naïve patients with active PsA.1 Herein, results are presented from a phase 3 trial (SPIRIT-P2; NCT02349295) with IXE in patients with active PsA and previous inadequate response to tumour necrosis factor-inhibitors (TNF-i).

Objectives: To explore the impact of IXE, as assessed by composite endpoints that incorporate multiple disease domains including peripheral arthritis, skin disease, enthesitis, dactylitis, spinal disease, function, and global disease assessment, up to 24 weeks (wks).

Methods: In this phase 3, multicentre, double-blind study, 363 adult patients with active PsA and a history of inadequate response to TNFi-α were randomly assigned at a 1:1:1 ratio to subcutaneous administration of 80-mg IXE either every 4 wks (Q4W; N=122) or every 2 wks (Q2W; N=123) following a 160-mg starting dose at Wk 0 or placebo (PBO; N=118). TNF-i inadequate response was defined as lack of efficacy to one or two TNFi-α intolerance to TNF-i. Response to treatment and disease activity were measured at Wks 12 and 24 by the following composite endpoints: minimal disease activity with skin component measured with the Psoriasis Area and Severity Index (MDA) or the static Physician Global Assessment of psoriasis (mMDA) and Composite Psoriatic Arthritis Disease Activity Index (cDAPSA), as well as traditional measures by Psoriatic Arthritis Response Criteria (PsARC). Treatment comparisons were made by a logistic regression model for categorical data with missing values imputed by nonresponder imputation (NRI); a mixed model for repeated measures analysis was used for continuous data.

Results: At Wks 12 and 24, significantly more patients receiving IXEQ4W or IXEQ2W achieved MDA, mMDA, and PsARC compared with patients receiving PBO (Table). Results for MDA were similar to mMDA results within each treatment group at each time point. CPDAI total scores for patients receiving IXEQ4W or IXEQ2W were significantly improved compared with results for patients receiving PBO.

Table: Summary of Composite Endpoints at Weeks 12 and 24

VALIDATION OF NEW POTENTIAL TARGETS FOR REMISSION IN PSORIATIC ARTHRITIS IN PATIENTS TREATED WITH GOLIMUMAB

L.C. Coates1, P. Rahman2, E. Psaradellis3, A. Karellis3, E. Rampakakis3, B. Osborne4, G. Tkaczyk4, A.J. Lehman5, F. Nantel4, 1Leeds University, Leeds, United Kingdom; 2Memorial University, St-Johns, NL; 3JSS Medical Research, Montreal, QC; 4Janssen Inc, Toronto, ON, Canada

Background: Treat to target recommendations in psoriatic arthritis (PsA) stated that the target of treatment should be remission or inactive disease. At that time, no definitions of remission or inactive disease existed and the only validated target available was the minimal disease activity (MDA) criteria. Since then, other potential targets have been developed including very low disease activity (VLDA) and the Disease Activity in PsA (DAPSA) score remission.

Objectives: Using an existing dataset allowing calculation of DAPSA and clinical cDAPSA scores and the Vlda criteria, the objectives were to calculate the proportion of patients achieving these criteria, their prognostic value and the overall patient impact of these disease states.

Methods: BioTRAC is an ongoing, prospective registry of inflammatory arthritis patients initiating treatment with infliximab, golimumab (GLM) or ustekinumab. PsA patients treated with GLM or included. Data collected at baseline, 6 and 12 months (mts) were used. DAPSA remission was defined as: TJC + SJ + Pga + Pt pain + CRP ≤0.4. cDAPSA Remission was defined as: TJG + SJG + PtgA + Pt pain ≤0.4. Low disease activity (VLDA) was achieved when all 7 MDA criteria were satisfied: TJC28≤1, SJ28≤1, PASI<1, Pain (VAS)<15mm, PGA (VAS) <20mm, HAQ ≤0.5 and tender enthesal points ≤1. Correlation between DAPSA, cDAPSA and VLDA were based on bivariate analysis.

Results: A total of 188 patients (53.2% female gender) were included with a mean (SD) disease duration of 5.46 (6.91) years. DAPSA remission was achieved in 5.1%, 24.2% and 30.0% of patients at baseline, 6 mts and 12 mts, respectively. Those patients had a significant reduction in the number of TJC, SJC, enthesitis and dactylitis (<0.043). cDAPSA remission was achieved in 5.2%, 33.1% and 38.3% of patients at baseline, 6 mts and 12 mts, respectively. Those patients had a significant reduction in the number of TJC, SJC and enthesitis only (p<0.002). VLDA was achieved in 2.1%, 17.2% and 15.6% of patients at baseline, 6 mts and 12 mts, respectively and those patients had a significant reduction in the number of TJC, SJC, enthesitis and PASI (p<0.002). The overall correlation for DAPSA or cDAPSA remission vs. VLDA achievement were both at 0.999 (Asymptotic Standard Error <0.027) although this is likely driven by the high number of patients who are not in either state. 75% and 53.3% of patients in DAPSA and cDAPSA remission, respectively, also achieved VLDA (<0.001). In contrast, patients who did not achieve either cDAPSA nor DAPSA never achieved VLDA. Nonetheless, patients in remission had significantly greater HAQ scores (p<0.03) if they had remaining dactylitis or active skin disease (BSA>10%; cDAPSA only).

Conclusions: DAPSA, cDAPSA and VLDA represent new potential target for remission in PsA with VLDA being the most stringent criteria. There was a high level of correlation between these scores although residual activity in dactylitis and skin despite DAPSA remission has some impact on patients’ function.

FR0504 APREMILAST EXPANDS IL-10-PRODUCING REGULATORY B CELLS, AND DECREASES TH1 AND TH7 CELLS IN PSORIATIC ARTHRITIS AND PSORIASIS

A. Mavropoulos1, E. Zafirou2, A. Varna1, E. Papadopoulou2, I. Alexiou1, A.-V. Roussaki-Schulze2, D.P. Bogdanos3, L.I. Sakkas1, 1Rheumatology and Clinical Immunology; 2Dermatology, University of Thessaly, School of Health Sciences, LARISSA, Greece

Background: IL-10-producing regulatory B cells (Bregs), also known as B10 cells, are decreased and inversely correlated with IFN-γ and IL-17-producing NK and T cells in patients with psoriatic arthritis (PsA) and psoriasis (Ps) (1-3)

Objectives: To assess whether or not apremilast, a PDE4 inhibitor recently approved for the treatment of Ps and PsA, is able to induce IL-10-producing B cells and decrease Th1 cells and Th17 cells in vivo

Methods: PBMCs and magnetically purified B cells were isolated from 21 patients (7 PsA, all responders; 14 Ps, 9 responders) at baseline and post-apremilast treatment (3 months and 6 months in responders; at 3 months in non-responders, as they switched to biologics). Phenotypic analysis of CD3, CD19, CD24, CD27, CD86 and intracellular expression of cytoklastic IL-10, IFN-γ, IL-17 after bacterial CpG (ODN2006) and PMA/ionomycin stimulation was examined by flow cytometry

Results: At 6 months, apremilast significantly increased IL-10-producing Bregs (IL-10+CD19+, B10 cells) compared to baseline and 3 months. B10 cells increase was confined mainly to the transitional Bregs (CD19+CD27+CD24high). IFN-γ+CD3+ (Th1) and IL-17+CD3+ (Th17) cells were significantly decreased at 3 and 6 months (p<0.05, for both). There was an inverse correlation between percentages of B10 cells and IFN-γ+producing CD3+ cells. The percentage of B10 cells were not changed post-treatment in non-responders.

Conclusions: Our data suggest that apremilast may exert its therapeutic effect through the expansion of IL-10-producing Bregs and the decrease of IFN-γ- and IL-17-producing T cells.

FR0506 HLA PROFILES AND THEIR ASSOCIATIONS WITH DISEASE PHENOTYPES IN A CANADIAN PSORIATIC ARTHRITIS (PSA) COHORT

M. Khraishi1, C. Molta2, Z. Khraishi3, A.M. Lewis4, 1Rheumatology, Memorial University of Newfoundland, St. John’s, Canada; 2Rheumatology, MainLine Rheumatology Lankenau Medical Center, Philadelphia, United States; 3University of Western Ontario, London; 4Epidemiology, Memorial University of Newfoundland, St. John’s, Canada

Background: PSA is a chronic disease with known genetic predisposition that affects 0.3% to 1% of the general population. Certain HLA alleles were reported to be more predominant in PSA and to be associated with certain manifestations

Objectives: To determine HLA alleles prevalence in PSA patients and their association with clinical features and the severity of PSA in these patients

Methods: Two cohorts of early established PSA were followed prospectively.Clinical and laboratory data were collected at 6 months intervals, included PASI scores, nail involvement, joint counts, patient reported outcomes, comorbidities and laboratory parameters. We performed a data-driven consensus on the optimal target to use but also active coaching of the patients and their physicians to adjust treatment according to the optimal targets. Data on patients with HLA typing results that were collected longitudinally during the observation period was used

Results: The cohorts included 265 patients. Of those, one hundred thirty five patients had their HLA analysis done. Fifty one percent of the patients were male, the mean age at onset of PSA 43.07 (19–76) years. Mean age of PSA diagnosis was 33.47 years. Sixty four percent had polyarticular involvement at base line and 17% had documented axial involvement. Forty four haplotypes were reported in our cohort of patients: HLA B27 was present in 33% of the patients (as compared to 6.77% in an Irish control population). HLA A1 was present in 31%, B8 in 21%, B57 in 6%, B44 in 24.5%, B51 in 10%, HLA B62 in 5.6%, HLA B62 in 7%, HLA B4 in 43.6% and Bw6 in 46.5%. The following associations were found to be significant: HLA B49 was negatively associated with age of onset of PSA with a Pearson correlation of -0.10 (P = 0.057), also, HLA A23 had a correlation of -0.23 (P = 0.016). HLA B44 was associated with increased total number of comorbidities, Pearson correlation was 0.33 (P = 0.001).

Conclusion: HLA B22 was associated with more severe PASI score with a correlation of 0.488 (P = 0.008).

Of note: the only case in the cohort with Crohn’s disease had HLA B12 which was previously reported in spondylitis

135 patients were studied,51% were male. The mean age of PSA onset was 43.07 years and 33.4 for PsO. 64% had polyarticular disease while 17% had axial involvement. 42 alleles were studied, of those, HLA B27 was present in 33% of patients (vs.77% controls) HLA A1 in 31%, B8 in 21%, B27 in 6.6%, B44 in 24.5%, B51 in 10%, B58 in 5.6%, HLA B62 in 7%, HLA Bw4 in 43.6% and Bw6 in 46.5%. The following associations were significant: HLA B49 & HLA A23 were associated with age of onset of PSA (correlation of -0.610 (P = 0.007), also, HLA A23 had a correlation of -0.232 (P = 0.016). HLA B44 was associated with increased number of comorbidities (correlation 0.332 (P=0.001)). HLA B22 was associated with severe PASI score (correlation of 0.488 (P = 0.008). Of note: the only case in our cohort with Crohn’s disease had HLA B12 which was previously reported in spondylitis

Conclusions: The majority of patients had polyarticular involvement.HLA B27, HLA Bw4 and HLA B4 were the most frequent alleles. We found high percentage of patients with HLA B27, HLA A1 vs controls.HLA B27 prevalence was higher in patients with axial involvement but it did not reach significance in our cohort. HLA B44 was strongly associated with increased comorbidities (previous reports suggested protective effect of this allele). HLA B22 was associated with more severe PASI scores.

Disclosure of Interest: None declared

The relationship between 10-year cardiovascular risk scores and disease activity in patients with psoriatic arthritis

N. Ikumi1, F. Farkas1, A. Szentpetery1, B. Kirby2, O. FitzGerald1.

1Rheumatology; 2Dermatology, St. Vincent’s University Hospital, Dublin, Ireland

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with an increased prevalence of cardiovascular (CV) disease. This increase may in turn be due to a higher prevalence of traditional CV risk factors as well as to persistent inflammatory musculoskeletal and skin disease. Disease activity in PsA is associated with Composites Psoriatic Arthritis (CPSA) across 5 domains of involvement: peripheral joints, skin, entheses, dactylitis and spinal manifestations. Long-term CV risk is evaluated using several methods for general population.

Objectives: (1) To describe CV risk factors and 10-year CV risk scores among patients with PsA; and (2) to correlate with baseline CPDAI in this longitudinal study.

Methods: PsA patients fulfilling the CASPAR criteria were enrolled consecutively from Rheumatology clinics. Fasting bloods were obtained for glucose, insulin, lipids. Patients underwent thorough physical examination, joint and skin assessments and completed questionnaires on health, depression/anxiety and quality of life. Four different CV risk scores were calculated: (1) Framingham Coronary risk score (FCS); (2) American College of Cardiology and American Heart Association (ACC/AHA) 10-year atherosclerotic cardiovascular disease (ASCVD) risk score (FCS); (3) Systematic Coronary Risk Evaluation (SCORE) algorithm; and (4) QRISK2 (2016). CPDAI was calculated with CPDAI cutoff ≤4 representing low/minimal disease activity (LDA) or remission. CPDAI ≥4 represented active disease requiring treatment change.

Results: 100 PsA patients were recruited with mean age 52.4±10.5 (male 55%), Mean disease duration for PsA was 17.9±10 years. 58 patients (age 52.4±9.6, male 60.3%) had CPDAI<4 (LDA Gp) and 41 patients (age 52.4±11.9, male 48.8%) had CPDAI>4 (active Gp) at baseline. There were significantly more patients with BMI ≥35 in active Gp, but mean BMI, waist/hip ratio, blood pressure, fasting glucose, insulin, lipids, and patients taking NSIADs, oral corticosteroids, Metformin and/or biologics treatment were otherwise similar compared to LDA Gp. Skin (Psoriasis Area Severity Index (PASI); Dermatology Life Assessment Questionnaire (DLQI)) assessments together with levels of inflammatory markers such as C-reactive protein (CRP) were also similar in both groups. More active Gp had enthesitis (58.5%) and acute dactylitis (14.6%) (P<0.01 and 0.02, respectively). The mean FCS, ASCVD, SCORE and QRISK2 were similar in both groups (8.5±7.1% vs. 6.2±8.9%, P=0.11, 9.8±9.5% vs. 7.8±7.9%, P=0.54, 2.2±2.6% vs. 2.0±2.7%, P=0.81; 11.2±9.2% vs. 11.3±11.%, P=0.97, LDA Gp and active Gp, respectively). Interestingly, there were more smokers in LDA Gp (60.3% vs. 39.0%; P=0.04) and this likely accounts for the higher number of LDA Gp patients with FCS ≥10%.

Conclusions: We found similar prevalence of traditional CV risk factors and similar 10-year CV risk scores in PsA patients regardless of their CPDAI. Further correlation with measures of disease activity over time will be required.

The effect of certolizumab pegol on extra-articular manifestations of psoriatic arthritis over 4 years of treatment in patients with and without prior anti-TNF exposure

1St. Vincent’s University Hospital and Conway Institute for Biomolecular Research, University College Dublin, Dublin, Ireland; 2UT Southwestern Medical Center and Dallas Metropole Clinical Research Center, Dallas; 3TUC San Diego School of Medicine, La Jolla, United States; 4UCB Pharma, Monheim, Germany; 5UCB Pharma, Raleigh, United States; 6Krembil Research Institute, Toronto Western Hospital, Toronto, Canada

Background: Extra-articular manifestations (EAMs) of psoriatic arthritis (PsA) include nail psoriasis, dactylitis, and enthesitis, which can significantly impact patients’ (pts’) quality of life.1 In the Rapid-Psa trial (NCT01087788), certolizumab pegol (CZP) improved the signs and symptoms of EAMs in pts with PsA over 96 weeks (wk).

Objectives: To report improvements in EAMs of PsA in pts treated with CZP over 4 years, both with and without prior anti-TNF exposure.

Methods: The Rapid-Psa trial was double-blind and placebo-controlled to Wk4, dose-blind to Wk48, and open-label (OL) to Wk216. Pts had active PsA and had failed ≥1 DMRD. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose at Wk0), 4 continued their assigned dose in the OL period. We present EAM data for those pts originally randomized to CZP, with involvement of the particular EAM at baseline (BL), and without prior anti-TNF exposure. EAMs assessed include nail psoriasis (modified Nail Psoriasis Severity Index [mNAPSI]), BL involvement = BL mNAPSI >0), enthesitis (Leeds Enthesitis Index [LEI], BL involvement = BL LEI >0), and dactylitis (Leeds Dactylitis Index [LDI], BL involvement = BL LDI >1). Differences were analyzed with the Wilcoxon non-parametric test and Hedges’ g calculated.

Results: A total of 409 PsA pts were randomized; 273 received CZP from Wk0. Among CZP-randomized pts, 197 had nail psoriasis at BL (199 without, and 38 with, prior anti-TNF exposure), 172 had enthesitis (133 without, and 39 with, prior anti-TNF exposure), and 73 had dactylitis (56 without, and 17 with, prior anti-TNF exposure). Although relatively few pts were anti-TNF experienced, a large proportion of pts both with and without prior anti-TNF exposure with BL involvement went on to achieve total resolution of the respective EAM following 48 wks of CZP treatment (Table). Among pts completing the study, the proportions achieving total resolution were maintained or further increased from Wk48 to Wk216 (Table). Mean scores of all EAMs showed improvements by Wk48 of CZP treatment in pts both with and without prior anti-TNF exposure, which were maintained to Wk216 in pts completing the study (Table).

Table: Improvements in extra-articular manifestations of PsA over 216 weeks of CZP treatment in patients with and without prior anti-TNF exposure (observed values)

SAFETY AND EFFICACY OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, UP TO 24 MONTHS IN PATIENTS WITH ACTIVE PsORATIC ARTHRITIS: INTERIM DATA FROM OPAL BALANCE, AN OPEN-LABEL, LONG-TERM EXTENSION STUDY

1Department of Medicine, University of Queensland, St Lucia, Brisbane, Australia; 2Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 3Department of Rheumatology, Altona Center for Clinical Research, Duncansville, PA; 4Swedish Medical Center and University of Washington, Seattle, WA, United States; 5Department of Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada; 6United Rheumatology, LLC, San Antonio, TX, USA; 7Columbia University Medical Center and University of South Carolina, M.C.P.ended, Yucatan, Mexico; 8Pfizer Inc, Groton, CT; 9Pfizer Inc, Collegeville, PA, United States

Background: Tofacitinib is an oral Janus kinase inhibitor under investigation for psoriatic arthritis (PsA). Interim data (database not locked) from <24 months’ participation (3 years’ total treatment duration) for patients (pts) with active PsA in an ongoing, open-label, long-term extension study (LTE; NCT01976364 OPAL Balance) is reported.

Objectives: To evaluate the safety, tolerability and efficacy of tofacitinib in pts with active PsA.

Methods: Pts who were ≥18 years of age, with active PsA (≤35% DAPSA score, ≥12/14 – 14; high disease activity (HighDA): >28; mild disease activity (ModDA): ≤14; low disease activity (LowDA): ≤12). The Kappa statistic was used to describe the agreement between the numbers of pts in respective disease activity categories reported by the 2 independent assessors. A significance level of 0.05 was used.

Results: Amongst the 151 and 162 pts randomized to receive ADA and PBO, respectively, there was 100% agreement between the numbers of pts in respective disease activity categories reported by the 2 independent assessors.

Acknowledgments: This post hoc analysis used data from the ADEPT trial, which included pts with active PsA despite prior DMARD therapy who were randomized to receive ADA or PBO for 24 weeks (wks). Mean RAPID-3 was summarized by visit for each treatment group. Correlations between RAPID-3 and DAPSA over time were assessed through Pearson and Spearman coefficient. Pts were categorized at wk 24 according to DAPSA Remission: ≤12; LowDA: 13-24; ModDA: >24 – ≤; HighDA: >28; low disease activity (MALDA-28) and 54% (PBO) in HighDA. At wk 24, 39% and 34% of pts in ADA and PBO, respectively, exhibited HighDA when assessed by RAPID-3 (13.1 for ADA, 13.3 for PBO) [129]. The Kappa statistic was used to describe the agreement between the numbers of pts in respective disease activity categories reported by ADA, DAPSA, and MDA. Data were as observed.

Conclusions: In a PBO-controlled trial of ADA in pts with PsA, there was good correlation between disease activity captured by pts’ self-assessment, via the RAPID-3, and physician assessment, suggesting the potential utility of pt-derived measures in assessing disease activity.

SECUKINUMAB DEMONSTRATES CONSISTENT SAFETY OVER
LONG-TERM EXPOSURE IN PATIENTS WITH PSORIATIC
ARTHRITIS AND MODERATE-TO-SEVERE PLAQUE
PSORIASIS: UPDATED POOLED SAFETY ANALYSES

P.J. Mease 1 , I.B. McInnes 2 , K. Reich 3 , P. Nash 4 , M. Andersson 5 , K. Abrams 6 ,
L. Pricorp 6 , T. Fox 5 . 1 Swedish Medical Center and University of Washington,
Seattle, United States; 2 University of Glasgow, Glasgow, United Kingdom;
3
Dermatologikum Hamburg and Georg-August-University Göttingen, Hamburg,
Germany; 4 University of Queensland, St Lucia, Australia; 5 Novartis Pharma AG,
Basel, Switzerland; 6 Novartis Pharmaceuticals Corp., East Hanover, United
States
Background: Pooled safety data from secukinumab psoriasis (PsO) and psoriatic
arthritis (PsA) clinical trial programs after ∼1 year of exposure have been
reported.1,2
Objectives: To report updated longer-term secukinumab exposure safety data
from PsO and PsA studies (data cut-off: 25 June 2016).
Methods: The PsO data pool consisted of 9 Phase III studies in moderate-tosevere plaque PsO and PsA pool consisted of 3 Phase III studies in active PsA.
Secukinumab doses differed in the studies and included intravenous (up to 10
mg/kg) or subcutaneous (s.c.; 75–300 mg) loading, followed by s.c. maintenance
dosing (300, 150 or 75 mg). Placebo patients were re-randomised to secukinumab
at 12–24 weeks depending on study design. Only data for approved secukinumab
300 and 150mg doses were included in analysis. Exposure adjusted incident
rates (EAIR) were used to adjust for differences in exposure.
Results: In both PsO and PsA, the most frequently reported adverse events
(AEs) with secukinumab were non-serious infections of the upper respiratory
tract, headache and arthralgia (Table). The EAIRs of AEs of special interest with
secukinumab including Crohn’s disease, Candida infections, serious infections,
inﬂammatory bowel disease, major adverse cardiac events and neutropenia
(reported in the Table) were similar in both PSO and PsA indications, and
comparable to those reported previously.1,2 No cases of tuberculosis (new onset
or reactivation) were reported.

Conclusions: The safety proﬁle of secukinumab was similar for PsO and PsA
patients supporting its long-term use in these chronic conditions. Secukinumab
long-term exposure safety data is consistent with that previously reported with
shorter-term exposure, including being well tolerated, and without any new safety
signals identiﬁed.

CabriniHealth, Melbourne, Australia
Background: In PALACE psoriatic arthritis (PsA) studies, the Bath Ankylosing
Spondylitis Disease Activity Index score (BASDAI) was used as an exploratory
measure in a subset of patients (pts) considered by investigators to have axial
involvement, although PsA spondylitis was not conﬁrmed by imaging.
Objectives: Report the impact of apremilast 30 mg BID (APR) treatment on
BASDAI over 156 wks using pooled PALACE 1–3 data of pts with active PsA
despite prior conventional DMARDs and/or biologics.


Methods: APR treatment outcomes were evaluated in a subset of pts with baseline (BL) BASDAI ≥4 ("subset") over 156 wks.

Results: BL BASDAI ≥4 was reported for 454/1493 (30%) pts. Mean PsA duration was similar between the subset and rest of the PALACE 1–3 population (n=1039); mean BL psoriasis body surface area (BSA) and percentage of pts with ≥3% were slightly higher. The subset had higher mean BL values vs the rest of PALACE 1–3 pts for C-reactive protein (1.12 vs 0.93), pain VAS (83.6 vs 53.8 mm), pt's global assessment of disease activity (62.2 vs 53.5 mm), and physician’s global assessment of disease activity (PhGA; 59.0 vs 53.0 mm) and markedly worse mean HAQ-DI (1.41 vs 0.88), SF-36v2 Physical Functioning (30.6 vs 35.8), and FACIT-F (25.7 vs 31.8) scores. Despite disease activity differences, BL concomitant oral DMARDs were similar in both groups: 1 DMARD in 61.0% (subset) vs 57.8% (rest of PALACE 1–3 pts); methotrexate was the most common DMARD. In the subset, 73.6% had been treated with only oral DMARDs pre-study (44.9% with only 1); 21.5% had prior biologic use. Mean BL BASDAI in the subset was 6.6 with APR and 6.4 with placebo (PBO). Mean BL BASDAI question 2 score, referring directly to spinal and hip pain, was 6.7. APR resulted in greater mean improvement in BASDAI vs PBO at Wk 16 (−1.53 vs −0.91; P=0.0173) and Wk 24 (Table). As early as Wk 16, a 19% mean decrease in the question 2 score was observed vs placebo. Few APR vs placebo pts had BL VAS >50. Other disease measures significantly improved early in treatment, including HAQ-DI, fatigue, PhGA, and mPsARC (Table). Long-term improvement was seen across measures, with mean BASDAI reductions of 2.18 at Wk 52 and 2.19 at Wk 156 (Table) and question 2 reductions of 1.94 and 2.28, respectively; treatment resulted in a shift toward lower BASDAI across the subset, with a significant proportion reaching BASDAI ≤4.

Outcomes at Wk 24, Wk 52, and Wk 156 in Pts With BASDAI ≥4 at BL

In the may vary slightly for the end points at each time point. For Wk 24, it is the number of pts randomized at BL in the subset, last observation carried forward methodology and non-responder imputation were applied to all pts who did not complete Wk 24 or had missing visits at Wk 24. For Wk 24, only continuous data and binary response, respectively. For Wk 52, it is the number of pts randomized to APR at Wk 16, in the subset with an outcome measured at Wk 52. For Wk 156, it is the number of pts who were randomized to APR (at Wk 16, Wk 156). Wk 156 was calculated as Wk 24 + (Wk 156 − Wk 24). Component level scores were expressed as HR-QL (mPsARC) and PSART (mPsART) scores.

Conclusions: In this post hoc analysis of pooled data, pts reporting BASDAI ≥4 at BL appear to experience greater disease burden, including disability, pain, and fatigue; effective treatment strategies may not have been available. APR treatment resulted in long-term improvements in BASDAI and other measures in pts with clinically suspected axial disease.

FR0513 LONG-TERM (156 WEEKS) IMPROVEMENTS IN PHYSICAL FUNCTION OF DMARD-NAÏVE AND DMARD/BIOLOGIC-EXPERIENCED PSORIATIC ARTHRITIS PATIENTS TREATED WITH APREMILAST: DATA FROM A LARGE DATABASE OF 4 PHASE III CLINICAL TRIALS

P.J. Mease 1, A. Wells 1, J. Wollenhaupt 1, S. Hall 1, F. Van den Bosch 3, E. Lespessailles 4, M. McIlraith 5, D. Nguyen 5, L. Teng 5, C.J. Edwards 8

Swedish Medical Center and University of Washington School of Medicine, Seattle; 2Rheumatology and Immunotherapy Center, Franklin, United States; 3Schön Klinik Hamburg Eilbek, Hamburg, Germany; 4Monash University, CabirinHealth, Melbourne, Australia; 5U2 Gent, Gent, Belgium; 6University of Orléans, Orléans, France; 7Celgene Corporation, Summit, United States; 8University Hospital Southampton, United Kingdom

Background: Improving and preserving patient (pt) physical function is an important goal for psoriatic arthritis (PsA).

Objectives: To evaluate apremilast’s (APR) effects on physical function/functional status for up to 3 yrs in DMARD/biologic-experienced (PALACE 1–3 [PAL1–3] pooled data) and DMARD-naïve (PALACE 4 [PAL4]) pts with active PsA.

Methods: Pts were randomized (1:1:1) to placebo (PBO), APR 30 mg BD (APR30), or 20 mg BD (APR20) at baseline (BL). The primary endpoint was at Wk16; a long-term extension is ongoing. A detailed study design has been previously presented. Assessed were mean change from BL HAQ-DI scores and proportions of pts reaching HAQ-DI MCID and reaching scores ≤1.0 (below clinical significant disability). APR30 and PAL4 pts had similar BL SJC/TJC and DAS-28 (CRP), indicating active PsA. APR1–3 pts had longer mean duration of PsA and psoriasis, higher PASI scores, and greater corticosteroid use at BL. Despite differences, BL physical disability was clinically significant in both populations (mean HAQ-DI, PAL1–3: 1.0; PAL4: 1.1; PAL4 vs PAL1–3: −0.21 vs −0.30; P=0.0049). At Wk16, physical function significantly improved with APR30 vs PBO (mean HAQ-DI change, PAL1–3: −0.23 vs −0.08; PAL4: −0.21 vs 0.03; both P<0.0001) and more PAL3 vs PAL4 APR30 pts had BL HAQ-DI >1.0 (60% vs 54%), 1.5 (marked difficulty/need for assistive devices, 31% vs 21%), and 1.75 (major disability, 19% vs 10%), highlighting need for early, effective treatment (tx). Few APR30 pts had BL scores ≤0.5 (18–22%) or ≤0.25 (10–14%). As Wk16, overall disability levels also shifted; more APR1–3 vs PAL4 pts had achieved HAQ-DI ≤1.0 (PAL1–3: 56% vs 48%; PAL4: 60% vs 52%). At Wk156, marked achievement of HAQ-DI ≤1.0, ≤0.5, and ≤0.25 was observed in both populations (Table). LOCF analyses confirmed Wk156 results.

Conclusions: With APR30 tx, physical disability improved early; functionality was maintained for up to 3 yrs. Most pts achieved HAQ-DI ≤1.0; many attained minimal/mild physical impairment. Over 40% of pts receiving APR30 earlier in the tx paradigm had functional ability similar to that of population norms after 3 yrs; shorter disease duration and no prior DMARD/biologics use in this population suggests that earlier APR tx may increase the likelihood of maximal functionality for some pts.

FR0514

**PSORIATIC ARTHRITIS IS ASSOCIATED WITH DIAGNOSTIC DELAY AND WORSE OUTCOME AT THREE MONTHS WHEN COMPARED TO RHEUMATOID ARTHRITIS: RESULTS FROM THE UK NATIONAL AUDIT FOR INFLAMMATORY ARTHRITIS**

R. Holland 1, A. Davis 2, A. Green 3, A. Nightingale 4, R. Charlton 2, E. Cullen 3, N. McGugh 1, 1 Royal National Hospital for Rheumatic Diseases; 2 University of Bath, Bath; 3Celgene Ltd, London, United Kingdom

**Background:** Psoriatic arthritis (PsA) is underdiagnosed in primary care, and can be difficult to distinguish from osteoarthritis. Accumulating evidence suggests that diagnostic delay is associated with poorer functional outcome despite treatment.

**Objectives:** To develop a better understanding of the diagnostic delay and burden of disease in patients with PsA, and to investigate management within the first three months of diagnosis.

**Methods:** Data were analysed on all participants with a final diagnosis of PsA from The National Clinical Audit for Rheumatoid and Early Inflammatory Arthritis, undertaken by the British Society for Rheumatology and commissioned by the Healthcare Quality Improvement Programme, recruited between 1/2/2014 and 30/10/2015. Data were collected from patients and clinicians at baseline and three months. 1016 participants with PsA (mean age 49.4±14.5 years; 54% female) were matched 1:1 by age and sex with participants with Rheumatoid Arthritis (RA).

**Results:** Patients with PsA had a significantly longer delay to presentation and diagnosis than those with RA (p<0.02, Table 1), and this remained significant when adjusted for age, sex, ethnicity and deprivation index; p<0.05). In those with paired results, the mean improvement in IAID score was 1.32 (95% CI 0.99–1.65) in PsA vs 2.37 (95% CI 2.07–2.67) in RA. In patients with high disease activity at baseline (DAS28 >5.1) a good EULAR response was seen in only 21.4% in PsA vs 30.3% in RA. There was a marked difference in the DMARDs initially prescribed, and the differences remained significant when only those with a DAS28 score indicating moderate or high disease activity at presentation were analysed, as shown in Figure 1.

**Conclusions:** This study demonstrates that patients with PsA have a longer delay to diagnosis between both symptom onset and presentation to primary care, and referral to secondary care and diagnosis than those with RA. Despite similar disease impact and physical function at diagnosis, patients with PsA are less likely to receive combination DMARD treatment, and have increased disease burden at three months.

**Disclosure of Interest:** None declared

**CLASSIC CARDIOVASCULAR RISK FACTORS AND MINIMAL DISEASE ACTIVITY IN PSORIATIC ARTHRITIS: RESULTS OF A SPANISH MULTICENTER STUDY**

R. Quero 1, J.D. Castro 2, J. Cortés 3, M.A. Abad 4, M. Montero 4, S. Gómez 3, A. Cabeza 2, J.C. Correa 1, J.A. Román 1, J. Sanz 3, J. Salvaterra 3, J. Calvo Alén 3, A. Selias 1, F.J. Rodríguez 3, A. Bermúdez 3, M. Romero 3, M. Riesco 2, J.C. Cobeta 2, F. Medina 3, A. Aragón 3, M.L. García 3, A. Urruticochea 3, 1 Rheumatology, Hospital Universitario Central de Asturias, Oviedo; 2 Rheumatology, HU, clinic and IDIBAPS, Barcelona, Spain; 3 Affiliation not proved

**Background:** Some cardiovascular risk factors (CVRF) have been related to poorer responses to biological therapy 1. We aimed to evaluate the potential link between the MDA response and the presence of CVRF in patients treated with traditional and/or biological DMARDs.

**Objectives:** The objective has been to evaluate the potential association between classic CVRF and the probability of reaching an MDA response in PsA patients.

**Methods:** Cross-sectional study carried out at 25 rheumatology outpatient clinics in patients who fulfilled the Classification for Psoriatic Arthritis (CASPAR) criteria with at least one year disease duration, and treated with biological or conventional synthetic (cs) DMARDs according to routine clinical practice in Spain. Patients were considered in MDA if they met at least 5/7 of the MDA criteria 2.

**Results:** The relationship between MDA and CVRF was evaluated by uni and multivariate analyses.

**Results:** 227 patients were included, 133 (58.6%) were in MDA state (52% on anti-TNFα monotherapy, 24% on csDMARD monotherapy, 24% on anti-TNFα in combination with csDMARD). Among the classic CVRF, tobacco (crude OR: 1.05), sedentary lifestyle (crude OR: 1.95), hyperuricemia (crude OR: 2.01) and obesity (crude OR: 1.54) were related to the likelihood of MDA in the univariate model (p<0.25). The only CVRF related to the MDA response in the multivariate analysis was a sedentary lifestyle (OR 3.13, 95% CI: 1.50–6.53; p=0.002). We did not find any association between the number of CVRF and the MDA response.

**Conclusions:** Contrary to what has been found in other studies, in this cross-sectional multicenter study we could not find any relationship between traditional CVRF (except for sedentary lifestyle) and MDA. In any case, patients with psoriatic disease should be encouraged to maintain healthy lifestyle habits.

FR0516

**ASSESSMENT OF DISEASE REMISSION BY POWER DOPPLER ULTRASONOGRAPHY IN PATIENTS WITH PSORIATIC ARTHRITIS**

S. Monov 1, R. Shumailaleva 1, D. Monova 2, A. Kopchev 1, 1 Department of Internal Medicine, Clinic of Rheumatology, Medical University - Sofia; 2 Medical Institute-MVR, Medical University-Sofia, Sofia, Bulgaria

**Background:** Treatment strategies nowadays are targeting clinical remission or low disease activity. In some patients with psoriatic arthritis (PsA) clinical findings defer from the ultrasonographic evidence of inflammation which raise the need for revising the remission criteria in the clinical practice.

**Objectives:** The aim of our study was to estimate the presence of subclinical synovitis by power Doppler ultrasonography (PDUS) in PsA patients, who were considered as being in clinical remission defined by DAS28-ESR (Disease activity score of 28 joints – erythrocyte sedimentation rate) for at least 6 months during the treatment course.

**Methods:** 64 PsA patients in clinical remission based on DAS28 – ESR <2.6 were included in the study. The patients were examined by two independent rheumatologists. The affected joints were assessed by PDUS (MyLab 60, Esaote) for the presence of synovial hypertrophy (SH) and synovitis scored from 0 to 3 based on the presence and intensity of PD signal. Disease activity was determined by the presence of SH ≥2 degree and a positive PD signal.

**Results:** We found a persistent synovitis in 23 (35.9%) of the PsA with clinical remission of the peripheral joint involvement. Active synovitis was also found in 7
Psoriatic arthritis (PsA) is a chronic systemic inflammatory disease. Affecting skin, joints, entheses and dactyly, its impact on health-related quality-of-life (HRQoL) could be substantial. The emergence of tumour necrosis factor inhibitor (TNFi) therapy has dramatically changed the course of disease. Over the past decade new TNFi therapies have emerged (certolizumab pegol and golimumab), changing the synovitis will establish correct criteria for defining and monitoring the disease activity in PsA.

FR0518

PRESCRIPTION PATTERNS OF TUMOUR NECROSIS FACTOR INHIBITOR AND USTEKINUMAB IN PSORIATIC ARTHRITIS: A NORDIC POPULATION-BASED COHORT STUDY

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disorder associated with skin manifestations, several extra-articular symptoms, various comorbidities, and disability. The emergence of tumour necrosis factor inhibitor (TNFi) therapy has dramatically changed the course of disease. Over the past decade new TNFi therapies have emerged (certolizumab pegol and golimumab), and recently ustekinumab and secukinumab have also become available for PsA.

Objective: The objective of this study was to assess the relative use of biological agents (bDMARDs) in PsA from 2006 through 2014, using data from the Nordic Rheumatology registers.

Methods: Based on data from the observational registers DANBIO, ICEBIO, NOR-DMARD, ROB-FIN, and SRQ registers, PsA patients initiating treatment with bDMARDs as a first or subsequent biological therapy were identified. Adalimumab, etanercept and infliximab were grouped as “first generation TNFi therapies”; certolizumab pegol and golimumab were grouped as “second generation TNFi”. Treatments with ustekinumab during the study period were also identified. Descriptive statistics for prescription patterns of bDMARD therapy were calculated.

Results: A total of 11,458 treatment initiations were identified (DANBIO 3,068, ICEBIO 357, NOR-DMARD 1,113, ROB-FIN 708, SRQ 6,212). 54% of the patients were female. Overall, 5,695 patients initiated a first generation TNFi, 912 a second generation TNFi, and 16 ustekinumab, as their first course of biological therapy. The corresponding numbers for those initiating a second (or more) biological treatment were 3,606, 1,090 and 139 patients, respectively. The figure displays the annual number of treatment initiations stratified by treatment type. The total yearly number of first course biological treatment increased significantly throughout the period (p<0.001), and this was also the case for patients switching therapy (p<0.001), indicating a previously unmet need for biological therapies in the Nordic population. The annual number of patients initiating first generation TNFi both as first and subsequent course of therapy decreased significantly towards the end of the study period (p<0.001). This drop was more than offset by a rapid increase in initiation of second generation TNFi treatments (p<0.001). Ustekinumab was primarily used as second or subsequent course of therapy in PsA. The same pattern was seen when stratified for country (data not shown).

Conclusions: Across the Nordic countries the prescription pattern for biological therapies for PsA has changed significantly over time. After 2012 initiation of the first generation TNFi is decreasing both as first and second course therapy, whereas second generation TNFi are increasing both as first and second course of biologic intervention. Collaboration across registers will allow for robust assessment of the uptake of newer biological therapies.

Acknowledgements: This study was partly funded by a grant from NordForsk and Janssen Pharmaceuticals.

FR0519

EFFECT OF BIOLOGICS ON FATIGUE IN PSORIATIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW WITH META-ANALYSIS

T. Reynaerts1,2, S. Mitrovic1, B. Fautrel1, L. Gossec1. 1 Service de Rhumatologie, Pitié-Salpêtrière Hospital, Paris, France; 2 Service de Rhumatologie et de Médecine Physique, Erasme Hospital, Bruxelles, Belgium

Background: Fatigue is an important aspect of disease both in rheumatoid arthritis (RA) and in psoriatic arthritis (PsA) and is of high priority for patients. In RA, a recent Cochrane meta-analysis found a small effect of biologics on fatigue (standardized mean difference, SMD, 0.43; 95% confidence interval, CI: 0.38–0.49). (1) Little is known about this effect in PsA.

Objectives: To assess the effect of biologics on fatigue in PsA randomised controlled trials (RCTs) and to compare this effect with the effect in the same trials, on pain, through a systematic literature review (SLR) and meta-analysis (MA).

Methods: SLR up to January 2017 in PubMed, Embase and Cochrane trials database and in recent congress abstracts, using key words related to PsA and biologics. All RCTs in PsA of any biologic therapy, assessing fatigue (whatever the...
score used), with data available for fatigue were included. Data were collected by 2 regarding levels of fatigue (6 trials used FACIT, 1 VAS) and pain (if available) at baseline and at the timepoint closest to 24 weeks after the biologic introduction. A MA was performed using RevMan and SMDs were calculated for each trial and each study dose, with fatigue and pain. A SMD >0.5 is usually considered small, between 0.5 and 0.8 moderate and >0.8 as important.

**Results:** After screening 295 publications, 7 RCTs were included in the meta-analysis and assessed TNF blockers (N=3: adalimumab N=2, certolizumab pegol, N=1), secukinumab (N=2), apremilast (N=1) and ustekinumab (N=1) with or without methotrexate, compared to placebo. The studies included 2340 PsA patients: weighted mean age ± standard deviation (SD), 48.7±1.3 years, disease duration 7.7±1.3 years, 53.3% were females. At baseline, joint disease activity was high (weighted mean swollen joint count: 13.0±3.1, HAQ-DI: 1.2±0.1, PASI: 10.4±3.3). Fatigue levels were high at baseline (weighted mean FACIT score: 29.2±1.5). The pooled SMD for fatigue was 0.44 (95% CI 0.35, 0.54) and it ranged 0.04 to 0.71 across drugs and trials with a small to moderate effect (Graph). In 6 of the same studies, the pooled SMD for pain was 0.62 (95% CI 0.52, 0.73) and ranged 0.46 to 0.84.

**Conclusions:** Biologics had a mild to moderate effect on fatigue at 24 weeks in PsA RCTs. No notable differences across drugs were apparent. Effect sizes were higher on pain with a moderate effect. This effect seems similar to effects noted in RA in the Cochrane meta-analysis (1). These results confirm fatigue may be multifactorial in PsA; biologics bring some improvement at the group level but other treatment modalities should be further explored also.

Secureukinumab Provides Sustained Improvements in Work Productivity and Health-Related Quality of Life in Patients with Active Psoriatic Arthritis: 2-Year Results from Future 1 and Future 2

1Stanford University School of Medicine, Palo Alto, CA, United States; 2St. Vincent’s University Hospital, Dublin, Ireland; 3University of Leeds, Leeds, United Kingdom; 4University of Utah, Salt Lake City, United States; 5Hospital Clinic de Barcelona e IDIBAPS, Barcelona, Spain; 6Novartis Healthcare, Hyderabad, India; 7Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; 8Novartis Pharma AG, Basel, Switzerland

Background: Patients (pts) with PsA experience significant impairment of work productivity (WP) and health-related QoL (HRQoL). Secukinumab (SEC) has previously been shown to rapidly improve symptoms, physical function and HRQoL in pts with active PsA.1,2

Objectives: To assess the impact of SEC on WP and HRQoL through 2 years in TNF inhibitor (TNF)-naive PsA pts and those with an inadequate response or intolerance to TNF inhibitors (TNF-IR) at Week 16/24.

Methods: 606 and 397 pts were randomized to SEC or placebo (PBO) in FUTURE 1 (10 mg/kg IV followed by 150 or 75 mg SC) and FUTURE 2 (300, 150 or 75 mg SC), respectively. PBO pts were re-randomized to SEC at Week 16/24. WP was assessed using the WP and Activity Impairment-General Health (WPAI-GH) questionnaire. WPAI-GH included 6 questions to measure absenteeism, presenteeism, work productivity and impairments in unpaid activity because of health problems during the preceding 7 days. HRQoL was assessed using the PsAQoL questionnaire, encompassing 20 statements that pts rate as true or false on the day of completion. Across both trials, approximately 68% of employed pts in both FUTURE 1 and FUTURE 2 were working at baseline (BL); 61 of 100 and 59 of 100 were employed and working at BL in the SEC 300 mg and 150 mg groups of FUTURE 2, respectively. Improvements in all elements of WPAI were also evident with SEC in TNF-naive and TNF-IR pts in both FUTURE 1 and FUTURE 2. Improvements in PsAQoL were reported as early as Week 4 and sustained through Week 104. At Week 104 of FUTURE 2, PsAQoL scores had improved by approximately 46% from BL with SEC 300 mg and 49% with SEC 150 mg in the overall population. Similar improvements were seen in TNF-naive (47% and 51%, respectively) and TNF-IR pts (45% and 45%, respectively). Consistent results were reported in FUTURE 1. The efficacy of SEC was consistent regardless of concomitant MTX use.

Results: SEC provided sustained improvements in WP and PsAQoL in pts with PsA for up to 104 wks, regardless of prior TNF exposure.

The Association between Occupational-Related Mechanical Stress and Radiographic Damage in Psoriatic Arthritis

W. Zhou1, R. Cook2, V. Chandran1,3, D.D. Gladman1,3, L. Eder4,6, Department of Medicine, University of Toronto, Toronto; 4Department of Statistics and Actuarial Science, University of Waterloo, Waterloo; 5Centre for Prognosis Studies in the Rheumatic Diseases, University Health Network; 6Women’s College Research Institute, Women’s College Hospital, Toronto, Canada

Background: Mechanical stress is thought to play a role in the development of psoriatic arthritis (PsA). Mechanical stress is thought to play a role in the development of psoriatic arthritis (PsA). To determine the association between occupational-related mechanical factors and the severity of radiographic peripheral and axial joint damage in patients with PsA.

Methods: A retrospective cohort study was conducted in patients with longstanding PsA (>10 years duration). Patients were asked to report all paid employment since the age of 18. The key predictor variables included various occupational-related mechanical exposures. For each job, the Occupational Information Network (O*NET) was used to rate the level of exposure to 11 workers’ abilities and 16 occupational exposures. The outcomes of interest were the severity of radiographic peripheral and axial joint damage in patients with PsA. Mechanical stress is thought to play a role in the development of psoriatic arthritis (PsA).

Results: 307 eligible patients were analyzed. Univariate analysis identified several occupational factors associated with radiographic damage (Table 1–2). In the multivariable regression analysis prolonged repetitive hand movements were associated with increased Steinbrocker score adjusting for age, sex, PsA duration and lifestyle habits.

*Each model was adjusted for age, sex, duration of PsA, smoking, BMI, Biologics therapy (ever), DMARDs therapy (ever).
was associated with a higher peripheral joint damage score by mSS, adjusted β=29.5, 95% CI 8.2, 50.8, p=0.007, Table 1), while the association between prolonged time spent sitting and lower mSS was of borderline significance (p=0.085, Table 1). Additionally, occupations that required higher finger dexterity were associated with higher mSS (adjusted β=5.4, 95% CI 1.6, 9.2, p=0.005, Table 2). Regarding axial damage, occupations that involved prolonged walking/running were associated with a higher mSASSS score (adjusted β=4.4, 95% CI 0.1, 8.7, p=0.04). PsA duration was independently associated with both peripheral and axial joint damage (p<0.001).

Conclusions: High level of occupation-related mechanical stress is associated with increased radiographic peripheral joint damage. These findings support the potential role of micro-trauma in the pathogenesis of PsA.

**FRI0523 SHORT-TERM EFFICACY AND SAFETY OF NEW BIOLOGICAL AGENTS TARGETING THE IL-6, IL-12/23 AND IL-17 PATHWAYS FOR ACTIVE PSORIATIC ARTHRITIS: A NETWORK META-ANALYSIS OF RANDOMISED CONTROLLED TRIALS**

W. Dong et al. Department of Medicine & Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, China

Background: IL-6, IL-12/23 and IL-17 inhibitors have been found to be highly effective for both skin and joint manifestations of psoriatic arthritis (PsA). Nonetheless, reliable evidence of the comparative benefits and harms for these interventions is absent for treatment selection in daily practice.

Objectives: To investigate the comparative efficacy, safety and tolerability of IL-6, IL-12/23 or IL-17 inhibitors and the proportion attributable to overall treatment for patients with active PsA.

Methods: Randomized controlled trials (RCTs) evaluating the efficacy, safety and tolerability of IL-6, IL-12/23 or IL-17 inhibitors at weeks 24 were identified by a comprehensive systematic literature review (PROSPERO 2016: CRD42016048166). Quality of evidence was assessed following the Grading of Recommendations, Assessment, Development and Evaluations (GRADE) approach. Treatment effects were evaluated based on the intention-to-treat efficacy rates (ACR20, ACR50, safety parameters (any adverse effect [AE], serious adverse effect [SAE]) and tolerability (discontinuation due to AE [DAE]). Pair-wise meta-analyses and Bayesian network meta-analyses using the random-effects model were performed to estimate pooled odds ratios (ORs) and 95% credible interval (CrI). A subgroup analysis was performed to investigate the effects of prior anti-TNF exposure on the efficacy of ustekinumab and secukinumab.

Results: Six trials were identified which included 2411 participants and 11 treatments. All trials were of generally high quality according to Cochrane compliant rules and GRADEpro assessment. Direct comparisons of each biologic showed that secukinumab (300mg monthly) had the highest efficacy in achieving ACR20 and ACR50, safety parameters (any adverse effect [AE], serious adverse effect [SAE]) and tolerability (discontinuation due to AE [DAE]). Pair-wise meta-analyses and Bayesian network meta-analyses using the random-effects model were performed to estimate pooled odds ratios (ORs) and 95% credible interval (CrI). A subgroup analysis was performed to investigate the effects of prior anti-TNF exposure on the efficacy of ustekinumab and secukinumab.

Conclusions: In conclusion, from the available evidence, secukinumab and ustekinumab were found to be the safest and most efficacious short-term treatments for active PsA amongst all the new biologics targeting the IL-6, IL-12/23 and IL-17 pathways.

**FRI0524 CAROTID ATHEROSCLEROSIS IS ASSOCIATED WITH COMPROMISED VOLUMETRIC BONE MINERAL DENSITY AND MICROSTRUCTURES IN PATIENTS WITH INFLAMMATORY ARTHRITIS**

T.H. Cheng et al. 1Department of Medicine & Geriatrics, Tai Po Hospital; 2Department of Orthopaedics and Traumatology, the Chinese University of Hong Kong, Hong Kong, Hong Kong

Background: Carotid atherosclerosis is associated with compromised volumetric bone mineral density and microstructures in patients with inflammatory arthritis.

Objectives: The aim of this study was to explore the relationship between volumetric bone mineral density (vBMD)/microstructural features and presence of carotid plaque (CP) in patients with inflammatory arthritis.

Methods: 175 inflammatory arthritis patients (81 [46%] PsA, 94 [54%] RA; 70 [40%] males; age: 53±12 years) were recruited into an ongoing prospective study assessing the relationship between inflammation, osteoporosis and carotid atherosclerosis. Carotid plaque and intima-media thickness (IMT) were measured by carotid ultrasound. Areal BMD (aBMD) was measured by dual energy X-ray absorptiometry (DXA). Microstructure features and vBMD of distal radius were measured using high-resolution peripheral quantitative computed tomography (HR-pQCT).

Results: No patients had established cardiovascular disease (CVD). Data from 172 patients at baseline were analyzed for this cross-sectional study. Patients were sub grouped according to the presence or absence of carotid plaque (CP+ group, n=68 [40%] and CP- group, n=132 [60%]). CP+ group were older (59±10 vs 49±11, p<0.001), more likely to be male (54% vs 31%, p=0.002), had higher systolic blood pressure (130±19 vs 124±17 mmHg, p=0.034) and CVD risk (15.7±14.2 vs 7.9±8.6, p<0.001) according to the Framingham Risk Score (FRS) then the CP- group. aBMD, vBMD and microstructure were significantly compromised in the CP+ group. Distal radius aBMD, distal radius total vBMD, trabecular (Tb) vBMD, Tb thickness, cortical (Ct.) vBMD, Ct. thickness and bone volume fraction were 5% (p=0.004), 12% (p=0.001), 8% (p=0.007), 8% (p=0.004), 4% (p=0.007), 10% (p<0.001) and 8% (p=0.007) lower in the CP+ group. The differences remained significant after adjustment for gender, disease type and FRS (Table 1).

Conclusions: Inflammatory arthritis patients with carotid plaque had lower aBMD, vBMD and compromised bone microstructure in the distal radius even after adjustment for gender, disease type and FRS, suggesting that inflammation may be the common link for both conditions.

ASSOCIATION OF DYSMOBILITY SYNDROME WITH FRACTURE RISK IN THE MROS COHORT

B. Buehring 1,2, B.L. Lewis 1, K.E. Hansen 1, S.R. Cummings 3, N.E. Lane 4, N. Binkley 1, K.E. Ensrud 3, P.M. Caithorn 3, 1Department of Medicine, University of Wisconsin-Madison, Madison, United States; 2Rheumazentrum Ruhrgebiet, Herne, Germany; 3California Pacific Medical Center Research Institute, San Francisco; 4University of California - Davis, Sacramento; 5University of Minnesota, Minneapolis, United States

Background: Osteoporosis, obesity and sarcopenia are risk factors for fractures and their combination has a negative effect on musculoskeletal health (MSKH). We proposed a score-based approach to define this combination as “dysmobility syndrome (DS)”. DS increases mortality in the NHANES cohort but no data exist on fracture risk. The most widely used fracture risk calculator, the WHO FRAX® tool, does not incorporate several measures of MSKH such as appendicular lean mass, muscle mass or falls. In this analysis of the Osteoporotic Fractures in Men (MOS) cohort, we examine whether individuals with impaired MSKH/DS have a higher incidence of fragility fractures and whether this composite score confers additional risk for fracture, beyond risk estimates provided by FRAX®.

Methods: The MrOS cohort was utilized in this study. The score-based approach to define DS includes six factors with one point assigned to each: appendicular lean mass/height^2 < 7.26 kg/m^2, body fat > 30%, T-score < -2.5, grip strength < 30 kg, gait speed < 1.0 m/s, and falls in last 12 months. A score ≥ 5 indicated DS. We use odds ratios and cox proportional hazard models to analyze risks of major osteoporotic fracture (MOF). Men were censored at the time of fracture or last follow up. We determined the hazards of fracture using presence of dysmobility syndrome, the FRAX® score, and the FRAX® score in quartiles. We used the program R (www.r-project.org) to perform all analyses.

Results: 5827 men ages 74±6 years with a mean BMI of 27.4±3.8 kg/m^2 had complete data necessary for this analysis, 391 males (6.7%) met criteria for DS. 571 (10%) experienced a MOF including 245 (4%) hip fractures. DS increased the hazards of major osteoporotic fracture, beyond risk estimates provided by FRAX®.

Conclusions: In this analysis of the Osteoporotic Fractures in Men (MOS) cohort, we examine whether individuals with impaired MSKH/DS have a higher incidence of fragility fractures and whether this composite score confers additional risk for fracture, beyond risk estimates provided by FRAX®.

LACUNARITY OF TRABECULAR BONE MICROARCHITECTURE, TBLβ, AS A PREDICTOR OF BONE FRIAGILITY FRACTURE AND POTENTIAL INDEX OF ÖSTEOPOROSIS TREATMENT EFFICACY. THE LOTO STUDY

A. Zaia 1, R. Rossi 2, R. Galeazzi 3, P. Sccondi 3, 1Scientific Direction; 2Medical Imaging and Services, INRCA Italian National Research Center on Aging, Ancona, Italy; 3Rheumatology Division, INRCA Italian National Research Center on Aging, Ferrano, Italy

Background: Bone mineral density (BMD) by dual-energy X-ray absorptiometry (DXA) is still the routinely diagnostic approach for osteoporosis. However, BMD alone is not a good predictor of fracture risk while bone microarchitecture emerges as a determinant of bone fragility independent of BMD. High-resolution magnetic resonance imaging (MRI) represents an effective tool for in vivo characterization of trabecular bone microarchitecture (TBA) by noninvasive/nonionizing methods. Nevertheless, texture analysis is not used in clinical practice because of the large number of parameters to be calculated and analyzed. We previously developed a MRI method to provide one parameter (TBLβ) sensitive to TBA changes in aging and osteoporosis 1. Fractal lacunarity was chosen for TBA texture analysis as it is able to describe bone network discontinuity and sizes of bone marrow spaces, whose changes are index of increased fracture risk.

Methods: An observational, cross-sectional and prospective study on over 50s women at risk for bone fragility fractures was designed to validate the method. Sample size was estimated equal to 280 osteopenic/osteoporotic women with/without prior vertebral bone fragility fractures. The main outcome measure is TBLβ as an index of osteoporotic fracture risk. It is calculated by a software prototype of the gray-scale version of our method on L4 axial images acquired by 1.5T MRI spin-echo multislice technique. Results: A complete set of baseline recording, including DXA-BMD, conventional column Rx morphometry, and lumbar spine MRI-spin echo images for TBA characterization, was obtained for 279 out of 309 subjects eligible for the study. Prevalent VF were found in 31.5% subjects, 47.7% of which defined osteoporotic at lumbar spine by DXA-BMD and 67% younger than 65 years. Baseline results from ROC analysis show that the contribution of TBA degeneration (TBLβ=40) to prevalent fractures is statistically higher (p=0.032) than BMD (T-score=-2.5). TBLβ results (Table 1) show that the proposed method is able to discriminate between antosteoporotic therapy developed cancer (p=0.004). After adjusting for potential confounders, patients with antosteoporotic therapy still had a lower cancer risk (p=0.038; HR: 0.428, 95% CI: 0.192–0.955). The cancer risk also increased among smokers (p=0.002; HR: 10.505; 95% CI: 2.375–46.462).

Conclusions: In this study, anti-osteoporotic therapy decrease cancer risk. So we could safely use these drugs in osteoporotic management.
Successful implementation of a pharmacist-led fracture liaison service (FLS) intervention with the goal to prevent additional fragility fractures (FF) in US veterans. We found a high percentage of FF care goals met when pharmacists were involved, whereas it was lower when no pharmacist was involved. Furthermore, 70% of patients had a bisphosphonate ordered, whereas it was 9% when no pharmacist was involved. We included patient education and applied a treatment protocol to be started by Primary Care. The only difference between hospitals was a dedicated nurse from a FLS intervention. The ideal approach to secondary fracture prevention is a pharmacist-led outpatient FLS model. The current results suggest that pharmacists in the FLS model can very effectively implement a FLS intervention.

**Background:** Worldwide, an osteoporosis (OP) care gap exists for individuals with a fragility fracture (FF). Published data shows that US veterans are no exception. To address the OP care gap, fracture liaison services (FLS) are being implemented with the goal to prevent additional FF.

**Objectives:** Here we report the patient outcomes after initiating a FLS at a US Veterans Affairs (VA) hospital.

**Methods:** We identified veterans with a pelvic, hip, and/or femur shaft fracture by querying a central database. Veterans with traumatic fractures, active OP medication, recent dual-energy X-ray absorptiometry (DXA) and/or hospice status were excluded. The remaining veterans were contacted via letter and the responsible primary health care team was sent a template letter with OP management recommendations via the electronic medical record. Recommendations included DXA, laboratory evaluation, and pharmacologic and non-pharmacologic interventions. In most cases, trained clinical pharmacists serving as FLS coordinators performed all tasks with an expert physician available for questions. Presented data are based on a review 4 months after recommendations were sent.

**Results:** The initial query revealed 149 veterans with pelvic, femoral, and/or hip fractures without a recent DXA and/or active OP therapy. Of those, 32 (31 males, 1 female) patients suffered a FF and were included in the FLS intervention. Our study suggests that a pharmacist-led FLS improves post-FF care in US veterans. We found a high percentage of OP care goals met when patients interacted with clinical pharmacists. This observation might be due to the fact that most pharmacists had dedicated training in OP management and their interaction with the patient focused on their FF. In summary, our data suggests that clinical pharmacists trained in OP management can very effectively implement a FLS intervention.

DUAL ENERGY X-RAY ABSORPTIOMETRY TESTING IN DUAL ENERGY X-RAY ABSORPTIOMETRY TESTING INCIDENCE AND RISK FACTORS OF OSTEOPOROTIC FRACTURE

M.E. Suarez-Almazor
University of Texas School of Public Health; 4Health Science, MD Anderson

Background: Estrogen receptor positive breast cancer is commonly treated with aromatase inhibitors (AI). A well-known adverse effect of this therapy is osteoporosis and related bone fractures. National guidelines have promoted the use of dual energy X-ray absorptiometry (DXA) for screening purposes.

Objectives: To evaluate the association between use of DXA among women with breast cancer treated with AI enrolled in Medicare, and subsequent fracture risk.

Methods: Retrospective cohort study using the Texas Cancer Registry (TCR) and the National Cancer Institute’s Surveillance, Epidemiology and End Results (SEER) data linked with Medicare claims. To help estimate the likelihood of performing a DXA, a multivariable logistic regression model was used. Covariates of age, ethnicity, stage, residence area, and socioeconomic variables were controlled for the analyses. The outcome variable a DXA claim within 12 months after the initiation of the AI therapy. Cox regression model to evaluate time to first fracture after initiation of AI.

Results: The total number of cases within the SEER-Medicare database was 15,350 and in the TCR 4,532. Women aged between 66–74 years and Non-Hispanic white were more likely to get DXA than were Hispanic and Non-Hispanic Black.

In TCR, 2714 patients did not get treatment for osteoporosis in the first 12 months after AI therapy initiation. 2989 patients did not receive treatment for osteoporosis within 12 months of obtaining their first DXA scan. 1330 patients who did not undergo DXA were not treated for osteoporosis; and 1384 patients who underwent DXA got treated for osteoporosis. The duration of AI treatment was negatively associated with the risk of fracture. Women who received DXA scan showed 11% lower risk of fracture than those who were not scanned (HR 0.89 [0.83, 0.94]).

Conclusions: National guidelines suggest to obtain a DXA and start bisphosphonate therapy in female breast cancer patients who are treated with AI therapy. Our data suggests that the majority of women in the TCR and SEER database were not treated for osteoporosis within the first 12 months after initiation of AI therapy. Women who received DXA scan showed a lower risk of fracture than those who were not scanned.

medication use for RA and osteoporosis, and then evaluated the incidence and risk factors for osteoporotic fracture.

**Results:**
The mean age of RA patients was 61.7±11.9 years, and 426 patients were female (88.9%) with 353 postmenopausal women (82.9%). The BMD score of L-spine in RA patients was significantly lower than that in healthy control (2.21±1.41 vs. 2.95±2.11, p<0.001). Osteoporotic fracture was detected in 81 (16.9%) patients with RA. In RA patients, 226 (47.2%) patients met the FRAX criteria for high risk of osteoporotic fracture, and 240 (50.1%) patients satisfied the WHO criteria. The result of the FRAX criteria was affected by the female sex, menopause, smoking, drinking, higher dose of glucocorticoid (<5mg/day), vitamin D use, calcium use and proton pump inhibitor (PPI) use (p<0.05). In multiple linear analysis, the FRAX score to 10-year probability of ≥3% of hip fracture was associated with age (β=0.384, p<0.001), body weight (β=-0.110, p=0.038), erythrocyte sedimentation rate level (β=-0.125, p=0.010), glucocorticoid dose (β=-0.123, p=0.010) and PPI use (β=-0.123, p=0.010). The proportion of patients with high risk of osteoporotic fracture was 47.2% in the FRAX model and 50.1% in the WHO model. Age, female sex, lower BMI, higher risk factors for FRAX criteria were age (OR 1.160, p=0.001), female sex (OR 3.942, p=0.010), body mass index (BMI) (OR 0.889, p=0.001), glucocorticoid dose (OR 1.167, p=0.025) and PPI use (OR 2.552, p=0.019), and those for WHO criteria were age (OR 1.021, p=0.040), glucocorticoid dose (OR 1.109, p=0.046) and smoking (OR 2.924, p=0.031).

**Conclusions:**
Osteoporotic fractures were found in 16.9% of RA patients. The proportion of patients with high risk of osteoporotic fracture was 47.2% in the FRAX model and 50.1% in the WHO model. Age, female sex, lower BMI, higher dose of glucocorticoid, PPI use and smoking were independent risk factors for osteoporotic fracture in RA patients.

**FR10534**

**REPEATED OSTEOPOROSIS SCREENING IN RHEUMATOID ARTHRITIS: ARE WE COMPLYING WITH GUIDELINES?**

A. Gorman 1, V. Sullivan 2, S. Khan 1, A. Mohammed 1, K. O’Rourke 1

1Rheumatology; 2Midlands Regional Hospital Tullamore, Tullamore, Ireland

**Background:**
Osteoporosis rates are higher in patients with rheumatoid arthritis (RA). Patients with RA diagnosed with osteoporosis have a 30% increased risk of major fracture [1]. Monitoring response to osteoporosis treatment is recommended however there is no consensus on how frequently this should be performed. The International Society for Clinical Densitometry (ISCD), National Osteoporosis Foundation (NOF) and the American Association of Clinical Endocrinologists (AACE) all recommend repeat Bone Mineral Density (BMD) assessment within two years after initiating osteoporosis treatment to assess response to treatment [2-4]. Furthermore, the NOF and AACE recommend repeat screening every two years after diagnosis [3,4].

**Objectives:**
To identify patients with RA and osteoporosis
To identify if international guidelines are being achieved for reassessment of BMD within two years of treatment commencement in keeping with international guidelines.

**Methods:**
A database of patients with a diagnosis of RA and osteoporosis who attend the Rheumatology department of the Midlands Regional Hospital, Tullamore since January 2013 was reviewed. Outpatient summaries, date of treatment are not being identified in a timely manner and therefore are at an increased risk of fractures. The results of this audit will make us more vigilant to identify those patients who are treated for osteoporosis that need repeat DEXA screening to ensure that treatment is efficacious.

**Results:**
Ninety-one female patients aged 13–45 years old were evaluated, baseline weight 39.4±5.6 kg and BMI 15.1±1.6 kg/m². Weight and BMI were significantly increased in all patients after treatment. The mean BMD values were significantly increased only at the spine (1.0±3.6%, p<0.009). A positive trend was demonstrated between post-treatment 25-OH-D and BMD changes at the spine (p=0.032). However, only the patients with post-treatment 25-OH-D ≥30 ng/ml showed significantly higher increases in BMD at the spine (2.5% vs 0.5% respectively for 25-OH-D ≥30 ng/ml and 25-OH-D <30 ng/ml, p<0.03; Figure 1). Both P1NP and PTH increased, whereas a significant decrease was found in 25-OH-D and CTX (p<0.05). Post-treatment CTX levels were inversely correlated with spine BMD. A positive relationship was found between changes in weight and P1NP (R²=0.27).

**Conclusions:**
In anorexia nervosa, a hypovitaminosis D status counteracts the efficacy of the weight restoration treatment because of an increase in bone resorption mediated by a secondary hyperparathyroidism. Our study strongly support the use of vitamin D supplements for bone health in anorexia nervosa.

**THE METHOD OF CALCULATING THE PROBABLE VALUE OF T-SCORE IN PATIENTS WITH MULTIFOCAL ATEROCALCIFICATION**

A.N. Kokov, V. Masenko, S. Semenov, O. Barbarash. Federal State Budgetary Scientific Institution Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russia

**Objectives:**
To determine probable value of T-score for early detection of osteoporotic syndrome in patients with multifocal atherosclerosis based on the multislice computed tomography (MSCT) evaluation of vascular calcification.

**Methods:**
186 male (60±6.7 years) with multifocal atherosclerosis. All the patients underwent the measurement of BMD with X-ray absorptiometry. Moreover, bone density (BMD) and bone turnover markers of osteoporosis (CS) of coronary and brachiocephalic arteries were obtained using Agatston method.

**Results:**
T-score values of lumbar vertebrae -1.07 [-1.54; 0.40], T-score of the proximal femur -2.01 [2.71; -1.49]. Calcification of the coronary arteries: CS=471.8 [118.2; 916.8], and carotid arteries: CS=113.9 [44.5; 309.8]. Factors that affect the
probable value of T-score in patients with known rates of calcification of the coronary and carotid arteries were obtained by regression analysis. These factors were equivalent density of coronary calcinosis (p=0.0046), the volume of the carotid calcifications (p=0.0039), the mass of calcifications of the carotid arteries (p=0.0054) and the presence of a stenosis of the carotid arteries (p=0.0001). The predictive models for estimating the probability value of T-score has been developed using regression coefficients of each of the factors. The value is equal to the Fisher statistic F=9.52, p-value <0.000001, multiple correlation model’s coefficient is 0.753.

Conclusions: The results of this study indicate that rates of calcification of the carotid and coronary arteries, resulting in the plotted survey on MSCT patients with multifocal atherosclerosis have a high predictive capacity for assessing the probable value of the T-score and early detection of osteopenic syndrome in these patients.

FRIO537 PREVENTION STRATEGY OF OSTEOPOROTIC FRACTURES IN PORTUGAL: AN ANALYSES ON A COHORT OF HIP FRACTURED PATIENTS

A. Daniel 1, M.L. Marques 1, L. Brites 1, C. Torres 2, A. Marques 1, J.A. Pereira da Silva 1, 1Rheumatology Unit, Centro Hospitalar e Universitário de Coimbra; 2Rheumatology Unit, Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Background: Despite the fact that Portugal has one of the lowest rates of hip fractures in Western Europe, more than 10,000 patients are admitted every year to the Portuguese Health Service due to hip fragility fractures. The burden of the problem will tend to increase in coming years, unless effective preventive measures are put in place.1

Objectives: The aim of our work was to evaluate the percentage of patients under osteoporotic treatment (OT) before and after a hip fracture (HF) and compare this result with the percentage of patients who should be under treatment according to FRAX model and Portuguese cost-effectiveness guidelines (PG) for OT.1

Methods: Patients diagnosed with a HF, between May 1st and October 31st 2013, from a single tertiary hospital, were included in this transversal study. Patients or their primary caregiver were contacted by phone to gather data regarding demographic and clinical features, including risk factors for Osteoporosis (OP) defined by FRAX®. Clinical data was obtained from medical files. FRAX® without mineral bone density was used to calculate the 10 year fracture risk. For each patient the FRAX® was scored according to data available the day before the present HF (ie the current fracture was not considered as a previous fracture for the purpose of risk prediction). Thresholds for therapeutic intervention were defined according to PG: a 10-year probability of a major osteoporotic fracture (OF) ≥11% and/or a 10 year probability of HF <3%.1

Results: The mean age of the population (n=130) was 81.6±8.6 years, and 69.2% were female. Before the current HF, only 23 (17.7%) of the patients had been prescribed some form of medication for OP: bisphosphonates (n=2), strontium ranelate (n=3) and calcium + vitamin D supplementation (n=13); the other patients were not taking any medication. After hospitalization, all 30 patients had a previous fracture, of which 8 patients had ≥1 fragility fracture of the hip; 6 had ≥1 symptomatic vertebral fragility fracture and 16 had ≥2 fragility fractures, independently of the site of the fracture. According to PG, all the 30 (26%) patients should be under OT without the need for FRAX® risk calculation. The mean 10-year major OF probability was 21.2±14% and the mean 10-year HF probability was 13.7±12.9%. According to FRAX®, 104 (80%) of the patients had indication to start OT based on the 10-year risk of major OF and 117 (90%) based on the 10-year risk of HF.

After hospitalization, although all the patients had formal indication for treatment, only 11 (8.5%) patients had received a prescription for OT up to one year after the fracture event.

Conclusions: Similar to other countries, the percentage of patients under OT (before and after HF) in Portugal is extremely low. Risk estimation by FRAX® and application of current PG would allow physicians to identify these patients and introduce appropriate preventive measures. Continued efforts are needed to promote timely prevention, most especially after the first fragility fracture.

FRIO538 EVALUATION OF FACTORS THAT INCREASE FRACTURE RISK IN BREAST CANCER

A. Anand 1, M. Ghafari 2, M. Bukhari 1, 1University Hospitals of Morcambe Bay NHS Foundation Trust; 2Lancaster University, Lancaster, United Kingdom

Background: Women with breast cancer are at an increased risk of fractures. This is in patients with both active and treated disease. In addition to established risk factors of fractures, patients with breast cancer are exposed to additional factors that further compromise bone strength. These factors primarily include: the malignancy interfering with bone metabolism and breast cancer treatments inducing bone loss.

Objectives: To evaluate fracture risk in active and treated breast cancer patients, and to understand the role bone mineral density (BMD) plays in predicting fracture risk.

Methods: The study population included breast cancer patients with active and treated disease referred to dual-energy X-ray absorptiometry (DEXA) scanning at the Royal Lancaster Infirmary between 2004–2015. Patients on aromatase inhibitors were excluded because of its negative effect on osteostrogen. From this population, we collected BMD measurements of the femur and lumbar vertebra. Alongside information on physical characteristics such as age, height, weight, body mass index (BMI), average tissue thickness, lean and fat mass were measured.

To evaluate other precipitating factors known to increase fracture risk we included: smoking status, steroids use, alcohol, family history of fractures, diagnosis of rheumatoid arthritis and secondary osteoporosis.

Data analysis was done on R 3.3.2 software. Odds ratios were calculated using logistic regression and age adjusted models were compared using the likelihood ratio test. Categorical data was analysed using Chi squared and Fischer’s exact test, while continuous data was analyzed using t-test.

Results: The study population was a total of 306 patients with a mean age of 63.6 years. 146 of the study group had active disease, while 160 patient were breast cancer survivors. Of the total population 87 (28%) had sustained at least one fracture.

Active breast cancer insignificantly increased fracture risk in comparison to the cancer survivor population (OR=1.330, 95% CI=0.801–2.218, p=0.271).

Physical characteristics that significantly increased fracture risk included increased age and decreased average fat percentage (Table 1). BMD reduction in the femoral neck and all vertebrae significantly increased odds of having a fracture (Table 2).

External factors such as smoking status, alcohol consumption, family history and steroid use had no significant effect.

Conclusions: In conclusion, this study emphasizes DEXA measurements are the best predictive tool for fractures in breast cancer patients. Thus further supporting the need for increased BMD surveillance for those diagnosed with breast cancer who are not on aromatase inhibitors.

FRIO539 IMPACT OF THE IMPLEMENTATION OF A FRACTURE LIASON SERVICE IN PHARMACEUTICAL EXPENSES FOR OSTEOPOROSIS

A. Narango 1, S. Ojeda 1, S. Rodriguez 2, I. Bernards 1, A. Molina 1, F. de la Nuez 2, M. Negrin 2, 1Rheumatology; 2Geriatrics, Hospital Univ. Gran Canaria Dr. Negrin; 3 Rational Drug Use Service, Servicio Canario de la Salud; 4 Met. cuantitativos en Economia, Universidad de Las Palmas, Las Palmas de Gran Canaria, Spain

Background: In 2012 a Fracture Liaison Service (FLS) was implemented in Hospital Dr Negrin

Objectives: To analyze the economic impact of the FLS on pharmaceutical expenditure for osteoporosis.

Methods: Expenditure on osteoporosis medication (government input) was collected from January 1th, 2011 to October 1th, 2016. The data distinguish group I (calcium and vitamin D), group II (Bisphosphonates, denosumab, SERM, SeIF), strontium and teriparatide) and total expenditure (sum of groups I and II). Intravenous bisphosphonates were not included. Gran Canaria island is organized in two health areas; the North and the South areas. The population aged ≥ 65 years in the North and South areas in 2016 were
EVALUATION OF BONE QUALITY USING THE NEW PREVALENCE OF VERTEBRAL BODY DEFORMITIES RELATED TO TREATMENT IN POSTMENOPAUSAL PATIENTS

A. Casabella 1, A. Sulli 1, C. Seriolo 2, G. Botticella 2, L. Molfetta 2, M. Cutolo 1, AOU San Martino; 2Osteoporosis, Bone and Joint Disease Research Center

681 patients (17%) of the 3,917 who receive a drug from group II in the North area were under treatment at 12 and 24 months (1). The estimate is that approximately 75% have indication of bisphosphonate or equivalents. The average adherence for drugs in the January-September 2016 period was similar in both areas (2% in the North area and 2.873 units in the South area. That is, the prescription of group II drugs in the January-September 2016 period was similar in both areas (2% higher in the South area), while for group II it was 36% higher in the North area, being this difference stable between 2011 and 2016.

Between 2012 and 2016, 1,297 patients have been evaluated in the FLS, of which 75% have indication of bisphosphonate or equivalents. The average adherence to treatment at 12 and 24 months is 70% (1). The estimate is that approximately 681 patients (17%) of the 3,917 who receive a drug from group II in the North area in October 2016 derive from the FLS.

Conclusions: The implantation of a FLS, despite surrounding around 16% of the percentage of patients treated with bisphosphonates and equivalents in the health area, Gran Canaria North, does not seem to lead to an increase in pharmaceutical expenditure for osteoporosis. We believe that one of the reasons for the non-increase in spending is the rational use of drugs for osteoporosis.

FR0540 EVALUATION OF BONE QUALITY USING THE NEW TRABECULAR BONE SCORE (TBS) TOOL IN RHEUMATOID ARTHRITIS PATIENTS

A. Casabella 1, A. Sulli 1, C. Seriolo 2, G. Botticella 2, L. Molfetta 2, M. Cutolo 1, S. Paolino 1, B. Ruedo 1. Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS AOUG, San Martino; 2Osteoporosis, Bone and Joint Disease Research Center, CROPO, DI.M.I., University of Genova, Genoa, Italy

Background: Patients affected by Rheumatoid Arthritis (RA) show an increased risk of low bone mass, as a result of multi-systemic disorders including toxic drug, low vitamin D levels and physical inactivity. Trabecular Bone Score (TBS), is an index extracted from the dual-energy X-ray absorptiometry (DXA) images, that provides an indirect measurement (Score) of bone axial microarchitecture and allows to get information about bone quality (1,2).

Objectives: The aim of this investigation was to evaluate bone quality in RA patients (high risk population) receiving vitamin D supplementation from at least 6 months. The patients were divided into two groups; patients treated with bisphosphonates and equivalents (group I) and non treated (group II).

Methods: 108 female patients (mean age 61±8 years helped by RA and 60 age-matched controls (CNT) (mean age 64±11 years) were enrolled. Bone Mineral Density (BMD, g/cm2) of the lumbar spine (L1-L4) was analyzed using a DXA scan (GE, Lunar Prodigy). Lumbar spine TBS (Nlsight Medimaps) was derived for each spine DXA examination. All patients were evaluated for serum 25 hydroxyvitamin D (25(OH)D) concentrations.

Results: 78 RA patients (80%) presented a bone loss that was significantly lower when compared with control group (p<0.001). Likewise, lumbar spine TBS score was found significantly lower in RA patients compared with CNT (p<0.001).

Finally, RA patients showed lower 25(OH)D concentrations (18.4±1.3 ng/ml) than CNT (26.2±0.9 ng/ml; p<0.04).

Conclusions: This study shows in RA patients a reduction of TBS values that seem placed side by side with reduced BMD values and 25(OH)D serum concentrations. Therefore, TBS could become a new and safe diagnostic tool for the quantification of the bone quality and related osteoporosis, in chronic systemic inflammatory rheumatic diseases, such as RA.

FR0541 RELATIONSHIP BETWEEN CHRONIC PERIODONTITIS AND BONE MINERAL DENSITY IN A CASE-CONTROL STUDY OF PATIENTS WITH RHEUMATOID ARTHRITIS AND NON-INFLAMMATORY JOINT DISEASE

J.L. Garnier Rodríguez 1, J. González Febles 2, S. Dadiani 1, M.A. Gómez 3, A. González Díaz 4, L. Expósito Pérez 4, E. Trujillo 4, M. García González 4, B. Rodríguez-Lozano 4.

1Odontology/Periodontology, Dental Clinic Dr Garnier, Santa Cruz de Tenerife; 2Periodontology, UCM, Madrid; 3Nuclear Medicine Department; 4Rheumatology, Hospital Universitario Canarias, Tenerife, Spain

Background: The association between two chronic inflammatory diseases such as rheumatoid arthritis (RA) and periodontitis (PD) may be explained by causal and noncausal pathways. A possible mechanism in the increased PD observed in patients with RA is systemic bone loss due to the inflammatory process itself among others factors. Several studies have reported associations between OP and PD not confirmed in other studies.

Objectives: 1.To determine whether OP is associated with PD and with PD severity.

Methods: Observational cross-sectional, case-control study of RA patients ≥18 yo. meeting ACR/EULAR 2010 criteria for RA in a Rheumatology Dept. and a group with a non-inflamatory joint disease, with at least 4 teeth, without dental prophylaxis or antibiotic intake 6 months before. Socio-demographic and anthropometric variables with smoking status, Graffar scale, stress level, annual dental prophylaxis, and co-morbidities such as diabetes mellitus (DM), dyslipidemia (DS), ischemic cardiovascular disease (ICD) and history of low impact fractures. Dual-energy x-ray absorptiometry (DXA) (g/cm2) was performed with a DXA LUNAR (GE HealthCare) in lumbar spine and femoral neck. Periodontal Variables included plaque index, bleeding on probing, probing pocket depth, recession, clinical attachment level (CAL). Full mouth CAL and periapical x-rays were taken. CAL was classified according to the European Workshop in 2005 (Tonetti), into level 0 (absence), TL1 (mild), TL2 (severe). Statistical Analysis: t-student test, Kruskal Wallis, Chi-square with Stata 13.1.

Results: We studied 344 patients: 187 RA (147 F/40 M) and 157control (101F/56M). Both groups were comparable in age 54.9 (17.9) yo., body mass index 27.8 (4.6), stress level, DM and ICD. Differences in gender (n=0.018) of males in controls, socioeconomic status (lower level in RA), n=0. of current and former smokers RA (19.2%vs 8.9%24.6%vs 11.5%), OP (23.4% RA vs 7.8%), DS (hperglycemia 11.2% RA vs 4.4%). PD was found in 97.3% of RA patients vs 66.2% of controls. DXA was performed in 303 patients: 163 RA/140 controls that showed OP in 38 (23.3%) and 13 (9.3%) of RA and control groups as well as osteopenia in 47 (32.4%) and 16 (11.3%) respectively (p<0.001); 81% of these patients presented PD. There was association between PD and OP/osteopenia, so patients with PD had greater abnormal BMD 88% vs 76.3% with normal BMD; patients without PD showed greater normal BMD with statistically significant difference (23.7% vs 11.1%) (p=0.008).

Conclusions: 1. PD was observed in 81% of the patients evaluated with BMD, of these, 89% and OP/osteopenia, and among the patients without PD a significant normal BMD predominated. 2. PD was found in 97% of RA patients versus 66% of controls; similarly OP was present in 23.3% of RA patients versus 9.3% of controls, with the difference being significant. 3. There was no association between BMD and PD severity.

FR0542 PREVALENCE OF VERTEBRAL BODY DEFORMITIES RELATED TO OSTEOPEOROSIS IN PATIENTS WITH NON-TRAUMATIC LUMBAR OR DORSAL ACUTE PAIN

C.A. Guillen-Astete, C. Pijón-Moratalla, J.R. Quiñones-Torres, Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain

Background: Presence of vertebral body deformities is considered a relevant issue in order to choose a particular treatment in patients with osteoporosis. However, only remarkable deformities are properly identified and registered while the remainder, usually, striking can just be unnoticed in radiological studies not related to osteoporosis studies. One of the most usual radiographic study of the axial skeleton is the lumbar and dorsal acute pain. This group of patients is, indeed, suitable to establish proportions of any grade of vertebral body deformities as a result of multi-systemic disorders including toxic drug, low vitamin D levels and physical inactivity. Trabecular Bone Score (TBS), is an index extracted from the dual-energy X-ray absorptiometry (DXA) images, that provides an indirect measurement of bone axial microarchitecture and allows to get information about bone quality (1,2).

Objectives: The goal of present study is to determine prevalence of vertebral body deformities in postmenopausal patients radiologically assessed due to lumbar or dorsal non traumatic related pain.

Methods: We performed a simple randomization of the registers of female patients with 65 years old or more who consulted due to dorsal or lumbar pain under treatment in septiembre 2016 was calculated.

References:
non-traumatic acute pain. Between 2014 and 2015, all included registries must have had a radiological assessment. The gathering of registries concluded after reach 120% of the estimated sample size for a non finite theoretical population, a precision of 3% and a hypothetical estimated prevalence of 7% based on local previous studies of prevalence of vertebral osteoporotic fractures. Vertebral body measurement criteria were performed according to González et al recommendations from D7 to L5 as far as possible according to the field of study of the radiological chart plate.

**Results:** 275 randomized registries of dorsal and lumbar pain were included (total=550). Among patients with dorsal pain we identified 62 (22.5%), 30 (10.9%) and 16 (6.5%) vertebral deformities grade I, II and III respectively. Among patients with lumbar pain we identified 31 (11.2%), 49 (17.8%) and 33 (12%) vertebral deformities grade I, II and III respectively. Prevalence of any grade of dorsal vertebral deformity was 40.00% (CI 34.39 – 45.89) and lumbar was 41.09% (CI 35.44 – 46.99). The vertebral body deformity grade I and II summed 70.7% while dorsal grade I and II summed 83.6%. From the 93 vertebral body deformities grade I, 6.4% were recognized in their clinical histories, 20.2% of the grade II deformities and 92.1% of the grade III deformities. (P<0.001).

**Conclusions:** Although our population sample is circumscribed to symptomatic patients, our results contribute with prevalence of vertebral body deformities in postmenopausal patients grade I and II and who were mostly unnoticed. Proper identification of vertebral body deformities in patients with osteoporosis is crucial to decide treatment strategies in patients with known osteoporosis. Due to that, prevalence studies of this kind are relevant and useful to avoid diagnostic mistakes.

### FR0543 WHICH FACTORS CAN HELP PREDICT FRACTURE RATES IN PATIENTS DIAGNOSED WITH INFLAMMATORY BOWEL DISEASE? A CASE-CONTROL STUDY

D. Ahmed1 , M. Bukhari2, 1Lancaster Medical School; 2Rheumatology, University Hospitals of Morecambe Bay NHS Trust, Lancaster, United Kingdom

**Background:** Inflammatory Bowel Disease (IBD) is a known risk factor for developing low bone mineral density (BMD) osteoporosis, due to malabsorption and treatment with steroids. These patients are more susceptible to fragility fractures. Though the percentage of such fractures is low, they can be associated with impaired mortality and morbidity. The difficulty lies in early detection of patients at an increased risk of fractures. Currently the diagnosis of osteoporosis and prediction of fracture risk are calculated assessing patient BMD on dual energy X-ray absorptiometry (DEXA). However, previous studies suggest that despite a decreasing BMD being significantly associated with an increased risk of fracture, its measurement alone is fairly restricted in predicting them; other patient factors must also be brought into consideration (1).

**Objectives:** To identify specific factors which may assist in the prediction of fracture rates in a cohort of patients diagnosed with IBD.

**Methods:** Patients referred to a DEXA scan in the North West of England were identified and those with a referral reason of IBD were studied. Factors measured at BMD scanning include patient age, height, weight and femoral head bmd, BMD, smoking history, alcohol use, family history of fractures, steroid exposure, rheumatoid arthritis and secondary osteoporosis. Patients were then grouped into cases and controls after adjusting for age and gender. They were then analysed using T tests for continuous variables and Chi squared tests for categorical variables. Univariate and multivariate logistic regression models were then used to identify factors predicting fractures.

**Results:** 938 patients were identified of which 721 (76.9%) were female with an average age of 58 as compared to an average age of 53 in men. 274 patients (29%) had fractures of which 238 were females (87%), at an average age of 63 compared to 60 in men. Men were shown to have a greater risk of fractures. Results of the univariate analysis are shown below.

### FR0545 COMPARISON OF MINERAL BONE DENSITY IN HIV-INFECTED PATIENTS FOLLOWED IN A SPANISH TERTIARY HOSPITAL WITH THAT OF NON HIV-INFECTED SPANISH POPULATION

F. López Gutiérrez1, W.A. Sifuentes Giraldo2, J.L. Casado Osporio3, M. Vázquez Díaz1, 1Rheumatology; 2Infectious Diseases, Ramón y Cajal University Hospital, Madrid, Spain

**Background:** Patients with human immunodeficiency virus (HIV) have a higher prevalence of low bone mineral density (BMD) and fractures than the general population, but there are no comparative studies in Spanish population.

**Objectives:** To assess the BMD in HIV-infected patients followed in a tertiary hospital of Madrid and compare it with the ESOSVAL cohort, which included 11035 patients and is representative of non-HIV population seen in Spanish tertiary centers.

**Methods:** We performed a cross-sectional study in which BMD values were determined in a prospective cohort that included HIV-infected patients seen in our center during the period 2010–2015. Collected data included demography, comorbidities, treatment and densitometric variables.

**Results:** 93 patients from a total of 924 with BMD data were eligible for the study after discarding those younger than 55 years, because that group is not included in the ESOSVAL cohort. Mean age of patients of our whole cohort was 53 years (range: 17–83), 117 (74.4%) were women older than 55 years, of whom 83 were men (83%). Most of them were Caucasians, with a mean body mass index 24.1 (range: 14.7–40.6). Median time of HIV infection was 162.6 months (interquartile range [IQR]: 77.7–283.3), median CD4+ cells nadir was 224 (IQR: 100–332) and median maximum viral load was 4.9 log (IQR: 4.3–5.4); concomitant hepatitis C
virology infection was present in 29%. 25% were treated with tenofovir plus protease inhibitors, and 47% with tenofovir plus a non-nucleoside reverse transcriptase inhibitor. The mean value of BMD in lumbar spine (LS) was 0.93 g/cm² (range: 0.84–1.02) and in femoral neck (FN) 0.78 g/cm² (range: 0.69–0.86). For the comparison with the ESOSVAL cohort the worst value of T-score in either LS or FN was chosen and the WHO definitions (osteoporosis ≤ -2.5, osteopenia -1.0 to -2.5); the results are presented in the table. Only the data for the 50-64 and 65-74 years groups were compared because the number of older HIV patients in our center was small. Significant differences were found between the categories of osteoporosis in men in the 65–74 years old group, and that of osteopenia in women in the 55–64 years old group.

**Conclusions:** We observed a statistically significant increase in prevalence of osteoporosis in women in the 65–74 years group, and in osteopenia HIV-infected men in the 55–64 years group, in accordance with the presumed greater risk derived from a variety of causes (treatment, chronic inflammatory status, comorbidities, etc.). A non significant trend towards an increased prevalence of osteoporosis in the 55–64 years group, and in osteopenia in the 65–74 years group was seen. As for women, there was a statistically significant increase in osteopenia prevalence in the 55–64 years group with HIV and a non significant trend towards increased prevalence of osteoporosis in that age group, whereas no significant increase was observed in the 65–74 years HIV group, presumably due to the small number of patients included in it.

### FR0547

**OSTEOPOROSIS AND BONE METABOLISM IN SYSTEMIC SCLEROSIS**

A. Horváth1, K. Gulyás1, H.P. Bhattoa2, G. Szücs1, Z. Szekaneč1, S. Szamosi1, I. Ghozlani1, I. Ghozlani2. 1Department of Rheumatology, Rheumatology Division, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

**Background:** Systemic sclerosis (SSc) has been associated with bone loss and increased risk for bone fractures. Disease-related factors, age, corticosteroid therapy may be associated with bone loss. More recently, it has been shown to be associated with disease duration, anti-Scl70, and anti-centromere antibodies.

**Objectives:** Here we performed a detailed study on osteoporosis in SSc. We performed bone density assessment by DXA, as well as percutaneous peripheral quantitative CT (pQCT). In addition, we assessed bone biomarkers and correlated bone density and disease-associated measures.

**Methods:** Altogether 44 SSc patients (36 women, 8 men; age: 64.1 years; disease duration: 17.6 years) were randomly recruited for the study. Bone density was assessed by DXA at the lumbar spine and femoral neck. pQCT (Stratec) was able to assess total, trabecular and cortical density. We also determined FRAX, levels of vitamin D, as well as bone markers (Ca, PTH, osteoclast, P1NP, beta-CTX), markers of autoimmunity (ANA, ACA and anti-Scl70) and clinical manifestations of the disease. Statistical analysis was performed by SPSS v2.0.

**Results:** Vitamin D levels were lower (53.9 +/- 36.8 nm) than the normal range (75–100 nm). 34 out of 44 patients (77%) had D-hypovitaminosis. Abnormally increased PTH, P1NP, OC, CTX levels were observed in 10, 7, 2 and 6 patients, respectively. Previous fractures occurred in 19 patients (43%). The vertebral and hip FRAX values were 13.5% and 4%, respectively. By DXA, osteoporosis of the lumbar spine and hip was detected in 10 and 10 patients, while osteopenia was found in 16 and 20 patients, respectively. With respect to pQCT, total and trabecular bone density in SSc patients (248.4 ± 150.9 mg/cm³) was significantly lower than in healthy controls (354 ± 193 mg/cm³, respectively). Higher OC levels were associated with the diffuse form of SSc (R=0.330, p=0.035). Longer disease duration correlated with lower pQCT total (R=–0.341, p=0.023) and trabecular density (R=–0.336, p=0.026). Interestingly, most bone markers (P1NP, OC, CTX) positively correlated with gastrointestinal manifestations. Furthermore, pQCT total bone density was significantly lower in patients with pulmonary hypertension, digital ulcers and DM.

**Conclusions:** A high proportion of SSc patients have osteoporosis or osteopenia, as well as low vitamin D levels. As determined by pQCT, trabecular loss is more common. Both total and trabecular bone loss, as well as bone markers may be associated with disease duration, anti-Scl70 and some organ manifestations. SSc patients should be screened and treated for osteoporosis.

### FR0548

**INFLUENCE OF HOMOCYSTINE AND VERTEbral FRACTURES ON PREVALENT ABDOMINAL AORTIC CALCIFICATION IN POSTMENOPAUSAL WOMEN: A MULTICENTRIC CROSS-SECTIONAL STUDY**

A. Ghooz1, A. El Maataoui2, M. Ghazi1, A. Kherb1, N. Namane2. 1Rheumatology Department, Military Hospital; 2Chemistry-Biochemistry Department, Faculty of Medicine and Pharmacy, Ibn Zohr University, Agadir; 3Rheumatology Department, Military Hospital Avicenne, Marrakech, Morocco

**Background:** Osteoporosis and cardiovascular diseases are two major public health problems. Both are associated with high morbidity, long-term hospitalization, mortality and loss of independence leading to institutionalization. Vertebroplasty using dual-energy X-ray absorptiometry (DXA) also known as vertebral fracture assessment (VFA) is a fast, minimally invasive technique which produces images that are of sufficient quality to be used to diagnose the presence of vertebral deformity consistent with fracture. VFA has demonstrated utility for vertebral visualization and thus is an important tool for fracture detection in women and men. It has been shown also in many populations that this technique can simultaneously identify abdominal aortic calcification (AAC). Hyperhomocysteinemia, a condition that recent epidemiological studies have shown to be associated with increased risk of vascular disease. A potential role of homocysteine in bone fragility has been considered from the observation of a high prevalence of osteoporosis in subjects with homocystinuria.

**Objectives:** The present study aims to investigate the influences of homocystine and vertebral fractures on prevalent abdominal aortic calcification in postmenopausal women.

**Materials and Methods:** A total of 3645 postmenopausal women (50–64 years) were randomly recruited for this study.

**Results:** The prevalence of vertebral fractures was 13.5%. The prevalence of homocystine was 7.5%. The prevalence of AAA was 10.7%. The prevalence of homocystine and vertebral fractures was 10.4%. The prevalence of AAA and vertebral fractures was 9.3%. The prevalence of AAA and homocystine was 7.5%. The prevalence of AAA, homocystine and vertebral fractures was 7.2%.

**Conclusions:** Homocystine and vertebral fractures are associated with prevalent abdominal aortic calcification in postmenopausal women. This study highlights the importance of screening for homocystine and vertebral fractures in postmenopausal women to prevent abdominal aortic calcification.

**Disclosure of Interest:** None declared

Objectives: The main of this study was to examine the relationship between plasma homocysteine (HCy), asymptomatic osteoporotic vertebral fractures (VF), using vertebral fracture assessment (VFA) and prevalent abdominal aortic calcification (AAC) in Moroccan postmenopausal women.

Methods: The study cohort consisted of 188 consecutive postmenopausal women with no prior known diagnosis of osteoporosis or taking medication interfering with bone metabolism. Mean age, weight, height, body mass index and plasma homocysteine were determined. Lateral VFA images and scans of the lumbar spine and proximal femur were obtained using a Lunar Prodigy Vision densitometer (GE Healthcare Inc., Waukesha, WI). VFs were defined using a combination of Genant's semiquantitative approach and morphometry. VFA images were also scored for prevalent AAC using a validated 24 point scale.

Results: Fifty-eight (30.9%) patients had densitometric osteoporosis. VFs were identified using VFA in 76 (40.4%) patients: 61 women had grade 1 VFs and 15 had grade 2 VFs. The prevalence of VF on the lumbar spine was 8% (65/812) in the 282 patients seen by the VFA. In the 282 patients seen by the VFA, the prevalence of VF in LS was 3.8% (10/262). In the 282 patients seen by the VFA, the prevalence of VF in FN was 0.9% (2/210).

Conclusions: This study did not confirm that homocysteine is important determinant of extended AAC in postmenopausal women. However, this significant atherosclerotic marker is independently associated with VFs regardless of age.

FR0550 MALE PATIENTS WITH RHEUMATOID ARTHRITIS HAVE AN INCREASED RISK OF OSTEOPOROSIS: FREQUENCY AND RISK FACTORS

J.-H. Park1, S.-G. Lee1, E.-K. Park1, S.-M. Kweon1, D.H. Sohn2, Y.-K. Kim3, H.-S. Tag1, G.-T. Kim4, J.-W. Lee4, 1Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital; 2Microbiology and Immunology, Pusan National University School of Medicine; 3Internal Medicine, Kosin University College of Medicine; 4Internal Medicine, Busan St. Mary’s Hospital, Busan, Korea, Republic Of

Background: Osteoporosis is a well-known extra-articular manifestation of rheumatoid arthritis (RA) and almost 2 times higher prevalence of osteoporosis was reported in female patients with RA than in healthy subjects. Accordingly, patients with RA are at increased risk of fragility fractures that lead to significant morbidity and mortality and higher healthcare cost. However, most previous epidemiologic studies regarding osteoporosis in RA have focused on female subjects, and little attention has been given to male patients with RA.

Objectives: To compare the prevalence of osteoporosis between male patients with RA and healthy subjects and to identify the risk factors of osteoporosis in male patients with RA.

Methods: By using a cross-sectional design, we recruited 76 male patients with RA aged 50 years and over and 76 sex-matched and age-matched healthy subjects at a university-affiliated rheumatology centre in South Korea from August 2014 to August 2016. We measured bone mineral density (BMD) at L1—4 levels of the lumbar spine and the hip. The prevalence of osteoporosis was evaluated by using dual-energy X-ray absorptiometry (DEXA). We assessed the prevalence of osteoporosis defined as a T-score of ≤−2.5 according to the WHO criteria. We also investigated potential risk factors of decreased BMD and the presence of osteoporosis in male patients with RA using linear and logistic regression analyses.

Results: The mean age and body mass index (BMI) of the male patients with RA were 64.5 years and 22 kg/m², respectively, which were comparable with those of the healthy controls. The overall prevalence of osteoporosis at either the spine or the hip in the male patients with RA was significantly higher than that of the healthy controls (22.4% vs 10.5%, respectively; p=0.049). However, no significant differences in the prevalence of osteoporosis at the spine (19.7% vs 10.5%, respectively; p=0.13) and the hip (3.9% vs 0%, respectively; p=0.245) were found between the patients with RA and the controls. For the male patients with RA, the median disease duration was 37 months, the mean 28-joint Disease Activity Score (DAS28-ESR) was 3.28 and the median modified total Sharp score was 6. An increased titre of anti-cyclic citrullinated antibody showed a trend toward lower L1—4 BMD (p=0.007, p=0.057) in the multivariable linear regression analysis. In addition, DAS28-ESR of ≥3.2 was independently associated with the presence of osteoporosis (OR=3.85, 95% CI=1.13—13.17, p=0.032) after adjusting for confounding factors. The patients with RA whose BMIs were <22 kg/m² had a higher risk of osteoporosis (OR=3.43, 95% CI=1.04—11.33, p=0.043).

Conclusions: Similar to their female counterparts, the frequency of osteoporosis in male patients with RA had an osteoporosis prevalence of about 2.1 times higher than that of the healthy subjects. Increased DAS28-ESR was an independent risk factor of osteoporosis. Our data suggest that appropriate management for osteoporosis in patients with RA is crucial not only for postmenopausal women, but also for men aged 50 years and over.

FR0549 IMPACT OF CHEMOTHERAPY ON BONE MINERAL DENSITY IN POSTMENOPAUSAL WOMEN WITH BREAST CANCER IN TREATMENT WITH AROMATASE INHIBITORS

J. Leare-Martos1, W.A. Sillientes Giraldo1, L.V. Maldonado Romero1, M. Rojas-Luna T., C. Velázquez Arce1, N. Martínez Jaure2, M. Vázquez Díaz3, 1Rheumatology, 2Oncology, Ramon y Cajal University Hospital, Madrid, Spain

Background: Aromatase inhibitors (AI) have been related to an increased risk of bone loss and fractures in women receiving these drugs as adjuvant treatment, but few studies have assessed the impact of prior chemotherapy (CT) on bone mineral density (BMD) levels associated to AI.

Objectives: To assess the impact of CT prior to the initiation of AI on BMD in postmenopausal patients with breast cancer (BC) seen at a Spanish tertiary care hospital.

Methods: We perform a longitudinal study in patients who received AI after initial CT (CT group) or as adjuvant therapy without prior CT (non-CT group) followed up for 12 months. BMD was assessed by DXA in lumbar spine (LS) and femoral neck (FN) at baseline and after 12 months of AI treatment following the usual protocol of our center, with in vitro coefficient of variation of 1% in both locations and estimated minimal significant change (MSC) of 0.0223 g/cm² in LS and 0.0288 g/cm² in FN. Demographics, neoplastic disease data, and osteoporosis risk factors were collected.

Results: 69 patients (CT group, non-CT group) attended at our center between August 2011 and December 2014 were included. Mean age at diagnosis was 59±7.7 years, most of them have BC stage I-II (84%). Most frequent AI in both groups were letrozole (95%). Baseline characteristics were similar, except for age at diagnosis that was significantly higher in the non-CT group; these data are presented in the table. Mean BMD at the start of AI was significantly lower in LS in the CT group (0.7793 g/cm²) than in the non-CT group (0.8483 g/cm², p=0.018), but no difference in FN (0.6764 g/cm² and non-CT 0.7077 g/cm², p=0.123). A significant difference in LS (CT 0.7685 g/cm², non-CT 0.8397 g/cm², p=0.003) was found in the comparison of BMD means between the two groups at 12 months but not in FN (CT 0.6598 g/cm² and non-CT 0.6689 g/cm², p=0.369).

After 12 months of treatment with AI, mean BMD change in the CT group in LS was -0.0085 g/cm² (95% CI -0.0349, +0.0279, p=0.7077 g/cm², p=0.123) and in FN -0.0107 g/cm² (95% CI -0.0269, +0.0055, p=0.0369) and in FN -0.0165 g/cm² (95% CI -0.0339, +0.0099, p=0.063), while in the non-CT group the mean changes were in LS -0.0085 g/cm² (95% CI -0.0146, +0.0244, p=0.599) and FN -0.0388 g/cm² (95% CI -0.0707, -0.0088, p=0.019). During the study period there was a fracture in each group (CT 2.6%, non-CT 3.3%).

Conclusions: Our results do not demonstrate that CT prior to AI treatment significantly decreased BMD during the first year. Mean change in both LS and FN in CT group was not superior to MSC nor to the change in non-CT group, although they had a significantly lower mean BMD in LS than the latter group and this difference was maintained at the end of the study period.

practice, and it is very important to know risk factors that attenuate its effect in the treatment of osteoporosis.

Objectives: The aim of this study was to identify risk factors for inadequate response to the treatment of osteoporosis by DMAB.

Methods: Sixty-six patients treated with DMAB were observed retrospectively for one year. The mean age was 74.4 years, and 24 women and 42 men were included. We measured BMDs at lumbar and hip by dual-energy X-ray absorptiometry (Hologic Discovery) at baseline and one year later. We evaluated the effects of age, body mass index (BMI), use of glucocorticoid (GC), previous treatment for osteoporosis, BMD at baseline, bone metabolic markers (BAP; bone alkaline phosphatase, NTX; urinary N-telopeptide), serum Ca and P levels and the previous vertebral fractures for inadequate response to DMAB. We defined the cases who could not gain the increase of BMD over 2% at the lumbar vertebrae and 4% at the hip as inadequate responders by taking the measurement error into account.

Results: Dose of PSL was significantly high in non-responder at non-RA trochanter and RA lumbar BMD (p=0.028, 0.006). BAP was higher in non-responder at RA lumbar BMD (p=0.007). Urinary NTX was significantly high in non-responder at non-RA lumbar and RA trochanter BMD (p=0.026, 0.048). Previous treatment for osteoporosis was significantly high in non-responder at non-RA lumbar, total hip and trochanter BMD (p=0.026, 0.022, 0.003). Multivariate logistic analysis including age, BMI, dose of PSL, BMD at baseline, BAP, NTX, Ca and P level as confounders revealed that dose of PSL was the significant risk factors for non-responder at lumbar BMD (OR=6.64, 95% CI 0.433–9.93, p=0.02).

Conclusions: Patients receiving GC might gain an adequate response to the treatment by DMAB for osteoporosis. Reducing dose of GC or alternative treatment regimens might be necessary.

associated with osteoporosis. Adiponectin levels of 43.9 μg/ml and lower were associated with normal bone density.

**Conclusions:** Thus, we revealed that Adiponectin levels depend on osteoporosis presence in RA patients. We suppose that Adiponectin determination may be a useful laboratory marker for OP diagnosis.

**LEFT VENTRICULAR EJECTION FRACTION AND BONE MINERAL DENSITY AFTER CARDIAC TRANSPLANTATION**

**Rheumatology, Reina Sofia University Hospital/IMIBIC University of Cordoba, Cordoba, Spain**

**Background:** Left ventricular ejection fraction (LVEF) has been directly associated with BMD in patients with heart failure. Nevertheless, no study has linked yet the left ventricular ejection fraction to bone mineral density and fragility fractures in cardiac transplantation.

**Objectives:** The main aim of this study was to evaluate the possible relationship between LVEF and BMD in heart transplantation and the association of LVEF with other factors related to bone metabolism (vitamin D, parathormone (PTH) and markers of bone remodeling in patients with heart transplantation (osteocalcin, telopeptide C terminal (CTX)).

**Methods:** Seventy nine patients (66 male) were included in this cross-sectional study with a mean age of 55.75±14.81 years, body mass index (BMI) values of 26.89±5.35 kg/m² and an average post-transplantation period of 8.46±8.71 years. The LVEF of each patient was evaluated in the beginning of the study using Doppler echocardiography, and the BMD was measured using dual energy X-ray absorptiometry (DXA) at the femoral neck, lumbar spine and hip level. The patients were divided into two groups based on LVEF values: Group A, LVEF ≥ 54% and Group B, LVEF < 54%.

**Results:** A total of 79 patients were included in this present study. BMD in osteoporotic range was found in 31.2% of patients (17.7% in spine,16.52% in femoral neck and 13% in hip). Vitamin D deficiency (<20ng/dl) was detected in 68.4% of patients. Vertebral fracture was found in 30.4% and a 2.6% hip fracture. Bivariate analysis showed that the group of patients with FEV ≤ 65% had a higher proportion of femoral neck osteoporosis (p=0.04), higher proportion of osteoporosis in total hip (p=0.03) and a higher percentage of vertebral fractures (p=0.04) compared with group with LVEF > 65%.

The multiple linear regression analysis indicated that LVEF was independently associated with osteoporosis in spine (B = -5.225, p=0.011), femoral neck osteoporosis (B = -5.411, p=0.015) and vertebral fractures (B = -5.433, p=0.002). In addition, LVEF was associated with osteocalcin levels (B = -0.105, p=0.002).

**Conclusions:** These results suggest that post-transplantation LVEF may have an influence on bone remodeling. However, further studies are needed in order to confirm this in other institutions.

**DOES WEIGHTED KYPHO-ORTHOSIS (WKO) REDUCE RISK OF FALL IN WOMEN WITH OSTEOPOROSIS? A PRELIMINARY STUDY**

**Rheumatology, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal**

**Background:** Osteoporosis is a major health problem, particularly in the elderly, because of fragility fractures and their consequences. Hip fractures (HF) are the most ominous outcomes in terms of morbi-mortality.

**Objectives:** The aim of our work was to establish the current mortality and re-fracture rate at 1 and 3 years after HF, as well as their predictors.

**Methods:** The study included all patients aged >40 years, admitted to Coimbra University Hospital between May and October 2013 with the diagnosis of HF. Demographic and clinical data related to the fracture episode was collected from medical files. Patients or the caregivers were contacted to assess potential risk factors at baseline and major post-fracture events at 1 and 3 years after the index HF. The mortality and re-fracture rate 1 and 3 years after fracture were calculated. Possible predictor variables were tested by cox regression analysis: age, gender, Charlson index.

CORRELATION OF THE FRACTURE RISK ASSESSMENT TOOL (FRAX) AND ASYMMETRIC MORPHOMETRIC VERTEBRAL DEFORMITIES IN HIV-INFECTED PATIENTS

M. Liop Vitale 1, C. Medina Quiñones 1, C. Macía Villa 1, W.A. Sifuentes Giraldo 1, M. Vázquez Díaz 1, J.L. Caicedo Osorio 1. 1. Rheumatology, Infectious diseases, Hospital Universitario Ramón y Cajal, Madrid, Spain.

Background: Patients infected with the human immunodeficiency virus (HIV) have a high rate of low bone mineral density (BMD) and is thought to be multicausal. Some instruments have been developed to estimate the risk of osteoporotic fracture in the general population such as the WHO Fracture Risk Assessment Tool (FRAX), which allows calculating the 10-year probability of fractures in men and women from clinical risk factors with or without the measurement of femoral neck BMD. The cut-off values for high risk of hip fracture >3% and for major osteoporotic fracture >20%. Although FRAX has been validated in multiple large studies there are no clear recommendations of its use in HIV-infected patients older than 50 years.

Objectives: To evaluate the utility of FRAX tool in the prediction of risk of vertebral morphometric deformity (MVD) in HIV-infected patients over 50 years old seen in a Spanish tertiary care center.

Methods: We performed a cross-sectional study in HIV-infected patients with age 50 years treated in our centre during the period 2014–2016. Demographics and risk factors were collected through a specific survey. FRAX was calculated and risk factors were collected through a specific survey. FRAX was calculated with increasing mortality in patients who suffered a fragility HF.

PREDICTORS OF FRACTURES IN FEMALE PATIENTS WITH ANOREXIA

M. Rahm, M. Bukhari. Rheumatology, Royal Lancaster Hospital, Lancaster, United Kingdom.

Background: Anorexia Nervosa (AN) is an eating disorder characterised by extremely low body weight and body image distortion. It is more common in females and is expected to become increasingly more prevalent. Numerous studies have found AN to have a detrimental effect on bone health. The evidence shows that anorexia is associated with reduced bone mass and strength which increases fracture risk. Few studies have looked at other predictors of fracture in these patients.

Objectives: The aim of this study was to determine whether further predictors of fracture could be found in female patients suffering from anorexia nervosa (AN).

Methods: Female patients with anorexia referred for a bone mineral density (BMD) DEXA scan from June 2006 to October 2014 were identified. This cohort of patients was split into two subgroups depending on their fracture status. Demographics collected on scanning and factors such as age at DEXA scan, height, weight, body fat percentage, BMI, lumbar spine L1-L4 BMD and femoral neck BMD were used to compare the fracture group against the controls. Categorical variables such as smoking, comorbidities (Rheumatoid arthritis), alcohol, family history and steroid use were compared using chi squared test and the T test was used to compare continuous variables. Logistic regression models were used to model fractures unadjusted and adjusting for age at scan.

Results: A total of 193 female patients with anorexia were included: 45 (23.3%) had sustained a fracture. The results of statistical analysis are shown in Table 1. The data showed there is a significant association between having a low femoral neck BMD and increased fracture risk OR 0.036 (95%, CI 0.003, 0.497). The case group was also significantly taller OR 1.061 (95%, CI 1.009, 1.117) and older P 0.0027 (95% combined CI 39.193, 42.682). There was no correlation with any of the categorical variables and fracture risk, see Table 2 for results.

Conclusions: This study demonstrates that fractures in female patients with anorexia are more likely to occur in those who are taller, older at DEXA scan and in those who have a lower femoral neck BMD. This would indicate that cortical bone loss and taller stature are indepent risks in this cohort. Further work using vitamin D levels as a risk should be performed.

SAFETY OF DENOSUMAB IN POST-MENOPAUSAL OSTEOPOROSIS AND IN CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Aubailly 1, T. Barretche 2, B. Combe 3, C. Gauloux-viala 3, C. Lukas 1, J. Morel 1, H. Ohe 1, 1. CHU lapérouse, Montpellier; 2. CHU bordeaux, Bordeaux; 3. CHU Nîmes, Nîmes, France.

Background: Denosumab is a RANK ligand antibody (1) used for the treatment of post-menopausal osteoporosis (OP) and prevention of bone metastases complications (2,3).

Objectives: The aim of this meta-analysis was to assess the safety of Denosumab.

Methods: Data sources included MEDLINE, EMBASE, Cochrane Library, and recent abstracts from ACR and EULAR congresses were searched until March 2016. Randomized controlled trials comparing the safety of Denosumab to placebo or bisphosphonates (BP) in postmenopausal OP and in cancer (either cancer with bone metastases or with hormone therapy) were selected. Data were

Conclusions: The FRAX tool does not identify properly the HIV-infected patients older than 50 years with MVD as well as the patients who need DXA. An alternative could be to perform X-rays of thoracic and lumbar spine as a screening method in HIV-infected patients with risk factors.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.5205
extracted by one investigator, confirmed by another, and pooled in meta-analysis using Review Manager software (Cochrane collaboration).

**Results:** 6136 articles were of potential interest, and 19 met the inclusion criteria. 7 articles compared the safety of Denosumab to BP in post-menopausal OP. There was no significant difference when comparing Denosumab with bisphosphonates in 3 articles (RR=0.98, 95% CI=0.98–1.01) or in osteonecrosis of the jaw (ONJ) (RR=1.04, 95% CI=0.81–1.33). Regarding Denosumab versus placebo in post-menopausal OP, 7 studies were included and there was no significant difference in AAE (RR=0.99, 95% CI=0.94–1.01), SAE (RR=1.03, 95% CI=0.96–1.11), however cellullitis was more frequently found with Denosumab (RR=8.03, 95% CI=1.37–48.30). No cases of SAE were recorded. 5 articles were pooled to compare Denosumab with BP in patients with bone metastases and no significant difference was found in AEE (RR=0.99, 95% CI=0.98–1.00), SAE (RR=0.99, 95% CI=0.95–1.03), and ONJ (RR=1.40, 95% CI=0.92–2.13). 4 articles were selected concerning patients treated with placebo and Denosumab in men with prostate cancer without bone metastases. Although no significant difference was found in AEE (RR 1.01, 95% CI=0.99–1.03), use of Denosumab was associated with a significantly increased risk of hip haemorrhage (RR 5.20, 95% CI=1.34–20.13) and of cholecystitis (RR 3.43, 95% CI=1.01–11.69).

**Conclusions:** In post-menopausal OP, Denosumab had a relatively safe profile although significantly more cellullitis occurred when compared with placebo. For patients who were less than 50 years of age, Denosumab was associated with more hip haemorrhage and cholecystitis than placebo.

<td>0.38 (0.24; 0.52)</td>
<td>0.10 (0.08; 0.12)</td>
</tr>
</tbody>
</table>

*Based on data published elsewhere.*

Conclusions: The proportion HF/NHF observed in Portugal is similar to the Swedish reference values (0.44/0.56). The highest cost were attributed to hip fractures in both countries, followed by vertebral fractures and lastly by wrist fractures. The HRQoL mean loss was higher for vertebral fractures in both countries. The reported costs of vertebral fractures are much higher than in Portugal which may significantly affect the calculation of cost-effectiveness thresholds for intervention.

**FR0562 USE OF TERIPARATIDE AS A CALLUS ACCELERATOR IN NONUNION OF LOWER LIMB**

M. Muratore 1, O.E. Casilli 2, V. Russi 3, P. Piccinni 2, L. Meccarriello 2, L. Quarta 1, E. Quarta 1, G. Rolo 2, M. Filipponi 2, 1U.O. Reumatologia- P.O. “V. Fazzi” Lecce, LECCe, Italy

**Background:** The use of teriparadise in fracture management by high-energy trauma with loss of bone substance and muscle and skin with possible nerve/vascular lesions is poorly documented. The aim of our study is to evaluate how the intermittent administration of teriparadise may affect the bone consolidation newly generated and compression in patients with bone loss and my-skin during treatment reconstruction with the technique of resection Ilizarov-lengthening.

**Objectives:** In large or in the outcomes of these, in which there is loss of bone substance and muscle and skin the technique of reconstruction of Ilizarov (1 mm/day) is used; the main problem is the long time required to reach complete healing with optimal bone consolidation newly generated and the compression of the fixator to ensure the mechanical strength necessary to be able to remove the external fixator (1). The rationale of this study, therefore, was to evaluate the influence of treatment with teriparadise, administered subcutaneously 1 dose 1 day/time/day from a pre-filled syringe of 20mcg and for a period of three months, the evolution radiographic, on the healing time and the external fixator removal and on the functional recovery quality in multiple trauma patient.

**Methods:** In our prospective study, we evaluated two groups of patients: Group 1: 9 patients treated with PTH during bone transport; Control Group 2: 10 patients treated with bone transport.

**Results:** The group compared to the 2 (control group) showed a bone radiographic progression slower newly-generated in the first month of administration of teriparadise; subsequently it was observed an acceleration of bone maturation but not uniform; after about 3 months, the bone maturation accelerates further also at the level of the compression outbreak if already in compression, allowing the removal of the fixator about 1.5 months earlier than the estimated time. This is due to the reduction of the time allowed for “elongation stage” bone that physiologically is around 1mm/day, thus ensuring an optimal functional recovery.

**Conclusions:** The action of teriparadise (2) on bone healing is derived from increased differentiation of cells responsible for bone callus formation, chondrocytes and osteoblasts, mediated in part by increased activation of genes that produce the Wnt, Osterix and Runx2, all fundamental elements in the osteoblastogenesis. Although the sample examined is small for the specificity of the described treatment, the data reported showed that the intermittent administration of teriparadise is able to accelerate the timing for the “elongation stage” bone and therefore the bone healing and reconstructive treatment times in serious loss of substance.

128 PATIENTS WITH SUBACUTE SYMPTOMATIC FRAGILITY VERTEBRAL COMPRESSION FRACTURES: HIGH INCIDENCE OF MORTALITY, FALLING, MONOCONAL GAMMAPATHY OF UNCERTAIN SIGNIFICANCE AND MYELOMA, PERNICTIONS ANEMIA AND VITAMIN B-12 DEFICIENCY: IS THIS A PROFILE OF AN OSTEOPOOROTIC OR AN AGED POPULATION?

M. Dey 1, N. Ben-Shlomo 2, J. Udoff 3, Desert Oasis Healthcare, Palm Springs, California, United States; 2Ben-Gurion Medical School, Beer Sheva, Israel; 3University of California, San Diego Medical School, San Diego, California, United States

Background: Epidemiological studies have identified risk factors for falling and fractures. However there is a paucity of observational studies of patients with symptomatic fragility vertebral compression fractures (VCF). These studies were not done in community based populations and did not evaluate the contribution of factors.

Objectives: To study factors contributing to both osteoporosis and falling in a cohort of community based patients with symptomatic subacute fragility VCF.

Methods: We saw 128 patients with symptomatic subacute fragility VCF in our community based outpatient fracture clinic over a two year period. We performed a complete history and physical, review of past medical records and radiographs, complete blood count, sedimentation rate, chemistry profile, TSH, urinalysis, vitamin B-12, PTH, 25-OH vitamin D, and serum protein electrophoresis (SPE). We performed testosterone level, methylnolonic acid, antiplatelet cell antibody and parathyroid hormone in select cases. We recorded diseases including diabetes, COPD, cardiac, neurological for each patient.

Results: There were 92 females aged 45–98 years (mean 77.7), 36 males aged 39–94 years (mean 77.6). Factors contributing to falling included peripheral neuropathy-61, use of sedatives-43, blindness-12, foot drop-6, dementia-5, Parkinson’s-3, hyponatraemia-2. VCF were precipitated by falls in 94 patients, of which 87 occurred at home. VCF occurred with falling in 8 patients, bending in 3, and were spontaneous in 23. Use of steroids was reported in 18 patients and associated with multiple (-3) fractures (p < 0.0008). Blindness (p = 0.022) and multiple multiple fractures (p = 0.008) were found to be significantly more likely to have peripheral neuropathy (p = 0.056) and 3 or more medical conditions (p = 0.008), Age correlated with the number of diseases (p = 0.0001). Diagnosis based on laboratory studies included vitamin D insufficiency-29, vitamin D deficiency-12, pernicious anaemia-6, vitamin B-12 deficiency-3, monoclonal gammapathy of uncertain significance (MGUS)-10, myeloma-2, hypogonadism-2, and iatrogenic hyperthyroidism-2. Ankylosing spondylitis and lymphoma were diagnosed in one patient each. The average age of those that died was 83.9 years compared to 76.8 of the remaining group (p = 0.0033).

Conclusions: Conditions that increase with age and are associated with an increased risk of falling and fracture include neurological diseases, visual loss, use of steroids and sedatives, MGUS, myeloma, pernicious anaemia and vitamin B-12 and vitamin D deficiencies. These were all in common with our cohort with subacute symptomatic fragility VCF. Accordingly we recommend vitamin B-12 levels and SPE in the evaluation of all patients with VCF. These findings support the emphasis on interventions to reduce the risk of falling in the elderly and to recognize and treat these age-related conditions in an attempt to mitigate the risk of VCF.

FR01565 FRAGILITY FRACTURES IN PATIENTS ON DEPO-PROVERA ARE ASSOCIATED WITH USUAL RISK FACTORS FOR FRACTURE

M. Dey, M. Bukhari. University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom

Background: Depo-Provera is one of the most widely-used contraceptives. The side-effects includes loss in bone mineral density (BMD), increased fracture risk (1.2), It is not known if conventional fracture risk factors impact fracture risk in these patients.

Objectives: We set out to determine if the usual risk factors for fracture are associated with increased risk of fragility fractures in patients exposed to Depo-Provera.

Methods: Patients referred for bone densitometry at a scanner in North West of England were analysed. Femoral and vertebral BMD, height, weight and body mass index (BMI) were recorded, in addition to age, diagnosis of rheumatoid arthritis, smoking status, alcohol consumption, family history of fractures, history of secondary osteoporosis, corticosteroid use, total average proportion fat, average tissue thickness, fat mass, and lean mass. Patients with exposure to Depo-Provera were selected for analysis. Initially patients with and without a fracture were compared using Chi-squared test and T-Test. Logistic models were fitted univariately and adjusted for age to analyse association between traditional risk factors and fracture.

Results: 304 females (103 currently and 201 previously on Depo-Provera) were included. 62 (20.4%) had sustained at least one fragility fracture. There was no significant difference in fracture risk between those currently and previously on Depo-Provera (p = 0.176 95% CI). Decreased left femoral BMD significantly impacted fracture risk (p = 0.035 95% CI). All other factors investigated did not significantly increase fracture risk in this cohort (see table below).

FR01665 TERIPARADIP AND ALENDRONATE IMPROVED BONE LOSS AND HYPERALGESIA IN A MOUSE MODEL OF OSTEOPOOROSIS

N. Nagao, H. Wakabayashi, S. Kato, G. Miyamura, Y. Naito, A. Sudo. Department of Orthopaedic Surgery, Mie University Graduate School of Medicine, Mie, Japan, Tsu, Japan

Background: Osteoporosis may cause not only fractures but also chronic back pain in elderly women. Teriparatide (TPTD) and alendronate (ALN) are widely used in clinical for treatment of osteoporosis. Several studies have demonstrated that TPTD and ALN treatments improved skeletal pain in osteoporosis patients.

Objectives: We investigated the effect of TPTD and ALN on pain-related behavior in ovariectomized (OVX) mice. We investigated expression of inflammatory cytokines treated OVX mice.

Methods: 8-week-old female ddY mice were OVX and assigned to 4 groups; SHAM-operated mice treated with vehicle (SHAM), OVX mice treated with vehicle (OVX), OVX mice treated with TPTD (TPTD) and OVX mice treated with ALN (ALN). Mice were started treatment immediately after surgery. For 4 weeks, mice were injected subcutaneously with vehicle or 40 μg/kg ALN twice a week or 40 μg/kg TPTD 5 times a week.

The spinal cord was harvested after 4week, the bilateral distal intercostal metaphys were analyzed three-dimensionally by μCT 4 weeks after surgery (each group; n=8).

Mice mechanical sensitivity was tested using von Frey filaments 4 weeks after surgery. To evaluate the 50% withdrawal threshold, seven von Frey filaments with forces of 0.07, 0.4, 0.6, 1.0, 1.4 and 2.0 g were arranged on the middle of the plantar surface. Data was collected using the up-down method.

To evaluate expression of interleukin-1β (IL-1β), IL-6 and tumor necrosis factor-α (TNF-α), mice were anesthetized and the bilateral hindlimb bone excised. We performed quantitative polymerase chain reaction (q-PCR) from hindlimb bone.

Results: μCT analysis of the distal femur metaphysis showed that bone volume/tissue volume (BV/TV) and trabecular number (Tb.N) were significantly less in the OVX group than in the SHAM group, whereas trabecular separation (Tb.Sp) was significantly greater in the OVX group than in the SHAM group. In the TPTD and ALN group, BV/TV and Tb.N were significantly greater than the OVX group, whereas Tb.Sp was significantly less than in the OVX group. In the ALN group, BV/TV and Tb.N were significantly greater than in the TPTD group, but Tb.Sp was no significance.

The 50% withdrawal threshold was significantly lower in the OVX group than in the SHAM group, and it was significantly higher in the TPTD and ALN group than in the OVX group. And the 50% withdrawal threshold was no significance between the TPTD and ALN group.

The expression levels of TNF-α was increased in the OVX group compared with those in the SHAM group. Other cytokines were not increased significantly in the
Differences in Adherence to Osteoporosis Medications in Patients with Rheumatic Diseases: A 3-Year Retrospective Cohort Study

O. Nikitskaya, N. Toroptsova. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Patients with rheumatic diseases (RD) have an increased risk of fracture compared with the general population. To maintain bone health, anti-osteoporotic medications are usually prescribed, but patient adherence to these is often low, leading to limited beneficial effects. The study aims to evaluate adherence to anti-osteoporotic medications in a cohort of patients with RD, and to determine the reasons for non-adherence.

Methods: We conducted a retrospective study of 204 patients (82% women, mean age 54±11 years) with RD (93% = rheumatoid arthritis, 48%= systemic sclerosis, 39%= systemic lupus erythematosus and 24%= ankylosing spondylitis), who were prescribed at least one anti-osteoporotic medication. Patients were followed for 3 years. Visits to rheumatologist and BMD measurements increased subject’s contact for patient’s self-reporting.

Results: 196 (96%) patients started the OP treatment. Among them 26%= alendronate, 24%= received alfacalcidol or supplements of calcium and vitamin D, 16%= strontium ranelate, 12%= ibandronate, 9%= zoledronic acid, 8%= risedronate, 24% received alfacalcidol or supplements of calcium and vitamin D only, 16%= strontium ranelate, 12%= ibandronate, 9%= zoledronic acid, 8%= alendronate, 24% received alfacalcidol or supplements of calcium and vitamin D only, 16%= strontium ranelate, 12%= ibandronate, 9%= zoledronic acid, 8%= alendronate. 105 patients received only the AIs treatment (Group A), whereas the remaining 49 patients (Group B) received also an additional Denosumab treatment, in order to contrast the BMD reduction induced by AIs administration. Follow-up measurements were conducted at two different time points: 12 (T1) and 18 (T2) months from AIs treatment starting. At time T1, patients underwent both DXA and EchoSound scans, while at time T2 only the echographic scans were performed, since DXA cannot be used for short-term follow-ups.

Results: At time T1, the following results were obtained on lumbar spine: Group A showed a BMD decrement, which was equal to -2.07±1.66% (p<0.01) according to DXA and to -2.22±0.89% (p<0.01) according to EchoSound; Group B showed a BMD increase of 4.06%±1.49% (p<0.01) and 4.31±0.62% (p<0.01) as measured by DXA and EchoSound scans, respectively. At time T2, Group A showed a further BMD decrement, resulting in a total decrease of -3.56%±1.07% (p<0.01) according to EchoSound. In the TPTD treatment, a total decrease of 4.88%±0.65% (p<0.01) was observed. Similar results were obtained for femoral neck BMD: a total BMD decrease of -2.37±0.97% (p<0.01) during the whole treatment period was observed in Group A, whereas a total BMD increment of 3.53±0.43% (p<0.01) was measured in the same period in Group B.

Conclusions: By using the EchoSound technology the short-term follow-up of the positive Denosumab effects on BMD reduction in patients treated with adjuvant AIs was feasible and accurate. This approach can be also useful to monitor the therapy effectiveness in patients undergoing specific anti-osteoporotic treatments.

Evaluation of Bone Microarchitecture in Systemic Sclerosis Patients: Relationships between Trabecular Bone Score (TBS) and Disease Severity

S. Paolino 1, E. Goteili 1, A. Sulli 1, B. Ruaro 1, M. Ghiò 1, C. Pizzorni 1, E. Alessandri 1, V. Tomatis 1, G. Seriolo 2, L. Molletta 2, M. Cutolo 1, A. Casabella 1, M. Di Paola 1, E. Casciaro 1, M. Di Paola 1, E. Franchini 2, R. Tarparelli 2, S. Casciaro 1, 1National Research Council, Institute of Clinical Physiology, 2OLO of Rheumatology Galliera Hospital, San Cesario di Lecce, ASLE; 3OLO of Oncology Vito Fazzi Hospital, ASLE; 4Echolight Spa, LECCE, Italy

Background: Systemic sclerosis (SSc) is a rare connective tissue disorder characterized by an increased synthesis and deposition of extracellular matrix in the skin and internal organs (1). Several studies described SSc as potential risk factor for osteoporosis, however, to date the bone quality in SSc is unclear (2). Trabecular bone score (TBS) has been recently proposed as an indirect measure of bone microarchitecture (3).

Objectives: The aim of this study was to assess bone microarchitecture in SSc patients and possible association with disease severity and microangiopathy.

Methods: Twenty-three female SSc patients (mean age 63±12.8 SD years, mean disease duration 92±66 SD months, mean Raynaud’s Phenomenon duration 15±15 SD months) were enrolled after written informed consent. The assessment of disease severity was performed using the Medsger’s severity scale (4). Bone Mineral Density (BMD) measurements at L1-L4, femoral neck and total hip, were performed using DXA Prodigy Densitometer (GE Lunar). TBS was derived for each spine DXA examination using the TBS index (TBS iNsight Medimaps). Nailfold videocapillaroscopy (NVC) was used to assess the microangiopathy based on nailfold video capillaroscopic pattern (NVC) analysis and the microangiopathy evolution score (MES) (5-6). Using the FRAX (Fracture Risk Assessment Tool) we also evaluate the 10-year risk of hip and major joints fractures.

Results: A positive correlation was observed between TBS and Medsger’s general organ score (r=0.5; p=0.01); no other correlations were found between TBS and Medsger’s score. Interestingly, TBS was positively and significantly correlated with modified Rodnan skin score (mRSS) (r=0.01). When the patients were divided in two groups according to presence of linear joint involvement by mRSS, TBS was found significantly higher in the group with mRSS >15 compared to the group with mRSS <15 (1.25±0.08 vs 1.16±0.03; p<0.01) No correlations were found between NVC patterns/MES and bone quality assessment (TBS) or bone density assessment (BMD), only a significant correlation, as expected, was observed...
between MES and skin involvement (mRSS) (p=0.05). On the other hands, FRAX, the major osteoporotic fracture risk, positively correlates with Medsger's kidney disease severity (p=0.04) and Medsger’s lung disease severity (p=0.04); in addition, FRAX, for hip fracture risk, seems to correlate significantly with Medsger's lung involvement severity (p<0.04).

Conclusions: This study demonstrates in SSC patients a relationship between clinical disease severity (organ fibrosis/failure) and altered bone microarchitecture (TBS). In addition, skin involvement was found significantly correlated with altered quality of the trabecular bone architecture (TBS) and a significant increase of osteoporotic fracture risk (FRAX) was found correlated with kidney and lung involvement.

OSTEOCYTES ARE INVOLVED IN THE PATHOGENESIS OF OSTEOPOROSIS IN CHRONIC CHELOSTASIS. EFFECTS OF BILIRUBIN AND BILE ACIDS ON OSTEOCYTIC CELL LINES

Liver and Metabolic Bone Diseases Units, CIBERReh-Hospital Clinic, University of Barcelona, Barcelona, Spain

Background: Mechanisms underlying osteoporosis in chronic cholestasis are complex and not well understood. In this study, we evaluated the effects of unconjugated bilirubin and lithocholic acid on osteocytes, to elucidate the role played by the liver in bone loss.

Objectives: The aim of this study was to analyze the direct effects of increased molecules of cholestasis, such as bilirubin (Bil) and lithocholic acid (LCA), and the potential protective effect of ursodeoxycholic acid (UDCA) on the osteocytes.

Methods: MLO-Y4 in SFM and MLO-A5 osteocyte cell lines were exposed to different times and concentrations with Bil, LCA and UDCA were used to determine: 1) Viability: WST-1 colorimetric method; 2) Differentiation: quantification of alkaline phosphatase (AP) activity; 3) Mineralization: Alizarin red staining quantification; and 4) Apoptosis: quantification of DNA fragmentation and caspase-3 activity.

Results: For LCA (100 μM) and Bil (50 μM) significantly decreased viability in MLO-Y4 from 72 hours (10%) and 48 hours (11%), respectively (p<0.01), and Bil decreased viability (49%) in MLO-A5 from 96 hours (p<0.01). Bil decreased AP activity by 47% after 96 hours, under conditions of differentiation in MLO-Y4 (p<0.01). There were no effects on AP activity in MLO-A5. After 14 days, Bil was associated with a significant mineralization decrease, as high as 87%, in MLO-A5 (p<0.02). Moreover, Bil and LCA increased apoptosis in MLO-Y4, determined by DNA fragmentation (242% and 119%, respectively) and caspase-3 activity (190% and 251%, respectively) after 24 hours. In contrast, UDCA (100 μM) increased viability after 72 hours (11%) and decreased the deleterious effects of LCA or Bil (p<0.02). UDCA increased AP activity in MLO-Y4 after 72 hours under growth conditions (p=0.018), and after 24 hours under differentiation conditions (p<0.01).

Conclusions: Bilirubin and lithocholic acid have damaging effects on osteocyte cells, decreasing viability, differentiation and mineralization, and increasing apoptosis, effects that are neutralized by the UDCA. These results indicate that substances retained in cholestasis impair osteocytic functions, and therefore may be involved in the pathogenesis of osteoporosis in cholestatic diseases.

SAFETY OF DENOSUMAB IN A MONOCENTRIC COHORT OF KIDNEY TRANSPLANT RECIPIENTS

S. Doddiol, P. Lafargue, T. Pham. Bouches Du Rhones, Aix Marseille University, APHM, Marseille, Marseille, France

Background: The safety of Denosumab, a fully human monoclonal antibody against RANKL, which was developed for treatment of osteoporosis and prevention of fractures, remains unclear in kidney transplant recipients.

Objectives: Our aim was to assess its clinical and biological tolerance in this specific population.

Methods: Design: Prospective observational monocentric cohort. Inclusion criteria: kidney transplant recipient who received at least one subcutaneous injection of denosumab in his medical history. Analysis: Denosumab was given at a dose of 60 mg every 6 months.

Results: Safety assessment: the following variables were collected every 6 months: infection, reaction at the injection site, plasmatic parameters of renal function and mineral metabolism (estimated glomerular filtration rate, serum creatinine, calcium, 1–25 [OH] vitamin D, PTH).

Patients: Results: Patients were recruited from April 2014 to September 2015. All patients received immunosuppression therapy including prednisolone ≥ 5 mg/d. The main baseline characteristics of the 37 kidney transplant recipients were the following [mean]: male: 41%, age: 60.5 years, BMI: 24.1, transplantation duration: 7.1 years, osteoporotic patients: 36%, osteoporotic patients: 64%, total lumbar spine T-score: -2.04 SD, total hip T-score: -4.22 SD, femoral neck T-score: -2.7 SD, T-score femoral neck: 0.67 g/cm², serum creatinine: 132.8 mmol/L, calcium: 2.33 mmol/L, 1–25 [OH] vitamin D: 93.5 mmol/L, PTH 95: ng/l. All patients were prescribed vitamin D and calcium supplementation.

Conclusions: Bilirubin and lithocholic acid have damaging effects on osteocyte cells, decreasing viability, differentiation and mineralization, and increasing apoptosis, effects that are neutralized by the UDCA. These results indicate that substances retained in cholestasis impair osteocytic functions, and therefore may be involved in the pathogenesis of osteoporosis in cholestatic diseases.

QUALITY OF LIFE ASSESSMENT IN POSTMENOPAUSAL OSTEOPOROSIS

S. Novokovic 1, G. Stanoevic 2. 1Institute of rheumatology; 2Health Center "Zvezdara", Belgrade, Serbia

Objectives: To compare two questionnaires a specific one-Osteoporosis Quality of Life Questionnaire (OQLQ) and a general one-Short Form-36 (SF-36), in women with decreased mineral bone density (BMD) and vertebral fractures, and to estimate which one is more useful for everyday work.

Methods: Cross-section study included 50 postmenopausal women with osteoporosis (OP), who were divided in the general questionnaire, and all known risk factors for osteoporosis were confirmed. Osteodensitometry scan (DXA) was performed on lumbar spine, and based on T index value and BMD the subjects were divided in two groups: first group (women with OP), n=25; second group (women with fractures due to OP regardless of BMD), n=25, and with at least 4 months since the last fracture. The quality of life was assessed by two questionnaires: a specific one OQLQ consists of 30 questions divided into 5 areas, which are evaluated from 1 to 7 (the lower the score the more severe function damage and worse quality of life) and the general questionnaire SF-36 containing 36 questions divided into 8 areas (scores from 0 to 100, where the lower value is also a poorer quality of life). Questionnaires were converted into two summarized scales, so as to obtain the total score for: physical (PCS) and mental functions (MCS). The two questionnaires were compared using appropriate statistical methods in SPSS.

Results: There was no significant difference between groups regarding: mean age: first=63.3±6.0, second=64.9±7.8, mean age at the start of the menopause (first=46.8±5.3, second=48.2±4.2 years), mean duration of menopause (first=16.4±6.9, second=17.1±5.9 year), but there was statistically significant difference in the number of risk factors for OP (first=1.81±1.2, second=2.8±0.9, p<0.01). Statistically significant difference between group population (p<0.01) in mean BMD and T score (first-BMD 0.807±0.057 g/cm², T score -3.1±0.249SD, second- BMD 0.931±0.172 g/cm², T score -2.09±1.45SD). The following DXA values were measured in the second group:8 patients normal,6 osteopenia,11-
Objectives: To compare the ability of FRAX and BMD alone in discriminating patients with and without fracture, and their effectiveness in identifying anti-osteoporotic treatment needs

Methods: 1300 rheumatic disease patients on long-term glucocorticoid were screened for vertebral fracture by radiograph from 7 rheumatology clinics. 220 osteoporotic treatment needs were screened for vertebral fracture by radiograph from 7 rheumatology clinics. 220 osteoporotic treatment needs were screened for vertebral fracture by radiograph from 7 rheumatology clinics. 220 osteoporotic treatment needs were screened for vertebral fracture by radiograph from 7 rheumatology clinics.

Results: Both groups of patients were matched in gender, disease type and cumulative glucocorticoid dose (p < 0.1). Patients in the fracture group were older (63±14 vs 59±12 years, p < 0.01), of lower body mass index (22.7±3.5 vs 24.3±7.3kg/m², p < 0.05), with a higher prevalence of previous fracture [38 (34.5%) vs 10 (9.0%), p < 0.01]. Daily intake of vitamin D [77 (70%) vs 54 (49.1%), p < 0.01], and bisphosphonates [23 (20.9%) vs 7 (6.4%), p < 0.01]. A receiver operating characteristic (ROC) curve analysis was performed to determine the ability of FRAX score with or without BMD and MOF alone to discriminate fracture status (Table 1). FRAX at the femoral neck and FRAX score with BMD were able to provide adequate discrimination with their area under curve (AUC) = 0.70. With regards to treatment indication, only 53/110 (48.2%) of the patients with vertebral fracture were identified as having osteoporosis (T-score < -2.5 at hip/spine) by DXA. In contrast, FRAX with BMD were able to identify 71/110 (64.5%) of the fracture patients whom treatment criteria were met, with a power of 0.97 and effect size of 0.38 (a medium effect) at the 0.05 level.

Conclusions: In rheumatic patients on long-term glucocorticoid, FRAX score was more effective in identifying patients with intervention needs than BMD alone. It is suggested that FRAX should be used as a routine assessment to identify patients, even asymptomatic, for anti-osteoporotic treatment.

FR10578 ODONTOID FRACURES IN THE ELDERLY: AN UNKNOWN OSTEoporotic FRACtURE?

Laura Natella1, N. Bronsard2, J. Aliha3, L. Hekayam4, L. Euler-Ziegler5, F. De Perets6, V. Brelou3, 1Rheumatology/University of Nice, Rheumatology/ University of Nice; 2Department of Orthopedic Surgery; 3Emergency Room Department, University of Nice, Nice, France

Background: Current WHO definition of osteoporosis excludes cervical fractures. However, in atrumatic odontoid fractures, mainly reported by orthopedic surgeons, bone status has not been described yet [1].

Objectives: To investigate bone status in elderly patients suffering a low energy odontoid fracture.

Methods: We conducted a prospective study from January 2016 to January 2017 in patients ≥65 years old, hospitalized in Nice University hospital for low energy odontoid fracture. An evaluation of bone status was proposed within 3 months after fracture event. Evaluation included demographic data, clinical risk factors of osteoporosis, bone mineral density (BMD) at spine and hip and vertebral fracture assessment (VFA) by dual x-Ray absorptiometry and serum and urine analysis to detect secondary osteoporosis.

Results: 38 patients were hospitalized for odontoid fracture: 8 patients <65 years always after a major trauma (mean age 37±14.5 y) and 30 patients ≥65 years including 3 after a high energy impact. 27 odontoid fractures followed a low energy impact: 18 women and 9 men, mean age 83.8 y. (±10.7). 8 patients died before bone status assessment (5 men and 3 women), 6 died during hospitalization with a mean delay of 3.5 days (±1.87) and 2 after discharge (1 month and 5 month). 3 patients refused bone status evaluation, 5 were lost to follow-up and 1 is awaiting evaluation. Finally 10 patients had bone status evaluation, all women, mean age 84.2 y. (±8.9). None had parental history of hip fracture, 1 had an early menopause, 1 received aromatase inhibitors for breast cancer and 2 had a history of steroid therapy (≥3 months). 3 patients had previously received hormone replacement therapy, 1 received bisphosphonate for 5 years and 4 had calcium + vitamin D supplements. Lumbar spine mean T-score was -1.45 (±1.08), femoral neck mean T-score was -0.99 (±1.6). VFA analysis revealed 4 unknown vertebral fractures. The table summarizes population bone status: 8 patients out of 10 fulfilled diagnostic criteria of osteoporosis, including 6 with previous fractures. 2 patients with T-score > -1 DS didn’t have bMD assessment because of bilateral hip replacement but had previous major osteoporotic fractures.
secondary osteoporosis was detected. Serum vitamin D concentration was \(<30\) ng/mL in 5 patients, including 2 with concentration \(<10\) ng/mL.

**Conclusions:** Our study reveals that odontoid fractures mainly occur in elderly osteoporotic patients after a low energy impact. Although WHO osteoporosis definition excludes cervical fractures, odontoid fracture may be considered as an osteoporotic fracture. Further studies are required to confirm these results.

**FR0579** **INFLUENCE OF ORAL PREDNISOLONE ON EFFECT OF DENOSUMAB ON OSTEOPOROSIS IN PATIENTS WITH JAPANESE NEUMATOID ARTHRITIS; 24 MONTHS OF FOLLOW-UP - A MULTICENTER REGISTRY STUDY-**

Y. Kanayama, Y. Hirano, N. Takahashi, S. Asai, N. Ishiguro, T. Kojima on behalf of TBCR-BONE study group. 1Orthopedic Surgery and Rheumatology, Toyota Kosai Hospital; 2Rheumatology, Toyohashi Municipal Hospital; 3Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan

**Background:** Denosumab (DMB) is a fully human monoclonal antibody to the RANKL that blocks its binding RANK, inhibiting the development and activity of osteoclasts, decreasing bone resorption, increasing bone density and reducing fracture risk. Osteoporosis (OP) is more frequent in patients with rheumatoid arthritis (RA) than in the general population due to active systemic inflammation as well as the use of glucocorticoid and immobility. However efficacy of DMB is not clear in patients with glucocorticoid-induced OP in RA. Therefore we investigated the influence of oral prednisolone on effect of DMB in patients with Japanese RA from initiation to 24 months at this time.

**Objectives:** This prospective study investigated the efficacy of DMB for 24 months on glucocorticoid-induced OP in RA patients.

**Methods:** Patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria who had been prescribed DMB from Tsumari Biosciences Communication Registry (TBCR)-BONE between October 2013 and October 2015 were enrolled. The final study cohort of 63 patients received continuous DMB therapy more than 24 months. The DMB dose was 60 mg at once every 6 months. In all cases native or activated vitamin D has been used. We reviewed the results for 24 months about the increase and decrease of bone mineral density (BMD) of lumbar spine (LS) and total hip (TH) by DXA and bone turnover markers, intact n-terminal propeptide type I procollagen (PINP) and tartrate-resistant acid phosphatase 5b (TRACP-5b).

**Results:** In the patients receiving oral prednisolone group (n=23, GC+) and not receiving group (n=40, GC-) the number of female was each 21 (91%) and 39 (98%) cases (p=0.548). The mean age was 69.8±7.0 and 71.0±7.3 years old (p=0.622); disease duration was 16.0±8.9 and 15.7±12.6 years (p=0.592); the body mass index was 20.7±3.5 and 19.7±3.0 (p=0.335) and the FRAX was 34.2±19.1 and 24.6±13.9 (p=0.040). Clinical findings related to RA and OP at baseline were as follows: CRP 1.2±1.4 and 0.5±1.0 mg/dl (p=0.030); DAS-CRP 3.16±1.7 and 2.50±1.27 (p=0.025); m-HAQ 1.24±0.90 and 0.82±0.82 (p=0.065); P1NP 60.1±38.6 and 56.9±33.5 μg/l (p=0.711); TRACP-5b 513±257 and 505±220 μg/dl (p=0.689); LS-BMD 0.87±0.18 and 0.80±0.14 g/cm² (p=0.074) and TH-BMD 0.60±0.11 and 0.59±0.08 g/cm² (p=0.457). The rate of decreased P1NP from baseline to 6, 12, 18 and 24 months were each -25.6% vs -41.6% (p=0.129) at 6 month, -8.0% vs -42.6% (p=0.031) at 12 month, -19.5% vs -27.5% (p=0.235) at 18 month and -13.8% vs -33.8% (p=0.134) at 24 month and TRACP-5b were each -26.5% vs -38.7% (p=0.710) at 6 month, -22.0% vs -35.1% (p=0.229) at 12 month, -25.2% vs -38.1% (p=0.792) at 18 month and -20.6% vs -27.3% (p=0.063) at 24 month in the GS+ vs GS- group. The rate of increased LS-BMD from baseline to 6, 12, 18 and 24 months were each 4.1% vs 4.6% (p=0.671) at 6 month, 5.3% vs 7.0% (p=0.361) at 12 month, 8.1% vs 8.1% (p=0.438) at 18 month and 10.0% vs 7.7% (p=0.104) at 24 month and TH-BMD were each 3.3% vs 2.7% (p=0.690) at 6 month, 6.4% vs 4.3% (p=0.269) at 18 month and 5.7% vs 4.3% (p=0.945) at 24 month in the GS+ vs GS- group (Fig.1,2).

**Conclusions:** DMB was effective in OP of RA patients. Oral prednisolone use did not influence the efficacy of DMB for 24 months.

**FR0580** **PREDICT SARCOPENIA BY SONOELASTOGRAPHY OF QUADRICEPS MUSCLE IN OSTEOPOROTIC PATIENTS**

Y.-C. Chen, C.-H. Ko. Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China

**Background:** Reduced muscle mass had associated with high mortality. So it is urgent for simple techniques to early detection sarcopenia. Our objective was to examine the validity of sonoelastography to predict sarcopenia in osteoporotic patients.

**Objectives:** To evaluate the association of sonoelastography and dual-energy X-ray absorptiometry in patients with sarcopenia and osteoporosis.

**Methods:** We conducted an observational study in Kaohsiung Chang Gang Memorial Hospital. Sarcopenia was determined using a dual-energy X-ray absorptiometry. Osteoporosis was defined through estimated bone mass (BM). Sonoelastography was performed over mid thigh over quadriceps muscle. We measure hardness and elastography ratio of quadriceps over subcutaneous fat tissue. ROC analysis was used to find best cut-off point.

**Results:** A total 47 (23 sarcopenia, 24 non-sarcopenia) osteoporotic patients were enrolled. The mean age was 71.04±9.64 years, and most patients (88.9%) were women. Sonoelastography showed sarcopenia patients had more soft than non-sarcopenia patients, furthermore the elastography ratio of quadriceps over subcutaneous tissue was lower than non-sarcopenia patients. When the cut points determined by receiver operating characteristic (ROC) curve analysis were applied, The best cut-point of hardness was 42.5 (sensitivity, 0.969; specificity, 0.066), while the best cut-point of quadriceps over subcutaneous tissue was 70.5% (sensitivity, 1.000; specificity, 0.079).

**Conclusions:** Sonoelastography was easily applicable in patients with sarcopenia and osteoporosis. Using hardness content and elastography ratio of quadriceps over subcutaneous ratio render more information of muscle character. Early detection of sarcopenia with sonoelastography in patients with osteoporosis afford future trend of preventive medicine in geriatric patients.

HEPATITIS B INCREASE MORTALITY IN PATIENTS WITH OSTEOPOROTIC VERTEBRAL FRACTURES

Y.-C. Chen, C.-H. Ko. Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China

Background: Hepatitis B virus (HBV) is a major cause of chronic liver diseases worldwide, particularly cirrhosis and hepatocellular carcinoma, and the most important liver disease in Taiwan. However, little is known the impact of hepatitis B on osteoporotic patients.

Objectives: This study aimed to determine if hepatitis B can increase the risk of mortality in patients with osteoporotic vertebral fracture.

Methods: This retrospective study reviewed of cases of osteoporosis patients with acute vertebral fractures between 2001 and 2008. All associated co-morbidities were recorded. Kaplan-Meier and cox regression analysis were performed.

Results: There were 432 patients with acute vertebral fractures. The mean age of 72.85±9.28. 31 (7.2%) patients had chronic hepatitis B. Using the Kaplan-Meier curve, hepatitis B had a significant effect on mortality (p<0.001, by log rank test). After adjusting for potential confounders, patients with hepatitis B still had a high mortality rate (p=0.019; HR: 2.436–5.136) 2.137, 95% CI: 1.156–5.136. The mortality rate also increased among smokers (p=0.026; HR: 3.6043.891; 95% CI: 1.056–12.301).

FR010583 | IGG4-RELATED DISEASE AMONG PATIENTS PREVIOUSLY DIAGNOSED WITH IDIOPATHIC RETROPERITONEAL FIBROSIS. A NATIONWIDE DANISH STUDY

N. Lomborg1, M. Jakobsen2, C.S. Bode3, P. Junker4, 1Department of Rheumatology; 2Department of Pathology, Vejle Hospital, Vejle; 3Department of Pathology; 4Department of Rheumatology, Odense University Hospital, Odense, Denmark

Background: IgG4-related disease (IgG4-RD) is a recently recognized systemic disease of unknown etiology and prevalence [1]. Retrospective single center series have provided evidence that 13–63% of patients with idiopathic retroperitoneal fibrosis (IRPF) could be reclassified as IgG4-RD. Since immunosuppressants or B-cell targeted therapies may halt or reverse progression, early diagnosis and treatment is important to prevent terminal fibrosis.

Objectives: To confirm the occurrence of IgG4 related retroperitoneal fibrosis (RPF) in Danish patients diagnosed with IRPF.

Methods: The National Danish Pathology Register was searched for biopsy codes relating to retroperitoneal tissue and inflammation from 01.01.2004 through 31.12.2013. Patients below 18 years of age, secondary causes, malignancies, infections, and specimens with multinucleated giant cells or granulomas were excluded. Among 724 candidate cases 68 were identified with IRPF. Among these 25 were left out due to small tissue samples, unavailable patient files or lack of consent. Clinical, laboratory data and imaging were reviewed. Paraffin-embedded tissue blocks were retrieved from 18 pathology departments. Four sections were processed and stained with hematoxylin-eosin, Weigerts elastin and IgG4 immunostaining. Histopathologic features suggesting an IgG4-RD background were recorded (table). Cut-off levels for IgG4 positive cells at ≥ 10 HPF and IgG4: total IgG ratio > 40% were applied. Patients were categorized as definite, possible, or non-inflammatory IRPF according to international consensus [2].

Results: Forty three patients (29 males), median age 56 years were included among which 19(44%) met the criteria for IRPF-RD comprising 7 with definite, 12 with possible IRPF-RD and 24 with 40% or greater IgG4+ cell counts. Twenty-three patients (53%) had ≥ 10 HPF and 4 patients ≥ 10% of IgG4+ cells or IgG4 in IgG4 RPF.

Objectives: To confirm the occurrence of IgG4 related retroperitoneal fibrosis (RPF) in Danish patients diagnosed with IRPF.

Twenty-three patients (53%) had ≥ 10 HPF and 4 patients ≥ 10% of IgG4+ cells or IgG4 in IgG4 RPF.
Methods: We retrospectively investigated factors related to REOI and NDOI in 86 IgG4-RD patients whose follow-up period was more than 12 months. For assessment of factors related to REOI and NDOI, we performed uni- and multivariate Cox regression analysis. On stepwise multivariate analysis, we applied the variables with $P<0.1$ in univariate analysis and the predictors of relapse defined in previous literature, i.e., sex, serum IgG4, IgG, and Ig levels, eosinophil counts, and RF positivity [2, 3], and used the forward selection method (including factors presenting with $P<0.05$).

Results: The patients comprised 57 men and 29 women (mean age 65.9 years). Mean follow-up period was 63.1 months (range 14–150). At diagnosis, their mean serum IgG4 level was 718 mg/dL (range 10.7–5,150). Seventy-one patients were treated with glucocorticoid (GC). REOI was detected at 52.3 months (range 1.0–120) after the diagnosis in 20 patients, including 4 not receiving GC at that time. On the other hand, NDOI was detected at 37.6 months (range 5.0–120) after their diagnosis in 15 patients, including 11 not receiving GC. In univariate Cox regression analysis, blood eosinophil counts [per 100×/L], hazard ratio (HR) 1.072, 95% confidence interval (CI) 1.018–1.129, $P=0.008$ and continuation of GC (vs discontinuation or observation without GC, HR 0.245, 95% CI 0.076–0.793, $P=0.019$) had a significant impact on the time to NDOI, whereas age (per year, HR 0.942, 95% CI 0.899–0.986, $P=0.011$) and ANA positivity (vs negativity, HR 6.632, 95% CI 1.892–23.255, $P=0.003$) had a significant impact on the time to REOI.

Conclusions: The present study suggests that the risk factors of REOI and NDOI in IgG4-RD are different.

CANCER IS FREQUENT IN PATIENTS WITH ANTICENTROMERE PATTERN

M. Akiyama

Methods:
The aim of this study was to examine the association of sIL-2R activity of lymphoproliferative disorders and autoimmune diseases.

Soluble interleukin-2 receptor (sIL-2R) is known as an indicator for T cell activation status of lymphocytes and could be a potential biomarker for disease exacerbation. In some diseases such as lupus, the increase of sIL-2R is observed in some patients with active disease [5,6]. In Sjögren’s syndrome, the levels of sIL-2R are closely correlated with the extent of organ involvements and extra-dacryosialadenitis lesions in patients with IgG4-RD, compared with serum IgG and IgG4, with a cut-off value of 424 U/mL (AUC=0.917, p=0.0001), and in patients with pSS with 513 U/mL (AUC=0.894, p=0.0001). The sIL-2R levels in patients with IgG4-RD decreased significantly after glucocorticoid treatment. Notably, the cases which could be followed up at disease relapse or during glucocorticoid therapy showed the re-emergence of sIL-2R levels.

Cancer preceded the diagnosis of ACA in 19 patients (48.7%), with a mean time to diagnosis of 9.1 years (range 1–18). In the cohort of 350 patients with ACA the prevalence of cancer at some time (10.6%), 3 of them with 2 types of cancer. The most frequent were: Sjögren’s syndrome, 4.6% autoimmune hepatitis and 11 other SAD (polyarthritis, SLE, Raynaud phenomenon, sarcoidosis, mixed connective tissue disease, etc). 45 of these patients (15.9%) had any overlap syndrome. 39 patients had cancer at some time (10.6%), 3 of them with 2 types of cancer. The most frequent were: breast in 9 (23.1%), lung in 5 (11%), NHL in 5 (11%) and colorectal in 4 (10.3%). Cancer preceded the diagnosis of ACA in 19 patients (48.7%), with a mean time to diagnosis of 9.1 years (range 1–18). In the cohort of 350 patients with ACA the incidence was 1.14 per 100 patients per year (20). The mean time to diagnosis of cancer was 7.3 years (range 1–27). The oldest age was the only risk marker of cancer identified (70.8±13.29 years vs 63.9±14.32, p=0.005). There were no differences in the other variables analysed including sex, tobacco, diagnosis of SAD, capillaroscopy pattern, ANA titrations and mortality.

Conclusions: Cancer was frequent in patients with ACA, with a prevalence of 10.6% and incidence of 1.14 per 100 patients per year. The only risk marker of cancer identified in this population was the oldest age

FRI0589 | CANCER IS FREQUENT IN PATIENTS WITH ANTICENTROMERE PATTERN

C. Vázquez-Tirán[1], V. Alende[2], E. González[3], R. Lorenzo[3], T. Cainzos[3], L. González[3], S. Rodríguez[3], B. Sopeña[2] on behalf of Círculo de estudio de las enfermedades autoinmunes de Galicia (CEAG).

Background: Anti-centromere pattern (ACA) is infrequently seen among antinuclear antibodies (ANA) detected by indirect immunofluorescence (IFI). ACA is associated with systemic autoimmune diseases (SAD), especially systemic sclerosis (SSc). Some studies had recently related ACA with cancer, mostly with breast and lung cancer [1]. However, most published series of patients with ACA lack information about cancer occurrence. A prevalence of cancer of 11.1% was the only reported data, on a series of 45 unselected patients with ACA [2].

Objectives: Our aim was to study the prevalence of cancer in the largest series of patients with ACA, with a long follow-up. Our second objective was to make a cohort to calculate the incidence of cancer and to try to identify risk markers of cancer in these patients.

Methods: We included consecutive patients with at least 2 positive determinations of ANA with ACA by IFI on Hep2 cells between January 1st of 2011 and June 30th of 2015 in 6 Galician hospitals. The authors reviewed each patient’s chart to determine the presence of cancer, its occurrence, and a prevalence of cancer of 11.1% was the only reported data, on a series of 45 unselected patients with ACA [2].

Results: 369 patients with ACA were studied, of which 333 were women (90.2%), with a mean age of 64.7 years (range: 22–92). The mean follow-up from the first positive determination of ACA was 67.6 months (76.7% had a follow-up of patients with ACA at some time (10.6%), 3 of them with 2 types of cancer. The most frequent were: breast in 9 (23.1%), lung in 5 (11%), NHL in 5 (11%) and colorectal in 4 (10.3%). Cancer preceded the diagnosis of ACA in 19 patients (48.7%), with a mean time to diagnosis of 9.1 years (range 1–18). The cohort of 350 patients with ACA the incidence was 1.14 per 100 patients per year (20). The mean time to diagnosis of cancer was 7.3 years (range 1–27). The oldest age was the only risk marker of cancer identified (70.8±13.29 years vs 63.9±14.32, p=0.005). There were no differences in the other variables analysed including sex, tobacco, diagnosis of SAD, capillaroscopy pattern, ANA titrations and mortality.

Conclusions: Cancer was frequent in patients with ACA, with a prevalence of 10.6% and incidence of 1.14 per 100 patients per year. The only risk marker of cancer identified in this population was the oldest age.

FRI0590 | SOLUBLE INTERLEUKIN-2 RECEPTOR LEVELS REFLECT DISEASE ACTIVITY IN IgG4-RELATED DISEASE AND PRIMARY SJÖGREN’S SYNDROME

M. Akiyama, T. Sasaki, Y. Kaneko, H. Yasuoka, K. Suzuki, K. Yamaoka, T. Takeuchi, Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan.

Background: IgG4-related disease (IgG4-RD) is a fibroinflammatory disease characterized by elevated serum IgG4 and infiltration of IgG4* plasma cells at affected organs. The patients with IgG4-RD respond to glucocorticoids (GCs), but one-third of the patients experience disease relapse during tapering of GCs [1]. The risk factors for disease relapse following treatment are unclear.

Objective: The aim of this study was to identify the risk factors of disease relapse following reducing dose of glucocorticoid.

Methods: Consecutive, newly diagnosed patients with IgG4-RD who were followed over 6 months after treatment with GCs in our department were enrolled. The patients were divided into two groups according to the presence or absence of disease relapse. Disease relapse was defined as the appearance of new lesions or the re-enlargement of involved organs that required dose-increase of GCs alone as initial treatment. Ten patients (29.4%) experienced relapses during GCs alone as initial treatment. Ten patients (29.4%) experienced relapses during GCs alone as initial treatment. The patients with ACA were excluded. We checked the presence of any tumour in patients of this cohort at the end of follow-up to calculate the incidence of cancer. Finally, we compared patients with and without cancer by multivariate analysis, with the patients enrolled in this study.

Disclosure of Interest: None declared

by 3 (20%), 0 and 1 (14%) and 4 (8%). Histological confirmation was obtained by transthoracic biopsy (66%), cutaneous (12%) or lymph node biopsy (12%) in 90% of the patients. 90% of patients have been treated with oral glucocorticoids and 42% associate immunosuppressive therapy. The ACE levels showed no statistical association with any of the variables studied, although a very clear association (p=0.04754) was observed between the course of the disease and the presence of extrapulmonary symptoms: from the 25 patients without extrapulmonary symptoms, only in 35% of cases the process became chronic.

Conclusions: Our results, in general, coincide with what is published in the literature. In our cohort, initial diagnosis of S was relatively high (29/50 =58%), while misdiagnosis was relatively low (6/50 =12%). The level of ACE does not seem to be clearly associated with the presence of extrapulmonary symptoms, nor with the course of S. However, the presence of extra-pulmonary symptoms seems to lead to a chronic evolution.

FRIO593 ASSOCIATION OF THYMOMA WITH AUTOIMMUNE DISEASES IN A SERIES OF 83 CASES
A. Gonzalez García 1, W.A. Sifuentes Giraldo 2, J.L. Morell Hita 2, J.L. Patier de la Peña 1, 1Rheumatology, 2Rheumatology and Immunology; Ramon y Cajal University Hospital, Madrid, Spain

Background: Thymoma is the most common neoplasm originated from the thymus gland and accounting for 50% of anterior mediastinal tumors. Within its clinical manifestations are included the loss of self-tolerance and the development of autoimmunity.

Objectives: To study the frequency of autoimmune diseases (AD) in patients with thymoma and to describe their clinical characteristics and outcome.

Methods: We performed a retrospective observational study of a cohort of patients diagnosed with thymoma and followed-up in our center between January 1985 and September 2016. The variables evaluated included demographics, thymoma characteristics, clinical and analytical manifestations of autoimmunity, treatment and outcome.

Results: A total of 83 patients were included, 56.6% of them women, with a mean age at diagnosis of the thymoma of 58.4±15.8 years (range: 16–94), 31.3% of which corresponded to type I The classification of Masaoka, 39.1% to II, 17.2% to III and 10.9% to IV. There were one or more AD associated in 41 cases (49.4%). The most frequent diagnoses were myasthenia gravis (19), systemic lupus erythematosus (SLE) (4), subacute cutaneous lupus erythematosus (1), Sjögren’s syndrome (1), rheumatoid arthritis (1), spondyloarthritis (1), sarcoidosis (1), hemolytic anemia (2), pernicious anemia (1), aplastic anemia (1), cutaneous limited systemic sclerosis (1), urticaria-vasculitis, erythroblastopenia (1), recurrent pericarditis (1), thyroid disease (2) and lichen planus (1). The diagnosis of AD preceded to thymoma in 38.2% of cases and was later in the remaining cases. In 4 cases there was also a concomitant primary immunodeficiency (variable common immunodeficiency 3, CD4 immunodeficiency 1). The most frequently identified autoantibodies were anti-acetylcholine receptor (14/41, 34.1%), anti-synthetase muscle (3/41, 7.3%), ANA (11/41, 26.8%), anti-SSA (3/41, 7.3%), antiphospholipids (2/41, 4.9%), and antineutrophil cytoplasmic (1/14, 2.4%). In the comparison of patients with and without associated AD, no significant differences were found regarding age, sex or Masaoka classification. There were 6 deaths, 4 in group with associated AD and 2 in the group without AD, but without significant difference (p=0.3797).

Conclusions: In the analyzed population of patients with thymoma of our center, almost half of them developed AD, which in a major group preceded the diagnosis of neoplasia. The spectrum of autoimmunity associated with thymoma was quite broad, including organ-specific AD such as myasthenia gravis (which is most frequently described in the literature) and autoimmune cytopenias, but also to systemic AD, the most common being SLE. The autoimmunity study should be included in the assessment of the patient with thymoma as it could contribute to the early diagnosis of associated AD.

FRIO594 A CASE OF MOSAICISM IN TNF ASSOCIATED PERIODIC SYNDROME (TRAPS)
A. Kontzias 1, C. Calabrese 1, Y.-W. Cheng 2, 1Rheumatology and Immunology; 2Laboratory Medicine, Cleveland Clinic, Cleveland, United States

Background: Tumor necrosis factor receptor (TNFR)–associated periodic syndrome (TRAPS) is an autosomal-dominant disease caused by gain-of-function mutations in the TNFRSF1A gene, which encodes the 55-kd TNFR type I (TNFRI) protein. Mosaicism has been recently identified in a single patient. A 60 year old male presented with a 6 year history of intermittent fever as high as 103.5, lasting 3–4 days with associated peripheral symptoms, arthralgias, myalgias, lymphadenopathy, bilateral episceritis, erythromelalgia rash in his torso. Prednisone up to 60 mg daily only partially alleviated his symptoms and colchicine was ineffective.

Objectives: To explore the role of mosaicism in a patient with adult onset TRAPS phenotype.

Disclosure of Interest: None declared

FRIO592 CLINICAL, ANALYTICAL AND RADIOLOGICAL CHARACTERISTICS IN A COHORT OF PATIENTS WITH SARCOIDOSIS
A. Ruiz Román 1, C. Aguilera Cros 1, M. Arcila Durán 1, M. León Luque 1, M. Lisbona Muñoz 1, J.P. Sanchez Serrano2, J.A. Rodriguez Portal 3, A. Kontzias 1, C. Calabrese 1, Y.-W. Cheng 2, 1Rheumatology, 2Laboratory Medicine, Cleveland Clinic, Cleveland, United States

Background: sarcoidosis is a systemic granulomatous disease, frequently affecting lungs, eyes and skin, although it may damage other organs, among them the musculoskeletal system.

Objectives: To describe the clinical characteristics and radiological pattern in a cohort with predominantly pulmonary sarcoidosis, and to determine the relationship between the levels of angiotensin converting enzyme (ACE), pulmonary radiological stage and sarcoidosis course (chronification or remission)

Methods: Data from 2328 patients in an Interstitial Lung Diseases consultation during the first half of 2016 were analyzed. Out of these, 50 had sarcoidosis.

The delay in the diagnosis of sarcoidosis was defined as the difference in years between the diagnostic suspicion and diagnosis of sarcoidosis.

Chi square tests were used, assuming an error of the first species not higher than 0.05, in order to: 1. Study the association between angiotensin converting enzyme (ACE) levels and binary variables (extrapulmonary symptoms, radiological stage and evolution of S) 2. Determine the association between evolution, the radiological stage and the presence of extrapulmonary symptoms.

Results: We included 29 (58%) women and 21 (42%) men, (mean age of 44±11.7 years). Initial diagnosis: 88% S, 8% lymphoma and 4% tuberculosis. Of the 44 diagnosed cases of S, 24 were on the first visit, 11 the following year and 1 seven years later. Of the 4 lymphomas, 2 were diagnosed of S that same year and the other 2 were diagnosed the following year. Of the 2 tuberculosis, one was diagnosed of S in one year and the other at 4 years. The most frequent extrapulmonary manifestations were cutaneous 24%, followed by the articular, cardiac and ocular in 10%, neurological 8% and renal 4%. In 6% of patients, the first clinical manifestation of the disease was bilateral arthritis of the ankles. The ACE title is increased in 62% of patients, normal in 34%. The mean and standard deviation of the title of patients with an increased ACE value was 150.5 and 35.4 IU/L, respectively. In all patients, x-ray and high resolution tomography were performed, with stage 2 being the most frequent (44%), followed

the higher likelihood of disease relapse following GCs therapy in patients with IgG4-RD.

Acknowledgements: We sincerely thank all the physicians and others caring for the patients enrolled in this study.

Disclosure of Interest: None declared
Methods: DNA was extracted from the patient’s whole blood, saliva and hair root. The TNFRSF1A gene was analyzed by Sanger sequencing in all tissues, and next-generation sequencing in whole blood. In silico molecular modeling was performed to predict the structural and functional consequences of the tumor necrosis factor receptor (TNFR) type I protein mutation.

Results: Sanger sequencing and next-generation sequencing methods revealed differential tissue presence of a missense mutation at c.265 T→C p.Phe89Leu (F89L) Chr12(GRCh37):g.6442960A→G ex3 rs104895245. The mutant allele was present in whole blood and buccal mucosa and absent in hair root, supporting the presence of somatic TNFRSF1A mosaicism. In silico prediction modeling with SIFT and PolyPhen2 suggested that this mutation led to numerous structural rearrangements which resulted in changes in the protein surface profile. The patient had a complete response to treatment with canakinumab an interleukin-1 beta blocker, with resolution of symptoms and normalization of acute-phase protein levels.

Conclusions: This is the second reported case of TNFRSF1A mosaicism in a patient with TRAPS, which was attributable to a de novo mosaic missense mutation in the TNFRSF1A gene, (c.265 T→C) p.Phe89Leu (F89L). The clinical picture in this patient, including the complete response to IL-1 blockade, was typical of that found in TRAPS. This case suggests that adult onset TRAPS phenocopies may be attributed to somatic (or postzygotic) mutations.

FRIO595 | EPIDEMIOLOGY AND COMPLICATIONS OF HOSPITALIZED PATIENTS WITH ADULT ONSET STILL’S DISEASE IN UNITED STATES: A NATIONWIDE ESTIMATE
B. Mehta1, W. Briggs2, P. Ethimou3,4, 1Rheumatology, HSS; 2New York Presbyterian/ Brooklynn Methodist Hospital, New York, United States; 3Rheumatology, New York Presbyterian/ Brooklynn Methodist Hospital; 4Medicine, Weil Cornell Medicine, New York, United States

Background: There is a dearth of epidemiological studies in the US and worldwide on Adult Onset Still’s Disease (AOSD). Currently, there is no consensus on its incidence and prevalence in different populations. Most studies report a majority of patients below the age of 35.[1]

Objectives: To describe the demographics, complications and mortality of hospitalized patients with AOSD in United States.

Methods: All adult (>18 years) hospitalized patients in 2013 from a nationwide inpatient sample (NIS) database were captured. AOSD patients were identified using the ICD-9 code 714.2 that was in use in 2013. Patients also coded for Rheumatoid Arthritis, Lupus, Myositis, Polymyalgia Rheumatica, Ankylosing Spondylitis and Psoriatic Arthritis were excluded. This was done in order to truly capture patients with strictly AOSD. NIS is the largest all-payer inpatient care database in the United States with approximately 8 million hospitalizations each year. Discharge weights were used to enable nationwide estimates. Descriptive statistics were represented as means/medians for continuous and as frequencies and percentages for categorical variables.

Results: In 2013, 1,410 US patients were coded with the ICD-9 code 714.2 and, after excluding concomitant rheumatic disease diagnoses as per protocol, 1,265 AOSD patients were analyzed. AOSD patients had a mean age of 53.8 (SD - 18.1) years and a median age of 54 years. 70.4% were females. The racial/ethnic distribution showed that 61.6% white, 13.9% African American and 11% Hispanic patients were affected. 56.9% were hospitalized in urban teaching hospitals. The Mid-Atlantic census division had the highest number of patients – 240 (Figure). 35 (2.8%) of patients developed Macrophage Activating Syndrome (MAS). 30 (2.4%) patients had other severe complications of AOSD like disseminated intravascular coagulation (DIC) and thrombotic thrombocytopenic purpura (TTP). Median length of stay was 4 days and median hospital charges were $31,400 (Table). There were 35 inpatient deaths (mortality 2.8%): 71.4% of deaths were in females, 50% in Asians, and 71.4% were in patients in the 54-67 age group.

Conclusions: In hospitalized American AOSD patients, the average age was higher than previously thought. This may indicate an aging population with a higher number of comorbidities that justify hospitalization. Mortality increased with age and was higher among women and Asians. To our knowledge, this is the largest epidemiological study of AOSD today in the USA.

FRIO596 | ANAKINRA TREATMENT IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER: A SINGLE-CENTER EXPERIENCE (CASE SERIES)
B. Ergenç, S. Ugurlu, H. Ozdogan. Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey

Background: Approximately in 5 to 10% of FMF patients there is insufficient response and/or intolerance to colchicine treatment. Several reports have pointed out the efficacy of IL-1 blockade in colchicine resistant FMF subgroup.

Objectives: To review the patients followed in our center with FMF who received Anakinra, an anti-IL-1 receptor antagonist, in terms of outcome and side effects.

Methods: 43 FMF patients who were treated with Anakinra were retrospectively
reviewed with regard to indication, effect on disease activity and acute phase response, adverse events and patient global assessment.

Results: There were 43 patients with FMF (20 M/23 F) who were treated with Anakinra for various indications (colchicine resistant recurrent febrile attacks in 39, colchicine related side effects in 3, both in 1). The mean age of the patients was 39.4±12.6 years. The mean duration of the disease was 19.90±10.52 years. There were various co-existing pathologies among this study group like Ankylosing Spondylitis (4), Psoriasis (1), Behçet’s disease (1), Gout (1), Vasculitis (1), Adult-onset Still’s disease (1), Polymyalgia Nodosa (1) and Celiac disease (1). The mean colchicine dose was 1.84±0.31 mg/dl. As for the dosage, 35 patients were on 100 mg/day, 6 were on 100 mg on alternate days, 2 were on 200 mg/day. The mean duration of anakinra treatment was 10.76±13.64 months. After the initiation of anakinra 29 patients became attack-free, 9 patients reported more than 50% decrease, 3 patients less than 50% decrease, and 2 patients no change in the frequency of the attacks. Mean global pain intensity decreased from 7.55±2.34 to 2.82±2.63 under Anakinra treatment (<0.001).

For the adverse events, eight patients (18%) had allergic reactions under Anakinra treatment (severe disseminated rash in 1 patient and severe joint injection site reaction in 4 patients and tolerable injection side reaction in 3) which necessitated termination of treatment in 5 patients. Anakinra was stopped because of genital rashes and urinary tract infection in one other patient. Worsening of psoriatic lesions was observed in another patient. There were no adverse events in the remaining 41 patients during the course of treatment. On the other hand, treatment was terminated in case of inadequate response in 11 (25%), remission in 2 and patient preference in 3 patients. Nineteen patients are still on Anakinra treatment for 10.09±14.51 months.

Conclusions: Anakinra is an effective and relatively safe alternative treatment in FMF patients with inadequate response or intolerance to colchicine, however, approximately one fourth of the patients stop anakinra for insufficient response. Disclosure of Interest: None declared doi: 10.1136/annrheumdis-2017-eular.5436

FRIO597 | FATIGUE IN FAMILIAL MEDITERRANEAN FEVER (FMF) AND ITS RELATIONS WITH OTHER CLINICAL PARAMETERS
C. Unal Ertekin1, T. Duruz2, D. Karali1, F. Flutuatlar1. 1PM&R Department, Rheumatology Division; 2FM&R Department, Marmara University, School of Medicine, Istanbul, Turkey.

Background: Fatigue is a common problem in patients with rheumatic disease. It may cause disability and poor quality of life (1). Although fatigue and its determinants are studied in several rheumatic diseases, there is no study in Familial Mediterranean Fever (FMF).

Objectives: The aim of this study is to investigate fatigue in FMF patients as a disabling symptom and its associations with clinical and demographic variables.

Methods: FMF patients were recruited into the study according to FMF Tel Hashomer criteria (2). Control group composed of healthy individuals. Patients with myopathies, erosive arthritis, myopathies, erosive arthritis, systemic sclerosis and certain auto-antibody profiles were excluded. Age, gender, disease duration, education, marital status were noted as demographic features. Number of attacks in the last year, type of attacks (arthritis, myalgia, rash), duration of attacks, dosage of colchicine, genotype and severity of FMF was assessed with PRAS score, visual analogue score of pain (VAS-pain) and VAS-fatigue were used as clinical parameters. Pittsburgh Sleep Quality Index (PSQI), Multidimensional Assessment of Fatigue (MAF), Nottingham Health Profile (NHP), Fatigue Severity Scale (FSS), Fatigue Impact Scale (FIS) and Hospital Anxiety and Depression Scale (HADS) were filled out by both control and study group. Assessment of normality was analyzed with Shapiro-Wilk test. Differences in the mean scores of control and study group were compared with independent samples Mann-Whitney U and Kruskal-Wallis test. Relationships between continuous variables was assessed with Spearman’s correlation coefficient (rho).

Results: 61 FMF patients and 61 age, gender (44 female, 17 male in each group) matched controls were enrolled into the study. Mean age of FMF and control group were 43.5±11.8 and 35.8±11.7 years, respectively. The mean disease duration was 82.5±81.7 months. Differences between mean of VAS-pain, VAS-fatigue, PSQI total score, MAF, all subsets of NHP, FSS, FIS, HADS scores of FMF patients were statistically higher than control group (<p=0.001). The correlations between scales assessing fatigue and other outcome measures in FMF patients were significant (rho).

Conclusions: This study has shown that fatigue in FMF is associated with a number of psychological, sleep, quality of life and disease related factors. FMF group had increased pain, fatigue, sleep disturbance and decreased quality of life compared to control group. FMF patients with fatigue may benefit from pharmacological and psychological interventions which target these factors. References:

FRIO598 | CHARACTERIZATION OF PATIENTS WITH AN INITIAL DIAGNOSIS OF UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE. OBSERVATIONS FROM A LONGSTANDING MONOCENTRIC COHORT
C. Sepúlveda1,2,3, A. Taulaigo1,2, C. Carrero1,2,3, M. F. Moraes-Fonts1,3. 1Servicio de Medicina, Centro hospitalar Médio Tejo, Abrantes; 2Unidade de Doenças Auto-imunes/Medicina 7.2, Hospital de Curry Cabral, Centro Hospitalar de Lisboa Central; 3NEDAI - Núcleo de Estudos de Doenças Autoimunes da Sociedade Portuguesa de Medicina Interna, Lisboa. 1Servicio de Medicina, Hospital do Divino Espírito Santo, Ponta Delgada, Azores, Portugal.

Background: Evolution from Undifferentiated Connective Tissue Disease (UCTD) to a defined Autoimmune Disease (AID) remains unexplained and usually occurs in the first 3 to 5 years.

Objectives: To determine the frequency and predictors of differentiation from UCTD to AID in a selected cohort of patients originally labelled as UCTD within the first 3 years of follow-up.

Methods: Demographic and clinical features were retrieved: (i) retrospectively, from the AID’s Unit current database in December 2016 (n=195), including Systemic Lupus Erythematosus (SLE), incomplete SLE, Sjögren’s Syndrome (SS), Systemic Sclerosis (SSc), Vasculitis and Mixed Connective Tissue Disease (MCTD); and (ii) from a prospectively UCTD database created in January 2012 (n=48). Inclusion criteria for the latter pertain to ANA positive patients, not fulfilling any of the existing classification criteria for AID and without severe organ involvement [1]. Patients with cutaneous lesions suggestive of lupus, inflammatory myopathies, erosive arthritis, systemic sclerosis and certain auto-antibody profiles were excluded a priori from the definition of UCTD as these are thought to herald defined conditions, as previously defined [2]. Definition of stable UCTD includes patients with at least one clinical manifestation of AID, positive ANA results and disease duration of at least 3 years [3]. Comparisons between stable UCTD and progressing patients were made using Wilcoxon Rank Sum and Chi square tests, p values of <0.05 were considered statistically significant.

Results: Each individual patient was analysed for differentiation into AID at yearly intervals. Overall, the main features of the prospective UCTD cohort were arthralgia (79%), rash (31%), arthritis (19%), sicca symptoms (19%), photosensitivity (17%) and Raynaud (13%). Prospective analysis in the UCTD cohort revealed differentiation in 4/48 patients (8.3%): into rheumatoid arthritis (n=2), psoriatic arthritis (n=1) and SLE (n=1). The main difference between stable UCTD and those that progressed to AID was the presence of arthritis (p=0.003). Median age of onset and symptom duration was similar between both groups. Retrospective analysis yielded very few patients presenting as UCTD (n=5/195); 2/106 SLE; 1/13 incomplete SLE; 1/43 SS; 1/19 SSc; 0/7 VEDOSS and 0/7 MCTD with no distinguishing feature.

Conclusions: Very few patients differentiated in the UCTD cohort after 3 years of follow-up and in our retrospectively studied cohort, in accordance to a previous study [4]. Apart from arthritis, there were no other predicting factors for differentiation to AID. UCTD at disease onset seems to be a rare event.

FRIO599 | A RETROSPECTIVE OVERVIEW OF CLINICAL FEATURES, SEROLOGY AND HISTOLOGY OF IGG4 RELATED DISEASE IN HONG KONG: A DATASET OF 108 PATIENTS FROM FOUR REGIONAL HOSPITALS
C.P. Tang1, K.L. Lee1, K.W. Lee2, W.L. Ng3, M.C. Wan4, K.Y. Yuen5. 1Medicine, PUNHHC, Medicine, HKSH; 2Medicine, UCH; 3Medicine, RH; 4Medicine, QMH. HK, Hong Kong.

Background: IgG4 related disease (IgG4RD) is a spectrum of immune mediated disease with multiple organ involvement characterized by organ enlargement, function loss or obstructive symptoms (1, 2).

Objectives: In this retrospective study, clinical, serological and histological features of IgG4RD patients over the past ten years from four regional hospitals were reviewed.

References:
Methods: Four regional hospitals participated with study period from 1/1/2006 to 30/6/2016. IgG4RD patients were classified into definite, probable and possible IgG4RD according to Japanese Comprehensive Diagnostic Criteria for IgG4RD (3).

Statistical analysis: Association between the individual categorical covariates and the different organ involvement were analyzed by Fisher’s exact test.

Results: 108 patients were included. There were 81 male patients and 27 female patients and the male to female ratio was 3:1. The mean age of diagnosis was 62.8 year old. 57 patients were diagnosed as definite IgG4RD (53%), 14 patients as probable IgG4RD (13%) and 37 patients as possible IgG4RD (34%). Salivary glands involvement was the commonest (M=46.7% vs F=33.3%), followed by pancreas (M=28.4% vs F=18.5%) and biliary system in male (M=24.7% vs F=11.1%) and orbital in female (M=23.5% vs F=18.5%). 53% patients also had multi organ involvement.

Conclusions: Most patients were male with the peak diagnosis at age 50 to 70. Salivary gland and pancreas were the most common organ involved. Most patients had a raised IgG4 level and most histological specimens showed a raised IgG4/IgG ratio greater than 40% per high power field which accounted for 86.9% of the specimens.

FR0601 | HYPERFERRITINEMIC SYNDROME IN A GENERAL UNIVERSITY HOSPITAL

F. Pieringer, I.J. Gandino, J.M. Martinez Perez, S. Ruta, M. Scolini, E.R. Soriano. Rheumatology Section, Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

Background: Hyperferritinemia is associated with severe inflammatory conditions, such as rheumatic diseases with systemic inflammatory responses, and multiorgan dysfunction syndromes.

Objectives: To determine which diseases are associated with hyperferritinemia in a tertiary hospital; to compare ferritin levels between these different entities and to evaluate relationship between levels of ferritin and mortality in these patients.

Methods: A retrospective study was carried out in which all patients over 18 years of age with at least one determination of serum ferritin equal to or greater than 1000 ng/ml were identified in the laboratory database of our hospital between 1/1/2006 and 6/30/2016. Corresponding electronic medical records were reviewed and demographic and clinical data were collected. Mortality was assessed at the end of follow-up. Descriptive statistical analysis and logistic regression analysis were performed in order to identify variables associated with mortality.

Results: A total of 1979 patients were included, 1235 men (62.4%) with a mean age of 63.2 years (SD 17.2). Only 36 patients (1.8%) presented a diagnostic approach for the diagnosis of IgG4-RD, 2011. Modern Rheumatology. 2012;22(1):21–30.

FR0602 | NATIONAL RECOMMENDATIONS ON THE USE OF IMMUNOMODULATORY DRUGS IN PATIENTS WITH NON-INFECTIONOUS NON-MALIGNANT ANTERIOR UVEITIS

Conclusions: Disease control in FMF is important to prevent amyloidosis and improve the quality of life. Recent studies contribute to the determination of treatment goals. Reducing the colchicine dose may increase drug compliance in this lifelong treatment. In our study, there was no difference between the treatment groups in amyloidosis, MEVF gene mutation or subclinical inflammation. These findings suggest that the dose of colchicine maybe reduced in inactive patients who determined by the number of annual episodes and the ISSF score.

Clinical implications of ultrasonography in monitoring disease activity of relapsing polychondritis in cases

H. Nishikawa, T. Taniguchi, Y. Terada.
1Department of Autoimmune Diseases, Institut Clinic de Medecina i Dermatologia, Hospital Clinic, Barcelona; 2Rheumatology, Hospital Universitario Infanta Sofia, Madrid; 3Immunology, Complejo Asistencial Universitario de León, Leon; 4Ophthalmology, Hospital Clínico Universitario de Valladolid, Valladolid; 5Ophthalmology, Complejo Asistencial Universitario de León, Leon, Spain

Background: Anterior uveitis (AU) is the most common pattern of uveitis, that might lead to important ocular complications including blindness. Immunomodulatory drugs have been used in order to prevent recurrences of uveitis. Nevertheless, it is not clear which drug could be preferred in each patient.

Objectives: To access the clinical implications of ultrasonography (US) in monitoring disease activity of relapsing polychondritis (RP).

Results: The 33 recommendations were accepted. They include specific recommendations on patients with non-infectious, non-neoplastic AU, as well as different treatment lines. Methotrexate (MTX) or Sulfasalazine were recommended as a first line drugs in refractory cases to topic treatments in patients with AU and spondyloarthritids, inflammatory bowel disease, psoriasis, idiopathic HLA-B27 positive or negative AU. Etanercept was recommended for patients with TRAPS syndrome, and for those with other autoinflammatory syndromes canakinumab or anakinra. In case of bilateral sarcoidosis, relapsing polychondritis or TINU syndrome, MTX was recommended along with systemic steroids. For patients with a flare of AU and Behçet disease, systemic steroids along with azathioprine or a calcineurin inhibitor were recommended. The indication of an immunomodulatory drug in patitines with multiple sclerosis was considered to be decided with a neurologist. For patients refractory to all above exposed and or intolerant, depending on AU type, a change to another immunomodulatory drug or to an anti-TNF was recommended (adalimumab, infliximab, certolizumab or). Except for patients with TINU, etanercept was not recommended because current evidence does not support the use of it to prevent AU flares.

Conclusions: In patients with non-infectious, non-neoplastic AU, these recommendations on the use of immunomodulators might be a guide in order to help in the treatment decision making, due to the lack of robust evidence in other globally accepted algorithms.

Methods: Three cases of a 78-year-old man with RP, a 74-year-old woman with RP associated with optic perineuritis and a 42-year-old woman with RP associated with uveitis were assessed by US before and after treatments.

Results: Ultrasonography (US) of the auricle before treatment showed low-echoic swollen auricular cartilage with increased power Doppler signals (PDS) in all cases. US findings corresponded to the above-mentioned biopsy findings. After treatment with prednisolone combined with methotrexate, the auricular swelling completely resolved in all cases. Then, US findings also showed dramatic reductions in swelling of cartilage with the decrease in PDS.

Conclusions: US imaging can be used to differentiate between inflammation, vascular lesions, and tumors in the ear pinna. RP could be differentiated from the damage of repeated trauma (i.e. rugby) with producing subperichondrial serous effusion. As in the present cases, US imaging of the external ear and auricular cartilage in RP also facilitates evaluation of auricular lesions and monitoring of disease activity, especially when we consider the treatment response and the timing of drug tapering.

SUCCESSFUL TREATMENT OF ARTHRITIS INDUCED BY CHECKPOINT INHIBITORS WITH ANTI–INTERLEUKIN-6 RECEPTOR ANTIBODY: A CASE SERIES

1Rheumatology; 2Melanoma Medical Oncology, MD Anderson Cancer Center; 3Rheumatology, Baylor College of Medicine, Houston, United States

Background: Immune checkpoint inhibitors (CPIs) have significantly improved outcomes for patients with various cancers. However, CPIs are associated with immune-related adverse events (irAEs). Two to three percent of patients receiving a CPI develop arthritis. In general, severe irAEs are treated with a high-dose steroid and a tumor necrosis factor inhibitor (TNFi), usually infliximab; however, TNFi treatment is sometimes contraindicated and, furthermore, entails a theoretical concern of impairing antitumor immunity. Therefore, evidence showing the clinical benefits of non-TNFi biologics in the treatment of irAEs is of immediate interest.

Objectives: We described the effects of anti–IL-6R antibody for the treatment of arthritis-irAE.

Methods: Three patients receiving CPI developed arthritis and were treated with anti–IL-6R antibody. Patients were followed up to 15 months.

Results: All patients had metastatic melanoma (Table 1). No patient had a
history of autoimmune disease at the time of initiation of CPI treatment. One patient developed arthritis 8 weeks after the completion of anti-CTLA-4 antibody treatment. Two patients were receiving anti-PD-1 antibody when they developed arthritis. Patient 2 continued to receive anti-PD-1 antibody despite of arthritis-irAE while patient 3 discontinued anti-PD-1 antibody due to arthritis-irAE. The pattern of arthritis symptoms consisted of small and large joints. Patient 1 had a positive rheumatoid factor (unknown baseline) and patient 3 had a positive ANA (known positive prior to CPI treatment). All patients were treated with anti-IL-6R antibody, which was well tolerated. All patients experienced a 40–100% reduction in global assessment, swollen joint count, and tender joint count, and these effects were maintained for up to 15 months of treatment (Figure 1). As of December 2016, all patients were alive; one patient was in complete remission and two patients had experienced progression of their melanoma.

Conclusions: These three cases suggest that anti-IL-6R antibody is an effective alternative to NFi for the treatment of arthritis-irAE.

DOI: 10.1136/annrheumdis-2017-eular.6532
Results: We studied 100 patients/180 affected eyes (54M/46W), mean age 40.7±10.1. The ocular pattern was panuveitis (n=62), posterior (27) and anterior uveitis (11). Before IFX they received iv MP (28), cyclosporine (75), azathioprine (56), metotrexate (43) and others (33). IFX dose ranged between 3–5mg/kg/4 or 8 weeks. In patients in remission IFX was optimized (n=28) or stopped (n=20).

Conclusions: IFX is an effective long-term treatment in refractory Uveitis of BD. Optimization and even discontinuation of IFX after remission is possible.

FR0608 | STUDY OF ARTICULAR SARCOIDOSIS IN A TERTIARY CARE HOSPITAL

M. Garío Bufort1, E. Vallejo Pascual2, C. Moriano Morales1, M. Retuerto Guerrero1, C. Arrizubiaga1, A. Crespo Golmar3, A. López Robles4, C. Álvarez Castro5, E. Díez Álvarez2, M. Martín Martínez1, T. Pérez Sandoval5.

1Rheumatology Department of the University Health Care Complex of León; 2University of León, León, Spain

Background: Sarcoidosis is a systemic granulomatous disease, being the joint involvement a poorly studied manifestation.

Objectives: To describe the clinical and demographic characteristics of patients with sarcoidosis, paying particular attention to the joint involvement and its possible relationship with other extra-articular manifestations, as well as the treatment received.

Methods: A retrospective, observational study that included 104 patients who were admitted to the Hospital of León between January 2011 and December 2015 with main or secondary diagnosis of sarcoidosis; according to clinical onset, imaging tests and/or anatomopathological study. The variables studied were: age at onset, sex, type of joint involvement, forms of extra-articular involvement, serologic parameters and drugs received. Statistical analysis was performed using SPSS v22.0, p<0.005.

Results: 57.7% of the patients included in the study were women with a mean age of 53.4±18.4 years. At the systemic level, 35% of them presented fever, 66.3% lymphadenopathy and 4.8% splenomegaly. 97.1% of the patients presented pulmonary involvement, with stage II being the most common (46.2%). Only 8 patients had cardiac abnormalities. Ocular involvement was observed in 10.6%.

Conclusions: To the factors to predict relapse. Recent research has shown the usefulness of FDG-PET/CT for IgG4-RD because it is more sensitive than conventional imaging to detect organ involvement of the disease. It has been suggested that FDG-PET/CT is also useful for monitoring therapeutic response of IgG4-RD.

Objectives: We investigate the usefulness of FDG-PET/CT imaging and serological biomarkers to predict relapse in IgG4-related disease.

Methods: We analyzed 24 patients with IgG4-RD treated for more than 1 year between 2008 and 2016 in our facility. The diagnosis for IgG4-RD was based on comprehensive diagnostic criteria for IgG4-RD. All cases underwent FDG-PET/CT at least once, and laboratory data were collected from the medical records retrospectively. Levels of serum C-reactive protein (CRP), eosinophil/leukocyte ratio, serum IgG, IgG4, IgA, IgM, sIL-2R and serum complement were investigated.

Results: The patients had a mean age of 67.9 years (range: 50–87 years). In the cases with high FDG uptake on FDG-PET/CT, they had a greater number of organ involvements, higher serum IgG and sIL-2R levels. Eight patients experienced relapses following treatment. Higher serum IgG predicted relapses of IgG4-RD. FDG-PET/CT findings at baseline were not associated with relapse. FDG-PET/CT was performed in 13 patients after initiation of treatment and 4 patients had a relapse. There were no significant reduction of abnormal FDG uptake in 6 patients, and 4 of 6 patients relapsed.

Conclusions: In this study, we examined the factors to predict relapse in IgG4-RD. Patients with higher serum IgG were regarded as a risk of relapse, but FDG-PET/CT findings at baseline were not associated with relapse. FDG-PET/CT reexamined after initiation of treatment is useful to predict relapse of IgG4-RD.

FR0610 | PROBLEMS IN THE DIAGNOSIS OF FAMILIAL MEDITERRANEAN FEVER IN TURKEY

M. Erdogdu, Y. Ozyugler, G. Karazemiz, S.N. Esatoğlu, G. Guzelant, E. Dinçes, S. Uğurlu, G. Haterim, H. Ozdogan, E. Seyahi. Internal Medicine, Division of Rheumatology, Cerrahpaşa Medical Faculty, University of Istanbul, Istanbul, Turkey

Background: The diagnosis of FMF (Familial Mediterranean Fever) can be missed or delayed even in a country like Turkey, one of the most prevalent places for FMF (1).

Objectives: We compared the duration of delay in diagnosis before and after the publication of MEF1, and assessed the patients related with the diagnosis of FMF.

Methods: We studied 143 (102 F, 41 M) consecutive patients with FMF seen 2000-2016 in the Rheumatology Outpatient Clinic of Istanbul Cerrahpaşa Medical Faculty. The median age of the patients was 34 years [IQR:27–45]. The F/M ratio was 2.4. The initial symptom was abdominal pain in the majority (n=134, 89%), followed by fever (n=114, 75%), arthritis (n=66, 44%), pleuritic pain (n=21, 14%), arthralgia (n=11, 7%) and other complaints (n=14, 9%). The median age at initial symptom was 10 years (IQR:6–23). The median delay in diagnosis was 8 years [IQR:2–15]. This was significantly shorter in Group 2 (median: 4 years [IQR:0–11]) than that observed in Group 1 (median: 10 years [IQR:6–17]), as shown in Table 1.

A total of 110 patients (73%) were diagnosed with one or more diseases or syndromes other than FMF. These were appendicitis (n=50, 45%), gastrointestinal diseases (n=44, 40%), acute rheumatic fever (n=36, 33%), inflammatory
arthritis (n=18, 16%), gynecological diseases (n=11, 10%) kidney stones (n=9, 8%) and others (n=34, 31%). As shown in Table, the frequency of patients with misdiagnosis, was significantly lower in Group 2 (66%) compared to Group 1 (84%). A total of 59 patients (39%) received other long-term treatments, mainly monthly penicillin (n=20, 13%). There were 41 surgical interventions in 36 patients (24%), before the diagnosis of FMF, the most common being appendectomy in 31, gynecological operations in 5, cholecystectomy in 3 and others in 2 occasions. It was noted, that the frequency of surgical operations was significantly decreased in Group 2 (12%) compared to Group 1 (27%) (Table). The absence or presence of MEVF mutations was assessed in 69 patients (46%) before the diagnosis or after to reinforce the diagnosis. As expected, this was significantly more frequent in Group 2 (59%) compared to Group 1 (33%) (Table). Seventy patients (46%) were diagnosed as FMF only after someone else in the family (n=44) or a friend (n=26) had a similar diagnosis. The frequency of these patients was similar when Group 1 and 2 were compared.

Table: Demographic and clinical characteristics of Group 1 (patients seen before 2000) and Group 2 (patients seen after 2000) .

ASSESSMENT OF PANNICULITIS CLINICAL OUTCOMES: RISK FACTORS FOR RECURRENCE AND PREDICTORS OF SLOW REGRESSION OF INDURATIONS

N. Savushkina, O. Egrova, B. Belov. V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Currently there’s no clear understanding of the clinical course and outcomes of panniculitis with predominant involvement of subcutaneous adipose tissue (SAT), which is often associated with the involvement of locomotor system and viscera. Consistent elaboration of both is of paramount importance, as it may give a deeper insight into clinical and curative factors which may have impact on the disease prognosis.

Objectives: To assess clinical outcomes of panniculitis (risk factors for recurrence and predictors of slow regression of inductions).

Methods: 186 pts (172 females, 14 males) aged 43.5±14.5 years with different types of Pn, who were at the record of V. A. Nasonova Research Institute of Rheumatology during 2009–2015 yy. Disease duration varied from 1 week to 20 years.

H-FERRITIN AND PRO-INFLAMMATORY CYTOKINES ARE INCREASED IN THE BONE MARROW OF ADULT PATIENTS AFFECTED BY MACROPHAGE ACTIVATION SYNDROME

P. Rusconi 1, P. Cipriani 1, F. Ciccia 2, P. Di Benedetto 1, A.R. Lizza 2, V. Liaoulis 2, O. Berarducci 1, F. Carubba 1, G. Guggino 2, G. D’Andrea 3, G. Tiolo 2, P. Giacoia 1

Background: During macrophage activation syndrome (MAS), an inflammatory life-threatening syndrome, extremely high levels of serum ferritin may be observed. Ferritin is an intracellular iron storage protein comprising 24 subunits that may be divided in heavy (H) and light (L) subunits, based on their molecular weight. The H/L-subunits ratio may change, depending on the specific tissue and the physiologic status of the cell. In the normal condition, ferritin enriched in H subunits (H-ferritin) may be mainly observed in the heart and kidneys [2].

Objectives: We investigated the tissue expression of both H- and L-ferritin as well as pro-inflammatory cytokines expressing these molecules, in the inflammatory BM infiltrate of MAS patients. In addition, the co-expression of IL-1β, TNF-α, IFN-γ and H- or L-ferritin, within the inflammatory cells, was assessed. Finally, we explored if the imbalance between H-ferritin and L-ferritin as well as the number of ferritin positive cells may be considered helpful bio-markers to assess the severity of these patients.

Methods: We analyzed the bone marrow (BM) biopsies, by immunofluorescence of 10 adult MAS patients affected by rheumatic disease to assess the presence of: i. both H- and L-ferritin; ii. the number of CD68+/H-ferritin+ and CD68+/L-ferritin+; iii. the tissue pro-inflammatory cytokines, IL-1β, TNF, IFN-γ, and we correlated these data with clinical and laboratory data. Furthermore, the presence of ferritin cells was assessed in the sera of the same patients by western blot analysis.

Results: We observed an increased tissue expression of H-ferritin and of pro-inflammatory cytokines (IL-1β, TNF, IFN-γ). Western blot analysis, in the sera, of H-ferritin microscopic cells of the tissue. Furthermore, an increased number of CD68+/H-ferritin+ cells and an infiltrate of cells co-expressing H-ferritin and IL-12, suggesting an infiltrate of M1 macrophages, were observed. Tissue H-ferritin levels correlated with the decreased counts of WBC (p=0.01) and PLT (p=0.002) and the increased values of serum ferritin (p=0.012) and C-reactive protein (CRP) (p=0.0058); and with the tissue expression of IL-1β (p=0.006). The number of CD68+/H-ferritin+ cells correlated with the decreased counts of WBC (p=0.03) and PLT (p=0.007), and with the increased serum ferritin levels (p=0.0086) and CRP (p=0.049). The analyses concerning tissues L-ferritin as well as the number of CD68+/L-ferritin+ cells and the same parameters failed to show any significant result.

Conclusions: We observed an increased tissue expression of H-ferritin associated with an increased expression of IL-1β. Interestingly, in the BM inflammatory infiltrate an increased number of CD68+/H-ferritin+ cells was shown. Of note, tissue expression of H-ferritin as well as the number of CD68+/H-ferritin+ significantly associated with the hematological involvement of the disease, suggesting possible bio-markers to assess the severity of these patients.

SARCOIDOSIS AND CANCER: DIFFERENT PATTERNS OF ASSOCIATION IN A MULTICENTER COHORT FROM SOUTHERN EUROPE

Background: Sarcoidosis was diagnosed with the criteria proposed by the ATS/ERS/WASOG SEMI) created a national registry (SARCOGEAS) of patients with sarcoidosis. The cohort included 1082 patients (82% biopsy-proven, 618 women, mean age 47yrs). Association with neoplasia was detected in 135 (13%) patients in whom cancer preceded the diagnosis of sarcoidosis had a higher frequency of sarcoidosis diagnosed incidental (20% vs 4%, p=0.011) and a lower frequency of ocular sarcoidosis (3% vs 16%, p=0.001, OR 4.06), and laboratory findings. The certainty of OM was classified as grade 0 (not investigated), grade 1 (no sign of OM), grade 2 (clinical sign of OM), grade 3 (signs of OM in laboratory findings or imaging) and grade 4 (histological proven OM), respectively.

Results: We included 151 patients with biopsy-proven chronic sarcoidosis. Mean age was 50±15 years with a male predominance (87 [57.2%] vs 65 [42.8%] patients).

FRI0613

H-FERRITIN AND PRO-INFLAMMATORY CYTOKINES ARE INCREASED IN THE BONE MARROW OF ADULT PATIENTS AFFECTED BY MACROPHAGE ACTIVATION SYNDROME

A complete response was achieved in 52.5% of patients and partial response (-50% of regression) in 40%. Two patients deceased due to l GV4-RD associated problems and no malignancy was observed (median follow up: 18 months).

Conclusions: We observed similar features with previous European cohorts although no male predominance was seen. Even though conventional immunosuppressive treatments were in use in more than half of patients, treatment had switched to rituximab ~50% patients owing to resistance or relapses.

FRI0614 FREQUENCY OF ORGAN MANIFESTATIONS IN CHRONIC SARCOIDOSIS

Background: Chronic sarcoidosis is a systemic disease of unknown etiology, characterized by the histological finding of granulomas in involved organ systems. The most often affected organ is the lung with approximately 90–95%. Systemic data of organ manifestations other than the lung are scarce and show a wide range from 1–2% to 50% depending on the series.

Methods: We analyzed data of newly diagnosed chronic sarcoidosis in 3 tertiary hospitals. We analyzed data on organ manifestations (OM), type of OM and laboratory findings. The certainty of OM was classified as grade 0 (not investigated), grade 1 (no sign of OM), grade 2 (clinical sign of OM), grade 3 (signs of OM in laboratory findings or imaging) and grade 4 (histological proven OM), respectively.

Results: We included 151 patients with biopsy-proven chronic sarcoidosis. Mean age was 50.8±9 years with a male predominance (87 [57.2%] vs 65 [42.8%] patients).

Discussion of Interest: None declared

FR0616 EYE MANIFESTATIONS OF PATIENTS WITH MUCKLE-WELLS SYNDROME

S. Cekic1, O. Yalcinbayir1, S.S. Kiliç1, 2

1Pediatric Rheumatology; 2Ophthalmology, Uluğad University Medical Faculty, Bursa, Turkey

Background: CAPS is a rare autoinflammatory disease associated with mutations in the CIAS1 gene, encoding for NLRP3 that result in overactivation of the inflammasome. Muckle-Wells syndrome (MWS) is a rare autosomal dominant disease which causes episodic fever attacks, sensorineural deafness, recurrent hives, arthritis and eye involvement.

Objectives: Here we present the findings of eye involvement in a family whose 11 members have MWS.

Methods: Clinical data was collected during the course of ongoing patient care.

Results: We evaluated the clinical features of 11 patients who were referred to a tertiary care center. The median age of the patients was 25 years (range: 9–65). The ratio of females/males was 1.2 (6/5). All patients had arthritis with exacerbation on exposure to cold and recurrent episodes of pink eye. The median age of onset of ocular involvement was 8 years (2–45). We observed severe eye involvement in 36% of our cases, including band keratopathy, severe damage of corneal stroma and neo-vascularization. Corneal involvement and clounding was detected in four patient. Two of those had the diagnosis of keratoconus as well. Patients with keratoconus had corneal scarring due to corneal hydrops verified with corneal topography. The other two patients with corneal clounding had band keratopathy. One of those patient was a 17 year old girl who had recurrent uveitis with hypopyon which necessitated the use of intravitreal dexamethasone implant. She also had posterior synchia of the iris to the lens. The other eye of that patient had signs of phthisis bulbi. The other patient with band keratophathy was a 46 years old male who had optic atrophy and tractional fibrovascular membranes at the posterior pole of the eye. Anakirna was used for treatment of 5 cases, and canakinumab of 3 cases. It was observed that the frequency of conjunctivitis decreased after anti IL-1 therapy. There was no mutation detected in the study of MEFV (all exons), TNFRSF1A (exons 2 to 7), MVK (all exons), NLRP3 (all exons). One of those patient was a 17 year old girl who had recurrent uveitis with hypopyon which necessitated the use of intravitreal dexamethasone implant.

Conclusion: Here we presented our clinical experience with MWS in a family of 11 members. The clinical manifestations of this disease varied from mild (e.g. arthritis) to severe (e.g. phthisis bulbi). The combination of anti IL-1 therapy and the use of intravitreal dexamethasone implants was useful in some patients.

FR0617 DIAGNOSTIC SENSITIVITY OF CUTOFF VALUES OF IGG4-POSITIVE PLASMA CELL NUMBER AND IGG4-POSITIVE/CD138-POSITIVE CELL RATIO IN TYPICAL MULTIPLE LESIONS OF PATIENTS WITH IGG4-RELATED DISEASE

S. Tsuge, I. Mizushima, Y. Fujisawa, S. Hara, F. Suzuki, K. Ito, H. Fuji, K. Yamada, M. Kawan. Division of Rheumatology, Department of Cardiovascular and Internal Medicine, Kanazawa University hospital, Kanazawa, Kanazawa, Japan

Background: Immunoglobulin G4-related disease (IgG4-RD) is a recently recognized systemic inflammatory disease with multi-organ involvement [1]. Diagnostically, two of the most important hallmarks of IgG4-RD are high IgG4-positive plasma cell (PC) counts and high IgG4/IgG ratios in affected organs. Although the International consensus statement (ICS) on the pathology of IgG4-RD adopted different IgG4-positive PC counts among affected organs for the diagnosis to differentiate IgG4-RD mimickers from IgG4-RD [2], histological and immunohistochemical findings of the specimens from not only one but multiple organs in the same patient has not been evaluated.

Objectives: This study aimed to investigate the diagnostic sensitivity of the cutoff values of IgG4-positive PC number and IgG4-positive/CD138-positive cell ratio proposed by the International consensus statement (ICS) on the pathology of IgG4-RD in typical multiple lesions of patients with IgG4-RD.

Methods: We evaluated IgG4-positive PC number and IgG4-positive/CD138-positive cell ratio in 35 samples from 16 IgG4-RD patients having more than two typical lesions of IgG4-RD.

Results: We evaluated twelve submandibular, eleven ophthalic, four skin, four kidney, two pancreatic, and one bronchus and prostate lesion each in 16 patients with typical clinical, serological, and radiographic features. Concerning IgG4+ PC number per high power field, most ophthalic (8/11), kidney (4/4), pancreatic (2/2) and bronchus (1/1) fulfilled the cutoff value of ICS, whereas many in the submandibular (5/12) and skin lesions (0/4) did not. In contrast to the absolute number, almost all lesions fulfilled the cutoff value of IgG4+CD138+ cell ratio. In five cases, only one or two lesions in the same patient fulfilled the cutoff value of ICS, while the others did not.

Conclusions: These results suggest that ICS criteria have different sensitivities among the affected organs in diagnosing IgG4-RD.

FR0618 ADALUMUMAB IN NON-INFECTIONOUS UVEITIS – EFFICACY ACROSS DIFFERENT ETIOLOGIES IN THE VISUAL I AND VISUAL II TRIALS

P.T. Merrill1, A. Vitali2, M. Zierhut3, E. Forton4, H. Goto5, M. Kron6, S. Tari7, S. Pathai8, 1Rush University Medical Center, Chicago; 2University of Utah, Salt Lake City, United States; 3University of Tuebingen, Center of Ophthalmology, Tuebingen, Germany; 4University of Montreal, Montreal, Canada; 5Tokyo Medical University, Tokyo, Japan; 6AbbVie Deutschland GmbH & Co KG, Ludwigshafen, Germany; 7AbbVie Inc., North Chicago, United States; 8AbbVie Ltd, Maidenhead, United Kingdom

Background: There is increasing interest in understanding the efficacy of adalimumab across different etiologies of uveitis. No prospective analysis has been conducted to date to determine the efficacy of adalimumab among non-infectious uveitis patients with different etiologies.

Objectives: To assess adalimumab (ADA) efficacy in active and inactive, non-infectious uveitis across different etiologies in patients who were recruited as part of the VISUAL program.

Methods: Exploratory data analyses from two global phase 3, double-masked trials: VISUAL I (patients with active uveitis despite ≥ 2 weeks of prednisone 10–60 mg/day) and VISUAL II (patients with inactive disease dependent on 10–35 mg/day of prednisone to maintain inactivity) were performed. Patients received placebo (PBO) or ADA subcutaneously (80 mg week 0, followed by 40 mg every other week from week 1 up to 80 weeks). In VISUAL I, all patients received a prednisone burst followed by taper to 0 mg by week 15. In VISUAL II, prednisone taper to 0 mg was mandatory by week 19. The primary endpoint was time to treatment failure (TF) at or after week 6 for VISUAL I, and at or after week 2 for VISUAL II. For this analysis, patients were categorized into different uveitis etiologies which they presented at study entry. Hazard ratios (HR) for time to TF were obtained for each uveitis etiology.

Results: The efficacy of ADA was significantly greater than PBO in the largest subgroup of patients with idiopathic uveitis (VISUAL I: 103 and VISUAL II: 90) etiology in both VISUAL I and VISUAL II trials. All other subgroups showed similar results.

Figure: Hazard ratios of time to treatment failure by uveitis etiologies.

VISUAL I (A) and VISUAL II (B) clinical trials.
a trend in favor of ADA, except for Sarcoidosis subgroup in the VISUAL II trial (Figure). Overall safety for both trials has been previously reported.2,3

Conclusions: These exploratory analyses from the VISUAL I and VISUAL II trials show significantly higher efficacy in ADA-treated patients over PBO in “idiopathic/other” diagnoses of patients with both active and non-infectious uveitis. Though beyond the aim of the study, these analyses suggest that ADA-treated patients had a prolonged time to treatment failure compared to PBO.

Accomplishments: AbbVie funded the VISUAL I and VISUAL II studies and provided writing support. All authors contributed to the development of the content. The authors reviewed the manuscript and approved the abstract. The authors maintained control over the final content. Medical writing assistance was provided by Gaurav Patki, PhD of AbbVie Inc.

FRI0619 COMPARING CANAKIMUNAB AND ANAKINRA IN YOUNG GREEK WOMEN WITH RESISTANT RECURRENT PERICARDITIS

P. Kiriyttopoulos 1, T. Michailidis 1, E. Papachanou 1, M. Charalampidis 1, P. Dimitriadis 3, A. Agorastos 4, T. Mpektsis 1.

Objectives: We studied 18 patients with RRR (all women, from 14 to 36 years old) determining the existence of mutation from the inference database (25 genes, from MEVF and TNFRSF1A to MVK and SLC29A3, all related with autoimmune diseases). All the patients were proven positive to one of the above mutations (all heterozygous) and then treatment with anakinra (n=9, 100mg sc once daily) and canakinumab (n=9, 150mg sc q4w) was practiced.

Results: During the study (3 years), all anakinra patients stopped receiving per os glucocorticoids and were free of any new pericarditis episodes. 3 of them (33%) stopped any treatment after a year of anakinra therapy and none was presented with any side reactions.

On the contrary, all canakinumab patients were not able to free themselves of the glucocorticoid treatment, since at least one new episode of pericarditis to each patient was recorded. Two of them were free of pericarditis the last year of the study (though being treated with 2.5mg prednisolone per os daily).

Statistically speaking, the use of IL-1R antagonist in recurrent – resistant pericarditis associated with autoimmune mutations was proven much more successful (p<0.01) than the use of the IL-1b Mab.

Conclusions: Though the sample of patients (n=18) was too small in order to set us able to reach any safe conclusions, it is quite possible that anakinra may be one effective solution that can prevent the long term administration of corticoids to patients with recurrent pericarditis Canakinumab was not recorded with similar positive results.

FRI0620 MIR-204-3P INHIBITS THE PRODUCTION OF TLR-RELATED CYTOKINES IN FAMILIAL MEDITERRANEAN FEVER BY TARGETING THE PIK3 SIGNALING PATHWAY

T. Koga 1,2, K. Migita 3, M. Umeda 1, F. Nonaka 1, S.-Y. Kawashiri 1, N. Iwamoto 1, K. Ichinose 1, M. Tamai 1, H. Nakamura 1, T. Oriuchi 1, K. Eguchi 1, A. Kawakami 1, 1Department of Immunology and Rheumatology, Unit of Advanced Preventive Medical Sciences, Nagasaki University Graduate School of Biomedical Sciences; 2Center for Bioinformatics and Molecular Medicine, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki; 3Fukushima Medical University School of Medicine, Fukushima Medical University School of Medicine; 4Department of Internal Medicine, Sasebo City General Hospital; 5Center for Rheumatic Disease, Sasebo Chuo Hospital, Sasebo, Japan

Background: MicroRNAs (miRNAs) are endogenous small RNAs and post-transcriptionally regulate gene expression by pairing with target. There has been emerging evidence showing the association of aberrantly expressed circulating miRNAs in the serum with the pathogenesis or progression of diseases including cancer and autoimmune disease. Although a number of circulating miRNAs associated with inflammation have been identified, the roles of them in patients with FMF and the underlying mechanism remain to be elucidated.

Objectives: The aim of this study was to identify a serum miRNAs profile and potential biomarkers in FMF and clarify their gene targets for understanding the pathogenesis of autoinflammatory diseases.

Methods: We performed miRNA microarray in the serum from FMF in attack and in remission. We subsequently examined the expression of miRNAs that varied before and after the attack in macrophages derived from THP-1 cells stimulated with toll-like receptor (TLR) ligands. Macrophages derived from THP-1 cells transfected with pre-miRNA and anti-miRNA were stimulated with TLR ligands for 24 hours. We collected the supernatants for the quantification of inflammatory cytokine production. To identify the target genes, we overexpressed its miRNA and performed Agilent expression microarray. Transfection with reporter construct and pre-miRNA and anti-miRNA was performed to confirm suppression of target mRNA.

Results: We found that mir-204–3p was greatly decreased in the serum from FMF patients in attack. In vitro study, the expression of mir-204–3p was suppressed by LPS stimulation in macrophages derived from THP-1 cells. Inhibition of mir-204–3p significantly induced the production of TLR4-related cytokines whereas overexpression of mir-204–3p inhibited their production. Bioinformatic analysis showed that mir-204–3p is predicted to target genes implicated in TLR pathway through regulation of PIK3 signaling. Reporter assay revealed that mir-204–3p directly suppressed the luciferase activity of 3’UTR of PIK3CG reporter construct.

Conclusions: These data suggest that serum mir-204–3p has a potential as a useful biomarker among patients with FMF and that mir-204–3p plays a critical role as a suppressor to regulate the production of TLR4 related cytokines by targeting the PIK3 signaling pathway.

FRIO621 PREDILETANCE OF DIFFERENT ORBITAL ANATOMIC STRUCTURES AFFECTATION IN IG44-RELATED OPHTHALMIC DISEASE: SINGLE CENTER EXPERIENCE

V. Vasilyev 1, E. Sokol 1, T. Safonova 1, S. Palshina 1, N. Kokosadze 1, A. Kovrigina 1, 1Nasonova Research Institute of Rheumatology, Moscow, Russia; 2Research Institute of Ophthalmic diseases; 3N.N. Blochin Russian Cancer Research Center; 4Hematology Research Center, Moscow, Russian Federation

Background: According to 2009 Japanese nationwide survey of IgG4-related Tissue Necrotizing Disease (IgG4-RD), orbit is the leading site of affection [1]. However diagnostic criteria and nomenclature of IgG4-RD were developed a few years later [2,3].

Objectives: To evaluate the peculiarities of clinical, laboratory, histological and immunohistochemical presentation of IgG4-related orbital disease (IgG4-ROD).

Methods: During 2004 – 2016, 82 patients were diagnosed with IgG4-RD GS of whom had IgG4-RD (men – 17, women - 66). The diagnoses of IgG4-RD and IgG4-ROD were established using comprehensive diagnostic criteria [2,3]. In all patients full clinical, ophthalmological, dental and serological (rheumatoid factor, C-reactive protein, IgG, IgD, IgM, IgA, ANA, anti-Ro/La, O3/O4 complement) examination was carried. In all cases diagnosis was verified pathomorphologically with immunohistochemical staining (anti-CD 138, CD 68, IgG, IgG4, k-chain, l-chain), but only in 43 patients the diagnosis of IgG4-RD was established on orbital tissues biopsy. Some patients at baseline were tested on B-cell clonality
A RETROSPECTIVE COHORT STUDY ABOUT THE CLINICAL CHARACTERISTICS OF IGG4-RELATED DISEASES

X. Wu, C. Wang, Y. Miao, Y. Huang, L. Dong. Department of Rheumatology and Immunology, Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, China

Background: Immune globulin (Ig) G4-related disease (IgG4-RD) is an increasingly recognized systemic autoimmune disease in the past decade, and encompasses a wide spectrum of disorders previously considered to be unrelated, but with common pathologic, serologic, and clinical features. There have been several hundred literatures on IgG4-RD published in the past few years, however, we still cannot well characterize this complicated disease, including clinical features, treatments as well as mechanisms, which promotues us to further describe this disease.

Objectives: To describe the clinical presentations, laboratory features, imaging manifestations, treatments and evolutions in a cohort of 34 Chinese patients with immune globulin G-related diseases (IgG4-RD).

Methods: A retrospective study was performed in Wuhan Tongji Hospital. Electronically stored records of clinical, laboratory, imaging, and histological features were reviewed. The diagnoses were made according to comprehensive features were reviewed. The diagnoses were made according to comprehensive

Conclusions: In our cohort of IgG4-RD patients orbit is the leading site of the disease (64.5% of patients) and the disease onset (75% of patients). The majority of patients have concomitant orbital lesions (89%) and systemic course of the disease with other organ involvement (72%). Most often affected orbital anatomic structures are lacrimal glands, extraocular muscles, retrobulbar infiltration with optic nerve thickening and fibroinflammatory lesions of eyelids. MALT-lymphoma of lacrimal gland and local AL-amyloidosis can complicate the long history of IgG4-ROD. Monoclonal serum secretion and B-cell clonality in the tissue in 23% of patients can potentially act as a background for lymphoma formation.

DOI: 10.1136/annrheumdis-2017-eular.4283
Methods: Twelve TNFi naïve AS patients (female 7/12; age 39±11 years) with high disease activity (BASDAI 5.5±1.1) were included. [18F]fluoride PET-CT scans were performed before initiation of TNFi therapy. In 2 patients, biopsies were obtained from PET identified spine lesions for histologic analysis. Of the remaining 10 patients, a second [18F]fluoride PET-CT scan was performed after 12 weeks of TNFi treatment. PET scans were scored visually for positivity by two blinded expert readers. Subsequently, [18F]fluoride uptake was quantified in PET positive (PET+) lesions using the standardized uptake value corrected for individual integrated whole blood activity concentrations (SUVAUC). Clinical response to TNFi was defined according to ASAS20 at 24 weeks.

Results: At baseline, in all patients at least one axial PET− lesion was found. In spine, 6/10 patients showed 84 lesions (range 2.30-63% thoracic spine, primarily costovertebral joints) and in the SI joints in 9/10 patients were PET+ (Fig A). Histological analysis of PET+ lesions in the spine confirmed local osteolysis and sometimes synovitis was present in PET− degenerative lesions. Quantitative PET analysis revealed significantly lower [18F]fluoride uptake in spine lesions at baseline in responders than in non-responders. This difference remained after 12 weeks of treatment (mean difference in SUVAUC: -0.5, 95% CI [-0.7,-0.2], p<0.001). After 12 weeks of TNFi treatment, [18F]fluoride uptake in clinical responders decreased significantly in the costovertebral (mean difference SUVAUC: -1.0, 95% CI [-1.3,-0.7]) and SI joints (mean difference in SUVAUC: -1.2, 95% CI: [-2.3,-0.2]) (fig B) in contrast to non-responders (mean difference in SUVAUC: -0.4, 95% CI: [-2.3,1.6]) and +0.4, 95% CI: [0.6, 1.4], respectively).

[18F]fluoride uptake in other spinal lesions such as bridging syndesmophytes showed heterogeneous response without a significant decrease in [18F]fluoride accumulation over time at a group level.

Conclusions: [18F]fluoride PET-CT enables non-invasive visualization of (changes in) lesions with bone formation of the whole spine and SI joints in clinically active AS patients, which is confirmed by histological signs of osteolysis formation. Part of these lesions, in particular costovertebral lesions in spine and SI joints, decreased in clinical responders to TNFi (and not in non-responders), whereas other spinal lesions remained unchanged at a group level.

FRIO0625 IMPROVEMENT OF JOINT INFLAMMATION AS ASSESSED BY MRI AND POWER DOPPLER ULTRASOUND (PDUS) IN AN OPEN LABEL STUDY IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS TREATED WITH SECUKINUMAB (PSARTROS)

E. Kampylafka, I. D’Oliveira, C. Linz, V. Lerchen, M. Englbrecht, A. Kleyer, J. Rech, G. Schett, A.J. Hueber. Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Ulmenweg 18, 91054 Erlangen, Germany, Erlangen, Germany

Background: Secukinumab, an anti-interleukin 17A monoclonal antibody, showed significant improvement of signs and symptoms of psoriatic arthritis (PsA) in FUTURE 1 study. Available studies used conventional radiography, not allowing a deeper imaging analysis of the inflammatory changes during application.

Objectives: To assess short term efficacy of secukinumab on inflammation and structural damage according to change in OMERACT-EULAR ultrasound score and the MRI PsAMRIS score in PsA patients.

Methods: PsA patients with active disease (TJC and SJC ≥ 6), were included in the 24 week open label prospective PSARTROS study and treated with subcutaneous secukinumab 300 mg once weekly over 4 weeks, then once every 4 weeks. Baseline 1.5T MRI hand scans and ultrasound imaging of 28 joints were performed at baseline and after 24 weeks of treatment. MRI was scored according to PsAMRIS, ultrasound for synovial hypertrophy and Doppler activity according to OMERACT scores. Statistical significance was set at p<0.05.

Results: 20 patients, mean age 52±9.9 years, 60% female, mean disease duration 6.7±5.9 years, 50% naïve for biological therapy, were included in the study. Three patients were early discontinued (recurrent pharyngitis, lack of efficacy, withdrawal of consent), and were not included into the longitudinal analysis. Baseline DAS28 was 5.0±2.96, baseline DAPSA was 32±12.1. On baseline MRI, all patients had at least one inflammatory sign (synovitis: 90%, osteitis: 20%, periaricular inflammation: 25%, flexor tenosynovitis: 35%, bone proliferation: 30%, erosions: 60%). Baseline composite PsAMRIS score showed a more severe phenotype when compared to antiDNA-negative patients (p from 0.026 to 0.041) and did not differ significantly from patients with MS. When regional hubs were analysed, patients with SLE and MS showed a reduced strength compared to HC (p from <0.0001 to 0.001 at multiple comparison). Hub strength impairment was more pronounced in MS when compared to SLE and preferentially involved hubs located in fronto-temporo-parieto-occipital cortices, subcortical nuclei (including the thalamus, caudate nucleus and putamen) and cerebellum (p from 0.001 to 0.05 at multiple comparison). No significant associations were found between global structural parameters, clinical diagnosis of neuropsychiatric SLE, other SLE sub-phenotypes, presence of antiphospholipid antibodies, antiphospholipid syndrome and SLE-related damage burden.

Conclusions: Structural alterations of global and regional brain connectivity occur in patients with SLE, irrespectively of the clinical phenotype. AntiDNA-positive patients are characterized by a more severe phenotype, which is similar to that of patients with relapsing-remitting MS.

FRIO0624 STRUCTURAL MRI-BASED CONNECTOMICS IN SLE: A PILOT STUDY

G.A. Ramirez 1,2, E.P. Bozzolo 1, P. Preziosa 2, M.A. Roca 2, L. Miola 2, L.A. Coletto 2, E. Tombetti 1,2, P. Rovere-Querini 1,2, M. Filippi 2,3, A.A. Manfredi 1,2.

1Unit of Allergy, Immunology, Rheumatology and Rare Diseases, IRCCS Ospedale San Raffaele; 2Università Vita-Salute San Raffaele; 3Institute of Experimental Neurology and Unit of Neurology, IRCCS Ospedale San Raffaele, Milano, Italy

Background: Neuropsychiatric manifestations are common in patients with systemic lupus erythematosus (SLE). Furthermore, subclinical brain damage occurs in a even higher fraction of patients. However, little is known about the effect of these phenomena on brain connectivity. MRI-based connectomics relies on graph analysis of structural and functional images to detect alterations of the topographic organization of the brain and has been successfully employed to dissect network disassembly in neuroinflammatory diseases such as multiple sclerosis (MS) and Devic’s syndrome.

Objectives: To investigate the topographic organization of the brain of patients with SLE with and without neuropsychiatric manifestations.

Methods: Thirty-two patients with SLE (12 with overt neuropsychiatric involvement as per ACR criteria) were enrolled and compared with 32 healthy controls (HC) and 32 patients with relapsing-remitting MS, all matched for sex, age and disease duration (where applicable). Diffusion tensor (DT) and dual-echo MRI scans were obtained. Structural connectivity matrices between 116 cortical and subcortical brain regions were estimated and global and nodal network metrics were calculated.

Results: Conventional MRI revealed that patients with SLE had significantly higher T2-lesional volumes when compared to controls (p<0.0001). Patients with definite NPSLE had a higher lesion burden (p<0.0006). Network strength, transitivity and global efficiency were all significantly impaired in patients with MS and SLE when compared to HC (p<0.0001). MS and SLE were also characterized by higher average path length when compared to HC (p<0.0001). Global structural alterations were more significant in MS patients than in patients with SLE (p from 0.005 to 0.01 at multiple comparison). However, antiDNA-positive patients (n=24)
was 11.6±12.8 and baseline PsAMRIS synovitis score was 3.7±3.3. Baseline ultrasound synovial hypertrophy and Doppler activity were 6.2±4.5 and 3.5±4.0, respectively. Specific MRI and ultrasound scores were significantly correlated with DAS28 and DAPSA at baseline. Clinical disease activity parameters significantly improved at follow up (DAS28: 2.9±4.05, p<0.001; DAPSA: 8.8±5.8, p<0.001). PsAMRIS synovitis score (r=0.24) as well as composite PsAMRIS score (r=0.810.0) decreased longitudinally with secukinumab treatment (p=0.034 and p=0.039, respectively). There was no progression in erosion or proliferation scores between baseline and follow-up. Synovial hypertrophy and Doppler activity in ultrasound also significantly improved with secukinumab treatment (2.3±3.5; p<0.009 and 1.8±2.7; p=0.003, respectively). A significant percentage of patients reaching minimal disease activity showed residual signs of synovitis in the MRI and US (66% and 50%, respectively).

Conclusions: Secukinumab significantly improves MRI and ultrasound signs of joint inflammation in patients with PsA.

FRIO627 | ULTRASOUND HAND EXAMINATION IS MORE SENSITIVE IN DIAGNOSING HAND OSTEOARTHRITIS THAN CONVENTIONAL RADIOGRAPHY: COMPARISON BETWEEN DIFFERENT ULTRASONOGRAPHIC SCORES

S. Hussain1,2, P. Sikavukamaran1,2, C. Ciurtin1, 1University College London Medical School; 2Department of Rheumatology, University London College Hospitals NHS Foundation Trust, London, United Kingdom

Background: Hand osteoarthritis (OA) diagnosis is based on a combination of clinical, imaging features and assessment of risk factors, together with clinical associations and outcomes (1). In a real-life context, clinicians face difficulty in differentiating between OA and other hand arthropathies, particularly when the clinical examination is equivocal (e.g. no obvious bony enlargement with the characteristic distribution for hand OA).

Objectives: This is the first study to investigate the usefulness of a standardised ultrasound (US) examination protocol for hand joints in diagnosing hand osteoarthritis (OA) and the correlations between several US scores and clinical, inflammatory and radiographic parameters, aiming to explore which type of investigations are the most useful for diagnosing hand OA.

Methods: We conducted a cross-sectional study including 62 patients, ultimately diagnosed with hand OA based on the ACR diagnosis criteria (2). We compared the 34 joint score of the hand, with smaller, pre-defined joint scores including two scores of 22 and 12 joint each, and another 10 and 6 joint scores for OA. We correlated the US findings with radiographic scores (2108 joints).

Results: Radiographic osteophyte scores correlated very well with the predefined US scores detailed above (R=0.381 to 0.645, P<0.05), despite having a low sensitivity for detection of osteophytes (58.6%), and an even lower sensitivity for detection of erosions (38.4%) when compared with the 34 joint US score. There was a good correlation between different US scores (R=0.53 to 0.97, P<0.05), apart from the 6 joint score excluding the proximal interphalangeal joints (R= -0.01 to 0.207, P<0.05).

Conclusions: US examination of the hands can facilitate the diagnosis of hand OA in patients who do not fulfil the ACR criteria, by identifying the presence of osteophytes with the particular distribution and number required for diagnosis in a proportion of patients that was three times higher than that of patients diagnosed based on clinical examination and hand radiography alone.

FRIO626 | ANALYSIS OF CORRELATION AND CAUSES FOR DISCREPANCY BETWEEN QUANTITATIVE AND SEMI-QUANTITATIVE DOPPLER SCORES IN SYNOVITIS IN RHEUMATOID ARTHRITIS

1Unit of Clinical Pharmacology, Department of Medicine, Karolinska University Hospital, Stockholm, Sweden; 2Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; 3Center for Rheumatology and Spine Disease, Rigshospitalet, Copenhagen, Denmark; 4Rheumatology, APHü, Hôpital Ambroise Paré, Saint-Quentin en Yvelines, Paris, France; 5Unit of Clinical Pharmacology, Department of Medicine, Karolinska Institutet, Stockholm, Sweden

Background: Doppler US is used for the evaluation of synovitis in RA. The amount of Doppler signals are measured in the synovial tissue according to either semi-quantitative (SQS) or quantitative scoring (QS) methods. None of the SQS amount of Doppler signals are measured in the synovial tissue according to either SQS method. Association between QS and SQS was studied using correlations and multilevel models taking into account the clustering of ratings at the rater, patient and joint levels.

Methods: Adult patients with RA and inadequate clinical response to anti-rheumatic therapy were examined with US. Dorsal US of the wrists, MCP and MTP 2–5 were performed. US images with sign of synovitis were collected and US scores detailed above (R=0.381 to 0.645, P<0.05), despite having a low sensitivity for detection of osteophytes (58.6%), and an even lower sensitivity for detection of erosions (38.4%) when compared with the 34 joint US score. There was a good correlation between different US scores (R=0.53 to 0.97, P<0.05), apart from the 6 joint score excluding the proximal interphalangeal joints (R= -0.01 to 0.207, P<0.05).

Results: Radiographic osteophyte scores correlated very well with the predefined US scores detailed above (R=0.381 to 0.645, P<0.05), despite having a low sensitivity for detection of osteophytes (58.6%), and an even lower sensitivity for detection of erosions (38.4%) when compared with the 34 joint US score. There was a good correlation between different US scores (R=0.53 to 0.97, P<0.05), apart from the 6 joint score excluding the proximal interphalangeal joints (R= -0.01 to 0.207, P<0.05).

Conclusions: US examination of the hands can facilitate the diagnosis of hand OA in patients who do not fulfil the ACR criteria, by identifying the presence of osteophytes with the particular distribution and number required for diagnosis in a proportion of patients that was three times higher than that of patients diagnosed based on clinical examination and hand radiography alone.

FRIO628 | ULTRASOUND SHOWS SIGNS OF INFLAMMATION IN MOST PATIENTS WITH RHEUMATOID ARTHRITIS IN LONGSTANDING CLINICAL REMISSION, IRRESPECTIVE OF CONVENTIONAL SYNTHETIC OR BIOLOGIC DMARD THERAPY

U. Møller Døhn, C.H. Brahe, M.L. Hetland, V. Fana, S. Krabbe, M. Ammitzbøll-Danielsen, M. Østergaard, L. Terslev, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark

Background: None of the currently accepted remission criteria in rheumatoid arthritis (RA) incorporate inflammation on imaging. Signs of inflammation on ultrasound (US) and magnetic resonance imaging are frequently seen in RA patients in clinical remission (1–3). It is not known whether patients in longstanding clinical and radiographic remission obtained through a DAS28 driven treat to target (T2T) strategy by conventional synthetic disease modifying anti-rheumatic drugs (csDMARD) or by biologic (bDMARD) therapy differ with respect to US detected synovitis.

*Cut-off between grade 0 (G0) and G1: 0%; between G1 and G2: 10%; between G2 and G3: 50%.
**OBJECTIVES:** In RA patients in longstanding clinical and radiographic remission, achieved by a DAS28-driven T2 strategy, to investigate if US signs of inflammation differ between RA patients, treated with csDMARD or bDMARD (+/- csDMARD).

**METHODS:** Eighty-seven patients with RA in longstanding clinical (continuous DAS28 >2.6 for the preceding year) and radiographic (no progression for at least 1 year) remission, were included in the study. US of elbows, wrists, MCP joints, knees, ankles and MP joints were performed. Inter-reader agreement was assessed in a random subset of 42 cases using the intra-class correlation coefficient (ICC). Proportion of patients with any sign of MRI inflammation was noted. Mann-Whitney U test was used to compare intra-class correlation coefficients (ICC) of psA and PsO patients. Clinical variables were compared with inflammation scores for any association.

**RESULTS:** Of the 87 patients fulfilling DAS28 remission criteria at entry and CDAI remission was fulfilled in 76% and 79% in the csDMARD and bDMARD group, respectively. Complete absence of any sign of US inflammation (GSS=0 and CDAI=0) was seen in 0% and 14% in the csDMARD and bDMARD groups, respectively (p<0.01), while minimal US inflammation (GSS≤1 and CDAI=0) was seen in 33% and 40% (NS). CDAI in at least one joint was seen in the majority of patients in both groups, 58% and 57% respectively.

**CONCLUSIONS:** This study corroborates a high proportion of psoriasis patients with subclinical disease of the small joints of foot. Patients with nail involvement had a higher risk of subclinical disease. The cohort is being assessed longitudinally to determine the clinical utility of MRI feet in predicting subsequent development of PsA in patients with psoriasis.

**FR00630 CAN WHOLE BODY MRI AT BASELINE IDENTIFY DEFINITE INFLAMMATORY ARTHRITIS PATTERNS IN UNDIFFERENTIATED ARTHRITIS?**

J.E. Freeston1,2, K.S. Manka1, M.A. D’Agostino1,3, R. Hodgson2, A. Grainger2,4, I. Matsuura1, N. Larkman4, P.G. Conaghan1, P. Emery1,1

1LIRMM, University of L’Arié; 2NIHR Leeds Musculoskeletal Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 3Université Versailles Saint Quentin en Yvelines, AP-HP Ambroise Paré, Boulogne, France; 4Radiology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

**Background:** When diagnosing inflammatory arthritis (IA) early, focal joint imaging may not reflect the overall inflammatory burden/distribution. Whole body MRI (WBMRI) offers the potential to feasibly scan most joints in a single session.

**OBJECTIVES:** The aims were (i) to describe the WBMRI pattern of disease in early IA (ii) to identify patterns associated with subsequent definite IA.

**METHODS:** Patients were recruited with early inflammatory joint symptoms and/or signs of IA. Clinical data included age, gender, symptom duration, CRP HLA-B27, RF, CCP Ab and tender/swollen joint counts. Using 3T WBMRI, T2-weighted fat suppressed spine/SIJ images pre contrast and 3D VIBE Dixon images of peripheral joints and entheses post IV contrast were acquired. Images were consensus scored for inflammation/erosion at the spine, SIJ, GHJ, SCJ, wrist, MCP,PIP, hip, knee, ankle, mid/ hind foot, MTP and IP joints plus shoulder, ASIS, greater trochanter, knee, Achilles and plantar fascia entheses. Subjects were clinically classified as IA baseline and 1 year as undifferentiated arthritis (UA), CCP+RA, CCP-RA or Spondyloarthritis (SpA). Clinicians were unaware of the MRI findings.

**RESULTS:** 39 patients (23 female) were recruited; mean age 43 years, median symptom duration 18 months (7, 24), TJC 5 (2.1), SJC 1 (0.3) and CRP 2 (2.2). At baseline, 14 were classified as definite disease (RA or SpA) and 25 (14 female) as UA with mean age 40 years, median symptom duration 16.5 months (9.8, 24.3), TJC 3 (1.8), SJC 0 (0.1), CRP 2 (2.2) and 3 (12%) were HLA-B27 positive. The distribution of WBMRI findings in the classified (i.e. definite IA) group was predominately small joint and tendon-based in the CCP+ RA group, large joint based with 50% having SIJ disease in the CCP- group and similar findings in the SpA group. In the non-classified group (i.e. pUA and rUA), the distribution of pUA was both axial and peripheral, involving joints and entheses, with 25% having SIJ disease, compared to 12% in the rUA group were similarly distributed but less frequent with no cases of SIJ disease. After 1 year of clinical/laboratory follow-up, 8 were identified as pUA, 6 rUA, 7 CCP-RA, 6 CCP-RA and 12 as SpA. Table 1 shows WBMRI disease distribution by 1 year diagnostic category. All the affected WBMRI sites in the diagnostic work-up would have appropriately classified 6 further cases of definite SpA, from the pUA and 3 from the CCP-RA groups.

**FR00629 MAGNETIC RESONANCE IMAGING (MRI) INFLAMMATION OF THE FEET DEMONSTRATES SUBCLINICAL INFLAMMATORY DISEASE IN CUTANEOUS PSORIASIS PATIENTS WITHOUT CLINICAL ARTHRITIS**

A.J. Mathew1, P. Bird2, A. Guddu2, R.E. George3, D. Danda1

1Clinical Immunology & Rheumatology, Christian Medical College, Vellore, India; 2University of New South Wales, Sydney, Australia; 3Dermatology, Christian Medical College, Vellore, India

**Background:** Up to 40% of patients with cutaneous psoriasis may develop psoriatic arthritis (PsA). Early detection of PsA by advanced imaging techniques results in better response to therapy. There are very few studies evaluating the MRI findings in feet of patients with psoriasis and PsA. The study was divided into those without arthritis (PsO) and PsA groups. All consenting patients underwent non-contrast MRI of the right foot. Demographic and physical examination details were recorded. PsO patients completed the early arthritis in psoriasis (EARP) questionnaire. Two trained readers scored the MRI inflammation (synovitis, tenosynovitis, enthesitis) using a modification of the PsAMRIS scores (PsAMRIS).

**Objectives:** This study sought to evaluate inflammation at the smallest joints of feet in a subset of psoriasis patients without clinical arthritis, using an office-based extremity MRI (eMRI) as compared to the findings in overt PsA patients. The inclusion of affected WBMRI sites in the diagnostic work-up would have appropriately classified 6 further cases of definite SpA, from the pUA and 3 from the CCP-RA groups.

**Results:** A total of 83 patients (30 PsO and 53 PsA) with 75% males and mean age of 42.2±11.6 years were included. ICC for all three variables between the readers was very good (>0.8). There was no statistical difference between the median eMRI inflammatory scores in PsA and PsO patients (p=0.493). Evidence of inflammation was present in 64% and 67% patients in the PsO and PsA groups, respectively (Table 1). Higher NAPSI scores were associated with presence of MRI inflammation (p=0.022).

Conclusions: In the persistent UA group and CCP-RA group, WBMRI findings at baseline already showed a definite pattern of spinal disease. Therefore the use of WBMRI findings at presentation in addition to clinical assessment would allow clinicians to classify a proportion of patients earlier.

**PREDICTIVE VALUE OF POWER DOPPLER ULTRASONOGRAPHY (PDUS) IN THE DIAGNOSIS OF EARLY RHEUMATOID ARTHRITIS**

L. Mayordomo1, C. Jurado2, M.L. Velloso1, A. Gutierrez-Leenlard3, P. Gonzalez-Moreno4, J.L. Marencio1, C. Almeida5, L. Hervás-Asensi1,2, I. Sanza1,2, M. Pujol1,2, A. Fischetti6, V. Tomatis1, S. Paolino4, M. Cutolo4, G. Garlaschi7, M.A. Cimmino1,1, Dipartimento di Medicina Interna, Clinica Reumatologica; 2Sezione di Radiologia; 3Università di Genova; 4Clinica Reumatologica, Genova, Italy

Background: There is a short window of opportunity for early diagnosis and treatment of rheumatoid arthritis, that may be crucial for reaching remission and a low rate of radiographic progression. High resolution power doppler ultrasonography (PDUS) is helpful in early detection of synovitis and allows an accurate classification of patients with joint inflammation.

Objectives: To establish whether the presence of basal power doppler signal in patients with very early arthritis may be helpful in order to establish the risk of final diagnosis of rheumatoid arthritis according ACR criteria 1987 at a year of follow up.

Methods: We studied the presence of ultrasonographic Power Doppler (PD) signal on 28 joints (shoulders, elbows, wrists, MCPs, PIPs, knees) and 44 joints (28 joints and in addition hips, ankles, tarsus, and MTPs), with a mid-range equipment GE L5, in 70 patients with suspected early arthritis. The patients were included with at least one of the following inclusion criteria: a) Swelling in 2 or more joints b) pain in MCPs, MTPs and/or the wrists c) morning stiffness of more than 30 minutes with < 12 months of duration of the symptoms. Presence or not basal erosions (score ≥ 5 in at least one joint by modified Sharp method) for each patient were registered (65 patients with basal hands and feet radiology available). Presence of RF and ACPA positive were recorded as well. At one year follow-up was established whether patients met criteria for RA according 1987 ACR or not. Statistical study: Chi-square, Fisher exact test, p univariant and Odds Ratio calculation.

Results: The presence of basal power doppler signal in ≥ 1 joints of 44 (PD44) in baseline view shows statistically significant association to RA diagnosis at 12 months by ACR 1987 classification criteria, p<0.003, OR=5.43 (1.71–17.24) but the presence of at least one joint with power doppler signal of 28 joints (PD28) did not (p=0.051). Presence hypertrophic synovium with PD44 or not, in at least one joint (HSORPD44) was associated to RA diagnosis as well p=0.024; OR=24.20 (2.98–196.34) and p=0.003 OR 12.93 (1.59–104.94). There was a correlation between DAS28 and the MRI synovitis score (r=0.59, p=0.04), REE (r=0.60, p=0.04) and RE (r=0.58, p=0.05), US Doppler in the long axis (r=0.60, p=0.04), but not with RAMRIS synovitis, erosions or BME nor with REE. The MRI wrist synovitis score did not correlate with the Doppler score on the sagittal and axial views, nor with US B mode score. This was true also for the three individual MRI joints slices of the wrist, the REE and the RE. The figure shows from the left the pre-contrast axial MRI image, the post-contrast and the fusion images.

Conclusions: Although both MRI and Doppler are good indicators of disease activity in RA, they seem not to be interchangeable. This may be due to the fact that MRI and US show different features of synovitis or, alternatively, that MRI comprised the whole wrist whereas US visualized only its dorsal area. Although our preliminary data do not support the use of fusion images, these should be investigated on larger number of patients with a more extended PD approach.

**MRI-US FUSION IMAGES FOR RHEUMATOID ARTHRITIS: CAN Doppler SUBSTITUTE FOR GADOLINIUM?**

F. Barbieri1, A. Muda2, S. Migone2, V. Prono2, I. Mussetto2, N. Romano2, A. Fischetti3, V. Tomatis1, S. Paolino4, M. Cutolo4, G. Garlaschi7, M.A. Cimmino1, Dipartimento di Medicina Interna, Clinica Reumatologica; 2Sezione di Radiologia; 3Università di Genova; 4Clinica Reumatologica, Genova, Italy

Background: MRI is increasingly used to objectively assess disease activity and damage in patients with rheumatoid arthritis (RA), especially in clinical trials. The preferred scoring method is the RAMRIS, which implies the use of gadolinium, an intravenous contrast agent, to assess synovitis.

Objectives: We evaluated in a small preliminary study if the fusion of MRI and US Power Doppler (PD) images could avoid gadolinium.

Methods: In 12 patients (10 women) affected by at least one involved wrist, were studied. Mean age was 58.8±9.1 years and mean disease duration was 54.5±56.1 months. Disease activity (DAS28-CRP) was evaluated on the day of the examinations.

MRI was performed on a 3.0 T extremity-dedicated machine (Osc an 0.3 T, Esaote, Genova Italy) and US by MyLab Twice ultrasound scanner with a virtual navigator software (Esaote, Genova, Italy). T3D sequences were used in the fusion images (parameters: TR/TE/NEX 38/16/1 matrix, 192*192*39, FOV 160°/160°). Magnetic field strength was 12.7 GHz and magnetic field gradient was 0.4 MHz. Gadolinium contrast agent was not used to acquire fusion images. MRI synovitis was scored by the RAMRIS and with the contrast-enhanced dynamic method resulting in rate of early enhancement (REE) and relative enhancement, (RE) The US score was the Global OMERACT-EULAR Synovitis Score (GLOESS) and its individual parts.

Results: Inter-reader agreement for PD by weighted kappa was 0.75 (75%CI 0.53–0.96) for the sagittal and 1 (75%CI 1–1) for the axial view. It was 0.85 (75%CI 0.69–0.98) for MRI synovitis.

There was a correlation between DAS28 and the MRI synovitis score (r=0.59, p<0.04), REE (r=0.60, p<0.04), and RE (r=0.58, p<0.05). US Doppler in the long axis (r=0.6, p<0.05) and in the axial axes (r=0.86, p<0.01), but not with B-mode synovial effusion (r=0.56, p=0.056). The GLOESS correlated with DAS28 (r=0.66, p<0.019), but not with RAMRIS synovitis, erosions or BME nor with RE.

The MRI wrist synovitis score did not correlate with the Doppler score on the sagittal and axial views, nor with US B mode score. This was true also for the three individual MRI joint slices of the wrist, the REE and the RE. The figure shows from the left the pre-contrast axial MRI image, the post-contrast and the fusion images.

Conclusions: Although both MRI and Doppler are good indicators of disease activity in RA, they seem not to be interchangeable. This may be due to the fact that MRI and US show different features of synovitis or, alternatively, that MRI comprised the whole wrist whereas US visualized only its dorsal area. Although our preliminary data do not support the use of fusion images, these should be investigated on larger number of patients with a more extended PD approach.

**WHICH ARE THE ULTRASOUND LESIONS UNDERLYING DACTYLITIS?**

A. Nzeusseu Toukap1,2, T. Kirchgesner3, F. Lecouvret1,3, P. Navarro2, B. Vande Berg1,3, A. Durmez2, M.S. Stoenioiu1,2, 1Institut de Recherche Expérimentale et Clinique (IREC), Université catholique de Louvain; 2Rheumatology department; 3Radiology department, Cliniques Universitaires Saint-Luc, Brussels, Belgium

Background: Dactylitis, defined as a diffuse swelling of a digit is a hallmark feature of peripheral spondyloarthritis (SpA), particularly in psoriatic arthritis, with a prevalence between 16% and 18%.

Objectives: This study aims to assess the frequency of the pathological lesions in dactylitis using ultrasonography (US) and to evaluate their association with patient-reported tenderness.

Methods: Thirty-four dactylitis from 20 consecutive patients suffering from peripheral spondyloarthropathy were examined by ultrasound. At US examination, the entire digit was scanned both on dorsal and palmar/plantar sides. The following US pathological lesions were scored: soft tissue thickness, soft tissue edema, soft tissue vascularity, synovitis of metatarsophalangeal (MCP)/metatarsophalangeal (MTP), of proximal interphalangeal (PIP) and of...
DO ANTHROPOMETRIC FACTORS INFLUENCE MEDIAN NERVE SIZE IN HEALTHY INDIVIDUALS? AN ULTRASOUND VOLUMETRY STUDY

Background: Some (but not all) ultrasound studies of median nerve dimensions at the wrist have suggested that anthropometric factors such as height and weight are among the possible sources of variability in the normal population but this has not been systematically studied.

Objectives: The purpose of our study was to establish if hand and wrist volume or other standard anthropomorphic factors influenced median nerve size in normal subjects using standard ultrasonographic techniques. If median nerve size is predictably related to anthropomorphic factors, adjusted normal reference ranges would improve the diagnostic precision of the test for carpal tunnel syndrome.

Methods: We studied 30 healthy subjects: 14 females and 16 males. We measured their height, weight, arm span, finger span and wrist circumference.

Ultrasoundography of the median nerve was carried out at the entrance to the carpal tunnel and at a second level 2 cm proximal to the wrist using an Esaote MyLab Class C ultrasound with a 12–18MHz linear probe. The wrist was marked at the distal wrist crease and 2cm proximally. Hand and wrist volume were measured using water displacement volumetry.

Results: The intra-rater reliability of volumetry measurements was excellent for both hand and wrist volumetry with a Cronbach alpha of 0.99 and 0.88 respectively. The intra-rater reliability for median nerve measurements was excellent with a Cronbach alpha of 0.96. The median nerve dimensions were not significantly different between male and female subjects, nor between the dominant and non-dominant hands. The mean median nerve cross sectional area (CSA) at the distal wrist crease was 10.68 mm² and at a point 2cm proximal to this it was 10.18 mm². The mean difference in CSA between these two points was 0.5 mm². The median nerve CSA was not significantly related to height, weight or hand size. It was not correlated with hand or wrist volume. No significant differences were found in relation to hand dominance or gender.

Spearman’s correlation between median nerve CSA (distal, right wrist) and anthropometric factors were assessed according to OMERACT scores (0–3). Nail bed vascularization architecture, dilatation of capillaries, presence of megacapillaries and avascular areas were found to be closely related to median nerve size in normal individuals.

endothelial dysfunction in systemic lupus erythematosus – a case-control study and an updated meta-analysis and meta-regression

A. Mak 1, N.Y. Kow 1, H. Schwarz 1, L.L. Gong 3, S.H. Tay 1, L.H. Ling 1. 1Medicine; 2Physiology; 3Cardiology, National University of Singapore, Singapore, Singapore

Background: Endothelium-dependent flow-mediated dilation (ED-FMD), a biological marker of endothelial dysfunction, is apparently impaired in patients with systemic lupus erythematosus (SLE). However, such observation is inconsistent because of the lack of standardization of the methodology of ED-FMD measurement and inclusion of patients with different comorbidities amongst different studies.

Objective: Firstly, we evaluated if ED-FMD is indeed impaired in SLE patients naïve of cardiovascular disease and its traditional risk factors. Secondly, we aimed to determine if the putative contribution of SLE to endothelial dysfunction is in fact confounded by demographic-, disease- and treatment-related factors.

Methods: We assessed and compared the brachial artery ED-FMD (baED-FMD) using the Prosound Alpha-10 ultrasound system® between SLE patients without cardiovascular disease and cardiovascular risk factors and healthy controls (HC) matched for age, gender and body mass index (BMI). Exclusions were pregnancy, a history hypertension, diabetes mellitus, chronic kidney disease, cardiovascular and cerebrovascular diseases, and statin therapy. SLE-related disease activity and organ damage are not apparently related to endothelial dysfunction, the presence of diabetes mellitus, renal disease and diastolic hypertension are potential contributors to endothelial dysfunction in SLE patients.

ENDOTHELIAL DYSFUNCTION IN SYSTEMIC LUPUS ERYSITEMATOSUS – A CASE-CONTROL STUDY AND AN UPDATED META-ANALYSIS AND META-REGRESSION

A. Adinolfi 1, V. Picerno 1, A. Scancu 2, C. Toscano 1, C.A. Sciri 1, G. Carrara 1, B. Frediani 1, A. Iagnocco 5, N. Damjanov 6, L. Punzi 2, G. Filippou 1. 1University of Siena, Siena; 2University of Padova, Padova; 3University of Ferrara, Ferrara; 4SIR-Epidemiology Unit, Milan; 5University of Turin, Turin, Italy; 6University of Belgrade, Belgrade, Serbia

Background: Ultrasoundography (US) has demonstrated to be an accurate tool for the diagnosis of calcium pyrophosphate deposition disease (CPPD) (1). Recently, the OMERACT “US in CPPD” task force, has created new definitions for CPPD identification by US, that demonstrated to be reliable at the knee joint, bridging a gap affecting the old definitions (2). The aim of this study was to evaluate the association between US, for the first time the new OMERACT US criteria for CPPD, and SFA findings for identifying patients affected by CPPD.

Objective: The aim of this study was to evaluate the association between US, for the first time the new OMERACT US criteria for CPPD, and SFA findings for identifying patients affected by CPPD.

Methods: We enrolled all the consecutive patients, aged more than 60 years referred to our outpatient clinic from September 2016 to December 2018, for knee pain and that presented knee effusion of any grade. Patients with suspected chronic inflammatory conditions were excluded.

Results: Seventy-one SLE patients and 71 HC were studied, and there were 6 men in each group. The mean±SD age and BMI of SLE patients and HC were 70.29±10.93. Subsequently, a US-guided arthrocentesis was performed, and the synovial fluid was collected and analyzed by a compensated polarized light microscopy (AxioLab A.1 [Zeiss]) by an expert observer in order to assess the presence of CPP crystals. Both observers were blinded to clinical and to each other findings. The Chi-squared test was used to correlate the US and SFA findings.

Results: Forty-nine patients (28 men and 21 women) were enrolled in the study, with a mean age of 70.29±10.93. Twenty-eight subjects were affected by CPPD at SFA and 26 patients were affected by CPPD at SFA and 26 patients...
were identified as affected by CPPD at US. In 4 patients, the SFA was positive and the US was negative, while in 2 patients the SFA was negative and the US positive. Using the chi-squared test, a very strong association was found between the exams, with a p-value <0.0001.

**Conclusions:** The new OMERACT US criteria for CPPD identification have already demonstrated to be reliable, considering the good to high kappa values yielded in previous multi-observer studies (2). This preliminary study, indicates that the new criteria seem to be also accurate for diagnostic purposes as they strongly correlate with the SFA for the presence of CPPD in knee joints. Further validation studies that will be able to assess the diagnostic accuracy of US are already in the research agenda of the OMERACT group “US in CPPD”.

**FR00639 COMPARISON OF ULTRASOUND AND MRI IN THE DIAGNOSIS OF PROXIMAL AND DISTAL BICEPS TENDON PATHOLOGY**

D. Huguet, C. Darrieutort-Laffite, B. Le Goff, Hopital Hotel Dieu Et Hme, Nantes Cedex 1, France

**Background:** Disorders of the long head of the biceps brachii tendon (LHBt) are commonly recognized as a source of shoulder pain. Ultrasound (US) is thought to be of limited value in the diagnosis of partial-thickness tear and non-tear abnormalities of the LHBt because of the difficulty to assess its intra-articular proximal portion. Braesseur recently described that placing the arm in extension/external rotation increased LHBt intra-articular portion visibility.

**Objectives:** The goal of this study was to determine if the systematic assessment of the intra-articular portion of the tendon, from the rotator interval to its glenoid insertion, with the arm placed in extension/external rotation could increase US sensitivity.

**Methods:** This was a cross-sectional study. All patients referred for the treatment of a rotator cuff disease (rupture, tendinopathy, calcific deposit) with an available US and MRI were included. US was performed blinded from the results of the clinical examination. LHBt was studied at the proximal, intra-articular part of the tendon remains challenging. MRI sensitivity to transdermal NSAID and a RR of 2.26 compared with oral NSAD treatment (P=0.001 and P=0.01, respectively). The only independent factor that demonstrated a 100% success treatment rate was the presence of power Doppler signal treated using steroid injection.

**Conclusions:** US findings are useful predictors of therapeutic response in patients with trochanteric pain. In general terms, we found that patients with US acute findings have an increased probability of treatment success when treated with steroid injection while those with US chronic findings have an increased probability of success when treated with NSAIDs (transdermal or systemic).

**FR00640 STRUCTURAL DAMAGE PROGRESSION IN LUPUS ARTHRITIS: A PROSPECTIVE OBSERVATIONAL STUDY**

C. Tan2, A. Delle Sedie1, D. D’Anello2, C. Stagnaro1, L. Carri1,2, R. Vaglioli1, F. Balestri1, S. Accogli4, D. Caramella4, M. Mosca1,2, Rheumatology Unit, University of Pisa; 1Emergency Department, Azienda Ospedaliero Universitaria Pisana, Pisa; 2GenOMacPhD, University of Siena, Siena; 4Diagnostic and Interventional Radiology, University of Pisa, Pisa, Italy

**Background:** Joint involvement is one of the main causes of chronic pain and disability in SLE patients (pts); despite arthritis in SLE is usually considered mild, joint erosions and deformities can be observed with significant impact on patient’s quality of life. Imaging techniques are more sensitive than joint count in detecting synovitis and early joint damage.

**Objectives:** This study was aimed at evaluating the progression of joint damage in SLE and at evaluating predictive factors for damage accrual.

**Methods:** Consecutive SLE pts with active hand-wrists synovitis (detected by joint

We calculated the sensitivity/specificity of MRI and US (at the proximal and distal level) in the detection of LHBt changes using arthroscopy as gold standard (Table 2).

**Conclusions:** US has a good specificity but a poor sensitivity in the detection of LHB tendon changes even when a systematic and careful study of the proximal part of the tendon is undertaken. If detection of distal changes of the tendon in the inter-tubercular groove seems feasible with US, the involvement of the more proximal, intra-articular part of the tendon remains challenging. MRI sensitivity remains also poor. Overall, arthroscopy still remains the gold standard to detect LHB tendon intra-articular pathology.

**Disclosure of Interest:** None declared

count and/or ultrasounds) were enrolled in this 5-years prospective observational study. Clinical assessments as well as joint ultrasound (US) and MRI were performed at baseline and after 5 years. Each patient underwent a non-dominant hand–wrist US examination using a Logiq 9 with a linear probe operating at 14 MHz. Synovitis was defined as the presence of synovial hypertrophy and/or the presence of PD signal (PD) at baseline or in at least a recent one of the arthritis (≤1 year of duration). 22 pts (26.8%) showed clinical signs of synovitis, 56 (68.2%) presented positive hand-wrists US (synovitis) and in 14 (26.6%) PD signal was also recorded. Six pts (11.7%) already showed erosions at standard X-Ray, while MRI revealed at least one BE in 30 and 54 patients respectively, for a cumulative mean erosive burden of 9.2 erosions (range 1–63). After 5 years of follow-up, 34 pts consented to repeat the assessment; 11 (33%) had JA and 18 (29%) were still presenting clinical signs of synovitis; 28 pts (82.3%) showed synovitis at US with PD in 7 cases (20.9%). The final mean erosive burden resulted 12.3 (range 2–82) with a significant increase from the baseline evaluation (p=0.001). Overall, 16 pts achieved joint damage. Interestingly, erosion progression was observed also in 12 pts with negative joint count but positive US at baseline. The presence of PD at US and BME at baseline was associated with higher erosive burden at follow-up (p=0.03 and p=0.02 respectively).

Conclusions: Arthritis and SLE can be persistent over time and progress to joint damage even in a short term period despite treatment; normal joint count at physical examination but US findings of synovitis can be associated with erosion progression over time. The presence of PD at US and bone marrow edema at MRI was associated with a more severe damage progression. US and MRI can be used for the clinician to identify patients at higher risk of severe damage to be treated with a more aggressive therapeutic strategy targeting arthritis.

FR0641 Wrist Inflammation as Assessed by Magnetic Resonance Imaging is Associated with Patient-Reported Physical, Impairment, Global Disease Activity and Pain in Early Rheumatoid Arthritis: Long-Term Results from Two Randomized Controlled Trials

D. Glinatsi 1, D.G. Jurik 1, A.G. Jurik 2, H.S. Thomsen 3, T. Torfing 8, S.M. Bisgaard 1, M.B. Axelsen 1, M. Østergaard 1,3.

Background: Studies in established rheumatoid arthritis (RA) have shown that radiographic progression is associated with increasing health assessment questionnaires (HAQ). However, most studies have failed to demonstrate this association at the early stage of the disease. In addition, little is known about how specific pathologies, e.g. joint inflammation, tenosynovitis and joint damage, contribute to different patient-reported outcomes (PROs).

Objectives: To examine the association between MRI wrist inflammation and damage with PROs in patients with early RA.

Methods: MRI of the wrist and hand were obtained from 210 early RA patients participating in two investigator-initiated, randomized, controlled studies (CIMESTRA/OPERA), which aimed at achieving inflammatory control by use of conventional and/or biologic drugs combined with intra-articular injection of glucocorticoids. The image-sets were assessed according to the RA MRI scoring systems for conventional and/or biologic drugs. Performing the scoring, a trained radiologist unaware of the clinical picture and diagnosis assessed the sections on tendon, bone erosion, synovitis and joint space narrowing. The MRI images were also reassessed for associations between MRI features and HAQ, patient global visual analogue scales (VAS-PtGlobal) and VAS pain for status and change scores, independently of swollen joint count and level of C-reactive protein.

Results: Fifty-seven pts were enrolled (female 91.2%, mean age 44±12.2 years, mean disease duration 15.9±9 years);43 (75.4%) completed the follow-up, 3 died (1.9%) and 14 (22.6%) were lost to follow-up. MRI inflammation, but not damage, showed statistically significant associations with HAQ, VAS-PtGlobal and VAS pain for status and change scores, independently of swollen joint count and level of C-reactive protein. Synovitis and tenosynovitis were the MRI features most consistently associated with PROs, particularly VAS-PtGlobal and VAS pain (Table 1). MRI synovitis and tenosynovitis mean scores increased with the level of difficulty to cut meat and open a milk carton (p<0.01), and similar patterns were seen for other hand-related HAQ items. As an additional analysis, the metacarpophalangeal joints were included in the analyses, but this did not strengthen the associations between MRI pathology and PROs.

Conclusions: MRI-assessed inflammation, but not damage, in the early RA wrist is associated with patient-reported physical impairment, global disease activity and pain, and the amount of wrist inflammation influences physical hand function.

FR0642 The Potential Value of Positron Emission Tomography (PET)-Scan in Systemic Sclerosis for the Quantitative Assessment of Interstitial Lung Disease

D.M. Peelen 1, B. Zwezerijnen 2, E.J. Nossem 3, L.J. Meiboorn 4, O.S. Hoeeka 5, C.J. van der Laken 6, A.E. Voskuyl 7, 1Rheumatology; 2Nuclear Medicine; 4RadioLOGY, VU University Medical Center, Amsterdam, Netherlands

Background: Interstitial lung disease (ILD) in systemic sclerosis is treated by immunosuppressive drugs (e.g. cyclophosphamide), aimed at reduction of inflammatory response. Differentiation between inflamed and non-inflamed fibrotic tissue might help to develop treatment stratification, with the aim of improving the prognosis of (subgroups of) SSc-ILD patients. 18F-Fluorodeoxyglucose Positron Emission Tomography (18F-FDG PET) scan might be a promising tool to detect inflamed lung areas, which are not currently shown in a semi-quantitative setting [1, 2].

Objectives: This study aims to investigate the potential role of 18F-FDG PET –scan for the quantitative assessment of metabolically active SSc related ILD.

Methods: 18F-FDG PET -scans of 22 patients with systemic auto-immune disease, including 9 with SSc, 9 with systemic lupus erythematosus (SLE) and 4 with primary Sjögren's syndrome (pSS), were retrospectively analyzed. FDG uptake was quantitatively measured within 2cm² Regions of Interest (ROI’s) at apical, medial and basal lung levels. A total of 22 ROIs were drawn in each patient. SUVmean values of all ROI’s were corrected by the median SUVmean bloodpool value. Subsequently, the average of 6 posterior basal SUVmean values
was divided by the average of 6 posterior apical SUVmean values (basal/apical ratio). High Resolution Computed tomography (HRCT)-scans and Pulmonary Function Tests (PFT) were examined to confirm the diagnosis of ILD and to specify the pattern of fibrosis. Results: Mean age of patients was 69.4 (SSc-ILD), 62.5 (SSc without ILD), 36.9 (SLE) and 49.3 (pSS). In SSc patients, the mean disease duration was 5.0 (SSc-ILD) and 4.4 (SSc without ILD) years. Diffuse cutaneous sclerosis was present in 2 SSc-ILD and 1 SSc without ILD patients, while other SSc patients were diagnosed with limited cutaneous SSc. ILD was present in 5 out of 9 SSc patients as confirmed by HRCT and PFT. ILD was active in 3 out of 5 SSc-ILD patients. Posterior basal/apical SUVmean ratios of SSc-ILD patients were significantly increased compared to SSc patients without ILD (p=0.016), and compared to SLE and pSS patients without ILD (p=0.001 and p=0.016, respectively), which is shown in Figure 1.

Conclusions: Our findings demonstrate that 18F-FDG PET -scan is potentially useful for the quantitative assessment of active ILD lesions in SSc patients. The technique may therefore provide opportunities to select the patients with inflammatory regions in ILD that are most likely to respond to immunosuppression.

FR10644 SUBCLINICAL ULTRASONOGRAPHIC CHANGES OF THE ANTERIOR CHEST WALL JOINTS IN ANKYLOSING SPONDYLITIS AND RHEUMATOID ARTHRITIS AND THEIR ASSOCIATION WITH CHEST EXPANSION

F.I. Abdelrahman 1, M.A. Mortada 1, A.B. Abdul, Sattar 1, A.A. El Sammak 2.
1Rheumatology and Rehabilitation; 2Radiology, Zagazig University, Zagazig, Egypt

Background: Anterior chest wall (ACW) joints can be involved during the course of Rheumatoid arthritis (RA) and ankylosing spondylitis (AS), however, its clinical implications appear to be undetermined by the rheumatoid arthritis community.

Objectives: To determine the prevalence and types of subclinical ultrasonographic changes in the ACW joints in RA and AS patients and their association with the chest expansion.

Methods: The study was conducted on 132 sternocostal joints (SCJ) and 66 manubriosternal joints (MSJ) in 66 subjects (22 AS, 22 RA, and 22 control). Ultrasound (US) assessments were performed to detect synovitis, erosions, ankylosis, osteophytes, or doppler signals. Chest expansion was measured. In each group, Disease Activity Score (DAS28) and Health Assessment Questionnaire Disability Index (HAQDII) were recorded. In AS group, Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional Index (BASFI) were recorded.

Results: US detected subclinical changes of ACW joints in (74.2%) of RA, (77.3%) of AS, and (21.2%) of control groups. There was a highly significant difference between total US changes in RA (74.2%) and control (21.2%) (p<0.001) and also between AS (77.3%) and control (21.2%) (p<0.001). Non of our control had neither erosions nor ankylosing in MSJ. MSJ ankylosing was significantly higher in AS (77.3%) than RA (18.2%) (p<0.001). MSJ ankylosing was highly associated with limited chest expansion in both RA and AS (P<0.001). All patients (100%) in both groups (RA and AS) with MSJ ankylosing by US had limited chest expansion. In RA group, ultrasonographic changes were found to be higher with smoking, longer disease duration and high DAS28. In AS group, ultrasonographic changes were found to be higher with older age, male sex, smoking, longer disease duration and high BASDAI and BASFI.

Conclusions: US detected subclinical changes of ACW joints in a high percentage of RA and AS patients. No erosions or ankylosing in MSJ were found in the healthy individuals. MSJ ankylosing is more in AS than RA. Relatively, ankylosing of MSJ by US is highly associated with limited chest expansion in RA and AS. Up to the best of our knowledge, our study was the first study that detected subclinical changes of ACW joints in RA and AS by US.

FR10643 ENTHESITIS AND FOOT DISABILITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Serce, A. Bal, D. Dulgeroglu, A. Cakici, Physical Medicine and Rehabilitation, Diskapi YB Education and Research Hospital, Ankara, Turkey

Background: Enthesitis is a primary clinical feature of ankylosing spondylitis (AS). Lower extremity entheseopathy may cause foot pain and functional disability. Detection of entheseal injury by using physical examination may be insufficient. Musculoskeletal ultrasonography is a noninvasive and low-cost method for detecting enthesis readily.

Objectives: The aims of this study were to evaluate enthesis by using musculoskeletal ultrasonography and foot disability in patients with AS, to compare healthy controls, and to determine the correlation of enthesis score and foot function with disease activity and functional status.

Methods: In this study, 101 patients with AS and 42 healthy controls were examined for enthesis site abnormalities by using gray-scale ultrasonography. The findings of enthesis were assessed by using the Glasgow Ultrasound Enthesitis Scoring System (GUESS). The foot function index (FFI), which comprised of pain, disability, and activity limitation subscales, was measured in all the patients with AS and healthy controls for assessment of foot function. Disease activity and functional status were assessed using the Bath AS Disease Activity Index (BASDAI) and Bath AS Functional Index (BASF), respectively, in patients with AS.

Results: The median GUESS score was 8.00 (1.00–23.00), and, the median total FFI and scores in all the pain, disability, and activity limitation subscales were 14.70 (0.00–75.20), 16.60 (0.00–82.80), 16.10 (0.00–84.40), and 4.00 (0.00–60.00), respectively in patients with AS. The GUESS score, total FFI, and all the subscales scores were significantly higher in the patients with AS than in the controls (p<0.000). GUESS score showed no correlation with BASDAI and BASFI. In patients with AS, total FFI and scores for all subscales showed positive correlations between BASDAI and BASFI, respectively (r=0.00, r=0.66, r=0.00, r=0.50, r=0.05; p=0.00, p=0.00, p=0.00, p=0.05, p=0.05). The severities of enthesitis and foot disability were higher in patients with AS. Patients with AS may undergo ultrasonographic examination for enthesal foot involvement. Foot disability is related with disease activity and function. Foot involvement and disability should be evaluated comprehensively and managed properly.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.5112
Background: Diabetes mellitus (DM) is characterized by chronic hyperglycemia states and the development of specific microvascular disorders such as retinopathy and nephropathy. Conventional methods are usually used to study the vascular compromise of this entity, however, the use of capillaroscopy for the evaluation of capillary microarchitecture is not frequently used.

Objectives: The objective of this study was to identify vascular alterations in patients with type II diabetes mellitus and to determine the relationship between capillaroscopic findings and clinical manifestations.

Methods: Observational, descriptive and prospective of patients with diabetes mellitus II selected by inclusion and exclusion criteria and after presenting signs/symptoms or history of any collagen disease, trauma presence in the nailfold due to cosmetic treatment or nail polish, were excluded. The capillaroscopy was performed by an experienced dermatologist in a room with an ambient temperature of 20–23°C. The fourth and fifth fingers of the nondominant hand were chosen. Capillaries were observed using a 10× magnification capillaroscope (Dino-Lite) and photographs of the last distal row of capillaries were taken.

The following capillaroscopic parameters were considered: capillary diameter (ectasia and giant capillaries), cross-linked capillaries, capillary tortuosity, ramified capillaries, avascular zones, hemorrhages, dominant morphology, subpapillary venousplexus visibility, cuticularis and SD pattern. The images were analyzed by an experienced dermatologist. Data was analyzed using SPSS. The non-parametric correlations were performed by tau_b Kendall and values were considered statistically significant when p<0.01 and they had two tails.

Results: 65 patients were included in the study, with a mean age of 57 years [39–80], of which 75% [49] were women and 25% [16] men. The capillaroscopic findings were evident in 83% of the study population. The most frequent alterations were tortuous capillaries in 63% [41], cross-linked capillary in 59% [38], avascular areas in 48% [34], ectasias in 31% [25]. In smaller frequency, giant capillaries 14% [9], arborified capillaries 11% [7], no haemorrhages, no SD pattern. The capillaroscopic findings representing vascular damage were greater in patients with Diabetes Mellitus than in the control group (Figure 1). Moreover, the capillary morphology in the control group was open versus tortuous in patients with DM. Those patients with capillaroscopic alterations had a longer time of evolution of the disease with an average of 12.8 years, compared to those who did not present alterations that had a mean evolution of the disease of 8.5 years, which shows that those capillaroscopic alterations represent progressive endothelial damage. In addition, an association between the presence of retinopathy and capillary damage at the nail bed level was demonstrated (p<0.001).

Conclusions: Capillaroscopy has proven to be a non-invasive, reproducible and reliable technique for the evaluation of vascular microarchitecture within a large group of rheumatoid diseases of the scleroderma spectrum. However, it has been shown previously that can be applied in other diseases outside the field of Rheumatology such as diabetes, being a tool that should be known by primary care physicians and healthcare workers.

Methods: Patients who have been receiving biologic therapy due to chronic inflammatory arthritis were included in this study. Demographic and clinical data, TST and IGRA results were recorded. The agreement between IGRA and TST results was evaluated by Kappa coefficient.

Results: A total of 35 patients were included; 15 (42.8%) were male and mean age was 43.74±12.72 years. Of the 22 TST positive patients, 13 (37.1%) were IGRA negative. Of the 13 TST negative patients, 3 (8.6%) were IGRA positive. Nine (25.7%) patients were positive for either of the two tests and 10 (28.6%) patients were negative for both tests. There was statistically significant discordance between two tests (p<0.021; p<0.05) (Table 1). While positive rate of TST was 62.9%, positive rate of IGRA was 34.3% and Kappa consistency coefficient between two tests was 15.4% (p=0.283; p<0.05).

Conclusions: It is very common in rheumatology practice to administer anti-tuberculosis prophylaxis according to the TST. IGRA may reduce the number of patients in whom tuberculostatics are prescribed, especially in BCG recipients in endemic populations, resulting in a benefit of avoiding possible side effects. Furthermore, IGRA is also important for detecting the cases of LTBI that would be missed by TST. Confirmation in larger studies is necessary.

3. FRI0649 STANDARDIZED PROCEDURES FOR ULTRASOUND IMAGING IN PAEDIATRIC RHEUMATOLOGY: PROGRESS OF A EULAR TASK FORCE

I. Janta 1, P. Collado Ramos 2, J. Vojinovic 2, E. Naredo 3, L. Carmona 4, 1Rheumatology, Hospital General Universitario Gregorio Marañón; 2Rheumatology, Rheumatic-Pediatric Unit, Hospital Universitario Severo Ochoa, Madrid, Spain; 3Pediatric Rheumatology, Clinical Center, Faculty of Medicine, University of Nis, Serbia; 4Rheumatology, Joint and Bone Research Unit, Hospital Universitario Fundación Jiménez Díaz and Autónoma University; 5Instituto de Salud Musculoesquelética, Madrid, Spain

Background: Musculoskeletal ultrasound (MSUS) is a useful imaging technique in paediatric rheumatic diseases (PRD). US has several advantages over other imaging techniques: it is non-invasive, radiation free, rapid, highly accepted by the patient and does not require sedation for scanning in younger children. However, MSUS examination is incriminated to be an operator dependent technique. Moreover, the variability of normal sonoanatomy in children, due to ossification, makes the acquisition and interpretation of MSUS images difficult. The variability in background and experience of ultrasonographers in different countries requires an international multidisciplinary effort for an optimal standardization of MSUS performance in PRD.

Objectives: To perform a systematic literature review on guidelines for MSUS in children published by international societies and articles on how to perform MSUS scanning in children. This represents the first step for an EULAR taskforce, which objective is to develop EULAR Standardized Procedures for Ultrasound Imaging in Pediatric Rheumatology through a consensus process among rheumatologists, paediatric rheumatologists, and radiologists highly experienced in the performance, teaching and research in paediatric MSUS in rheumatologic disease.

Methods: The objective was reformulated according to the PICO-adapted approach, as follows: body parts, ultrason, and scanning procedures. For each component several synonyms were used. Search limits were applied for animal studies and age. The literature search was performed in Medline and Embase from databases inception to 1st June 2016. References identified were imported into a bibliographic manager and duplicates were removed. To identify eligible studies the remaining articles were assessed by title and abstract. Only articles in English were retained. From the selected studies, data about the examined area, patient position, probe placement, scanning method, landmarks and pathologies using a predefined data collection form.

Results: The literature search resulted in 6059 articles, of which 4856 were captured in Medline and 1203 in Embase. Figure 1 shows the the study flow-chart for article selection. After removing duplicates and scanning titles and abstracts, 295 articles remained for detailed review. After full-text review, 107 articles were excluded. The main reason for article exclusion after full-text review was the lack of standardized examination. Of the remaining articles, 2 described shoulder structures, 14 elbow structures, 5 wrist structures, 9 hand structures, 25 hip
The OMERACT Ultrasound scoring system (USSS) of joint in RA

Informatics & IRIBHM, School of Medicine, ULB, Brussels, Belgium

Results: machine reproducibility was assessed by kappa statistics for discrete variables scoring of the OMERACT US expert was quantified by proportions. The inter-US agreement between each participant with the OMERACT US expert as gold standard. To assess the reliability of the USSS by using different US experts, 9 data (3 patients x 3 joints). The reliability was low for detecting JE (ICC ≤ 0.211. The reliability was low for detecting JE (< 0.001). Acceptable reliability among machines was found for SH, BE and PD (table 1).

| Correlation Coefficients (ICC) for UCOASMI and classical metrology measurements were calculated.

Conclusions: The reproducibility of the UCOASMI, obtained through the UCOTrack® motion analysis system in the 3 centers, was very high, in contrast to the lower reproducibility of the Schober test and other measures of classical metrology. The reliability of this system opens the door to using this technology to monitor SpA patients and in future research studies.

SALIVARY GLAND ULTRASOUND IS RELATED TO ULTRASOUND DETECTED PATHOLOGY IN THE ENTHESIS OF THE LOWER LIMB IN AN AGE STRATIFIED COHORT OF ASYMPTOMATIC SUBJECTS -A PROSPECTIVELY DESIGNED DESCRIPTIVE CROSS-SECTIONAL STUDY

Methods: We conducted a cross-sectional study comparing MN US parameters of SSc patients followed up at our Rheumatology Unit and control subjects. Exclusion criteria included body mass index (BMI) > 30, previous wrist trauma and known diagnosis of carpal tunnel syndrome. Forty-eight out of 62 SSc patients and 45 healthy age and sex matched controls were enrolled. Subjects were consecutively evaluated in our Department. A General Electric LOGIQ S8 US with a 15 MHz linear transducer was used for assessment. MN cross-sectional area (MNA) and perimeter (MNP) of both sides of each person were measured at the level of the carpal tunnel inlet. For comparative analysis, the mean MNA and MNP of combined right and left side were used. Patients’ relevant clinical and demographic data were collected. Modified Rodnan skin score (mRSS), hand mobility (HAMIS) and SSc Severity Scale (SScSS) were also assessed. Statistical analysis included Chi-Square test, Mann-Whitney U-test, Kruskal-Wallis and Spearman correlation coefficient. P value <0.05 was defined as statistically significant.

Results: A total of 186 MN were assessed by US. Both groups had the same proportion of diabetes and history of tunnel carpal surgery (>p=0.803 and p=0.339, respectively). Median of MNA and MNP were significantly higher in SSc patients (7.5 mm² [6.6 to 9.5] and 13.8 mm [12.4 to 15], respectively) (median [interquartile range]) compared with controls (7.0 mm² [6 to 8] and 12.9 mm [11.7 to 14], respectively) (p=0.021 and p=0.018, respectively). Higher mRSS correlated with higher MNA (Spearman’s rho=0.335, p=0.02) and MNP (rho=0.336, p=0.02).

Conclusions: We confirmed an increased MNA and MNP in SSc patients in comparison with healthy age and sex matched controls. Patients in the oedematous phase of skin involvement and patients with higher skin thickness assessed by mRSS showed higher MNA and MNP values. Wider mRSS, mRSS and mRSS were significantly different between the phases of skin involvement (p=0.007 and p=0.009, respectively), being higher in patients in the oedematous phase (median MNA of 9.25 mm² [7.5 to 11.5] and median MNP of 14.5 mm [13.5 to 16]).

SALIVARY GLAND ULTRASOUND IS RELATED TO AUTOIMMUNITY IN PRIMARY SJÖGREN SYNDROME

1Rheumatology, Hospital G.U. Gregorio Marañón; 2Psychology, Universidad Camilo José Cela; 3Rheumatology Hospital Universitario Fundación Jiménez Diaz, Madrid, Spain

Background: Primary Sjögren syndrome (pSS) is a systemic autoimmune disease involving exocrine glands, mainly ocular and salivary glands. Salivary gland ultrasound (SGU), of submandibular and parotid glands, in pSS is characterized by hypo/anechoic rounded areas within gland parenchyma, losing gland texture and homogeneity of the glands (typical SGU). SGU is a reliable imaging technique for assessing gland echostructure in pSS.

Objectives: The aim of our study is to evaluate the relation between typical SGU and clinical laboratory data in pSS

Methods: We performed SGU to 100 patients with pSS from our rheumatology department selected randomly from a database. We used a semiquantitative score from 0 to 3. Grades 0 and 1 were considered as normal and grades 2 and 3 were considered as typical for pSS. We retrospectively collected demographics (age, gender, disease duration), clinical (extra-glandular manifestations, parotid swelling and lymphomas) and laboratory data (ESR, CRP, rheumatoid factor (RF), antinuclear antibodies (AAN), anti-SSA and anti-SSB antibodies). We divided the patients into 3 groups depending on their autoimmunity profile. Complete seropositive group were patients with RF, AAN and antiSSA or antiSSB positives simultaneous or sequentially. Simple seropositive group were patients with any positive autoantibody (RF/AAN/antiSSA or antiSSB) but not all of them together. Finally, patients without positive autoantibodies were included in the seronegative group.

Results: We excluded 7 patients because they were diagnosed with secondary SS. From 93 pSS patients analyzed, 32 (frequency 34.5%) had a typical SGU. Demographics, extra-glandular manifestations and lymphomas were similar between patients with typical SGU and patients with normal SGU. Parotid swelling and longer disease duration were associated with a typical SGU (p<0.05). Parotid swelling positive autoantibodies (AAN, RF, antiSSA and antiSSB) had more frequently a typical SGU. Complete seropositive group had the highest frequency of typical SGU, followed by simple seropositive group. All seronegative patients had a normal SGU. SGU relate with autoimmunity is shown in table 1

Conclusions: Longer disease duration and parotid swelling were associated with typical SGU. Typical SGU was associated with positive autoimmunity, moreover all seronegative patients had a normal SGU

entheses or increased inflammatory markers in the blood. The dominant leg was examined with US using a Logiq 9 (GE Medical, Milwaukee, WI, USA) with a 6–15 MHz transducer and a fixed pre-set with Doppler settings optimised for inflammatory flow. Both GS and Doppler examination were made. The entheses were examined for hypoechoegenicity, increased thickness, enthesophyte/calcifications, erosions, and Doppler activity.

Results: No subjects had clinical signs of tendon or joint disease. Seven displayed various degrees of hypermobility and seven had various degrees of flatfoot; some in combination. None of the blood tests indicated any pathology.

On US erosions were only seen in one Achilles insertion (not shown in table). The Doppler activity was not measured in plantar fascia due to attenuation of the heel pad. All other US pathology present is seen in the table below.

Conclusions: Only minor pathological findings in the entheses of the lower limb were present in an age stratified cohort of healthy persons. The changes most frequently seen were bony changes in the insertion of the quadriceps and Achilles tendons. A weak tendency toward more pathological findings was seen in this cohort among men, compared to women, and additionally, with increasing age. The findings suggest that US can be used to diagnose/examine subjects for pathological changes of the entheses although with caution regarding entheseophytes of the quadriceps and Achilles tendon.

FR0055 ULTRASOUND FINDINGS OF FEEDING VESSELS AND BONE SURFACE IRREGULARITY IN WRIST JOINTS OF HEALTHY CONTROLS

K. Misaki 1, K. Ikeeda 2, K. Inoue 1, 2Rheumatology, Kita-Harima Medical Center, Oono; 2Chiba University, Chiba, Japan

Background: Musculoskeletal ultrasound (MSKUS) is capable of visualizing synovitis and bone damage such as erosion. In particular, synovial vascularity as measured by power Doppler (PD) is correlated to rheumatoid arthritis disease activity, and PD signal reveals the prevalence of subclinical synovitis overlooked on physical examination. It is frequently difficult to distinguish bone erosion from normal concave surface of the bone. It is necessary for us to know these normal structures well in evaluating disease activity by using MSKUS. Here we examine the normal feeding vessels and bone surface irregularity in wrist joints.

Objectives: To clarify the distribution of feeding vessels in wrist joints and lunate surface irregularity of healthy controls by using MSKUS.

Methods: The dorsal side of the bilateral wrists was scanned in 2 perpendicular planes with 2D-probe in healthy volunteers. The distribution and bilaterality of feeding vessels in healthy controls (n=30) were as follows:

Above-trapezoid (Rt:100.0%, Lt:100.0%, Blt:100.0%), intra-extensor digitorum tendon sheath (Rt:30.0%, Lt:30.0%, Blt:10.0%), above-trapezoid (Rt:23.3%, Lt:30.0%, Blt:10.0%), above-triangular fibrocartilage complex (Rt:16.7%, Lt:30.0%, Blt:6.7%), distal radial side of the radio-carpal joint (Rt:20.0%, Lt:23.3%, Blt:0.0%), distal end of the ulna (Rt:10.0%, Lt:16.7%, Blt:0.0%), dorsal side of the lunate (Rt:6.7%, Lt:0.0%, Blt:0.0%), palmar side of the extensor digitorum tendon sheath (Rt:0.0%, Lt:3.3%, Blt:0.0%). Feeding vessels from vascular channels were depicted at lunate (Rt:53.3%, Lt:46.7%, Blt:43.3%), the distal side of the radius (Rt:20.0%, Lt:16.7%, Blt:3.3%), triquetrum (Rt:10.0%, Lt:16.7%, Blt:0.0%) and capitate (Rt:6.7%, Lt:10.0%, Blt:0.0%). The frequency of the bone surface irregularity at lunate in healthy volunteers (n=47) and the transverse diameter (TD) (Mean±S.D.) of those were Rt longitudinal plane:57.4% (TD:21.6±3.3mm), Rt transverse plane: 51.1% (TD:20.2±3.1mm), Lt longitudinal plane: 68.1% (TD:26.2±2.8mm), and Lt transverse plane: 42.6% (TD:29.5±3.1mm). Bilateral evaluation of those was 53.2%.

Conclusions: MSKUS evaluation in wrist joints revealed various normal vessels and bone surface irregularity of lunate. It is necessary to distinguish a normal pattern from a pathological pattern in MSKUS examination.

Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.3745

FR0056 SEMIAUTOMATIC ANALYSIS OF EROSION VOLUME BY HR-PQCT IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Chiba 1, N. Iwamoto 2, M. Osaki 1, A. Kawakami 2, 1Department of Orthopedic Surgery, 2Department of Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Background: HR-pQCT is a high resolution CT dedicated to human extremities. It has been used mainly for osteoporosis, while in more recent years it has been applied to research in rheumatoid arthritis (RA).

Objectives: The purpose of this study is to develop a method to quantify the volume of erosions in RA patients semiautomatically using second generation HR-pQCT.

Methods: Twenty patients with RA (70±8 years, 15 female, 5 male) participated in this study. The second and third MCP joints were scanned using HR-pQCT (XtremeCT II, Scanco Medical, Switzerland) at the voxel size of 61μm. The erosion volume was measured semiautomatically using the dedicated software (TRI/3D-BON, Ratoc System Engineering, Tokyo).

Results: In a total of 37 joints (3 joints were excluded due to severe deformities), 40 erosions were detected by HR-pQCT (palpable size: 9 erosions, metacarpal side: 31 erosions). The average volume of the erosions was 1.84mm³, minimum 0.08mm³, and maximum 16.3mm³.

Conclusions: The semiautomatic method to quantify the volume of erosions at MCP joints in RA patients by HR-pQCT was developed. The opinion as to whether concave regions are pathological erosion or physiological concave, vascular channel or recess of osteophyte is occasionally difficult and should be performed by an experienced tester.

FR0057 COMPARATIVE STUDY OF PAROTID ULTRASONOGRAPHY AND PAROTID GLAND ECT IN PREDICTING THE PATHOLOGICAL BIOSPY OF THE SALIVARY GLAND IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

C. Xiaomei, L. Cong, W. Lijun, L. Caiain, S. Yamei, Department of Rheumatology and Immunology, People’s Hospital of Xinjiang Uyghur Autonomous Region, urumqi, China

Objectives: To investigate the value of Parotid Ultrasonography and parotid gland radionuclide imaging in predicting salivary gland biopsy of primary Sjögren’s syndrome (pSS).

Methods: Sixty - five patients with primary Sjögren’s syndrome and 38 patients with non - Sjögren’s syndrome were enrolled in the Department of Rheumatology and Immunology, Xinjiang Uyghur Autonomous Region People’s Hospital from October, 2015 to June, 2016. All patients were accepted the check of Parotid Ultrasonography, Parotid Glan ECT and labial gland biopsy. The data were analyzed statistically.

Results: The sensitivity and specificity of Parotid Ultrasonography in pSS were 65% and 76%, respectively. The area under the ROC curve was 0.935±0.024 for the diagnosis of pSS. The positive predictive rate of parotid gland ultrasonography was 84.0% and the negative predictive rate was 94.4%. Parotid scintigraphy in pSS in the sensitivity of 80.0%, specificity of 69.1%. The positive predictive rate of parotid gland radionuclide imaging for labial gland biopsy was 78.9% and the negative predictive rate was 87.5%. The diagnostic value of Parotid
Ultrasoundography in pSS group is superior to that of parotid gland radionuclide imaging, which can effectively reduce the complication of invasive operation.

Conclusions: The diagnosis of pSS by parotid gland ultrasoundography is superior to that of parotid gland radionuclide examination. For patients with atypical clinical manifestations who are negative for anti-SSA and/or anti-SSB antibodies, there is no need for a labial biopsy of the labial glands to reduce the number of complications associated with unwanted invasive procedures.

**FR00658** LEG ELEVATION DOES NOT SUBSTANTIALLY AFFECT TBS RESULTS

D. Krueger 1, E. Siglinsky 1, D. Tran 2, L. Del Rio 3, N. Binkley 1.

*Osteoporosis Clinical Research Program, University of Wisconsin, Madison, United States; R&D, Medimaps, Merignac, France; CETIR Grupo Médico, Barcelona, Spain*

**Background:** Lumbar spine dual energy X-ray absorptiometry (DXA) scans are typically acquired with the patient’s legs elevated on a positioning block thereby flattening the normal lumbar lordosis. With GE densitometers it is also possible to acquire lumbar spine scans with the legs down. BMI values obtained with legs down vs. legs elevated does minimally differ, however it is unknown if leg elevation affects trabecular bone score (TBS) results.

**Objectives:** The purpose of this study is to assess the effect of leg position on TBS.

**Methods:** Lumbar spine (L1-L4) DXA scans were acquired in legs up and legs down positioning using GE Healthcare Prodigy and IDXA densitometers. The ‘OneScan’ feature mode was not used. These scans were analyzed using enCORE software v 12.3 or 14.1. All scans were re-processed using Medimaps TBS Calculator v2.3 or TBS Insight v3.0.2 to obtain TBS results. Linear regression and Bland-Altman analyses were performed to compare TBS results in the legs up vs. legs down position.

**Results:** Sixty-four women, mean age and BMI 65.1 years (range 28.2–86.6) and 28.4 kg/m² (range 18.1–34.8) were studied on three Prodigy densitometers. Fifty women, mean age and BMI 68.6 years (range 15.2–92.5) and 26.2 kg/m² (range 19.9–35.1) were studied on a IDXA densitometer. With Prodigy and standard legs up positioning, the L1-L4 BMD ranged from 0.738–1.549 g/cm² and was highly correlated with legs down positioning, R² =0.99. TBS results ranged from 1.072–1.632 and were also highly correlated, R² =0.93 with a mean bias of -0.005 TBS units between leg positions (Figure). With IDXA and standard legs up positioning, the L1-L4 BMD ranged from 0.753–1.622 g/cm² and was highly correlated with legs down positioning, R² =0.97. TBS results ranged from 1.040–1.455 and were also highly correlated, R² =0.99 with a mean bias of 0.00 TBS units between legs positions (data not shown).

**Conclusions:** Leg positioning minimally affects TBS results with GE Healthcare Prodigy and IDXA densitometers but the difference from legs up to legs down is likely of no clinical significance.

**Disclosure of Interest:** D. Krueger: None declared. E. Siglinsky: None declared. D. Tran Employee of: Medimaps. L. Del Rio: None declared. N. Binkley: None declared

DOI: 10.1136/annrheumdis-2017-eular.5136

**FR00660** IMPACT OF ULTRASOUND IN TREATMENT DECISION OF RHEUMATOID ARTHRITIS

M. Gutierrez 1, C. Pineda 1, R. Espinosa 2, C. Hernandez 2, L. Ventura 1, C. Lozada 1, L. H. Silveira 3, G. Rodriguez 2, E. Cruz 2, A. Vargas 2, C. Bertolazzi 2, A.C. Lozada 1, 1Division of Musculoskeletal and Rheumatic Disorders; 2Instituto Nacional de Rehabilitacion; 3Instituto Nacional de Cardiologia, Mexico City, Mexico

**Background:** Ultrasound (US) is an important tool to support the clinician in the diagnosis and treatment monitoring of rheumatoid arthritis (RA). The EULAR recommended it for the follow up of RA patients. In spite of the evidence supporting the value of US, the real impact in treatment decisions is not clearly defined.

**Objectives:** To investigate the impact of US findings in the treatment decisions of rheumatologists in patients with RA in a real-life setting. Additionally, to verify the US findings that play a role in change of treatment, types of changes and their distribution.

**Methods:** RA patients were included. As a first step, the rheumatologist performed a clinical examination (including DAS28) and recorded the treatment approach suggested according his clinical evaluation (i.e. starting, changing or stopping the previous suggested therapy). Additionally, the clinical rheumatologist recommended it for the follow up of RA patients. In spite of the evidence supporting the value of US, the real impact in treatment decisions is not clearly defined.

**Results:** A total of 128 RA patients were included [female 117 (91.4%), male 11 (8.5%)], with mean ± SD disease duration of 9.88±8.22 years. Ninety-four patients (73.5%) had active disease according the DAS 28, whereas 34 (26.5%) were considered in remission. US findings influenced a change in the treatment in 56 cases (43.7%) (47 with clinical active disease and 9 in remission). Among the main reasons that induced a change in the treatment based on the US examinations were: grade of synovitis (25%), higher number of synovitis than clinical examination (16.6%) and presence of power Doppler (PD) (16.7%). The most frequent treatment changes were increasing dose or start a new combination of DMARDs [39 patients (69.5%)]. The multiple logistic regression analysis showed that synovitis of 2nd metacarpophalangeal joint (MCP) was the US finding that reported the reasons which induced to change or not the treatment after the US examination.

**Disclosure of Interest:** None declared

FR00661 | CAPILLAROSCOPY IN PATIENTS WITH SILICA EXPOSURE. A CASE CONTROL STUDY

M. Freire 1, A. Perez-Gonzalez 1, V. Arnalich 1, D. Boveda-Ruiz 1, A. Salgado 1, J.J. Blanco-Perez 2, 1Unidad de Enfermedades Autoinmunes Sistémicas y Trombosis, 2Servicio de Neumología, Complejo Hospitalario Universitario de Vigo, Spain

Background: Exposure to silica dust has been associated with different autoimmune diseases and immunological abnormalities in which microvascular involvement is very common, as systemic sclerosis, systemic lupus erythematosis, inflammatory bowel diseases, antiphospholipid syndrome or dermatomyositis.

Objectives: To show capillaroscopic findings in patients exposed and not exposed to silica and to analyze the differences between both groups.

Methods: A case control design was made. Cases (Si+) were subjects exposed to silica (with and without silicosis). Controls (Si-) were healthy subjects not exposed to silica. Capillaroscopy was made with ZO® Optical stereo microscope with Optikam® camera adapted and with USB Digital Microscope Video epiluminiscence Dino-Lite® in each patient. The capillaroscopic alterations were evaluated according to a semiquantitative method. Background data on CVRF and variables related to capillaroscopy were collected. A comparative study was done.

Results: Capillaroscopy was performed on 61 Si+ and 12 Si- subjects. Mean age was 56.4 years (SD: 8.2) in Si+ and 53.1 years (SD: 9.1) in Si-. There were no significant differences in CVRF: hypertension (13.5% Si+ and 8.3% Si-), diabetes mellitus (3.3% Si+ and 8.3% Si-) and tobacco exposure (18.0% Si+ and 25.0% Si-). It was observed capillary dilation in 24 (33.9%) Si+ and only in 3 (25.0%) Si-. The dilation score was mild in all Si- while in Si+ was mild in 41.7%, moderate in 36.6% and severe in 21.7%. It was observed capillary distortion in 12 (17.0%) Si+ and only in 1 (8.3%) Si-. The capillaroscopic general pattern showed differences between both groups: it was normal in 24 (42.1%) Si+ and 9 (75%) Si-; slightly irregular in 30 (52.6%) Si+ and 3 (25%) Si- and unstructured in 3 Si+ (5.3%) and in none Si-.

Conclusions: The current study shows significant differences between the capillaroscopic of subjects exposed and not exposed to silica, with a trend in more frequency and severity of capillary dilatation, greater frequency of tortuosity in a severe degree and more frequent irregular capillaroscopic pattern in the exposed patients.

FR00662 | ASSESSMENT OF BONE DENSITY, STRUCTURE, AND CORTICAL INTERRUPTIONS OF FINGER JOINTS IN PATIENTS WITH RHEUMATOID ARTHRITIS USING HIGH-RESOLUTION PERIPHERAL QUANTITATIVE CT

M. Peters 1, A. Scharmaga 1, A. van Tubergen 1, D. Loefen 1, R. Weijers 1, B. van Rietbergen 2, 1Unidad de Enfermedades Autoinmunes Sistémicas y Trombosis, 2Laboratorio de Nutrición y metabolismo, República Dominicana

Background: Rheumatoid arthritis (RA) is characterized by peri-articular bone loss. In patients with RA, lower bone density and structural integrity, and an increased number of erosions compared to healthy controls (HCs) has been demonstrated using High-Resolution peripheral Quantitative CT (HR-pQCT) (1,2). The assessment of such parameters using HR-pQCT is, therefore, a promising tool for the follow-up of bone involvement in MCP joints in patients with RA.

Objectives: To investigate the cortical and trabecular bone density, structure, and cortical interruptions in MCP joints in early and late RA patients compared to HCs using HR-pQCT imaging.

Methods: The 2nd and 3rd MCP joint of 70 subjects (mean age 53.1 (SD 9.2) years) were evaluated by HR-pQCT (82x-m isotropic voxel size); 38 HCs, 10 early RA (diagnosis <2 years ago) and 22 late RA (diagnosis ≥2 years ago). Images were analyzed for cortical interruptions, and for cortical and trabecular bone density and structure. Descriptors were analyzed per joint by one-way ANOVA with Bonferroni post-hoc testing or Kruskal-Wallis with Mann-Whitney post-hoc testing, as appropriate.

Results: Significant differences with respect to all parameters were found across the groups (Table 1). In early and late RA, the percentage of joints with at least 1 interruption was higher, and trabecular core thickness, total density and cortical density were lower than in HC. In addition, in late RA, number of interruptions, interruption volume and trabecular separation were higher, and trabecular density was lower than in HC. Bone loss at the cortical and trabecular bone was primarily observed at the rim of the joint (Figure 1, arrows).

Values are displayed as mean (SD) or otherwise described. *Significantly different from HC, p<0.05. v-p-value obtained across the groups. vBMD, volumetric bone mineral density.

Figure 1. Typical examples of MCP joints; (a) HC, (b) early RA patient, and (c) late RA patient. The 3D reconstructions are shown (I) with corresponding 2D slices thick axial slices (ii). The arrows indicate locations of loss of trabecular and/or cortical structure in the early and late RA patients compared to the HC.

Conclusions: Bone density and structural integrity were impaired in early and late RA patients compared to HCs whereas the number of cortical interruptions is increased. The assessment of such parameters using HR-pQCT is, therefore, a promising tool for the follow-up of bone involvement in MCP joints in patients with RA.

FR00663 | EVALUATION OF A FLUOREOENZYME IMMUNOASSAY (ELIA-CTD) IN THE SCREENING OF PATIENTS SUSPECTED FOR AUTOIMMUNE CONNECTIVE TISSUE DISEASES

M. Elkhalifa 1, R. Abdullahi 1, H. Ramadan 1, S. Barrientos 1, S. Salehi 1, O. Suhail 2, A.W. Al-Allaf 2, 1Laboratory Medicine & Pathology, Hamad Medical Corporation, Doha, Qatar, 2Medicine, Hamad Medical Corporation, Doha, Qatar

Background: Detection of auto-antibodies directed against nuclear antigens (nuclear antibodies or ANA) have important diagnostic and prognostic implications in connective tissue diseases (CTD). The conventional indirect immunofluorescence assay on Hep-2 cell line (ANA-IFA) is the most commonly used method to detect ANA. The ANA-IFA can be labor intensive and suffers from lack of specificity.

Conclusions: ANA-IIF can be labor intensive and suffers from lack of specificity. ANA-IIF can be labor intensive and suffers from lack of specificity. ANA-IIF can be labor intensive and suffers from lack of specificity.
Objectives: To evaluate the utility of a new fluoroenzyme Immunoassay “EliA-CTD” as an alternative for screening patients suspected for autoimmune connective tissue diseases.

Methods: Six hundred and fifteen (1600) consecutive patients’ sera submitted for anti-nuclear antibodies were tested using the ANA-IIF (Diasorin S.P.A., Saluglia, Italy) and the new automated EliA-CTD screen (Phadia GmbH, Frieiburg, Germany). ANA testing was ordered by both primary and secondary care physicians. The EliA-CTD screening assay is a fluoroenzyme immunoassay which is performed on the Phadia-250 automated platform. The EliA-CTD assay contains ANA-targeted recombinant antigens including dsDNA, Sm-D, Rb-P, PCNA, U1-RNP (70, A, C), SS-A/Ro, SS-B/La, Centromere B, Scl-70, Fibrillarin, RNA Polymerase III, Jo-1, Mi-2, and PM-scl. The test results are expressed as ratio, with >1.0 considered positive. For ANA-IIF, the cut off for positive results was 1:40 or greater. Additionally, further testing for dsDNA and other extractable nuclear antigens (ENA) was undertaken on a subset of sera that were ANA-IIF+ or EliA-CTD+ whenever there was discrepancy between the two methods.

Results: The overall agreement between the two methods was 84.2%. Three hundred and eight (308) out of 1600 (19.3%) samples tested positive by ANA-IIF positive as compared to 101/1600 (6.6%) for the EliA-CTD assay. Additional testing showed that 105 samples were positive for ENA including dsDNA. Of those, 101 were EliA-CTD positive and 81 were ANA-IIF positive. By incorporating those results, the calculated sensitivity and specificity for the EliA-CTD were 97.1% and 99.7% respectively with positive and negative predictive values for the EliA-CTD assay of 96.1% and 99.8%, respectively. The corresponding sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for the ANA-IIF assay at different dilutions is shown below:

<table>
<thead>
<tr>
<th>Dilution</th>
<th>Sensitive (%)</th>
<th>Specific (%)</th>
<th>PPV (%)</th>
<th>NPV (%)</th>

Conclusions: The new automated EliA-CTD assay shows superior sensitivity and specificity compared to the conventional labor intensive ANA-IIF. The EliA-CTD can be used as an upfront screening tool for connective tissue diseases. Depending on the clinical details, any EliA-CTD positive results could be confirmed by additional testing including ANA-IIF testing to elucidate the titers and pattern.

FRIO0665 ANTI-HETEROGENEOUS NUCLEAR RIBONUCLEOPROTEIN ANTIBODIES (ANTI-HRNRP) AND OTHER AUTOANTIBODIES FOR DETECTION OF EROSIve ARthropathy in Systemic Lupus Erythematous with Joint INVOLVEMENT in COMPARISON BY JOINT X-RAY

S.Y. Hussein¹, N.A. Fathi¹, S.H. Goma¹, N.A. Mohammed², E. Mosad³
¹Physical Medicine, Rheumatology & Rehabilitation, Faculty of Medicine, Assiut University, Egypt; ²Diagnostic Radiology, Assiut University Hospital; ³Clinical Pathology, South Egypt Cancer Institute, Assiut, Egypt

Background: Joint involvement in SLE is very common, affecting 90% of patients at some stage in the course of their disease. 1Arthritis featuring prominent radiological erosion in SLE is less common; however, in a small subset of patients an erosive pattern similar to RA develops. 2 Anti-heterogenous nuclear ribonuclear protein A2 (anti-hnRNP-A2) occur in about one-third of patients with RA but rarely in other arthritides such as OA, PsA or reactive arthritis. Interestingly, in SLE patients anti-hnRNP-A2 autoantibodies were found to be significantly associated with erosive arthritis (3).

Objective: To investigate joint involvement in SLEs and its relationship with autoantibodies to the hnRNP A2/B1 and A2, rheumatoid factor (RF), Antinuclear antibody (ANA) and Anti-double stranded DNA (Anti-DSDNA) and correlation with articular involvement by joint x-ray.

Methods: Case series study comparing diagnosis of arthritis by hand and wrist x-ray with anti-hnRNP A1 and A2 in Fourty SLE patients aged 17–60 years old with disease duration 1–17 years complaining of arthralgia or arthritis. A controlled group of 21 clinically normal persons, age and sex matched and blood

samples are drawn and centrifuged. RF and auto-antibodies to nuclear antigens anti-nuclear antibodies (ANA) and anti-double stranded DNA were determined in all the patients. All patients underwent X-rays of the hands and wrists.

Results: Anti-hnRNP A1 showed highly significant difference between study and control. Anti-hnRNP A2 showed significant difference between study and control.

Conclusions: This study showed a high frequency of erosive arthropathy and autoantibody to both hnRNP antigens might become useful marker for joint involvement in SLE patients and identify SLE patients prone to develop joint damage.

FR06667 INCREASED PREVALENCE OF SUBCLINICAL ATHEROSCLEROSIS IN MODERATE-SEVERE PLAQUE PSORIATIC PATIENTS

Background: Recent studies suggest that plaque psoriasis may be a risk factor for major adverse cardiac events. This has important therapeutic implications for cardiovascular (CV) risk stratification and prevention in patients with severe psoriasis. For that reason surrogate markers of subclinical atherosclerosis and CV mortality such as carotid plaques (CP) have been studied by carotid US examination.

In most studies of psoriasis done before, the results have shown an increased prevalence of carotid plaques, but it is not always the rule.

Objectives: To compare the prevalence of CP between patients with moderate-severe psoriasis and the general population.

Methods: A cross-sectional study that included 40 patients with moderate-severe psoriasis (PASI>10, BAS>10%), that fulfilled definitions for initiating treatment with a biological agent and 40 age-, sex- and traditional CV risk factors-matched healthy control subjects. Patients with history of CV events, diabetes mellitus, and chronic kidney disease or body max index (BMI) >35 were excluded. Carotid ultrasonography was performed by a MyLab 70 scanner (Esaote; Genoa, Italy), then carotid plaque was defined according to the Manheim Consensus Conference criteria. Statistical analysis: Qualitative data were expressed as number and percentages and quantitative data as (MD). Student’s t test or Mann-Whitney U were used to compare continuous variables, as appropriate. Chi2 test or Fisher test were used for qualitative variables.

Results: The main data of the patients are summarized in the Table. It is important to highlight that it is based on a young population (mean age=40 years). The two groups did not present significant differences except for high sensitivity C-reactive protein (hsCRP). As expected given the age of the group, CV risk measured by SCORE was low (0%) with a mean of 0.2 ± 0.15. No patient had a very high CV risk as measured by SCORE (>5%).

Patients with psoriasis had a long-standing disease (17.05±11.63 years). The presence of carotid plaques was found in a total of 10 patients with plaque psoriasis (25%), 5 of them had bilateral plaques) and one in the control group (2.5%) without bilateral plaques), p<0.003.

FR06666 THE RECALL SURVEY: CAN ULTRASOUND AFFECT CLINICIANS’ DECISIONS ABOUT CHANGING TREATMENT IN RA?

O. Epi, 1 P. Macchioni2, A. Delle Sedie3, M. Carozzo4, E. Filippucci5, A. Iagnocco6, S. Tropea7, C.F. Bonali8, 1Rheumatology Unit, Ospedale Niguarda Milano, Milano; 2Rheumatology Unit, Reggio Emilia Hospital, Reggio Emilia; 3Rheumatology Unit, Università di Pisa, Pisa; 4Local Health Unit (ASL) Rome 1, Rome; 5Rheumatology Department, Università Politecnica delle Marche, Jesi (AN); 6Academic Rheumatology Unit, Università degli Studi di Torino, Torino; 7ASP7, Buscasa Hospital, Ragusa; 8Rheumatology Unit, Ospedale San Paolo, Bari, Italy

Background: In Rheumatoid Arthritis (RA) treatment response is assessed using standard clinical disease activity measure. However ultrasound (US) is able to show subclinical synovitis in patients (pts) with RA who are in clinical remission (CR); further studies are still required to delineate the impact of US findings in the management of RA pts in daily clinical practice.

Objectives: To investigate the influence of US on the clinicians’ treatment choices in pts with RA.

Methods: In 2015 an educational event (RECALL Survey) focused on the added value of US in RA pts was held in 22 rheumatology centers in Italy. In every center, the local rheumatologists provided RA pts to be examined by US. Pts signed an informed consent and a brief history of them was collected by the local rheumatologists (previous and current therapy, DAS28, HAQ score). Bilateral US examinations of wrists, metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints were performed by rheumatologists expert in US, to assess synovitis (joint effusion, synovial proliferation, and power Doppler (PD) signal), and bone erosions, using a Logiq E R7, General Electrics, with a 4.2–13 MHz linear probe. All US findings were scored using a 4 degree semiquantitative scoring system.

Results: 465 pts were evaluated. Clinicians, after US evaluations, changed therapy in 23.7% of pts, did not change therapy in 35.5% of pts.In general changes of therapy tended to be made by clinicians when joint effusion or power Doppler signal were present (table 1–2). The presence of erosion did not influence the clinicians’ decisions.

Conclusions: Ultrasound may be a useful tool in daily rheumatologic practice to help clinicians make decisions about how to treat patients with RA. US results, especially joint effusion and Power Doppler signal, may influence the choice of clinicians to modify a patient’s treatment regime.

FR06668 SONOGRAPHIC AND ANATOMICAL DESCRIPTION OF THE SUBTALAR JOINT

P. Mandl1, D. Bong2, P.V. Balint3, H.B. Hammer4, M. Miguel5, E. Naredo6, I. Möller6 on behalf of Anatomy for the Image. 1Rheumatology, Medical University of Vienna, Vienna, Austria; 2Rheumatology, Universitat de Barcelona, Institut Pau de Reumatologia, Barcelona, Spain; 3Rheumatology, National Institute of Rheumatology and Physiotherapy, Bucharest, Hungary; 4Rheumatology, Diakonicheum Hospital, Oslo, Norway; 5Pathology and Experimental Therapeutics, Universitat de Barcelona, Barcelona; 6Rheumatology, Joint and Bone Research Unit. Hospital Universitario Fundación Jiménez Díaz and Autónoma University, Madrid, Spain.

Background: The subtalar joint is commonly affected in many rheumatic and musculoskeletal diseases; however, subtalar joint involvement is often neglected or missed during clinical examination due to the fact that the joint is difficult to examine and most clinicians have a limited understanding of its anatomy.

Objectives: To provide a detailed anatomical and US description of the subtalar joint, a single joint that, anatomically, is divided into two separate compartments: the anterior subtalar joint (ASTJ) and the posterior subtalar joint (PSTJ).

Methods: Cadaveric specimens of the ankle and foot were examined in detail by ultrasound (US) by rheumatologist experts in musculoskeletal US. The ASTJ of all
the specimens were injected with colored latex while the PSTJs were respectively injected with 1ml of latex of a contrasting color under US guidance. Following the injections, the joints were frozen and cut into 2 centimeter sections from medial to lateral in the sagittal plane. Sections were examined independently by three authors for the presence of latex within the ASTJ, PSTJ and, also, to look for the presence of synovial (sub)-articular latex extravasation or the spread of latex to adjacent articulations by means of a communication with the ankle joint or the adjacent portion of the subtalar joint.

**Results:** Six cryopreserved intact ankle-foot specimens from three male and three female cadavers (two right and four left), with a mean age of 74 years (range, 66–80 years) were studied. A recommended list of standardized scanning technique which allows sonographers to evaluate both compartments of the subtalar joint (ASTJ and PSTJ) from the medial, lateral and posterior aspect were developed. All of the specimens (6/6, 100%) contained the appropriate colored latex in the appropriate subtalar joint compartment with minimal leakage into the surrounding soft tissues (Figure 1). Of note, five of the six (5/6, 83%) specimens revealed communication between the PSTJ and the posterior subtalar joint. There was no communication between the ASTJ and the subtalar joint, nor was there evidence of spread of the latex, i.e. communication, from one subtalar joint compartment to the other.

![Figure 1](image.jpg) Anatomical specimen showing the anterior subtalar joint (filled with green latex) and the posterior subtalar joint (filled with red latex); C: calcaneus, N: navicular, T: talus.

**Conclusions:** Lack of communication between the ASTJ and the PSTJ and the communication between the PSTJ and the posterior recess of the tibiotalar joint are compatible with other studies. Our study highlights the importance of employing cadaver specimens in musculoskeletal ultrasound, and presents a number of options for US imaging of both the ASTJ and PSTJ that also provide access to these distinct compartments for the purpose of aspiration and injection.

**FR10669 VALIDITY OF SEVEN-JOINT VERSUS SIMPLIFIED TWELVE-JOINT ULTRASONOGRAPHY SCORING SYSTEMS IN ASSESSMENT OF RHEUMATOID ARTHRITIS ACTIVITY**

R. El-Gohary, A. Ahmed, A. Khalil, H. El-Gendy, K. Gado, Internal Medicine, Rheumatology & Clinical Immunology Subspeciality, Kasr Al-Ainy, New Kasr El-Aini Teaching Hospital, Cairo, Egypt

**Background:** Musculoskeletal ultrasonography imposes itself as a reliable tool for the disease activity assessment of rheumatoid arthritis (RA) being more sensitive than clinical in detection of synovitis. There is no consensus on the exact joint number should be examined. Naredo et al. developed reduced 12-joint count while Backhaus et al. scored only seven small joints. Although both were found to reflect disease activity it is suitable in a busy clinic to assess the lowest joint counts.

**Objectives:** To investigate the validity of 7-joint ultrasonography (US7) scores in assessment of disease activity in Egyptian RA patients compared with simplified 12-joint ultrasonography (US12) scores and correlate both to composite disease activity indices.

**Methods:** Fifty Egyptian RA adult patients diagnosed according to the ACR1987 criteria were subjected to detailed history, 28 tender & swollen joint counts (TJC, SJC). The disease activity was assessed by calculating DAS28-CRP, SDAI and CDAI. The Ultrasonographic assessment was performed using a LOGIQp6 with 10–13 MHz broadband linear array transducer by one well-trained blinded rheumatologist. The synovial hyperechogenicity on GS & PD images were graded using a semi-quantitative 0–3 scale. The simplified US12 was performed as originally described. However the GS & PD synovitis were computed in two separate scores instead of one. The US7 was performed at the clinically dominant side as described by Backhaus et al. Two Sum-US7 scores were added; Sum (GS)-US12 after grading the GS-tenosynovitis and Sum (PD)-US12 with SDAI and CDAI (V values 0.02, 0.009 and 0.001). Kappa values were 0.80 & 0.96 for GS & PD interobserver reliability and 0.96 & 1.0 for GS & PD intraobserver reliability.

**FR10750 THE COURSE OF SUBCLINICAL JOINT INFLAMMATION DURING PROGRESSION FROM ARTHRALGIA TO CLINICALLY DETECTABLE ARTHRITIS, A LONGITUDINAL MRI STUDY**

R.M. Ten Brinck, H.W. van Steenberghe, L. Mangus, A.H. van der Helm-van Mil, Rheumatology, Leiden University Medical Centre, Leiden, Netherlands

**Background:** Subclinical joint inflammation in the phase of arthralgia preceding RA can comprise synovitis, bone marrow edema (BME) and/or tenosynovitis. It is unknown in what time order the different tissues in a joint become inflamed or progress with inflammation. It has been postulated that synovitis is an initial process that is succeeded by bone involvement (“outside-in hypothesis” presuming that synovitis precedes BME and erosions). Alternatively, it is suggested that inflammatory cells in the bone marrow migrate via bone pores to the synovium, promoting synovitis (“inside-out”), then BME precedes synovitis. Thirdly, these processes can occur or progress simultaneously. Serial MRI studies can reveal time-relationships. This longitudinal MRI study on patient-level determined the course of joint inflammation during progression from arthralgia to clinical arthritis.

**Objectives:** To increase the comprehension on the course of MRI-detected subclinical joint inflammation during progression from arthralgia to clinical arthritis, both in ACRA-positive and ACRA-negative patients.

**Methods:** We longitudinally followed 29 patients that all progressed from Clinically Suspect Arthralgia to clinical arthritis. 1.5T MRI on hand and foot joints was performed at presentation with arthralgia and subsequently at the development of clinical arthritis. MRIs were evaluated for BME, synovitis and tenosynovitis (summed in the total inflammation score) and erosions by three readers (ICCs 0.98, 0.96 and 0.97) that were blind to clinical data and the order in time. Analyses were repeated in arthritis patients that fulfilled the 2010 criteria for rheumatoid arthritis, and in ACRA-positive and ACRA-negative patients separately.

**Results:** At presentation with arthralgia the mean age was 43 years, 72% was female, and 28% was ACRA-positive. Median duration to clinical arthritis was 17 weeks. At the time of arthritis development 65% fulfilled the 2010-criteria. During progression from arthralgia to clinical arthritis the median total inflammation score increased from 4.5 (IQR 2.8–7.6) to 8.9 (IQR 2.0–13.5), p<0.01. The BME score increased over time (p=0.04), as did the synovitis score (p=0.002). The tenosynovitis and erosion scores increased as well, though not statistically significant (p=0.10 and p=0.07 respectively). Analyses within the patients that developed 2010-RA revealed that BME (p=0.047), synovitis (p=0.005) and tenosynovitis (p=0.004) all increased significantly, in contrast to the erosion score. At presentation with arthralgia, BME and synovitis scores were higher in ACRA-positive than in ACRA-negative patients; during progression to clinical arthritis the different types of inflammation increased similarly in ACRA-positive and ACRA-negative patients.

**Conclusions:** During progression from arthralgia to clinically evident rheumatoid arthritis, BME, synovitis as well as tenosynovitis progress simultaneously.

**DOI:** 10.1136/annrheumdis-2017-eular.2908
This study aims to investigate the nail bed changes seen in patients with PsA and OA using US and MRI, and to determine the impact of nail bed score. There was no relationship between clinical or US detected nail scores and grip strength. There was a strong relationship between the presence of clinical nail change and the failure load (in Newton) and constraint (in Mpa) were measured. Bone Volume Fraction (BV/TV), Trabecular Thickness (Tb.Th), and Trabecular Spacing (Tb.Sp) were measured in MRI images using a Digital topological analysis (Bone J). Measurements were performed by two observers in order to characterize the inter-rater reliability. Statistical analyses were performed using SPSS. Correlations between variables were analyzed using Pearson's r, linear regression and Stepwise regression. A p value of 0.05 was considered as significant.

Results: The inter-rater reliability for bone microarchitecture parameters quantification was good. Tb.Th and Tb.Sp measured using high-field MRI were 0.94 and 0.95 respectively while the BV/TV fraction was 0.93. The mean BMD was 0.86±0.20 g/cm^2. The failure load and the constraint measured during the compression tests were 2600±1276N and 1.57±0.81 Mpa respectively. Interestingly, the variables measured during the mechanical tests were significantly correlated with the BMD. Regarding the bone indices quantified using high-field MRI, a significant linear relationship was observed between the trabecular spacing and the BMD (R=−0.23, p<0.01) and the constraint values to failure (R=−0.18, p=0.04). A stepwise regression with backward elimination demonstrated that combining BV/TV and BMD improved the relationship with the constraint measurements with an adjusted R^2=0.384 for BMD alone and an adjusted R^2=0.41 for BMD + BV/TV.

Conclusions: In the present study, we demonstrated for the first time that the variables characterizing the vertebral bone microarchitecture quantified using ultra-high field MRI were significantly correlated with biomechanical parameters. In addition, we illustrated that the vertebral bone strength was better described by a variable combining BMD and trabecular bone spacing.

Disclosure of Interest: None declared

4. In TCZ group, CRP and ESR were significantly lower than the other groups, although other clinical indicators were comparable (Table).

Conclusions: US revealed that CR in TCZ-using can be overestimated by BL-based, SDAI-based, and DAS28-based CR criteria. For TCZ users, CDAI-based CR criteria is more reliable than the other criteria.

FR10674 U sing Higher Image Resolution of Magnetic Resonance Imaging of the Cervical Spine Identifies More Inflammatory and Structural Lesions in Patients with Axial Spondyloarthrit is

S. Krabbe1, M. Østergaard1, J. Møller2, I.J. Sørensen1, B. Jensen1, O.R. Madsen1, S.J. Pedersen1. 1Center for Rheumatology and Spine Diseases, Rigshospitalet, Copenhagen; 2Department of Radiology, Herlev Hospital, Herlev, Denmark

Background: The vertebrae of the cervical spine are rather small and it may be difficult to assess if small areas with signal intensity changes represent the bones, joints or entheses, or derive from the surrounding blood vessels.

Methods: Forty-nine patients with axial spondyloarthritis according to the ASAS criteria started anti-TNF treatment and had "standard" resolution (std-res) and "high" resolution (high-res) MRI sequences of the cervical spine performed at baseline and after 48 weeks. 3 patients had follow-up scan already after 6–24 weeks due to study exclusion.

Std-res: STIR sequence: Voxel size 5.0 mm³ (slice thickness 4.0, spatial resolution 1x1.25); T1W sequence: voxel size 4.5 mm³ (slice thickness 4.0, spatial resolution 0.9x1.25).

High-res: STIR sequence: Voxel size 3.1 mm³ (slice thickness 3.5, spatial resolution 0.8x1.11); T1W sequence: voxel size 1.4 mm³ (slice thickness 3.0, spatial resolution 0.6x0.76).

Images were assessed in known chronology by an experienced axSpA MRI reader (SJF) blinded to clinical data. High-res and std-res were read in random order.

MRI lesions of inflammation, fat and new bone formation were defined according to the Canada-Denmark working group [1,2]. Erosions were not assessed.

Results: Inflammatory lesions: In 9 of 43 patients (21%), inflammatory lesions were detected in the cervical spine at baseline at std-res, while this was detected in 14 of 43 patients (33%) at high-res. Using high-res, as compared to std-res, 6 patients were reclassified from negative to positive for inflammation, 1 patient was reclassified from positive to negative, and 6/28 patients remained classified as positive/negative, p=0.13 by Exact McNemar test. The mean inflammation score was significantly higher at high-res compared to std-res (1.7 SD 4.5) vs. 0.8 (SD 2.7), p=0.04 by pair-test).

Fat lesions: 11 of 43 patients (26%) had fat lesions in the cervical spine at baseline using std-res, while 10 of 43 patients (23%) had this using high-res. The mean fat score was significantly higher at high-res compared to std-res (1.6 SD 3.5) vs. 0.8 (SD 1.8), p=0.02 by pair-test).

Bone spurs/ankylosis: 11 of 43 patients (26%) had bone spurs/ankylosis of the cervical spine at baseline at std-res, while 10 of 43 patients (23%) using high-res. The mean new bone formation score was significantly higher at high-res compared with std-res (2.7 (SD 6.1) vs. 1.4 (SD 3.5), p=0.01 by pair-test).

Responsiveness: Standardized response mean for inflammation score at std-res was 0.15, and at high-res 0.14. Structural lesions remained largely unchanged in all patients.

Conclusions: More patients were classified as having inflammatory lesions in the cervical spine when using high-res MRI compared to std-res. Likewise, mean scores of inflammatory lesions, fatty lesions and new bone formation were significantly higher compared with std-res. Further studies are needed to investigate the clinical significance of these findings as well as the frequency of these minor lesions in healthy controls.

ClinicalTrials.gov: NCT01029847.

FR10675 Obtaining Synovial Biopsies from the Wrist in Patients with Newly Diagnosed Untreated and Longstanding Rheumatoid Arthritis Followed by Intramuscular Glucocorticoid and Methotrexate Initiation Is Safe and the Glucocorticoid Treatment Significantly Reduces Disease Activity

S.A. Just1, C. Nielsen2, E.K. Højberg1, H.D. Schroder2, I.M.J. Hansen4, T. Barrington2, H.M. Lindengaard1, 1Rheumatology; 2Clinical Immunology; 3Clinical Pathology, Odense University Hospital, Odense; 4Medicine, Svendborg Hospital, Odense University Hospital, Svendborg, Denmark

Background: The minimal invasive ultrasound-guided synovial biopsy (USG-SB) method has been shown to be safe and tolerable. The method has accelerated the research field of using synovial biopsies focusing on early diagnosis, disease stratification, biomarker studies and in the future optimal treatment selection for the individual patient. Here synovial biopsies obtained from patients with early arthritis before therapy initiation are essential. A major issue in newly diagnosed RA patients but also in RA patients with longstanding active RA, is to combine an effective fast working treatment with safely obtaining synovial tissue without delaying therapy and patient’s initiation. In the EULAR early arthritis recommendations, prompt treatment initiation is recommended by combining glucocorticoid bridge therapy with disease-modifying antirheumatic drugs (DMARD). It is therefore essential that accepting synovial biopsy, does not delay start of fast remission-inducing treatment. Especially if synovial biopsies by the USG-SB method in the future shall be used systematically for detailed disease stratification and personalized treatment decisions.

Objectives: Safety of using intramuscular glucocorticoid injection (IGI) immediately after the USG-SB procedure in patients with newly diagnosed untreated RA and longstanding active RA, and the effect of IGI on disease activity after 4 weeks.

Methods: Wrist synovial biopsies were taken at inclusion and after 6 months from 22 patients with newly diagnosed, untreated RA and 15 with longstanding RA (>5 years). After biopsies patients were offered an IGI of 2 ml of methylprednisolone acetate (Depo Medrol) 40mg/ml. Early RA patients were also started on methotrexate. Disease activity scores in 28 joints (DAS28) were recorded at day of biopsy and again after 4 weeks. Safety data were obtained after 5 days (telephone), 2 weeks (questionnaire) and at first clinical evaluation (4 weeks) after biopsy. Patient-reported outcomes (PRO) with pain, swelling and stiffness of biopsied joint were obtained at day of biopsy and after two weeks.

Results: At present time, all patients have undergone first biopsy and 18/37 second biopsy. At the EULAR congress complete data will be presented. 68% of all patients accepted IGI after first biopsy currently 39% after second procedure. Patients accepting IGI after first biopsy did not have higher DAS-28 (early RA group (p=0.15), longstanding RA (p=0.06)). Time to first follow-up was not significantly different for patients accepting IGI (early RA group (p=0.17), longstanding RA (p=0.05)). Two weeks after biopsy, PRO was not significantly different when comparing IGI vs non-IGI treated. For all patients, DAS-28 was significantly reduced in the group receiving IGI at first clinical evaluation after synovial biopsy (p=0.004, without IGI ΔDAS28: -0.5, with IGI ΔDAS28: -1.7).

Conclusions: Start of treatment with IGI combined with DMARD after obtaining synovial biopsies by the USG-SB procedure from patients with early untreated RA and longstanding RA is safe, and reduces disease activity more than without IGI.

FR10676 A Proposal for a Simple Ultrasound Method for the Diagnosis of Early Rheumatoid Arthritis

T.Serban1,2, I. Satulu3, O. Vucan3, M. Milicescu1,2, C.M. Mihai1,2, M. Bojinca1,2, 1Internal Medicine and Rheumatology; “Dr. I. Cantacuzino” Clinical Hospital; 2Internal Medicine and Rheumatology, “Carol Davila” University of Medicine and Pharmacy, Bucharest, Romania; 3Rheumatology, Kalmar County Hospital, Kalmar, Sweden

Background: At this point, the classification criteria for rheumatoid arthritis (RA) are well known and generally applied in clinical practice. (1) Ultrasound (US) assessment can help in distinguishing the patients with early RA (ERA) within the patients with early inflammatory arthritides (EIA).

Objectives: The aim of this study was to develop an US method for the diagnosis
Concordance between fingertip and nailbed perfusion as assessed by PDUS is equal to 0.7988. The lower 97.5% confidence interval limit is 0.6433.

Association between capillary density, and fingertip and nailbed perfusion as assessed by PDUS is shown in Table 2.

Conclusions: To our knowledge, this is the first study to correlate NVC and PDUS findings in SSc patients. Fingertip and nailbed PDUS grade concordance was found to be satisfactory. The mean capillary density tends to be greater with respect to grade 1. This is particularly evident comparing grade 4 and grade 1. As such, these two imaging techniques provide different and potentially complementary information on SSc-related peripheral microvascular involvement.

There is potential clinical utility in these observations that has yet to be unlocked fully.

FR00678 | ULTRASOUND-GUIDED SYNOVIAL NEEDLE BIOPSY: SINGLE CENTER EXPERIENCE OF AN EMERGING, MINIMALLY INVASIVE TECHNIQUE IN CLINICAL PRACTICE AND RESEARCH
V.C. Romao 1, 2, J. Polido-Pereira 1, 2, R. Barros 1, E. Vieira-Sousa 1, 2, R. Luiz 1, E. Vitorino 1, F. Saraiva 1, J.E. Fonseca 1, 2, Rheumatology Department, Hospital de Santa Maria, CHLN, 2Rheumatology Research Unit, Instituto de Medicina Molecular, Faculty of Medicine, University of Lisbon; 3Pathology Department, Hospital de Santa Maria, CHLN, Lisbon, Portugal

Background: Synovial biopsy remains an important tool in clinical practice and research for the study of synovitis. Ultrasound-guided needle biopsy (USNB) has recently emerged as a minimally invasive technique, which enables collection of high quality synovial tissue with very good patient tolerance.

Objectives: To report the experience with USNB in our department, since its introduction in late 2013.

Methods: We reviewed the clinical files of all patients who had an USNB in our department. Degree of US joint synovitis was evaluated on a semi-quantitative scale (0–3) in terms of synovial thickness (ST) and power Doppler (PD). Since 2015, we assessed patient tolerance and acceptance of the procedure using a standardized questionnaire, which includes visual analogue scales (VAS) of pain, stiffness and swelling of the biopsied joint. Changes in US and VAS scores were assessed using the Wilcoxon signed-rank test.

Results: Forty-eight patients had 53 USNB, mostly for diagnostic purposes (79%), performed by 4 different operators - Figure 1. All types of joints were biopsied, mostly medium sized (26 wrists, 7 ankles), but also large (3 knees, 4 shoulders, 6 elbows, 3 hips) and small (1 sternoclavicular, 1 naviculocuneiform, 1 metacarpophalangeal and 1 proximal interphalangeal) joints, 2 bursae (subacromial) and 1 tendon sheath. USNB was repeated in the same joint (wrist) twice in 3 patients and three times in one patient. Procedures were well tolerated, with 67% of patients classifying it as easy or very easy, 28% reporting no or only mild discomfort and 77% considering likely/very likely to accept to repeat the biopsy. An increase in analgesic medication in the days following the biopsy was reported by 13 out of 44 questioned patients. After a median of 8 days following the procedure, a significant decrease was observed in VAS scores of pain, stiffness and swelling of the biopsied joint, although 23% and 31% of the patients reported small increases in these scores (median 9.5, 11 and 10mm, respectively). There was no significant change in US scores pre- and post-biopsy, with only 3 and 2 patients having an increase in ST or PD scores, respectively. Biopsies were overall safe, with 6 minor immediate adverse events (11%). There were no cases of haemarthrosis, joint/periarticular

FR00677 | ROLE OF NAILFOLD VIDEOCAPILLAROSCOPY AND 22-MHZ DOPPLER ULTRASOUND IN THE ASSESSMENT OF SYSTEMIC SCLEROSIS-RELATED DIGITAL VASCULOPATHY
T. Schioppo 1, 2, A. Orent 1, 2, P. Boracchi 1, 2, O. De Luca 2, A. Mugro 2, PL. Meroni 1, 2, F. Ingegnoli 1, 2 on behalf of OPERA study group.

Background: Microvascular damage plays a critical role in the initiation and perpetuation of systemic sclerosis (SSc). A comprehensive approach should investigate both superficial and deep layers of peripheral microcirculation. In addition to nailfold videocapillaroscopy (NVC), a well-established technique to evaluate outer skin layer vessels, power Doppler ultrasound (PDUS) has been recently used to study microcirculation in the inner levels [1].

Objectives: To study the severity of microvascular involvement in patients with SSc by using both NVC to measure capillary density (outer layer at the nailfold area) and PDUS to detect perfusion (deeper layers at the nailfold and pulp area).

Methods: 100 SSc consecutive patients fulfilling the 2013 EULAR classification criteria were enrolled. PDUS was performed at the 3rd and 4th finger of the dominant hand after exclusion of ulnar artery occlusion (UAO). In case of UAO non-dominant hand was examined. Ultrasound investigation was performed with Esaote MyLab 70 XVG by means of linear array transducer (10–22 MHz). Doppler Power settings were standardized (Doppler frequency 14.3 MHz, Gain 55%, PFR 750 Hz). PDUS measurements included sagittal scan of nailbed and fingertip qualitatively graded from 1 (no signal) to 4 (marked hyperemia) [2], and resistivity index (RI) of ulnar and radial proper digital arteries. Capillary density (number/mm) was calculated by NVC with magnification 200X performed on two images of the same digits examined by PDUS.

Results: 100 SSc patients, 87 (87%) women, 86 (86%) limited cutaneous SSc, median age 62.2 years old, median disease duration 8 years were evaluated. 7 (7%) patients had UAO. Concordance between fingertip and nailbed perfusion assessed by PDUS is reported in Table 1.

In ROC analysis, a cut-off of the US score of 4 had best results for sensitivity and specificity (73.3% and 82.1%, respectively), with an area under the curve of 0.812. The US score correlated with the levels of RF, ACPA, DAS28 and SDI (p < 0.001). The time needed for performing the ultrasound examination was less than 10 minutes.

Conclusions: The proposed US method proves to be reliable in identifying patients with ERA. The binary mode of US evaluation allows even persons with little training in US examination to diagnose patients. As the costs and time needed for US evaluation are low, the method is valuable in clinical practice for a rapid assessment of patients with ERA.

Table 2.
infection or neurovascular damage. Two patients reported transient limitation of the 5th and 1st digit extension following a biopsy of the wrist and 1st extensor compartment tendon sheath, respectively, with no detectable tendon ruptures on US; 1 patient had a muscular hematoma of the extensor muscles of the forearm following an elbow biopsy.

**Conclusions:** In our center, USNB has proved to be an effective technique for collection of synovial membrane that can be used for diagnostic and research purposes. The vast majority of the procedures were well tolerated, without significant worsening of local joint symptoms or synovitis, and safe, without major adverse events. Importantly, patients' concordance to repeat a USNB was mostly high.

CLINICAL VALIDATION STUDIES OF THE 2012 CLASSIFICATION CRITERIA FOR EARLY RHEUMATOID ARTHRITIS (ERA) IN A DOMESTIC MULTI-CENTER COHORT

Y. Li 1,2, W. Fan 3, H. Chen 4, P. Yu 5, H. Miao 1, K. Li 3, J. Xu 4, L. Cui 5, G. Zhang 1, K. Xu 1, L. Zhang 5, R. Li 2, 1Shanxi Academy of Medical Sciences, Shaxi Dayi Hospital, Taiyuan; 2Rheumatology and Immunology, Peking University People's Hospital, Beijing; 3Xinxiang Central Hospital, Xinxiang; 4the Third Hospital of Hebei Medical University, Shijiazhuang; 5Kailuan General Hospital, Tangshan, China

Background: Recently, a new classification criteria for early rheumatoid arthritis (ERA) have been developed.

Objectives: To evaluate the value of 2012 classification criteria for early rheumatoid arthritis (ERA), 2010 ACR/EULAR classification criteria, and 1987 ACR classification criteria in the diagnosis of early RA.

Methods: Early arthritis patients with age more than 16 years, disease duration no more than 1 year, Cat least one joint swelling and tenderness were enrolled in a multicenter, open, cross-sectional study cohort. The patients were diagnosed as RA or other non RA disease by 2 trained experienced rheumatologists. Detailed recorded the clinical and laboratory parameters include disease duration, morning stiffness duration, RF, anti-CCP, ESR, CRP etc.The sensitivity and specificity of three RA classification criteria were compared by McNemar test. The areas under the ROC curve (AUC) of each RA classification criteria were analyzed using MedCalc software.

Results: A total of 310 patients were randomly enrolled in this study, including 182 ERA and 128 non-RA. The sensitivity (88.5%) of ERA criteria were much higher than that of 1987 ACR criteria (45.6%, χ²=75.013, P<0.0001), and not significantly different with the 2010 ACR/EULAR criteria (91.8%, χ²=1.042, P=0.05). The specificity of ERA criteria (91.4%) were similar to those of 2010 ACR/EULAR criteria (87.5%, χ²=1.0, P=0.05) and 1987 ACR criteria (96.1%, χ²=3.1, P<0.05). The AUC of ERA criteria was 0.962 (95% CI: 0.934, 0.980), which was slightly better than that of the 2010 ACR/EULAR criteria [0.959 (95% CI: 0.931, 0.978), Z=4.0, P=0.0001], and much higher than that of the 1987 ACR criteria [0.885 (95% CI: 0.845, 0.919), Z=4.517, P<0.0001].

Conclusions: Overall evaluation, the diagnostic value of ERA criteria is better than 1987 ACR and 2010 ACR/EULAR criteria in early rheumatoid arthritis. Compared to 2010 ACR/EULAR classification criteria, ERA criteria is obviously more simple and practical.

FRI0681 FOLLOW-UP OF TREATMENT RESPONSE WITH DYNAMIC DOPPLER ULTRASOUND IN RAYNAUD'S PHENOMENON

U. Toprak 1, Z. Ozbaklan 1, M. Edugan 3, S. Parlak 1, S.C. Sandikci 1, T. Kaya 4, S. Sayilsoy 1, 1Department of Radiology, Suleyman demirel University, Isparta; 2Department of Rheumatology, Ankara Numune Education and Research Hospital, Ankara; 3Department of Rheumatology, Istanbul University, Capa School of Medicine, Istanbul; 4Department of Radiology, Ankara Numune Education and Research Hospital, Ankara; 5Department of Radiology, Eskişehir Demagi University, School of Medicine, Eskişehir, Turkey

Background: This study aims to investigate the role of flow parameters obtained by dynamic Doppler ultrasound in the objective follow-up of treatment response in Raynaud’s phenomenon (RP) cases.

Methods: The study included newly diagnosed 33 patients with primary RP (PRP), 31 patients with secondary RP (SRP), and 26 healthy controls. The control group was evaluated with Doppler once, while the patients before treatment and on the third month of the treatment. Baseline and post-cold provocation diameter (BD, CPD, mm) and flow volume (BFV, CPFV, mL/min); post-cold provocation flow starting time (FST, min), and flow volume normalization time (FVNT, min) were recorded. Statistical analysis: for comparison of the ex of the groups: chi-square test, for analysing the pre and post treatment doppler parameters: Wilcoxon test and to comaprison of the PRP and SRP post treatment values to controls using Krusal Wallis test. A p value less than 0.05 was considered statistically significant.

Results: Before-after treatment, there was no significant improvement in the BD in both PRP and SRP groups (0.79±0.17–0.82±0.19 vs. 0.66±0.13–0.68±0.14 PRP vs. SRP, respectively), while FST did not significantly improve in the PRP group (1.5±2.7–0.61±1.41 vs. 3.13±4.81–1.58±2.36 (p<0.05)). A significant improvement was observed in baseline flow volume (3.08±2.96 vs 3.91±3.39 (p: 0.002), flow volume normalization time (7.24±7.60 vs 3.84±3.39 (p: 0.0001), after cold provocation flow volume (1.18±1.26 vs 2.17±2.16) (p: 0.0001), after cold provocation diameter (0.63±0.15 vs 0.70±0.16) (p: 0.005) in PRP group after treatment.

In SRP group, only baseline iometer changes were not influenced by the treatment, all other post treatment parameters were improved in all SRP cases including baseline flow volume (2.14±1.94 vs 2.80±2.19) (p:0.009), after cold provocation diameter (0.56±0.15 vs 0.63±0.13) (p: 0.004), after cold provocation flow volume (1.07±2.40 vs 1.46±2.67) (p: 0.004), flow starting time (3.13±4.81 vs 1.58±2.36) (p: 0.021) and flow volume normalisation time (9.58±18.49 vs 3.32±3.56) (p: 0.0001).

There was an improvement in parameters after the treatment in both RP groups comparing by the control groups (p<0.01).

Conclusions: Doppler ultrasound is an objective, cost-effective, safe (does not include radiation), and easy-to-use method in the follow-up of RP patients on macrovascular level with or without cold provocation before and after treatment.

Epidemiology, risk factors for disease or disease progression

FRI0682 CAUSES OF DEATH IN 350 PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES (SARD)

J.G. Ovalles-Bonilla 1,2, O. Fernández 3, J. Martínez-Barrio 1, L. Valor 1, D. Hernández 1,2, I. Janta 1, B. Serrano 1, C. Sáenz 1, R. González 1, M. Correoyo 1, L. García 1, A. López 1, A. Silva 1, J.C. Nieto 1, C. González 1, I. Montesagudo 1, F.J. López-Longo 1,2, 1Rheumatology, Hospital General Universitario Gregorio Marañón; 2Instituto de Investigación Sanitaria Gregorio Marañón, Madrid, Madrid, Spain

Background: The major SARD have an increased mortality compared to the general population. It is well known that the main causes of death in Systemic Lupus Erythematosus (SLE) are infections (INF), cardiovascular events (CV), neoplasia...
early treatment with methotrexate was associated with lower risk estimates [HR 0.71 (95% CI 0.60,0.83)], which was not clearly seen with other DMARDs [HR 0.94 (95% CI 0.82,1.0)]).

Disclosure of Interest: None declared
Individuals who developed GCA after inclusion in the two health surveys were identified by linking the health survey database to the local patient administrative register and the regional patient administrative register. Four controls for every validated case, matched for sex, year of birth and year of screening, were selected from the database. Fasting blood samples had been obtained and analyzed using standard methods as part of the health survey. Potential predictors of GCA examined in conditional logistic regression models.

Results: There were 76 cases with a confirmed clinical diagnosis of GCA (61% female; 65% biopsy positive; 95% fulfilled the ACR criteria for GCA). The mean age at diagnosis was 70 years, and the median time from screening to diagnosis was 20 years (range 2–32). The cases had significantly lower fasting blood glucose (FB-glucose) at baseline screening compared to controls (mean 4.7 vs 5.1 mmol/l; odds ratio (OR) 0.49 per mmol/l; 95% confidence interval (CI) 0.30–0.79). Current smokers had a reduced risk of GCA (OR 0.35; 95% CI 0.18–0.70). The negative association between baseline FB-glucose and GCA remained significant in analysis adjusted for smoking (OR 0.46 per mmol/l; 95% CI 0.28–0.76). Both cholesterol (mean 5.6 vs 6.0 mmol/l) and triglyceride levels (median 1.0 vs 1.2 mmol/l) were lower among the cases at baseline screening, with significant negative associations with subsequent GCA in crude and smoking-adjusted (ORs with 95% CI 0.66 per mmol/l; 0.46–0.94 for cholesterol, 0.33 per mmol/l; 0.16–0.69 for triglycerides) models. The effect of FB-glucose on the risk of GCA was stronger in men compared to women (smoking-adjusted ORs per mmol/l 0.11; 95% CI 0.03–0.37, and 0.77; 95% CI 0.50–1.88, respectively). Apart from this, results were similar in women and men.

Conclusions: Development of GCA was associated with lower FB-glucose, lower cholesterol and triglyceride levels at baseline, all adjusted for current smoking. These findings are in line with the previous findings of a reduced prevalence of diabetes mellitus at the time of diagnosis of GCA (1). This suggests that metabolic factors influence the development of GCA.

FR00689 LIPID PEROXIDATION AS RISK FACTOR FOR ENDOTHELIAL DYSFUNCTION IN ANTIPHOSPHOLIPID SYNDROME (APS) PATIENTS

L. Stojanovich, N. Stanisavljevic, A. Djokovic, M. Zdravkovic. Internal medicine department, University Hospital Center Bezanjska Kosa, Belgrade, Serbia

Background: APS pathophysiology is not clear enough yet since it has been implicated that aPL can activate cells (endothelial cells, monocytes, platelets), interfere with hemoctatic reactions and activate complement reactions [1,2].

Objectives: The aim of this study was to evaluate oxidative stress markers and it relations to endothelial damage as risk factor for thrombosis in patients with primary (PAPS) and secondary (SAPS) antiphospholipid syndrome (APS) in correlation to traditional risk factors.

Methods: Flow mediated (FMD) and nitroglycerine (NMD) induced dilation of the brachial artery were studied in 140 APS patients (90 PAPS, 50 SAPS) and 40 controls matched by age, sex and conventional risk factors for atherosclerosis. Markers of oxidative stress: lipid hydroperoxides (LOOH), advanced oxidation protein products (AOPP), total sulphhydryl groups (SHG) and paraoxonase 1 activity (PON1) were determined by spectrophotometric method.

Results: Oxidative stress dominate in APS patients. LOOH and AOPP correlate to lipid fractions (p<0.05), unlike PON1, ISHG that correlated to antiphospholipid antibody positivity (p<0.05). FMD was lower in APS patients comparing to controls (p<0.001). Cholesterol is independent variable for FMD impairment in control group (p=0.011); LOOH in PAPS (p=0.004); LOOH, aCL and triglycerides in SAPS patients (p=0.009, p=0.049 and p=0.012, respectively); Combined predictive of aCL and LOOH is better for FMD impairment than LOOH alone in both PAPS and SAPS patients (AUC 0.727, p=0.001, 95% CI 0.616–0.837 and AUC 0.824, p<0.001, 95% CI 0.690–0.957, respectively).

Conclusions: Endothelial dysfunction is doubtlessly present in APS patients with oxidative imbalance as additional risk factor among other risk factors for clinical event. Anticardiopin antibodies affect endothelial dependent vasodilatation in SAPS patients. We demonstrated synergistic effect of aCL and LOOH as risk for endothelial impairment in both PAPS and SAPS patients.

FR00690 RISK OF FRACTURE AMONG PATIENTS WITH GOUT: A POPULATION-BASED COHORT STUDY

A. Abdul Sultan 1, R. Whittle 1, S. Muller 1, E. Roddy 1,2, C. Mallen 1, M. Blagoevick-Bucknall 1, T. Helliwell 1, S. Hider 1,2, Z. Paskins 1,2, 1Research Institute for Primary Care & Health Sciences, Keele University, Staffordshire;

2Haywood Academic Rheumatology Centre, Staffordshire and Stoke-on-Trent Partnership Trust, Stoke-on-Trent, United Kingdom

Background: Gout is the most common type of inflammatory arthritis, affecting 2.4% of adults in the UK and is associated with a number of co-morbidities. Our understanding of the association between gout and fracture risk is limited with previous studies offering conflicting results.

Objectives: To determine the role of ULT in fracture prevention.

Methods: Utilising primary care records from Clinical Practice Research Datalink we identified patients with gout between 1990 and 2004 who were followed up until 2015. Each gout patient was individually matched to 5 individuals without gout based on age, sex, and registered practice. Absolute rate (AR) of fracture and hazard ratios were calculated using Cox regression models. We further stratified our analysis by age, gender and ULT prescription.

Results: We matched 35,857 patients with incident gout to 148,407 controls. Overall, we found no increased risk of fracture among gout patients compared to controls. However, men with no evidence of ULT had higher absolute risk of fracture compared to controls (AR=39 versus 26 per 10,000 person-years, corresponding to a 23% (HR=1.23; 95% CI 1.12–1.36) increased risk. The risk was particularly high for vertebral (HR=1.50; 95% CI 1.20–1.87) and wrist fracture (HR=1.45; 95% CI 1.21–1.74). Those treated with ULT had a 12% (HR=0.88; 95% CI 0.79–0.98) lower risk of fracture. Similar findings were not observed for women.

Conclusions: We found higher risk of vertebral and wrist fractures among men with gout not prescribed ULT. Those prescribed ULT had lower risk of fracture compared to the general population. Further research is needed to understand the role of ULT in fracture prevention.

FR00691 ASSOCIATION BETWEEN PERIODONTITIS AND THE RISK OF PALINDROMIC RHEUMATISM: A NATIONAL, POPULATION-BASED, CASE-CONTROL STUDY

H.-H. Chen 1, W.-C. Chao 1, Y.-M. Chen 1, D.-Y. Chen 2, 1Department of Medical Research; 2Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China

Background: Some patients with palindromic rheumatism (PR) may develop a chronic connective tissue disease, mainly rheumatoid arthritis (RA). About one to two-thirds of PR patients developed RA during a period of follow-up. Periodontitis (PD) has been found to be associated with RA risk. However, the association between PD and PR is unknown.

Objectives: To estimate the association between a history of PD and the risk of incident PR.

Methods: This study used a nationwide, administrative database to identify PR cases and non-PR controls. After exclusion of individuals with rheumatoid arthritis, systemic lupus erythematosus, Sjögren’s syndrome, systemic sclerosis, dermatomyositis or polymyositis before the first PR diagnosis date (index date), we identified 4,421 newly-diagnosed PR cases from 2007 to 2012 and randomly selected 44,210 non-PR controls matched (1:110) for sex, age, and the year of the index date. After adjusting for comorbid diabetes mellitus, we estimated odds ratios (ORs) with 95% confidence intervals (CIs) by conditional logistic regression analysis to quantify the association between a history of PD and the risk of PR. The influences of the lag time and severity of PD were examined by calculating ORs for subgroups of patients based on time intervals of last PD-related visit and the index date and PD-related cumulative cost and visit number.

Results: This study showed an association between a history of PD and newly diagnosed PR (OR, 1.51; 95% CI, 1.41–1.61). The association remained significant after variation of PD definitions. The magnitude of the association was...
greater in those who had shorter lag time between the last date of PD diagnosis and PR index date and those who had a higher number of visits for PD or greater cumulative cost of PD-related visits.

Conclusions: This study demonstrated a time- and dose-dependent association between PD exposure and PR risk.

J. Singh, J. Cleveland, University of Alabama at Birmingham, Birmingham, United States

Background: Recent studies have shown that hyperuricemia and gout, a condition with hyperuricemia associated with joint inflammation and/or renal manifestations, are associated with a higher risk of coronary artery disease (CAD), acute cardiovascular events including myocardial infarction (MI) and stroke, and cardiovascular mortality. Emerging data suggest that gout and hyperuricemia may also be associated with cardiac arrhythmias such as atrial fibrillation.

Objectives: To assess whether allopurinol use is associated with a reduction in the risk of ventricular arrhythmias (VA).

Methods: We used the 5% random sample of Medicare beneficiaries from 2006–2012 to examine new allopurinol use and the risk of incident VA. Multivariable Cox regression analyses were adjusted for demographics (age, race, gender), comorbidity, cardiac medications and conditions associated with VA. We calculated hazard ratios (HR) and 95% confidence intervals (CI).

Results: Of the 28,755 episodes of new allopurinol use, 2,538 were associated with incident VA (8.8%). Among patients with incident VA, 54% were male, 78% were White, and the mean Charlson-Romano comorbidity score was 4.8. The crude incidence of VA per 1,000,000 person-days declined as the duration of allopurinol use increased: 1–180 days, 151; 181 days-2 years, 105; and >2 years, 85. In multivariable-adjusted analyses, compared to non-use, allopurinol use was associated with lower HR of VA of 0.82 (95% CI, 0.76 to 0.90). Compared to allopurinol non-use, longer allopurinol use durations were significantly associated with lower multivariable-adjusted HR for VA: 1–180 days, 0.96 (95% CI, 0.85 to 1.08); 181 days to 2 years, 0.76 (95% CI, 0.68 to 0.85); and >2 years, 0.72 (95% CI, 0.60 to 0.87). Multiple sensitivity analyses adjusting for cardiac conditions, anti-arrhythmic drugs and alternate definitions confirmed our findings with minimal/no attenuation of estimates.

Conclusions: Allopurinol use and use duration >6 months were independently associated with a lower risk of VA. Future studies need to assess the pathophysiology of this potential benefit.

FR10693 SYNOVIAL CHANGES DETECTED BY ULTRASONOGRAPHY AND THEIR ASSOCIATION WITH OSTEOARTHRITIS-RELATED KNEE PAIN: A 1-YEAR PROSPECTIVE COHORT STUDY
A. Sarmanova 1,2, M. Hall 1,2, G.S. Fernandes 1,4, A.M. Valdes 1,2, D.A. Walsh 1,2, M. Docherty 1,2, W. Zhang 1,2, Division of Rheumatology, Orthopaedics and Dermatology, The University of Nottingham; Pain Centre, Arthritis Research UK; 3School of Health Sciences, The University of Nottingham; 4Centre for Sports, Exercise and Osteoarthritis, Arthritis Research UK, Nottingham, United Kingdom

Background: Recently an important role for synovial pathology in the initiation and progression of knee osteoarthritis (OA) has been emphasized. Our previous cross-sectional study showed that synovial changes on US associated with knee pain (KP), but the association was confounded by radiographic severity [1].

Objectives: To examine whether these synovial changes associate with KP changes over 1 year.

Methods: 220 participants with early KP (<3yrs duration) identified from the Knee Pain and Related Health in the Community (KPIC, n=5614) survey in Nottingham, UK formed the cohort for this study. All participants had bilateral US and radiographic examination at baseline, and US was repeated after 1 year. KP was defined as pain in or around the knee on most days for at least a month, and KP severity was measured using a numerical rating scale (NRS 0–10). Change in KP severity was defined according to a Patient Global Impression of Change. Synovial changes (effusion, hypertrophy and Power Doppler (PD) signal) were measured by two observers (inter-observer concordance correlation was 0.8 (0.6 to 0.9) for effusion and 0.7 (0.5 to 0.9) for synovial hypertrophy). Standardised radiographs (semi-flexed weight-bearing and flexed skyline views) were scored using the Nottingham Line Drawing Atlas (NLSA). Radiographic OA was defined as definite joint space narrowing (grade 2) plus definite osteophyte (grade 2) in any compartment. An absolute change in effusion/synovial thickness/pain scores was calculated by subtracting the baseline measure from the follow-up measure within individuals. A correlation analysis was used to examine the association between changes in pain and changes in US values. Potential baseline predictors for KP worsening were examined using multivariate logistic regression analysis.

Results: Of 220 participants in this cohort, 165 (75%) had US measurements at baseline and follow-up (mean age 61yrs: 61% women; 24% ROA). The mean NRS score decreased from 4.4 to 3.01 mm. The mean depth of the effusion and synovial hypertrophy changed from 4.01 mm to 5.37 mm, and from 1.82 to 2.45 mm, respectively. There was no correlation between changes in pain in NRS and changes in US-detected synovial change (Figure 1).

At 1 year follow-up, 58% reported that their KP had improved from baseline, 16% reported worsening, and 27% reported no change in KP. After adjustment for age, gender and BMI baseline US features did not predict worsening pain, whereas ROA did (OR=4.06 95% CI 1.55 to 10.61).

Conclusions: This study extended previous work that US-detected knee “synovitis” was not a predictor of change in OA symptoms, whereas baseline radiographic OA severity was. It suggests that synovial changes detected by US might reflect aspects of OA pathology discrete from mechanisms driving OA pain change.

FR10694 PREVALENCE OF RHEUMATIC DISEASE IN AN ADULT POPULATION FROM COLOMBIA. A COPCORD METHODOLOGY STUDY
A.M. Santos 1, J.C. Rueda 1, J.L. Angarita 1, R. Giraldo 2, E. Forero 2, I. Pelaez-Ballestas 2, J.G. Ballesteros Muñoz 2, E.L. Saillardraga 2, J. Ramirez 2, C. Toro 2, J. Londono 2, 1Reumatología, Universidad de la Sabana, Chia; 2Medicina Interna, Reumatología, Universidad del Norte. Barranquilla, Colombia; 3Departamento de Reumatología, Hospital General de México, Ciudad de México, Mexico; 4Departamento de Medicina Interna, Hospital San José; 5Asociación Colombiana de Reumatología; 6Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá, Colombia

Background: Rheumatic diseases are the leading cause of permanent disability. In our country are the fourth cause of consultation in health institutions. The COPCORD model constitutes an effective tool in the determination of the prevalence of diseases. Globally, this model has been carried out in Asia, Europe and in some countries of Latin America. In Colombia the epidemiology of rheumatic diseases is not known globally; this would be the first national study that uses the data collection questionnaire using the COPCORD instrument.
Objectives: To estimate the prevalence of rheumatic disease and related factors in a Colombian population over 18 years of age in six Colombian cities.

Methods: A cross-sectional analytical study was designed in people older than 18 years. A probabilistic stratified sampling method using three stages. The first stage of sampling was the selection of cartographic sectors in each city. The second stage of sampling was the selection of blocks of each sector. The third stage of sampling was the homes of each block. All household members were surveyed.

The sample size was calculated to be 6,528 people (2336 from Bogotá, 1220 from Medellín and Cali each, 746 from Barranquilla, 503 from Bucaramanga and Cúcuta each). The COPCORD questionnaire adapted for Colombia, was applied in the first stage by standardized interviewers. Positive cases were reviewed at home by a first year rheumatology fellow. To assess whether it is a rheumatic disease; the positive cases for a probable rheumatic disease were reviewed by a second year rheumatology fellow and reviewed again with laboratory and image studies by a certified rheumatologist to establish the definitive diagnosis.

Results: 3,146 men and 3,547 women were included. Pain in the last 7 days not associated with trauma was reported in 3,213 (48%) participants. The most frequent sites were knees (right 31%, left 29%), hands (right 25%, left 24%), lumbar spine (16%) and shoulders (right 16%, left 14%). Table 1 depicts the prevalence of rheumatic diseases in Colombia.

Conclusions: Our study shows a similar prevalence to those worldwide in scleroderma, dermatomyositis, systemic lupus erythematosus, and spondyloarthritis. A lower prevalence was observed in Sjögren Syndrome, fibromyalgia, gout and osteoarthritis. A slightly higher prevalence of rheumatoid arthritis was observed in our population. The high prevalence of rheumatoid arthritis and soft tissue rheumatism should increase awareness in our governmental health entities given their long term disability risk.

FRI0696 IMPACT OF ADALIMUMAB THERAPY ON BRACHIAL ENDOTHELIAL FUNCTION AND LARGE ARTERY STIFFNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A.L. Demouy 1, K. Aissi 1, B. Chauvédier 2, S. Carinj 2, H. De Baillou 3, P. Rossi 3 1. Internal medicine department, public hospital of Marseille; 2. Internal Medicine Department, Laveran Hospital; 3. CONCERTO Association, Marseille, France

Background: Anti-TNFα treatment may improve endothelial function and mechanical properties of large artery stiffness in patients with inflammatory rheumatic diseases, however studies remain controversial.

Objectives: To study the effect of TNFα blocker with adalimumab for 24 weeks on brachial endothelial function and sub-clinical markers of atherosclerosis in patients with inflammatory rheumatic diseases.

Methods: A total of 26 patients (14 males, 12 females; mean age, 47±11 years) with inflammatory rheumatic diseases (16, rheumatoid arthritis; 9, anklyosing spondylitis, 1, psoriatic rheumatism), resistant to disease-modifying antirheumatic drugs, were studied before the first infusion of adalimumab and again after 24 weeks of treatment. Endothelial function was assessed by measuring flow mediated dilatation using an ultrasound Doppler technique on the brachial artery. Other markers of sub clinical atherosclerosis were assessed by arterial stiffness via aortic pulse wave velocity, augmentation index and central blood pressure, and carotid intima-media thickness. Data for body mass index, disease activity using DAS-PDR and BASDAI, C-reactive protein, fasting glycaemia, and lipid profile were collected before treatment and after 24 weeks.

Results: 24 weeks of adalimumab therapy resulted in a reduction of disease activity score and serum levels of C-reactive protein. No significant differences were found in body mass index, total cholesterol, triglycerides and fasting glycaemia. Brachial blood pressure and heart rate remained similar, as well as carotid intima-media thickness. After 24 weeks of treatment with adalimumab, flow mediated dilatation improved significantly; central systolic and diastolic blood pressure decreased significantly; however central pulse pressure, augmentation index and arterial pulse wave velocity remained unchanged.

Conclusions: In patients with inflammatory rheumatic diseases, treatment with adalimumab for 24 weeks resulted in a significant improvement of endothelial function and central arterial pressure.

FRENCH NATIONWIDE SURVEY OF CHRONIC PAIN PERCEPTION IN 1739 PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISM

A.-P. Trouvin1, C. Beller2, P. Preis3, S. Perrot4, Rheumatology, Hopitaux Universite Paris Centre - Cochin; 2Association AFPRic; 3Pain Centre, Hopitaux Universitaire Paris Centre - Cochin, Paris, France

Background: Pain is a major symptom in chronic inflammatory rheumatism. Pain intensity doesn’t always correlate with disease activity and it can persist even when RA seems in clinical and biological remission. Little is known about the patients’ perception of their treatment efficacy on pain, of pain in their life and their expectations for pain management. A French patients association (AFPRic) conducted a national survey to explore patient’s point of view on pain in their rheumatism.

Objectives: Describe in patients with chronic inflammatory rheumatism, their perception of treatment efficacy on pain, the impact of pain in their life and their expectations on pain care, in a nationwide survey.

Methods: A nationwide survey with a 20-item questionnaire was conducted. The questions were developed by patients and rheumatologists in focus groups. Questionnaires were e-mailed to every member of the association (9065 members). Answers were collected until the 17th July 2016. Answers were anonymous.

Results: One thousand thirty nine patients (response rate 19.2%) answered the questionnaire with 1510 women (86.8%), mean age was 59 years [18–85 years].

For more than half of the patients, their rheumatism had, since the 10 years of evolution. Rheumatoid arthritis was the main rheumatism with 1377 patients (87%). Among the 1194 patients (76%) under conventional DMARDs 46.4% considered the cDMARDs efficacy on pain was between 70 and 100%, on the other hand for 17.7% of the patients, cDMARDs efficacy on pain was less than 30%. Among the 744 patients (47.6%) receiving a biological DMARD, 66.2% considered bDMARDs efficacy on pain was between 70 and 100% and 10% considered it was 30% or less. Among the 658 patients (42.3%) receiving oral corticosteroids, 56.6% considered corticosteroids’ efficacy on pain between 70 and 100% and 12% not considered it was less than 30%. Patients were asked to rate the weight of pain among their symptoms, for 38% of the patients pain represents 70 to 100% of the symptoms of their rheumatism, for 31.7% it represents 40 to 60% and for 30.3% 30% or less. The mean weight is 51.55% Among the patients of the 46.8%, considered that pain is underestimated by health professionals. For 37.2% of the patients, their current treatments are not appropriate for their current pain intensity. Finally 528 (35.7%) patients are not wish to participate to support groups with health professionals. For 37.2% of the patients, their current treatments are not appropriate for their current pain intensity. Finally 528 (35.7%) patients are not wish to participate to support groups with health professionals specialized in pain care.

Conclusions: This nationwide survey on pain among chronic inflammatory rheumatism patients shows that even in the biological DMARDs era, pain is the main concernment symptom for the patients. It is striking in this large cohort that almost half of the patients consider their pain insufficiently taken care of.

FR0698

PREVOTELLA AND ALLOPREVOTELLA SPECIES CHARACTERIZE THE ORAL MICROBIOME OF EARLY RHEUMATOID ARTHRITIS

1Department of Conservative Dentistry, School of Dental Medicine, University Hospital Heidelberg; 2Dept. of Infectious Diseases-Medical Microbiology and Hygiene, University Hospital Heidelberg; 3Division of Rheumatology, Department of Medicine V. Ruprecht Karl’s University, Heidelberg, Germany

Background: We previously showed that in this early rheumatoid arthritis (ERA) cohort with a mean disease duration of <6 months, a clinically significant loss of clinical attachment loss as surrogate of alveolar bone loss is detectable compared with a matched healthy control cohort (1). Evidence is accumulating that distinct pathogens residing in reservoirs such as the oral cavity, the lung or the gut may play a role in driving the pathogenesis of RA (2–3).

Objectives: To characterize the oral microbiome associated with ERA.

Methods: 16S amplicon sequencing was used to analyze 88 samples of the supragingival and subgingival microbiome of 22 patients with ERA and 22 matched healthy controls. Oral and periodontal status, clinical activity of ERA and periodontitis, and socio-demographic parameters were used as explanatory variables in the next generation DNA sequencing analysis.

Results: Overall, a total of 4,702,161 16S RNA high-quality sequences were yielded. Using a distance-based similarity of ~97% for species-level operational taxonomic units (OTUs) clustering, a total of 1,048 OTUs were identified (Fig. 1). The oral microbiota was equally rich and diverse in ERA and control group. Subgingivally, Prevotella oris, Prevotella oralis, Prevotella nigrescens, Alloprevotella rava and Alloprevotella tannaeae were associated with early RA independent of severity of periodontitis.

Conclusions: Prevotella and Alloprevotella species were enriched in patients with early RA independent of severity of periodontitis. Further studies are needed to test a causal relationship of these species with onset and/or disease progression of RA.

Background: Biotherapies such as subcutaneous tumour necrosis factor-alpha inhibitors (SC-TNFis) have transformed the management of inflammatory joint diseases such as ankylosing spondylitis (AS). The assessment of SC- TNFis persistence and its determinants is needed.

Objectives: The objective of this study was to describe treatment persistence in real-world settings, and identify the determinants of persistence among AS patients initiating treatment with an SC-TNFi.

Methods: The French national health insurance scheme database lists all outpatient and inpatient healthcare consumption for individuals covered by the general health insurance scheme. Using French claims data, AS was diagnosed using Long Term Disease status and hospital admission, based on ICD-10 codes. Patients were then identified through prescription filled for adalimumab (ADA), etanercept (ETA), certolizumab pegol (CZP) and golimumab (GLM) between 2012/07/01 and 2013/12/31. A patient was considered as non-persistent in the event of a prolonged interruption of the therapy lasting 91 days or more. Persistence was estimated with Kaplan Meier analysis. Determinants of persistence in the 12 months before initiation were identified using Cox models.

Results: A total of 9,098 patients with AS were identified. In the descriptive analyses of the 12 months persistence, differences were observed for AS patients, with rawon-adjusted persistence rates of 93.2% for CZP, 49.3% for ETA, 52.4% for ADA and 54.5% for GLM. Results of the Cox model are presented, including hazard ratio for biotherapy, adjusted on sex, age, socio-economic status, and criteria on disease severity. The variables biotherapy, socio-economic status and hospital admission for IRMD did not meet the proportionality hypothesis of risks.
and were corrected by the addition of a variable integrating the interaction with time.

Table 1. Determinants of 12-month non-persistence (Cox model).

Conclusions: Non-persistent patients were more likely female, with deprived socio-economic status, multiple comorbid conditions, and multiple line of biotherapy. Age, hospital admission for IRMD and treatment with GLM (adjusted on C2P, ETA and ADA) decreased the risk of non-persistence. Further analyses are needed to assess the impact of non-persistence.

3. **DOES PARITY INFLUENCE JOINT DAMAGE PROGRESSION IN WOMEN WITH RHEUMATOID ARTHRITIS?**

4. **Abstract**

5. **FR0700**

6. **PHYSICAL ACTIVITY DECREASED SIGNIFICANTLY BUT MODERATELY DURING WEEKS WHERE PATIENTS REPORTED FLARES: A 3-MONTH STUDY OF 170 RHEUMATOID ARTHRITIS (RA) OR AXIAL SPONDYLOARTHRITIS (AXSPA) PATIENTS WEARING AN ACTIVITY TRACKER**

7. **C. Jacquemin,** 1, H. Servy 2, A. Molto 3, J. Sellam4, V. Foltz 1, F. Gandjbakhch 1, C. Hudry 2, S. Mitrovic 2, B. Fauret 1, L. Gossec 2, **Rheumatology, La Pitie-Salpetriere Hospital, Paris; 2**Sano, e-Health services, Gantanne, 3Rheumatology, Cochin Hospital; 4Rheumatology, Saint Antoine hospital; 5Rheumatology, Private practice, Paris, France

8. **Background:** RA and axSpA natural history comprises periods of low disease activity and flares. There is much interest in the concept of flares. Studies have indicated flares may alter patient quality of life, however, there are few data linking flares to quantifiable outcomes.

9. **Objectives:** The objective was to assess longitudinally the association between patient-reported flares and physical activity assessed objectively using an activity tracker.

10. **Methods:** This prospective multi-center observational study (ActConnect) included patients with definite RA (ACR/EULAR criteria) or axSpA (ASAS criteria) owning a smartphone. Physical activity was assessed continuously over 3 months by the number of steps using an activity tracker, and flares were self-assessed weekly using a specific flare question ("has your disease flared up during the last 7 days") with a categorical response according to: no flare, 1 to 3 days flare, or >3 days flare. The relationship between flares and physical activity for each week (time point) was assessed by linear mixed models adjusted on rheumatoid disease, sex, age, obesity, biologics and employment status.

11. **Results:** 170/178 patients (91 RA and 79 axSpA patients; 1553 time points) were analyzed: mean age 45.5±12.4 years, mean disease duration 10±8.7 years; 60 (35.3%) were males and 90 (52.9%) received biologics. Disease was well-controlled (mean DAS28: 2.3±1.2; mean BASDAI: 3.3±2.1). Physical activity was moderate (mean steps/day, 7067±2770). Flares were frequent (25.5% of the questionnaires); most (76.8%) were of short duration. Flares, in particular >3 days flares, were independently associated with less weekly physical activity (p=0.02–0.03), leading to a relative decrease of physical activity of 12–21% and an absolute decrease ranging from 836 to 1462 steps/day (Table 1).

12. **Conclusions:** Flares were frequent in these low-disease patients, though most flares were of short duration. Flares were related to a moderate decrease in physical activity, confirming objectively the impact of patient-reported flares.

17. **DOES PARITY INFLUENCE JOINT DAMAGE PROGRESSION IN WOMEN WITH RHEUMATOID ARTHRITIS?**

18. **C. Alpigaz-Rodriguez 1,** F. Förger 1, D. Courvoisier 1, C. Gabay 1, A. Finckh 1 on behalf of Physicians of the Swiss Clinical Quality Management Program for Rheumatoid Arthritis. **Rheumatology, Department of Medical Specialties, Geneva University Hospitals (HUG), Geneva; Inselspital, Bern, Switzerland**

19. **Background:** Disease activity and severity of rheumatoid arthritis (RA) appear to be worse in women than in men [1]. The role of parity on disease activity is controversial, since pregnancy is characterized by a lower disease activity, but the postpartum period may in increase in activity [2]. Radiographic joint damage progression represents the cumulative impact of disease activity and allows us to study the long term effect of parity.

20. **Objectives:** To study the impact of parity on radiographic progression in women with RA.

21. **Methods:** This is an observational cohort study of RA patients included in the Swiss Clinical Quality Management in Rheumatoid Arthritis (SCQM-RA). Patients enrolled are followed-up yearly and have x-rays assessments at regular intervals. Information about female hormonal factors, such as pregnancies, breastfeeding, menstrual cycles and hormonal treatment were retrospectively retrieved using a questionnaire. For this analysis we included women with at least two x-rays and full information on reproductive factors. The primary outcome was the rate of radiographic progression (Ratiening erosion score) and the secondary outcome was functional disability progression (Health Assessment Questionnaire-Disability Index (HAQ-DI)). We compared the rate of progression between parous and nulliparous women using a multilevel regression model for longitudinal data.

Results: A total of 726 women were analysed, of which 438 (60%) were parous, with a median number of pregnancies of 2 (IQR: 2–3), a mean of 4.8 x-rays per patient and 10.9 years of follow-up. Baseline patients and disease characteristics were balanced, but parous women were older than nulliparous (median of 49 vs 45 years, p=0.001) (Table 1). During follow-up, erosion progression did not differ significantly between parous and nulliparous women (p=0.94). In a subanalysis, the radiographic progression during the active parous period was not different [0.6% (95% CI: 0.5 to 0.8) vs 0.5% (95% CI: 0.4 to 0.7) by year, respectively, p=0.28]. The decrease of the HAQ-DI score overtime was not different between parous and nulliparous women (p=0.21), and it was not different during the active parous period [0.03 (95% CI: -0.03 to -0.01) vs -0.02 (95% CI: -0.03 to -0.01) by year, respectively, p=0.67]. We did not find differences in radiographic progression or HAQ-DI score between women with a singleton pregnancy and multiparous women.

Conclusions: In women with RA, the progression of structural damage and of functional disability did not differ between parous and nulliparous women. Among parous women, the active parous period was not associated with more radiographic damage progression. Although postpartum period is associated with increase in disease activity, our results suggest that parity does not have a negative long term impact on structural damage.

Results: The aim of the CAMPO-RE study was to assess the new incidence cases of Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Polymyalgia Rheumatic (PMR) attending a primary rheumatology outpatient’s clinic of new institution, integrated in the community of Campobasso, a small town in the centre of Italy.

Methods: Campobasso has a population of 49,501 inhabitants (1st January 2016) and Public Health is managed from a single health authority in the entire area. In Italy, all citizens are registered with a National Health System of General Practitioner Physicians (GPP). Between 1st June 2014 to 31st May 2016 all consecutive adult patients, sent by GPP of the municipality of Campobasso with a new incident case were included. A final diagnosis was made using the most recent classification criteria.

Results: Of the 1077 patients (96.3%) were included in the current analyses, of these 64.9% had 2-year follow-up data. Duration of joint swelling before inclusion (median [25–75 perc.]) was 34 (13–66) days, mean (SD) age 46.1 (14.8) years, 54.7% were females, 16.9% anti-CCP positive, and 21.9% anti-CCP and/or RF positive. Presence of mono-, oligo- (2–4 swollen joints), and polyarthritis (>5 swollen joints) had approximately the same frequency, 32.5, 35.7 and 31.8%, respectively.

After 2 years 33.0% used DMARDs, and a further 9.3% had joint swelling without DMARD use. The arthritis resolved in the remaining 57.6%. The most common clinical diagnoses and their respective outcomes are shown in Figure 1. The most common final diagnoses were undifferentiated arthritis (UA) (39.9%), rheumatoid arthritis (RA) (22.7%), reactive arthritis (17.1%), psoriatic arthritis (6.0%) and sarcoid arthritis/Löfgren’s syndrome (6.2%). A final diagnosis of sarcoid arthritis, reactive arthritis and UA carried the best prognoses, with resolution of disease without DMARDs in 91.0, 85.9 and 73.7%, respectively. Patients presenting with polyarthritis developed persistent disease more often than patients with oligo- or monarthritides (67.6%, 34.9 and 26.0%, respectively) (p<0.001).

Conclusions: Among 1077 patients with ≥6 weeks duration, UA was the most common diagnosis after 2 years. 22.7% were diagnosed with RA and 6.0% with psoriatic arthritis. The arthritis resolved without DMARDs in the majority of the patients. This, as far as we know, is the first study to describe the whole range of diagnostic outcomes in an unselected cohort of recent-onset arthritis, as well as the persistency of disease according to each diagnosis.

ANALYSIS OF RISK FACTOR FOR PREGNANCY OUTCOMES IN 142 PREGNANCIES COMPPLICATED WITH CONNECTIVE TISSUE DISEASE

H. Shimada 1, K. Kanenishi 2, T. Kameda 1, M. Izukawa 1, S. Nakashima 1, H. Ozaki 1, R. Wakiya 1, A. Kondo 1, N. Kadawaki 1, H. Dobashi 1, Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, 2Department of Perinatology and Gynecology, Faculty of Medicine, Kagawa University, Kagawa, Japan

Background: Recently, many connective tissue disease (CTD) patients wish to become a mother because immunosuppressants and biologics enable to improve the outcome of underlying CTD and quality of life respectively. However, CTD during pregnancy can cause major complications, especially in pregnant patients with underlying disease exacerbation, some complications during pregnancy especially in preterm birth, for light for dates (LFD) and premature rupture of membrane (PROM).

Methods: We investigated the risk factors of preterm birth, LFD (light for dates) and perinatal perinatal morbidity during pregnancy especially in preterm birth, for light for dates (LFD) and premature rupture of membrane (PROM) in 23 CTD patients.

Results: In 23 among all cases underlying disease were exacerbated, and these occurred most often in PM/DM (60%), MCTD (33.3%), RA (15.3%) and SLE (13.3%). In SLE, SS cSSc and PM/DM, preterm birth and LFD were closely related to disease exacerbation and LFD of corticosteroid, pulse therapy, and these were extracted as risk factors for these perinatal complications. Preterm birth was also associated with low complement (CH50) and high titer of anti-dsDNA antibody and LFD was associated with high titer of anti-dsDNA antibody before pregnancy. However, there was no significant association with these factors in threatened premature delivery and PROM. In RA, perinatal complications were more influenced by methotrexate and biologics before pregnancy. However, only LFD was related to doses of corticosteroid during pregnancy.

Conclusions: We extracted disease exacerbation and dose of corticosteroid, pulse therapy during pregnancy and also low complement, high titer of anti-dsDNA antibody before pregnancy. However, there was no significant association with these factors in threatened premature delivery and PROM. In RA, perinatal complications were more influenced by methotrexate and biologics before pregnancy. However, only LFD was related to corticosteroid during pregnancy.

FR0704

HLA-DRB1 ALLELES ARE ASSOCIATED WITH MARKERS OF ENDOTHelial INJURY IN FIRST-DEGREE RELATives OF RHEUMATOID ARTHRITIS PATIENTS

J.M. Hughes-Austin 1, M. Cerró 2, G.S. Firestein 3, V.M. Holers 4, K.D. Deane 1, J.M. Norris 1, J.H. Ti 5. 6. 1. Orthopaedic Surgery; 2. Rheumatology, Allergy, Immunology, UC San Diego; 3. Rheumatology; 4. Colorado School of Public Health, University of Colorado, Aurora; 5. Medicine, UC San Diego; 6. Nephrology, VA San Diego, La Jolla, United States

Background: Rheumatoid arthritis (RA) patients experience higher cardiovascular disease (CVD) risk and CVD-related mortality. MHC class II HLA-DRB1 alleles, or the shared epitope (SE), has also been linked to endothelial dysfunction in RA patients. It is not known whether this association exists in individuals who are RA-free, but who are at higher risk due to being a first-degree relative (FDR) of an RA patient.

Objectives: To determine the association between HLA-DRB1 alleles (*0401, *0404, *0405, *0408) and markers of endothelial injury in FDRs of RA patients, a population free of RA and RA-related medications.

Methods: From the Studies of the Etiology of RA, SERA, (a multicenter prospective study of preclinical RA, started in 2002), 113 FDRs who had been positive for any of 5 RA-related autoantibodies (Abs): rheumatoid factor (RF), RF isotypes – IgM, IgG, IgA, or anti-cyclic citrullinated peptide (anti-CCP2) on at least one of their visits, and 100 FDRs who had never been Ab positive were selected, frequency matched on age, sex, and field center site. No FDR met the 1987 ACR Criteria or 2010 EULAR/ACR Criteria for RA. In cross-sectional testing of single samples from baseline, the following were measured: inflammatory markers: soluble intracellular adhesion molecule-1 (sICAM), soluble vascular cell adhesion molecule-1 (sVCAM) and E-selectin; and high resolution HLA-DRB1 typing for the*0401, *0404, *0405, *0408 alleles using real-time polymerase chain reaction. ANCOVA was used to evaluate associations between HLA-DRB1 alleles, sVCAM, sICAM, and E-selectin, adjusting for age, sex, race, body mass index (BMI), Ab status, ever smoking, and current statin use.

Results: Among 213 FDRs, age was 50±18 yr, BMI was 27±6, 75% were women, 83% were Caucasian, 35% ever smoked, 11% were currently taking statins, and 38% were SE positive. sVCAM was significantly higher by 1.53ng/mL in FDRs with the HLA-DRB1*0404 allele (p=0.009) compared to FDRs without the *0404 allele (Table 1). E-selectin was higher by 23ng/mL in FDRs with the HLA-DRB1*0405

FR0707 DRUG LEVELS AND ANTIDRUG ANTIBODIES IN THE DEVELOPMENT OF PARADOXICAL PSORIASIS AND PALMOPLANTAR PUSTULOSIS

J. Ruwaard 1, E. van der Vlugt 1, B. Brevet 1, L. Berkhourt 2, T. Rispen 2, M. Nurmohamed 1, G.J. Wolbink 1,2 1: Amsterdam Rheumatology and Immunology Center | Reade; 2: Department of Immunopathology, Sanquin Research and Landsteiner Laboratory Academic Medical Centre, Amsterdam, Netherlands

Background: The pathogenesis of psoriasis and palmpoplantar pustulosis induced by Tumor Necrosis Factor inhibitors (TNFi) is largely unknown. Only one study, in rheumatoid arthritis patients, investigated the relation with infliximab drug levels in the development of psoriasis or palmpoplantar pustulosis and demonstrated no relation with of trough concentrations in these events (1). However, psoriasis and palmpoplantar pustulosis were not studied separately.

Objectives: To study the differences in drug levels and antidrug antibodies (ADA) of TNFi in rheumatoid arthritis (RA) and ankylosing spondylitis (AS) patients who developed de novo psoriasis, palmpoplantar pustulosis and those who did not develop skin adverse events.

Methods: In this retrospective study data was collected from the observational cohorts of consecutive RA and AS patients in whom TNFi was started. At every visit, serum samples were collected. We quantified the samples before/one time of the event the patients who developed psoriasis or palmpoplantar pustulosis, for the patients with no skin adverse events (control group) at 24 or 28 weeks. Drug levels and ADA were measured with an Enzyme-linked immunosorbent assay and antibody binding test respectively.

Results: A total of 830 TNFi naïve patients with RA and AS were included, of whom 21 developed psoriasis (n=11) or palmpoplantar pustulosis (n=10). These patients were only observed in the adalimumab and etanercept cohorts. Sixteen patients with an event and 585 patients in the control group had serum samples available to quantify drug levels and ADA. No statistical significant differences were found in drug levels of adalimumab and etanercept for both RA and AS patients (table 1). Moreover, no statistical significant differences were observed in the detection of ADA between the three groups. However, no ADA were detected in patients who developed psoriasis or palmpoplantar pustulosis compared to the overall 13.9% of the RA patients and 25.5% in AS patients.

FR0708 NEUROPATHIC PAIN IS A WEAK PREDICTOR OF NEW ONSET CHRONIC WIDESPREAD PAIN

J. McBeth 1, M. Mulvey 2, A. Rashid 3, J. Anderson 1, K. Druce 1, 1: Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester; 2: Leeds University, Leeds, United Kingdom

Background: Regional pain (e.g. back pain) predicts incident chronic widespread pain (CWP), the clinical hallmark of fibromyalgia. Up to 20% of patients with CWP have neuropathic pain (NP). People with CWP and NP report similar pain characteristics including allodynia (pain in response to normal touch), have common risk factors (age, sex, body mass index, smoking and socioeconomic status) and a shared genetic predisposition. Whether NP is a risk factor for CWP is not known.

Objectives: To test the hypothesis that among persons free of CWP, NP would increase the risk of developing CWP.

Methods: In a population based study participant’s pain reports were coded and those free of CWP (ACR criteria: pain lasting >3 months in the axial skeleton and contralateral body quadrant) were identified. Participants also completed the Pain Quality Questionnaire, a simple index for NP origin which has a significant impact on population levels of CWP. Therefore, the genetic predisposition to RA could contribute to parallel development of atherosclerosis during the preclinical period of RA.

FR0709 PREVALENCE OF RHEUMATIC DISEASES BASED ON COPCORD STUDIES: A SYSTEMATIC REVIEW

J. Moreno-Montoya 1, J. Rodriguez-Armas 2, R. Burgos-Vargas 3, I. Pelaez-Ballestas 4, 1: Universidad del Bosque, Bogota, Colombia; 2: Research Associate of South Florida, Miami, United States; 3: Rheumatology Unit, Hospital General de Mexico, Mexico, Mexico

Background: Despite many efforts, to date there has been no focused attempt to derive a robust estimate of the prevalence of rheumatic diseases (RDs) to quantify how this is influenced by other factors than they examined in every local study, however, the problems magnitude is rising and due the demographic transition and the increase in the life expectancy.

Objectives: To determine, through a systematic review and meta-analysis, the prevalence of RDs in the adult general population and explore its heterogeneity.

Methods: MEDLINE, EMBASE, BIREME, LILACS and Web of Science were searched using a search strategy combining key words and related database-specific subject terms to identify relevant cross-sectional based on COPCORD methodology studies. Also was developed a manual search. Included articles were assessed for risk of bias and quality based on the STROBE statement. Prevalence figures for RDs were analyzed according to female percentage of sampled individuals, mean age and sample size. A mixed effect model was used to obtain the combined prevalence and a meta-regression to estimate the effects of other variables.

Results: 44 out from 127 papers were included in English, Spanish or Portuguese. Estimates for any RDs prevalence ranged from 7.2% to 62.3% (26.9%; 95% CI 18.3%–25.6%). For rheumatoid arthritis (RA), the prevalence varied between 0.2% and 16.4%. SLE (systematic lupus erythematosus) was the less frequent (1.1%–6.2% [1.04%; 95% CI 0.4%–1.6%]). fibromyalgia (FM) had a mean prevalence of 2.1% (95% CI 1.0%–3.2%) and osteoarthritis: 13.5% (95% CI: 10.6%–16.4%). SLE (systemic lupus erythematosus) was the less frequent condition with average prevalence of 0.14% (95% CI: 0.05%–0.28%). The random-effects pooled prevalence for any RDs was 25% (95% CI: 18.0%, 31.1%). Prevalence was higher in studies with bigger sample size (Hedges’ g effect size coefficient: 0.0014, p<0.002). There was evidence of relevant heterogeneity in the analysis (p<0.001) and for RDs, RA and FM the sample size was positively associated to the perceived heterogeneity. No effects were found for SLE

Conclusions: This was found significant variation among the prevalence across this
review, in particular, related to the sample size used in each study. Two facts must be accounted for, first the statistical difficulties associated to the estimation of small prevalence and the consequent heterogeneity of the estimates, and, second the limited number of studies including in the meta-analysis. Nonetheless, there is evidence about big heterogeneity what can correspond to non-observed variables, in particular, life-styles, and environmental or genetic traits.

**MONOSODIUM URATE CRYSTAL DEPOSITION ASSOCIATED WITH THE CHANGE OF RADIOGRAPHIC GRADE AT THE SACROILIAC JOINT IN AXIAL SPA: A DUAL-ENERGY CT STUDY**

J. Zhu1, A. Aiyou Li1, 2, E. Jia2, Y. Zhou3, J. Xu2, S. Chen2, Y. Huang2, X. Xiao4, J. Li2
1Department of Rheumatology, Nanfang Hospital, Southern Medical University; 2Department of Internal Medicine of Traditional Chinese Medicine, College of Traditional Chinese Medicine, Southern Medical University; 3Department of Obstetrics, Guangdong Women and Children Hospital; 4Department of Radiology, Nanfang Hospital, Southern Medical University, Guangzhou, China

**Background:** Previous studies have revealed that ankylosing spondylitis (AS), as the progenitor of axial spondyloarthropathy (AxSpA), has been characterized by the insidiously progressive nature of sacroilitis and spondylitis. Dual-energy computed tomography (DECT) has recently been used to analyse the deposition of monosodium urate (MSU) crystals with higher sensitivity and specificity. However, it remains unclear whether the existence of the MSU crystal deposits detected by DECT at the sacroiliac joint in patients with AxSpA also contributed to the existing structural damage.

**Objectives:** We performed this study to show the DECT MSU crystal deposits in AxSpA patients without coexisting gout were recruited. The plain radiographs of the sacroiliac joint were obtained, along with the DECT scans at the pelvis and the clinical variables. All statistics based on the left or right sacroiliac joint damage grading (0–4) were calculated independently. Bivariate analysis and ordinal logistic regression was performed between the clinical features and radiographic grades at the sacroiliac joint.

**Results:** At painful joints or skeleton regions, large quantities of MSU crystal deposits were found in 186 patients with AxSpA, as depicted in green with DECT. The average MSU crystal volume at the left sacroiliac joint, the right sacroiliac joint, and the pelvis were 0.902±1.345, 1.074±1.878, and 5.272±29.44 cm³, values which were correlated with serum uric acid concentrations (r=0.727, 0.740, 0.896; p<0.001). At the left and right sacroiliac joint, the presence of MSU crystal deposits (+1.451, 43.684; p<0.01) and the volumes of MSU crystals (Z=9.198, Z=34.607; p<0.05) were statistically different among groups divided by the ASDAS scores. In bivariate analysis, wide clinical variables were associated with the changes in sacroiliac joint damage. When others factors were adjusted in the ordinal logistic models, the AxSpA duration, total back pain, BASFI score, and volume of MSU crystallization were the risk factors for the radiographic grade at the left sacroiliac joint (AOR=1.187, 1.428, 3.837, 2.018; p<0.05). The same risk factors were obtained for the right sacroiliac joint, except for total back pain. Additionally, the simplified models excluded the repeated variables; the AxSpA duration, BASFI score, and the volume of MSU crystallization at both sides of sacroiliac joint served as risk factors for the radiographic grade (left-AOR=1.180, 3.800, 1.925; right-AOR=1.190, 3.034, 1.418; p<0.01).

**Conclusions:** Large quantities of MSU crystal deposits detected by DECT were found in AxSpA patients without coexisting gout. In addition to AxSpA duration and BASFI score, the MSU crystal deposits at the sacroiliac joint in those patients independently increased the risk of structural joint damage.

**DISCORDANCE OF THE FRAMINGHAM CARDIOVASCULAR RISK SCORE AND THE 2013 AMERICAN COLLEGE OF CARDIOLOGY/AARHEUMATOLOGY CARDIOVASCULAR RISK ASSOCIATION RISK SCORE IN SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS**

K. Jafri1, A. Ogdie2, P. Katz1, J. Yazdany1, G. Schmajuk1, 2
1Rheumatology, University of California, San Francisco, San Francisco; 2Rheumatology, University of Pennsylvania, Philadelphia; 3Rheumatology, Veterans Affairs Medical Center, San Francisco, United States

**Background:** Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are associated with an increased risk of cardiovascular (CV) disease, and multipliers to traditional 10-year CV risk scores, such as a EULAR-recommended 1.5 multiplier in RA, have been proposed to capture this increased CV risk. The discordance between CV risk assessment by the Framingham risk score, a modified Framingham risk score (with a 1.5 multiplier), and the more recent 2013 American College of Cardiology/American Heart Association (ACC/AHA) risk score has not been well-studied in patients with rheumatic diseases.

**Objectives:** To determine the proportion of discordant 10-year Framingham risk scores and 2013 ACC/AHA risk scores in subjects with SLE and RA, both with and without a 1.5 multiplier to the Framingham risk score, and to assess demographic, CV, and rheumatologic clinical characteristics associated with discordant risk scores.

**Methods:** A cross-sectional study was conducted using SLE and RA subjects drawn from the University of California, San Francisco, Arthritis, Body Composition, and Disability project. 10-year Framingham risk scores, modified Framingham risk scores (with a 1.5 multiplier), and 2013 ACC/AHA risk scores were calculated. As per Adult Treatment Panel-III (ATP-III) recommendations, a subject with a Framingham risk score (or modified Framingham risk score)≥10% was defined as high-risk by that score, whereas a subject with a Framingham risk score (or modified Framingham risk score)<10% was defined as low-risk. A subject with a 2013 ACC/AHA risk score >7.5% was defined as high-risk by that score, whereas a subject with a 2013 ACC/AHA risk score ≥7.5% was defined as low-risk. A subject with a discordant risk score was defined as one who had a Framingham risk score (or modified Framingham risk score) that characterized him/her as low-risk and a 2013 ACC/AHA risk score that characterized him/her as high risk. Associations of demographic, CV, and rheumatologic characteristics with discordant risk scores were analyzed using chi-squared tests for categorical variables and using independent t-tests for continuous variables.

**Results:** 11 (7.0%) of the 157 SLE subjects and 11 (11.5%) of the 96 RA subjects had discordant CV risk scores with low Framingham risk scores but high ACC/AHA risk scores. When the 1.5 multiplier was applied to the Framingham risk score, the number of subjects with discordant risk scores did not significantly change. Rheumatologic disease duration, CRP levels, African American race, diabetes, current use of anti-hypertensive medication, higher age, and higher systolic blood pressure were all significantly associated with discordant risk scores.

**Conclusions:** Approximately 10% of SLE and RA subjects had discordant 10-year CV risk scores with low Framingham risk scores but high ACC/AHA risk scores, even when a 1.5 multiplier was applied to the Framingham risk score. Prospective studies are needed to address the ability of different CV risk assessment tools, such as the 2013 ACC/AHA risk score, Framingham risk score, and modified risk scores, to predict CV events in rheumatologic patients, especially those with risk factors associated with discordant risk scores.

**DRIVERS OF UNREFRESHING SLEEP IN PEOPLE WITH MUSCULOSKELETAL PAIN**

K.L. Druce, J. McBeth. Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom

**Background:** Waking feeling unrefreshed is associated with poor health outcomes including an increased risk of cardiovascular death. Pain is a robust predictor of waking feeling unrefreshed. Pain is a complex disorder and it is not clear whether the pain itself, or associated somatic symptoms, mental health conditions and lifestyle factors, predicts waking unrefreshed.

**Objectives:** To investigate whether reporting pain was an independent predictor of waking unrefreshed among people with musculoskeletal pain.

**Methods:** Participants in a population study completed the Estimation of Sleep Questionnaire (ESPS), a 3-item scale (ESPS), which represents the number of days in the past month participants have experienced unrefreshing sleep, problems with sleep onset, maintenance and night awakenings. Pain assessments (body map and duration >3 months) were used to classify participants as having no pain, acute pain, chronic pain and CWP (ACR criteria: pain lasting ≥3 months in the axial skeleton and ≥6 weeks in the peripheral joints). Participants also reported demographics (date of birth, sex, English Index of Multiple Deprivation); somatic symptoms (Chalder Fatigue Scale (CFS) 11) and Inflammatory Bowel Syndrome (IBS); mental health (Hospital Anxiety and Depression (HAD) scale); disability (Stanford Health Assessment Questionnaire (HAQ)) and lifestyle factors (average number of
of alcoholic drinks per week, smoking status and Rapid Assessment of Physical Activity (RAPA). Univariable ordinal logistic regression tested the relationship between pain and waking unrefreshed. The model was then cumulatively adjusted for sleep, somatic symptoms, mental health, disability and lifestyle domains. All models were age, sex and deprivation adjusted. The results of a complete case analysis were comparable to those which used multiple imputation for missing data and the results of the complete case analyses are shown. Results were expressed as odds ratios (OR) with 95% confidence intervals (CI).

**Results:** Of 1913 people who had complete data, 1376 (72%) woke unrefreshed on at least one day in the past month (41% ± 7 days; 31% ± 8 days). Compared to those with no pain, people with acute pain and chronic pain were two (OR 2.0, 95% CI (1.5–2.6) and 2.2 (1.9–2.7), respectively) times more likely to wake unrefreshed; those with CWP were five (5.0 (4.0–6.3)), times more likely to wake unrefreshed. Following adjustment for all other variables, the relationship between reporting chronic pain (1.5 (1.2–1.8)) or CWP (1.9 (1.4–1.5)) and waking unrefreshed was attenuated, but remained statistically significant. The reporting of acute pain was not an independent predictor of waking unrefreshed (1.4 (0.98–1.9)). Problems with sleep onset (±8 days vs 0: 2.9 (2.0–4.1) and maintenance (±8 days vs 0: 5.9 (4.1–8.4)), night awakenings (±8 days vs 0: 2.5 (1.7–3.7), IBS (2.2 (1.2–4.0)), current smoking (vs never: 1.5 (1.02–2.1)) and engagement in activities such as stretching and yoga (vs none: 0.8 (0.6–0.97), physical (1.3 (1.2–1.3)) but not mental (0.99 (0.9–1.1)) fatigue, and anxiety (definite vs no: 2.4 (1.8–3.1)), but not depression (definite vs no: 1.5 (0.8–2.6)), were associated with waking unrefreshed.

**Conclusions:** This study suggests that among people with chronic pain, the risk of waking feeling unrefreshed may be reduced through interventions that target factors such as smoking cessation, IBS management, physical fatigue and anxiety.

**FRID0714 LUPUS NEPHRITIS AND PROGNOSIS. EFFECT OF MEMBRANOUS AND OTHER COMPONENTS OF THE HISTOLOGY**

M. U. Martinez Martinez 1, C. Vallín-Orozco 1, H. E. Esparza-Holguín 1, G. Aguilera-Barragán Pinkens 1, D. Martinez-Galla 1, C. Abud-Mendoza 1, 1Unidad de Investigaciones Reumatológicas, 2Renal Pathology, Hospital Central "Dr. Ignacio Morones Prieto", Universidad Autónoma de San Luis Potosí, San Luis Potosí, Mexico

**Background:** In 1983 Austin et al. informed a series of prognostic factors (including histology) associated with the development of renal failure in patients with lupus nephritis (LN). Differences in actual therapies may have different hazard ratios of renal failure than the described by Austin et al. 1

**Objectives:** To evaluate histological factors associated with a decline in kidney function (DKF) in patients with SLE.

**Methods:** We evaluated all the patients in whom a kidney biopsy was performed. DKF was defined as a glomerulat filtration rate (GFR) of less than 60 ml/min/m² in two determinations in the follow-up. Histology was graded according to Austin et al. 1 (activity and chronicity) by a renal pathology specialist. Factors associated with the development of DKF were evaluated through Kaplan-Meier curves and Cox regression analysis (bivariate and multivariate).

**Results:** At this moment, we have followed 170 patients with LN and kidney biopsy. 130 (76.5%) women, mean age at kidney biopsy was 29.7±13.2 years; classes of LN were: 71 patients (41.8%) class IV, 30 (17.6%) class V, 22 (12.9%) class III/V, 19 (11.2%) class IV/V, 16 (9.4%) class III, and other classes 12 patients; 135 patients (79.5%) have a minimum follow-up of 12 months. There were statistically significant differences in four groups of LN: pure proliferative classes (III/IV/V), the combination with membranous (III/IV/V), pure membranous (V) or other classes (Figure1).

| Interstitial fibrosis | 0.80 (0.62–1.07) | 0.162 0.74 (0.47–1.16) 0.194012 |
| Tubular atrophy | 1.33 (1.02–1.74) | 0.035 1.10 (0.47–1.17) 0.613154 |
In the bivariate analysis, factors statistically significant associated with the development of DFK were: glomerular sclerosis, fibrous crescents, interstitial cell infiltration and tubular atrophy; having membranous component resulted as a "protector" factor for the development of DFK. The Cox regression model included all the factors with a p-value less than 0.25 in the bivariate analysis: independent factors associated with increased HR of DFK were glomerular sclerosis and fibrous crescents; however, hyaline thrombi and presence of membranous nephritis were associated with a decreased HR of DFK. (Table 1).

Conclusions: We describe factors associated with a DFK. We found that the proliferative LN in combination with membranous have a better prognosis than pure proliferative LN. Our study could help to evaluate the effects of therapies in LN.

FRI0715 BEING A WOMAN AND HAVING KNEE OSTEOARTHRITIS INCREASES THE LIKELIHOOD OF COMORBIDITIES
M. Herrera Barbero 1, S. Gimenez 2, J. Vergés Milano 6,14 on behalf of EMARTRO. 
1Department of Clinical and Biological Sciences, Center of Research of Immunopathology and Rare Diseases, Coordinating Center of Piemonte and Valle d’Aosta Network for Clinical and Biological Sciences, Center of Research of Immunopathology and Rare Diseases, Torino, Italy; 2Department of Rheumatology and Haemophilia, Guy’s and St Thomas’ Hospital, London, United Kingdom; 3S. Giovanni Bosco Hospital, Torino, Italy; 4Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom.

Background: Young adults with acute myocardial infarction are a critical group to examine for the purpose of risk factors stratification and modification [1].

In the setting of underlying systemic autoimmune diseases, premature cardiovascular disease deserves even more attention in these conditions, such as antiphospholipid syndrome (APS), the most common acquired thrombophilia.

Objectives: In this study we aimed to assess the clinical utility of the adjusted Global Antiphospholipid Syndrome Score (aGAPSS)[2] for the risk stratification of acute myocardial infarction in a cohort of young APS patients with thrombotic events.

Methods: The analysis included 83 consecutive APS patients (<50 years old) who presented with arterial or venous thromboembolic events. Data on cardiovascular risk factors and antiphospholipid antibodies (aPL) positivity were retrospectively collected. The aGAPSS was calculated for each patient by adding the points corresponding to the risk factors, based on a linear transformation derived from the β regression coefficient as follows: 3 for hyperlipidaemia, 1 for arterial hypertension, 5 for aCL IgG/IgM, 4 for anti-b2 glycoprotein I IgG/IgM and 4 for LA.

Results: Demographic, clinical and laboratory characteristics of the cohort are summarized in Table 1. Higher aGAPSS values were observed in patients with acute myocardial infarction when compared to the others [mean aGAPSS 11.9 (S.D. 4.15, range 4–18) Vs. (mean aGAPSS 9.2, S.D. 5.1, range 1–17); T test: p < 0.05]. Significantly higher aGAPSS values were also seen in patients with acute coronary syndrome compared to patients with a history of peripheral or cerebrovascular arterial thrombotic events [mean aGAPSS 11.9 (S.D. 4.15, range 4–18) Vs. (mean aGAPSS 6.7, S.D. 5.7, range 1–17); T test: p < 0.005]. When separating for cardiovascular risk factors and aPL positivity, hypercholesterolemia was significantly higher in the group that developed myocardial infarction compared with patients with a history of any thrombosis and patients with a history of peripheral or cerebrovascular arterial thrombotic events (Chi square test: p < 0.0001 and p < 0.0001) and significantly higher rate of multiple positivity.

for LA, aCL (IgG/IgM), anti-¿GPPI antibodies (IgG/IgM) were present in the group that developed myocardial infarction (Chi square test: p < 0.05 for all aPL) (Table 2).

Conclusions: The aGAPSS is based upon a quantitative score and could aid risk stratifying APS patients younger than 50 years for the likelihood of developing coronary thrombotic events and may consequently guide pharmacological treatment for high-risk patients.

FRIO718 POSITIVE CONVERSION OF TUBERCULOSIS SCREENING RESULTS AND INCIDENCE OF ACTIVE TUBERCULOSIS INFECTION IN PATIENTS RECEIVING BIOLOGIC TREATMENT

M.-C. Park 1, H.W. Kim 1, S.H. Han 2, Division of Rheumatology; 2Division of Infectious Diseases, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: Previous studies reported active tuberculosis infections can occur during biologic treatment in patients with negative baseline LTBI screening. Current recommendations suggesting the annual testing for latent tuberculosis infections are mainly issued for patients with rheumatoid arthritis (RA) receiving anti-TNF inhibitors and there are lacking evidence for patients receiving non-TNF biologic agents and for patients with ankylosing spondylitis (AS) or psoriatic arthritis (PsA).

Objectives: The study was performed to investigate the conversion rate of initially negative tuberculosis screening test results during biologic treatment and the usefulness of repeated screening test for detecting unexpected tuberculosis infection in patients with RA, AS, and PsA.

Methods: A total of 95 patients (43 with RA, 50 with AS, and 2 with PsA) who had negative baseline interferon-y releasing assay (IGRA) results, which were assessed using QuantiFERON-TB Gold in tube (QFT-GIT), prior to initiation of biologic treatment were enrolled in this study. All patients received biologic agents for the treatment of their diseases and rescreening with QFT-GIT were performed in all patients after median 12 months from baseline test. Clinical characteristics were compared between converters and non-converters and incidence of active tuberculosis infection was evaluated.

Results: Patients were treated with different biologics (23 with etanercept, 50 with adalimumab, 5 with infliximab, 4 with golimumab, 1 with certolizumab pegol, 3 with abatacept, and 9 with tocilizumab). Positive conversions of initially negative IGRA were found in 13 (6% in patients with etanercept, 4 patients with adalimumab, 2 patients with tocilizumab and 1 patient with abatacept) of 95 patients (13.7%) after initiation of biologic treatment. Age over 50 years and diagnosis of RA were more common in converters. Multivariate analysis showed that age over 50 was an independent risk factor for IGRA conversion with OR 4.36 (95% CI 1.10 – 17.34, p=0.038). During biologic treatments, active tuberculosis infections were found in 3 of 13 converters (23%).

Conclusions: Although initial screening test showed negative results, the serial follow-up of tuberculosis screening test should be considered during biologic treatment in patients with rheumatic diseases to prevent unexpected tuberculosis infection.

FRIO718 PREVALENCE AND PATTERN OF COMORBIDITIES IN CHRONIC RHEUMATIC AND MUSCULOSKELETAL DISEASES: THE COMORD STUDY

N.R. Ziade 1,2, F. Fayad 1,2, B. Khoury 3, M. Zoghbi 4, G. Merheb 5, G. Abi karam 6, K. Mroue 6, J. Missakyeh 7, 1Rheumatology, Hotel Dieu de France; 2Rheumatology, 3Medicine; 4Family Medicine, St-Joseph University, Beirut; 5Rheumatology, Zahra University Hospital, Beirut; 6Rheumatology, Monla Hospital, Tripoli, Lebanon

Background: Rheumatic and musculoskeletal diseases (RMD) frequently coexist with other conditions, resulting in multimorbidity, which may compromise arthritis management and lead to diminished quality-of-life and increased mortality. In 2016, EULAR published “Points to consider for reporting, screening for and preventing selected comorbidities in chronic inflammatory rheumatic diseases”, used to guide this study.

Objectives: The primary objective is to evaluate the prevalence and pattern of comorbidities in selected RMD in Lebanese patients. The secondary objective is to evaluate the gap between recommendations and routine comorbidities’ screening.

Methods: COMORD is an observational, cross-sectional, multicentric national study. Consecutive RMD patients (Rheumatoid Arthritis (RA), Osteoarthritis (OA), Systemic Lupus Erythematosus (SLE), Axial Spondyloarthritis (AxSpA) and Peripheral Spondyloarthritis (pSpA)) as diagnosed by the rheumatologist) were recruited at 6 practices from university hospitals and private clinics in Lebanon. Six axes of comorbidities (Cardiovascular, Malignancies, Infections, Gastrointestinal, Osteoporosis, Depression) were investigated using a case report form (patient interview). Optimal comorbidities screening was defined according to current recommendations and compared with monitoring in practice. Prevalences were presented descriptively. The number of comorbidities was correlated with predictive factors using Poisson Regression. Finally, Latent Class Analysis (LCA) was used to identify patterns of multimorbidity. All analysis were performed on IBM SPSS Statistics 23 and XLSTAT 18.07.

Results: 515 patients were recruited (196 RA, 161 OA, 75 AxSpA, 45 SLE, 40 pSpA). Mean age was 56y, 76% were female. There was no difference in the disease distribution between centers. The most common comorbidities were cardiovascular risk factors and diseases, followed by depression and osteoporosis. The number of comorbidities was significantly associated with age (p < 0.001), obesity (p < 0.001) and biotherapies (p = 0.05). LCA analysis identified 3 main clusters of multimorbidity: OA, RA, AxSpA (Fig 1). The most optimal screening was found for cardiovascular risk factors (84%). DXA was prescribed in 69% of correct indications. As for malignancies, mammograms and pap smears were the most optimally prescribed (26% and 28%). Colonoscopy and dermatology visit were prescribed in 22% and 18%. Correct vaccination (influenza and pneumococcal) was found in 17% and 8%. Predictive factors for optimal screening were age, university setting, social coverage, disease duration and biotherapy.

Conclusions: Comorbidities are prevalent in RMDs and follow specific multimorbidity patterns, with a predominance for cardiovascular, depression and osteoporosis. They are more frequent with age and obesity. Optimal screening needs to be improved.

BURDEN OF HEPATITIS E VIRUS INFECTION IN PATIENTS WITH RHEUMATIC DISEASES

P. Jacques 1,2, E. Padalos 1, E. Verheugen 1,2, L. Cattoir 3, X. Verheist 1, E. Nys 3, S. Van Gucht 5, V. Hutse 5, V. Suin 5, D. Elewaut 1,2, 1 Rheumatology, University Hospital; 2VIB, Ghent University; 3Clinical Chemistry, Microbiology and Immunology; 4Gastroenterology, University Hospital, Ghent; 5National Reference Centre for Viral Hepatitis, Sint-Bugellic Instituut of Public Health, Brussels, Belgium

Background: Hepatitis E virus (HEV) is considered an emerging pathogen in developed countries, potentially causing chronic hepatitis.

Objectives: This cross-sectional analysis was undertaken to determine the seroprevalence of HEV in patients with autoimmune or inflammatory arthritis. This subgroup of patients is often treated with immunosuppressive drugs, and is generally considered more susceptible to infections.

Methods: Serum samples were obtained from 449 consecutive patients consulting at the department of Rheumatology between October and November 2015. Patient characteristics with respect to diagnosis and treatment were collected. HEV IgM and IgG were measured by ELISA (Wantai Hepatitis E Virus IgG and IgM ELISA, Sardar SV). Positive or borderline samples were further analyzed for HEV RNA (RealStar® HEV RT-PCR Kit, Alton Diagnostics NRC WIV).

Results: A total of 449 patients were included, 211 men and 238 women. HEV IgG was positive in 82 samples (16.2%), 6 were borderline, and 5 were non-determinable (not enough serum). IgM was positive in only 2 samples (0.45%). These 2 patients had normal liver function tests. Additional PCR was performed on all positive and borderline samples, which turned out negative in all samples. Of the 88 IgG positive and borderline samples, 86 patients had a known diagnosis of chronic inflammatory arthritis, of which 50 patients had previously been diagnosed with rheumatoid arthritis, 18 with spondyloarthritis, 8 with psoriatic arthritis. Fifty patients were treated with biologics (37 TNF inhibitors), 43 patients were treated with methotrexate (mean dose 12.5mg weekly), and 20 were treated with corticosteroids (mean daily dose 5.9mg prednisolone equivalent).

Conclusions: In a consecutive cohort of patients with known diagnosis of autoimmune or inflammatory arthritis, seroprevalence of HEV IgG was 18.2%. No active HEV infection could be detected. We found this to be comparable to a historical cohort of healthy patients from the departments of Orthopedics and obstetrics1, where prevalence of HEV IgG was 14%.

CHARACTERISTICS OF PATIENTS WITH GOUT TREATED TO SUA TARGET THAT CONTINUE TO EXPERIENCE FLARES:

BACKGROUND, JOB RELATED, HEALTH RELATED AND PSYCHOSOCIAL FACTORS AND THREE DIFFERENT MEASURES OF PRESENTEEISM: RESULTS FROM EULAR-PRO AT-WORK PRODUCTIVITY STUDY

S. Leggett 1, D. Lacalle 2, A. Boonen 3, C. Mihai 4, S. Tall 1, S. Hagel 1, S. Dadoun 5, S. Ramiro 6, A. Bosworth 7, G. Sakellariou 8, 1Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom; 2University of British Columbia, Vancouver, Canada; 3Maastricht University, Maastricht, Netherlands; 4Dr. Ion Cantacuzino Hospital, Bucharest, Romania; 5East Tallinn Central Hospital, Tallinn, Estonia; 6Lund University and Skane University Hospital, Lund, Sweden; 7APHPH Pitié-Salpêtrière Hospital, Paris, France; 8Leiden University, Leiden, Netherlands; 9NRAS, Maidenhead, United Kingdom; 10IRCCS Policlinico San Matteo Foundation, Pavia, Italy; 11NIHR Manchester Musculoskeletal BRIU, Central Manchester NHS Trusts, Manchester, United Kingdom

Background: Several measures of at-work productivity loss (i.e. presenteeism)
exist, varying in concept, recall period, and attribution. As a consequence, the contribution of contextual factors may vary which has important implications when considering these factors in studies evaluating the impact of inflammatory arthritis (IA) and osteoarthritis (OA) on presenteeism.

**Objectives:** To determine demographic, job related and health related factors associated with three different global measures of presenteeism in patients with IA or OA.

**Methods:** This large cross-sectional international EULAR-PRO study (n=8 countries) includes patients with RA, PsA, AS or OA in paid employment. Data collection included: demographics, job characteristics, health related and psychosocial factors. Patients also completed three global measures of presenteeism, varying in content, attribution and recall period. The Work Productivity Scale–Arthritis (WPS-A) measuring the affect of arthritis on productivity during the last 7 days, the Work Productivity and Activity Impairment Questionnaire (WPAI) measuring interference of arthritis on productivity in the last month, and the Work Ability Index (WAI) a generic scale measuring current ability to work. For interpretation purposes the scale of the WAI was reversed in this study. Due to skewed data, univariable median regression analyses were performed to assess the association between independent variables with each individual presenteeism instrument.

**Results:** 503 patients with IA/OA were recruited in this study with a mean age of 47 (SD=10) yrs and disease duration of 12.6 (SD=10) yrs. Except for male patients reporting a lower WPS-A score, no other demographics were significantly associated with presenteeism (Table). Being neutral/unsatisfied about the job, not being able to organize one’s own work, reporting higher VAS well-being and disability scores, and experiencing reduced quality of life were all significantly associated with higher presenteeism, a result observed for all three instruments. Furthermore, those with higher anxiety and depression scores also reported having more problems at work due to ill health. Differences between instruments were especially observed between the WPAI (affect of ill health on productivity)/WPS-A (interference of illness on productivity) and WAI (generic scale on ability to work) in relation to job demands, receiving help from colleagues and the option to postpone work.

**Conclusions:** This is the first study investigating the association of many contextual factors with three commonly used global measures of presenteeism. Overall, job satisfaction and the ability to organize one’s own work are the most important job characteristics associated with presenteeism and should be considered when measuring presenteeism.

**FR10723 TEMPORAL PATTERNS OF SEDENTARY BEHAVIOUR AND PHYSICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS**

**S.A.M. Fenton1,2, J.L. Duda1, J.J. Veldhuijzen van Zanten1,2, G.S. Metsios3, P.C. Rousee4, C.-A. Yu5, G.D. Kitas2. 1School of Sport Exercise and Rehabilitation Sciences, University of Birmingham, Birmingham; 2Rheumatology, Russells Hall Hospital, Dudley; 4Department for Health, University of Bath, Bath; 5School of Biomedical Sciences, University of Leeds, Leeds, United Kingdom

**Background:** Rheumatoid Arthritis (RA) is associated with increased risk of cardiovascular disease (CVD). Recent evidence suggests sedentary behaviour (waking behaviour ≤1.5 metabolic equivalents whilst sitting/lying) may contribute towards the progression of RA outcomes, including heightened CVD risk. Sedentary behaviour occupies the majority of waking hours among people with RA (1). However, the proportion of time spent sedentary is likely to fluctuate over the course of the day, with periods of high sedentarity representing more optimal opportunity for intervention, and thus potentially higher intervention efficacy.

**Objectives:** The aims of this study were: 1) to explore temporal patterns of sedentary behaviour (and physical activity) among RA patients, and 2) to examine associations between temporal sedentary patterns and predicted 10-year risk of CVD.

**Methods:** Patients with RA (N=97) wore a GT3x accelerometer for 7 days to assess habitual sedentary time (<100 counts/min) and physical activity (PA; light =100–2000 counts/min). Accelerometer data were analysed separately for each hour (valid hour criteria; 60-minutes of data on ≥3 days, including a weekend day). To evaluate 10-year risk of CVD (Q-risk2), patients reported their medical history, provided a fasted blood sample and underwent assessments of blood pressure and body-mass index.

**Results:** Temporal patterns of sedentary time and PA are reported in Figure 1. Sedentary time declined throughout the morning (08:00–12:00). During the afternoon, sedentary time increased by 4.5 minutes (12:00–18:00; M =34.95±6.76 to M =39.06±7.91). A more marked increase in sedentary time was observed during leisure time (18:00–22:00; M =39.06±7.91 to M =47.90±6.30). Repeated measures analysis of variance (ANOVA) revealed sedentary time was significantly higher during leisure time (M =46.20±5.46) compared to the morning (M =36.89±5.81), and afternoon (M =39.50±6.7). Significant differences remained even after controlling for employment status (i.e., employed vs. unemployed/student, F(2,23)=1.40, p=0.27). Patients who accumulated M =45.31 sedentary minutes during their leisure time (18:00–23:00; median split), had significantly higher 10-year risk of CVD (M =22.93±13.85) compared to those accumulating M =45.31 sedentary minutes (M=6.09±7.62) [t(41)=3.92, p<0.01]. Finally, hourly patterns for light PA were the reverse of those observed for sedentary time. Hourly MVPA engagement was consistently <3 minutes (peak MVPA at 09:00–10:00, M =24.7±4.16).

**Conclusions:** Interventions targeting leisure time sedentary behaviour (18:00–23:00) may be more effective than interventions targeting work or travel time sedentary behaviour (08:00–18:00). Patients who accumulated higher sedentary time during leisure time may have the greatest potential for sedentary time reduction and associated improvements of CVD risk profile. Due to inverse patterns of engagement, replacing leisure time sedentary behaviour with light PA may offer an effective intervention approach.

**FR0724** PREDICTORS OF PRESENTEEISM AND ABSENTEEISM IN PATIENTS COMMENCING TREATMENT WITH METHOTREXATE MONOTHERAPY OR BIOLOGIC THERAPY FOR RHEUMATOID ARTHRITIS

S. Leggot 1, M. Lunt 1, A. Barton 2, K. Hyrich 1, K. Walker-Bone 3, S.M. Verstappen 1 on behalf of RAMS and BRAGGSS co-investigators. 1Arthritis Research UK Centre for Epidemiology; 2Arthritis Research UK Centre for Genetics and Genomics, The University of Manchester, Manchester, UK; 3Arthritis Research UK/MRC Centre for Musculoskeletal Health and Work, The University of Southampton, Southampton, United Kingdom

**Background:** The adverse effects of RA on absenteeism (i.e. days absent from work) and presenteeism (at-work productivity loss) are increasingly recognised as an important issue. Research suggests the reasons are multifactorial with many factors such as disease severity, quality of life and psychological well-being, amongst other factors, can predict improvements in presenteeism and absenteeism at one year in patients on either MTX or biologics for the first time.

**Objectives:** To identify predictors of presenteeism and absenteeism over one year in patients with RA commencing treatment with methotrexate (MTX) or biologics for the first time.

**Methods:** Patients recruited to the Rheumatoid Arthritis Methotrexate Starters study (RAMS) or the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS), and in full or part-time paid employment were included in this analysis. Demographic (e.g., age), clinical (e.g., DAS28), and psychological data (e.g., Hospital Anxiety and Depression scale (HADS)) were collected at baseline. Indicators were followed up at six months and one year in both cohorts. Absenteeism in the last month (days missed), and presenteeism (0 = no interference – 10 = complete interference), were measured at all three points using the RA specific Work Productivity Survey (WPS-RA). Patients with at least one follow-up post baseline were included in this analysis. Due to excessive zeros in the WPS-RA, a repeated measure zero inflated negative binomial regression (ZINB) was used to test the association between baseline demographic, clinical and psychological variables and presenteeism and absenteeism over one year.

**Results:** Data was available for 191 patients in BRAGGSS and 308 in RAMS. In BRAGGSS, 51% of patients (n = 98) reported >1 days absent from work at one year, median symptom duration was 8 years (IQR 5–13); 78% female. In RAMS, the mean age was 52 years (SD 9.6), median symptom duration was 8.5 months (IQR 5–23); 66% female. At baseline, 26% (BRAGGSS) and 27% (RAMS) reported ≥1 days absent from work, and the median presenteeism scores were 5 (IQR 3–7) and 4 (IQR 1–7) for BRAGGSS and RAMS respectively. Presenteeism scores significantly improved over one year in both cohorts (BRAGGSS: median 2 [IQR 0–5], RAMS: median 2 [IQR 0–4] ). Kruskal-Wallis p < 0.001), as did absenteeism for both cohorts although non-significant. The ZINB revealed similar predictive patterns in both cohorts for presenteeism and absenteeism (Table 1). For example, for every 0.06 increase in EQ-SD (clinically important difference), the odds of being in the zero presenteeism group (i.e. no at-work productivity loss) over one year increased by a factor of 1.2 in BRAGGSS, and was similar in RAMS. In RAMS, a one unit increase in VAS fatigue decreased the odds of having no absenteeism over one year by a factor of 0.97.

**Conclusions:** The results from this analysis support the notion of a multifactorial relationship between RA and work outcomes. The results suggest that greater quality of life and psychological well-being, amongst other factors, can predict improvements in presenteeism and absenteeism at one year in patients on either MTX or biologics for RA.

**FR0726** LONG TERM USE OF ANALGESICS AND NSAIDS IN EARLY RA: LESSONS FROM THE CARERA STUDY

S. Pazmino 1, R. Westhovens 1,2, V. Stouten 1, J. Joly 2, K. Van Der Elst 2,3, P. Verschueren 2,1 on behalf of CareRA study group. 1Skeletal Biology and Engineering Research Centre, KU Leuven Department of Development and Regeneration; 2Rheumatology, University Hospitals Leuven; 3Skeletal Biology and Engineering Research Centre, KU Leuven Department of Public Health and Primary Care, Leuven, Belgium

**Background:** One might consider pain accompanying musculoskeletal conditions as a separate illness entity deserving specific treatment. A subgroup of early Rheumatoid Arthritis (RA) patients has remaining pain despite adequate disease control and this might be reflected in the use of analgesics and NSAIDs.

**Objectives:** To investigate the usage of analgesics and antiphlogistics prospectively in the pragmatic randomized controlled CareRA trial and describe the users of such drugs taking into account body mass index (BMI), VAS pain and disease activity.

**Methods:** This study utilized data from the CareRA trial, a 2-year prospective randomized controlled trial investigating the use of conventional disease-modifying anti-rheumatic drugs (possibly/definitely RA-related or other). Meaningful sub-classifications were made (analgesics, cox2-selective and non-selective NSAIDs). We defined two dose classes of each drug, defined by the number of tablets, dose, frequency/timing, continuous/intermittent use, start/end date and indication.

**Results:** Of the total population, 15, 5% (53 patients) started long-term analgesics/NSAIDs before/at BL (pre-induction group) and 13% (45 patients) from w28-w52 (post-induction group).

**Conclusions:** Risk factors of ILD in MCTD are DLOC less than 60% of predicted, high titer RNP antibodies, no previous arthritis and increasing age.

Proportionally more patients were using NSAIDs in the post-induction group and paracetamol in the pre-induction group. Mean DAS28CRP (BL-w104) in the pre-induction group was 3.11 (±0.70) and mean VAS pain 32.7 (±16.3). In this group 62.3% had sustained low disease activity while taking continuous analgesics/NSAIDs. Results in the post-induction group were comparable.

Analgesics/NSAID use was not significantly associated with mean (BL-w104 BMI) DAS28CRP or VAS pain.

Conclusions: Analgesics/NSAID intake in early RA was high (90%) and remarkably about 30% continued using these drugs, despite overall low disease activity. This high consumption might be explained by the ambiguous nature of arthritis-related pain and the lack of differentiation between nociceptive and non-nociceptive pain. Therefore pain management in early RA deserves more attention.

FRI0727 IMPACT OF MATERNAL SYSTEMATIC AUTOIMMUNE RHEUMATIC DISEASES ON NEONATAL OUTCOMES: A POPULATION-LEVEL ANALYSIS

S.O. Keeling, A. Savu, P. Kaul. Department of Medicine, University of Alberta, Edmonton, Canada

Background: The impact of systemic autoimmune rheumatic diseases (SARDs) on peripartum outcomes is not well described at a population level despite the potential for active disease in this period.

Objectives: We examined the association between SARDs and neonatal outcomes in a contemporary pregnancy cohort in the province of Alberta, Canada.

Methods: The patient population consisted of women giving birth between January 1, 2005 to December 31, 2014 (n=312,081). For women with multiple births after January 1, 2009), and neonatal outcomes among women with and without SARDs were compared.

Results: Compared to women with no SARDs (n=311,755), women with SARDs (n=326; 0.1%) were slightly older (SARDs 31.3 vs No SARDs 29.3 years (p<0.01)) but did not differ in terms of rural residence, ethnicity, median household income or nulliparity. However, rates of pre-term delivery, emergent cesarean section, induction, hypertensive disorders/ecplampsia and mortality were higher among women with SARDs than those with no SARDs (Table 1). Offspring of women with SARDs had lower birth weights, were more likely small for gestational age (SGA), and had longer stays in neonatal ICU (Table 1). Among women with SARDs, prescription rates in the 270 days prior to delivery were highest for anti-malarials (Table 2). After multivariable adjustment, both NSAIDS use (OR (95% CI); 5.24 (1.57, 17.52), p<0.01) and steriod use (OR (95% CI); 3.15 (1.31, 7.59), p<0.01) were significantly associated with a higher risk of preterm delivery.

Conclusions: Women with SARDs are at an increased risk of adverse outcomes during pregnancy. The association between corticosteroid and NSAID use and preterm delivery requires further investigation. Our findings suggest the need for closer monitoring and coordinated care with obstetrics and perinatology in these high risk women.

FRI0728 OSTEOARTHRITIS AND GOUT: REAL-WORLD EVIDENCE EVALUATING PATIENT CHARACTERISTICS, TREATMENT PATTERNS, AND HEALTHCARE UTILIZATION

S. Krasnokutsky Samuels, M. Pillinger1, S. Kabadi2, D.C. Taylor3, R. Morlock4
1New York University, New York; 2AstraZeneca Pharmaceuticals, Gaithersburg; 3Ironwood Pharmaceuticals, Cambridge; 4YourCareChoice, Ann Arbor, United States

Background: Gout and osteoarthritis (OA) are common in the United States, but little is known about potential associations of OA and hyperuricemia/gout with clinical outcomes.

Objectives: This study examined variations in gout severity, management, and healthcare utilization among gout patients with and without OA.

Methods: Data were assessed from a survey of US physicians and patient chart audits. Participating physicians managed the care of >50 patients with gout annually; chart audits were of their most recent 5 consecutive adult patients with confirmed gout. Gout severity was measured by physician global assessment, flares, organ/joint damage, and tophi. Treatment characteristics, presence of clinician-confirmed OA, and sociodemographic factors were identified. Descriptive and multivariate (stepwise logistic regression) statistics analyzed the differences among gout patients with and without clinician-confirmed comorbid OA, and assessed urate-lowering therapy (ULT) use and gout control.

Results: Overall, 1159 charts of gout patients were abstracted (230 w/ OA, 929 w/o; 81% male; 71% white); the proportion of patients aged >61 was greater for those with gout and OA than those with gout but without OA (63% vs 32%; P<0.001). Patients with gout and OA had longer mean duration of gout (63 vs 41 months), were more likely to have tophi (44% vs 19%), joint damage (31% vs 11%), and clinician-rated severe gout (31% vs 12%) than those without OA (all P<0.01). Patients with gout and OA were also more likely to receive ULT (89% vs 70%; P<0.01), and among those receiving ULT, OA patients treated with allopurinol received a higher average daily dose (325 mg vs 286 mg; P<0.001). Gout patients with OA were more likely to have additional comorbidities (cardiovascular disease, kidney disease, COPD, depression, diabetes, hyperlipidemia, hypertension, obesity, prostate problems [men]) and have chronic pain than those without OA (all P<0.05). Gout patients with OA reported more office visits (4.0 vs 3.5), were more likely to have an emergency (31% vs 17%), and hospital (17% vs 11%) admission, and more likely to require surgery for gout in the past 12 months (3% vs 0.3%) (all P<0.01). In both groups, ULT use was associated with better gout control, but the specific factors predictive of ULT use and disease control varied between those with and without OA.

Conclusions: Gout patients with OA were more likely to have a greater impact on health system spending, with additional comorbidities and more severe gout than those without OA. These data suggest that gout patients with OA constitute a less healthy group in need of more careful monitoring and more aggressive gout management.

DEFINITION OF REMISSION AND MINIMAL DISEASE ACTIVITY IN PSORIATIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

T. Gedu1,1, R. Ionescu. Rheumatology, St Maria Hospital, UMF Carol Davila, Bucharest, Bucharest, Romania

Background: In psoriatic arthritis (PsA) a state of minimal disease activity (MDA) or remission are the target of treatment [1], but due to the heterogeneity of disease manifestations, it is still an unmet need. Coates et al [2] have developed and validated a composite score for MDA that encompasses most disease domains. However, for disease remission there is no accepted definition, whereas studies “borrowing” measures from rheumatoid arthritis or using their own criteria.

Objectives: The objective of this study was to analyse existing data on the definition of MDA and remission in studies on PsA.

Methods: A systematic literature review was performed. Studies evaluating remission or minimal disease activity in PsA either as a primary or secondary outcome, published between 2007–2017, were identified using the terms (“psoriatic arthritis”) AND (“remission” OR “low disease state” OR “low disease activity” OR “minimal disease state” OR “minimal disease activity”). Studies assessing disease activity in general, without specifically mentioning remission or MDA were not included; reviews and case-reports were also excluded.

Results: Two hundred and thirty-five publications were identified, of which 56 were included in the final analysis. The majority were observational studies (65.5%) and there were no RCTs identified. In total, 10843 PsA patients were analysed: 8779 in observational studies and 2064 in intervention trials; 4823 patients fulfilled the CASPAR criteria [3] and 6667 (31 studies) were taking a biologic drug at their inclusion. The majority of the studies assessed either MDA (65.5%) or remission (60%), but only 14 studies (25.5%) assessed both of the two outcomes. MDA or remission were mainly used as a secondary outcome (52.7% of the studies).

MDA was assessed mainly in observational studies (61.7%) and in almost all cases (89.9% of the studies) the definition used was the one proposed by Coates et al [2]. Remission was also assessed mainly in observational studies (63.8%). The most used definition (57.6%) was based on the disease activity score (DAS28), with values less than 2.6 considered as “remission”. Articular (63.8%). The most used definition (57.6%) was based on the disease activity outcome (52.7% of the studies).

Conclusions: None declared

THE NEED FOR HOSPITAL ADMISSION FOR SYSTEMIC LUPUS ERYTHEMATOSUS IN WESTERN AUSTRALIA LEADS TO A DOUBLING OF THE ALL-CAUSE MORTALITY RISK AS SEEN IN CONTROLS, ESPECIALLY FOR MEDICARE RELIANT AND MALE PATIENTS

W.D. Raymond1, D. Preen2, C. Ingerdeeth3, H. Keen4,5, J. Nossent1,6, 1School of Medicine & Pharmacology; 2School of Population Health, University of Western Australia; 3Rehabilitation and Aged Care, Sir Charles Gairdner Hospital; 4Rheumatology, Sir Charles Gairdner Hospital, Perth, Australia

Background: Hospitalisation for Systemic Lupus Erythematosus (SLE) is a significant event.

Objectives: We aimed to understand the factors leading to an incident admission and its impact on long term outcome in SLE patients in Western Australia (WA).

Methods: Using whole-population data linkage of hospital admissions, cancer registrations and death records in WA from 1980 to 2015, we performed a retrospective comparative analysis for all patients admitted with a first ever primary diagnosis of SLE (ICD-9-CM 695.4, 710.0, ICD-10-L93.0 & M32). For SLE patients, we analysed annual incident hospitalisation rates and compared patient characteristics, all-cause mortality and cancer risk (by Kaplan-Meier and Cox regression) versus age- and gender-matched controls free of rheumatic disease.

Results: The incident hospitalisation rate for SLE (mean 20.9/million/year; CI: 11–35) showed little variation. SLE patients were younger, more likely to be indigenous, uninsured, have kidney and cardiovascular disorders and to die during their first hospitalisation (Table 1). Cancer risk was equivalent, but a first admission for SLE doubled the risk of subsequent death (OR=1.99, CI: 1.5–2.7, p<0.001) (Figure 1/Table 2). Medicare reliance (OR 1.7, CI: 1.4 – 1.9, p<0.001) and male gender (OR 1.4, CI: 1.0 – 1.8, p<0.001) were the strongest independent predictors of death.

Conclusions: Hospitalisation rates for SLE in WA have not decreased over 25 years. Once hospital-based management for SLE was required, the risk of all-cause mortality doubled compared to age and gender-matched controls. This risk was greatest in Medicare reliant or male SLE patients and not due to increased cancer risk.

ARE THERE ANY IMPACT OF RAPID RADIOLOGIC PROGRESSION ON MORTALITY IN HUNGARIAN RHEUMATOID ARTHRITIS PATIENTS?

1Department of Rheumatology, University of Debrecen, Faculty of Medicine; 2Department of Rheumatology, Kénézy County Hospital, Debrecen; 3Department of Rheumatology, Hospital of Hospitalaller Brothers of St. John of God, Budapest; 4Department of Rheumatology, Pándy Hospital, Gyula; 5Department of Rheumatology, Hospital of State Railways, Szolnok; 6Department of Rheumatology, University of Szeged, Szeged; 7Department of Rheumatology, Fenes, Markhoz Hospital, Egér; 8Department of Rheumatology, András Jósa Hospital, Nyíregyháza; 9Department of Rheumatology, Semmelweis Teaching Hospital, Miskolc; 10Department of Rheumatology, Ferenc Fő Hospital, Kistarcas; 11Department of Rheumatology, Markusovszky Hospital, Szombathely, Hungary

Background: Prognosis of rheumatoid arthritis (RA) should be assessed early during the disease course. Rapid radiological progression (RRP) has been defined as a ≥1% unit increase in van der Heijde-Spear score within a year. The RA risk model has been developed by Vastesaeger et al in 2009. This tool calculates RRP based on non-radiographic indicators such as baseline CRP, RF and swollen joint count.

Objectives: We wished to test the matrix prediction model in the very first Hungarian cohort study.

Methods: In this non-interventional, cross-sectional retrospective study carried out in 11 Hungarian arthritis centres, we assessed high risk (≥40%) of RRP in biologic-naïve RA patients with active disease. In order to obtain a representative sample, patients were selected from each centre by a random technique. RRP was calculated according to the matrix model described by Vastesaeger et al. As a secondary endpoint, we compared methotrexate (MTX) responders vs non-responders with respect to RRP.

Results: We screened data of 1843 RA patients. Finally, data obtained from 1356 patients could be used for RRP prediction and MTX responsiveness. The mean age of patients was 55.5 years, 84.7% were women. The mean disease duration was 8.4 years. At the time of the assessment, mean CRP was 17.7 mg/l, RF was 139.3 IU/ml, mean DAS28 was 5.00 and mean swollen joint count was 6.56. High risk (≥40%) of RRP could be determined in 18.2% of patients. Among continuous variables other than those used for calculation of RRP risk, RA patients with the risk of RRP>40% (n=247) had significantly lower age than those with RRP<40% (n=1109) (53.33±12.31 vs 56.02±13.50 years; p=0.001).

With respect to binary variables, the risk of RRP>40% was significantly associated
with non-response to MTX (OR: 17.82), male gender (OR: 1.53), ACPA positivity (OR: 2.11), the presence of erosions (OR: 1.37) and current smoking (OR: 1.66). Binary logistic regression analysis revealed that MTX non-response (OR: 16.84), male gender (OR: 1.67) and ACPA positivity (OR: 2.18) were independent predictors of high-risk RRP (≥40%). With regards to MTX responsiveness, binary logistic regression analysis confirmed that both male gender (OR: 5.20) and the presence of erosions (OR: 7.98) were independent predictors of high RRP risk in the MTX responder subpopulation.

Conclusions: In the first biologic-naive Hungarian RA cohort assessed for RRP, RRP occurs in almost one-fifth of the patients. These patients differ from others in various clinical and serological parameters. RRP has also been associated with non-response to MTX.

particles are targeted by autotagonistic antibodies from RA and other systemic rheumatic diseases.

Methods: Using a protein macroarray we identified JKTBP in humans and animal models of inflammatory rheumatic diseases. Bacterially expressed recombinant JKBFP proteins were used to confirm the obtained data. Epitope, TLR7/9 and DNA methylation inhibitors determined by ELISA. JKTBP expression in cultivated cells and synovial tissue was analysed by indirect immunofluorescence, immunoblot and immunohistochemistry.

Results: Anti-JKTBP autoantibodies were detected in 46% of the patients with systemic lupus erythematosus (n=103), in 20–30% of the patients with rheumatoid arthritis (n=286), in 10% of the patients with mixed connective tissue disease (n=20) or spondyloarthropathy (n=20), and in <10% of patients with other autoimmune disorders (n=382). Sera positive to JKTBP as well as hNRNP-B1, revealed nearly two thirds of the RF IgM/CCP2-seronegative patients as early RA patients. Combining sensitivities to all autoantigens tested (JKTBP, AUF1, hNRNP-B1), it was possible to identify 92% of the early RA patients (n=91).

In the MRL/lpr mouse model of SLE, mice deficient of MyD88 and TLR7/9 lacked anti-JKTBP autoantibodies, whereas mice deficient of SIGIR/TIR8 showed enhanced anti-JKTBP autoantibody production. These results show that autoantibody generation against JKTBP, AUF1, hNRNP-B1 is dependent on TLR 7 and TLR 9 rheumatoid factor different to TLR 7 dependent generation of snRNPs. For all tested autotagons either their titter or generation are dependent on the activation of innate immune genes MyD88 and SIGIRIR/TIR8 gene.

Conclusions: These data identify SG as targeted particle in RA and JKTBP as a novel autoantigen in RA patients. JKTBP autoantibodies are also found in patients with models of inflammatory rheumatic diseases and autoimmune disorders.

Phagocytosis was superior in M2 (IL10) and M2 (IL4) activated MDM than in M1 MDM. Anti-TNF agents but not TCZ or RTX induced an increase of phagocytosis in M1 MDM.

**Conclusions:** Anti-TNF agents upregulate M2 alternative pro-resolving markers and downregulate M1 inflammatory markers in macrophages. Our results need to be extended by transcriptional analysis and evaluated in RA patients.

**GROUP 3 INNATE LYMPHOID CELLS NUMBERS IN PERIPHERAL BLOOD PREDICT USTEKINUMAB (STELARA) THERAPY RESPONSIVENESS IN PSORIATIC DISEASE CASES WITH SUBCLINICAL IMAGING ENTHESOPATHY**

Y. M. El-Sherbiny 1, 2, L. Savage 1, M. Wittmann 1, 2, P. Emery 1, 2, M. Goodfield 1, D. McGonagle 1, 2, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds 1, National Institute of Health Research Leeds Musculoskeletal Biomedical Research Unit 1, Department of Dermatology, Leeds Centre for Dermatology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

**Background:** Ustekinumab targets the common p40 sub-unit of interleukin-12 (IL-12)/interleukin-23 (IL-23). In patients treated with Ustekinumab for psoriasis where patients were selected on the basis of subclinical imaging enthesopathy, we have noted an improvement in subclinical imaging enthesopathy (Savage LJ et al submitted), raising the possibility that it may be possible to find a biomarker for predicting response to therapy in psoriatic disease. Innate lymphoid cells may be centrally involved in the pathogenesis of psoriatic skin and joints disease, since they express IL-23R receptor and are associated with IL-17/IL-22 production.

**Objectives:** This work was performed to test the hypothesis that peripheral blood ILC perturbations may be useful in defining response in psoriasis cases with imaging confirmed subclinical enthesopathy.

**Methods:** Peripheral blood collected at baseline (before therapy, 24 weeks, 54 weeks) from patients in the MUSTEK trial (Ustekinumab in psoriasis cases selected on the basis of subclinical imaging enthesopathy) was analysed. ILC3s were identified as lineage negative (CD3- TCR- CD14- CD11c- CD1a- CD303- FcεRI- CD34- CD123-) with positive expression of CD127, IL22, and CCR6. ILC2 cells were identified as Lineage- CD127+ and CRTH2 positive, while ILC1 were identified as Lineage- CD127-, CD127+ and CCR6 positive. No correlation was found with total ILCs (ILC1,2, AND 3) (R=0.104, p>0.05).

**Results:** No correlation was found with total ILCs (ILC1,2, AND 3) (R=0.104, p>0.05). ILC3s were inversely correlated with the reduction in the PASI score (R =0.404, p=0.038). Interestingly, those patients with reduction below 90% of PASI score has a significantly higher absolute numbers of ILC3+ cells in peripheral blood at the baseline than PASI (n=6/23) than super-responder group (n=17/23).

**Conclusions:** The data obtained indicate that, IFN-DCs from RA patients at baseline ILC3s was inversely correlated in with the reduction in the PASI score (R =0.404, p=0.038). No correlation was found with total ILCs (ILC1,2, AND 3) (R=0.104, p>0.05).

**DRUG THERAPY ENHANCES TOLEROGIC PROPERTIES OF DENDRITIC CELLS IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Y. Kurochkina 1, T. Tikhonova 2, T. Tyrynova 2, O. Leplina 2, A. Sizikov 2, A. Sulitjan 1, L. Konenkova 1, O. Chumasova 1, A. Ostaniin 1, E. Chernykhy 2, 1Department of Rheumatology; 2Laboratory of Cellular Immunotherapy, Federal State Budgetary Scientific Institution Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation

**Background:** Dendritic cells (DCs) are known to contribute to the pathogenesis of rheumatoid arthritis (RA) through presentation of cartilage glycoprotein, production of proinflammatory cytokines and activation of Th1/Th17 responses. Along with stimulating activity, DCs may exhibit suppressive functions via capacity to induce T cell apoptosis/anergy and to generate regulatory T cells. Since these DCs have potential to control auto-reactive T-lymphocytes, the enhancing of tolerogenic properties of DCs seems to be a new important strategy in treatment of RA. The experimental research in animals and human in vitro studies revealed the capacity of anti-rheumatic drugs to inhibit stimulating activity and to enhance tolerogenic functions of DCs. The aim of this work was to investigate the role of different drug therapies on DC functions in RA patients.

**Objectives:** The aim of our study is to investigate, whether drug therapies influence the properties of monocyte-derived DCs generated in the presence of IFNs (IFN-DCs) in RA patients, and if the effect of disease-modifying anti-rheumatic drugs differ from that of biological/pulse steroid therapy.

**Methods:** Thirty nine patients with RA with high and moderate activity of disease were recruited in this study. All patients fulfilled ACR/EULAR criteria (2010). Nineteen patients received methotrexate, lefunomide, sulfasalazine or their combination (RA1). Twenty patients were at pulse therapy (methypredinsolone 500mg No. 3) or biological drugs (adalimumab or rituximab) (RA 2). All studies were performed after receiving informed consent. DCs were generated from blood monocytes culturing for 5 days with GM-CSF and IFN-α in the absence and presence of dexamethasone, applied on third day (LPD) or as maturation stimuli added on fourth day. The expression of CD14, CD83, CD 86, B7H1, HLA-DR, TLR-2 on the surface of DCs was measured by flow cytometry. The functions of DCs were evaluated by measuring cytokine production and DC allostimulatory activity in mixed lymphocyte reaction (MLR).

**Results:** Both DC-RA1 and DC-RA2 where shown to display impaired maturation evidenced by elevated expression of CD14 and decreased number of mature (CD14+CD83+) DCs. Whereas, DCs-RA2 demonstrated several additional differences, including increased number of intermediate CD14+CD83+ cells (compared with donors DCs), higher expression of inhibitory molecule B7-H1 (PD-L1) (compared with donors DCs and DCs-RA1) and tendency to lower expression of CD86 and higher expression of TLR-2. Besides, DCs-RA2 produced higher concentrations of IL-6 and had 2-fold lower allostimulatory activity then DCs-RA1. These differences together with phenotypic changes suggested more pronounced tolerogenic properties of DCs-RA2. Despite the revealed DC differences in RA1 and RA2 patients both types of DCs preserved in vitro sensitivity to dexamethasone, that suppressed the production of TNF-α and reduced allostimulatory activity. The data obtained indicate that, IFN-DCs from RA patients at drug treatments are characterized by tolerogenic properties, which are more pronounced in patients with biological or pulse steroid therapy.

**DISTRIBUTION AND INTRACELLULAR SETTING OF GRANULYSIN IN WOMEN WITH KNEE OSTEOARTHRITIS**

G. Laskarin 1, T. Kehler 2, M. Dominiovic 2, V. Persic 4, M. Rogoznica 4, D. Rukavina 1, 1Medicinski fakultet Sveučilišta u Rijeci, Rijeka; 2Specialized Hospital ”Thalassemia-Obitelj”; 3Medicinski fakultet Sveučilišta u Rijeci; 47th Opatija, Opatija, Croatia

**Background:** The role of the cell-mediated immune response is recently recognized in osteoarthritis (OA) (1). Granulysin (GLY) is mediator of cellular immunity and cytotoxic molecule expressed in T and NK cells in regulatory (15 kDa) and cytotoxic (9 kDa) forms (2). Cytotoxic 9 kDa form of GLY mediates apoptosis of eukaryotic cells (3) and might be responsible for silent unscheduled apoptosis of joint tissue cells in patients with OA without clinically recognized

systematic immune reaction, as measured by erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) (4). We investigate GNLY distribution and intracellular setting in peripheral blood lymphocytes of patients with OA.

Objectives: Women with knee OA (17), and age and sex appropriated control (17) were tested. All of them signed informed consent before sampling of peripheral blood lymphocytes.

Methods: Medical history, clinical examination, X-ray and routine laboratory testing (ESR, CRP) were used for diagnosing OA. Peripheral blood mononuclear cells (PBMC) were isolated by gradient density centrifugation and used for multiple, simultaneous intracellular [total GNLY, 9 kDa GNLY, 15 kDa GNLY and Lyso-02-like membrane protein-1 (LAMP-1)] and surface antigens (CD3 and CD56) detection by immunofluorescence. Data were analyzed by flow cytometry or confocal microscopy.

Results: In OA and control samples the percentage of total GNLY+ cells and GNLY expressing NK and T cells did not significantly differ and correlate with ESR and CRP. The frequency of GNLY+ cells was always higher in natural killer (NK) then in T cells and 9 kDa GNLY dominated over 15 kDa GNLY. However, 9 kDa GNLY co-localized more with the marker of cell degranulation, LAMP-1 in polarized granules of OA patients when compared to the control or to the 15 kDa GNLY.

Conclusions: The increase in the expression of cytotoxic (9 kDa) over regulatory (15 kDa) GNLY form in PBMC and its intracellular setting in polarized exocytic granules suggests the involvement of activated GNLY+ lymphocytes in the immunopathogenesis of knee OA, indispensable of ESR and CRP.

SAT0010 | THE DAMP PROTEIN S100A8/A9 IS CRUCIALLY INVOLVED IN MYELOID-DERIVED SUPPRESSOR CELL (MDSC) DIFFERENTIATION AND FUNCTION IN COLLAGEN-INDUCED ARTHRITIS

M. Kuhlencord, Y. Kusche, S. Zenker, T. Vogl, J. Roth. Institute of Immunology, Münster, Germany

Background: Over the last years, the differentiation and activation of MDSC under tumor conditions has been studied extensively. Various tumor-derived factors have been identified in promoting the accumulation of this suppressive cell population. Recently, we determined the two ligands S100A8 and S100A9 as important factors in the differentiation of MDSC during tumor conditions. However, little is known about the S100A8/A9 driven expansion and activation, as well as the relevance of these cells in autoimmune diseases such as rheumatoid arthritis.

Objectives: We therefore analyzed the mechanisms involved in S100A8/A9 driven MDSC accumulation and their functional importance in a mouse model of rheumatoid arthritis.

Methods: To investigate the effect of S100A8/A9 on MDSC differentiation, bone marrow cells from wild type (wt), S100A8 knockout (A9ko) and S100A9 transgenic (A9tg) mice were analyzed. Accumulation of MDSC and their phenotypical characterization was performed by FACS analysis and functional characterization including arginase activity, NO- and ROS-production and T cell proliferation assays.

Results: The role of S100A8/A9 and MDSC in arthritus was investigated using the collagen-induced arthritis (CIA) mouse model. Accumulation of MDSC in different organs was analyzed by FACS and systemic S100A8/A9 levels were measured by ELISA. Ex vivo functional analysis of purified MDSC was performed to assess the potential of these MDSC to inhibit T cell responses.

Conclusions: Our in vitro studies reveal that, in the presence of S100A8, myeloid progenitor cells differentiate to immature cells that phenotypically as well as functionally resemble MDSC. These cells are characterized by co-expression and up-regulation of arginase activity, NO- and ROS-production, and exhibit strong inhibitory effects on the proliferation of both CD4- and CD8-positive T cells. Furthermore, accumulation of MDSC by extracellular S100A8 was found to be mediated via the Toll-like receptor 4 signaling pathway. In addition, lack of intracellular S100A8/A9 results in a decreased number of MDSC as well as a reduced suppressive activity of these cells, implying a dual role of these proteins for MDSC differentiation and function.

Investigating the role of S100A8/A9 and MDSC in a mouse model of CIA, a clear correlation between disease scores, MDSC numbers and systemic S100A8/A9 levels was observed. Furthermore, disease activity was reduced in wt and A9tg mice compared to A9ko mice and was in line with an increased accumulation of MDSC in the lymph nodes. Next to an enhanced suppressive activity of MDSC isolated from lymph nodes of wt and A9tg mice, these MDSC promoted the accumulation of regulatory T cells (Treg) whilst suppressing the differentiation of TH17 cells. In contrast, MDSC isolated from lymph nodes of A9ko mice had no effect on Treg differentiation and did not inhibit TH17 emergence.

Conclusion: Our in vitro data and results clearly show a S100A8/A9 dependent accumulation of cells that phenotypically as well as functionally resemble MDSC also under non-tumor conditions. In vivo data strongly support the importance of these findings. By influencing MDSC accumulation and function, S100A8/A9 is critically involved in regulating the disease outcome in rheumatoid arthritis, implying an important role for S100A8/A9 derived MDSC in regulating immune reactions during autoimmune diseases.

Disclosure of Interest: None declared.

SAT0011 | THE ACTIVATION OF MUSCARINIC ACETYLCHOLINE RECEPTORS INFLUENCES THE ONTOGENY OF NEUTROPHILS

S. Sommerlatte1, L. Kappes1, S. Pfitzner1, G. Marschner1, H. Heidecke1, P. Lamprecht1, A. Mueller1, T. Lange1, O. Cabral-Marques1, G. Riembekasten1, R. Rheumatology, University of Lübeck, Lübeck, CellTrend GmbH, Luckenwalde, Germany

Background: There is growing evidence that nervous and immune system communicate with each other through soluble mediators.1 Immune cells such as neutrophils express muscarinic acetylcholine receptors (mACHR), which are neuroimmune receptors and highly prevalent in the nervous system.2 Aberrant neuroimmune functioning plays an important role in various autoimmune diseases. Dysregulation of neutrophil immune responses such as oxidative burst and migration is one of the key mechanisms leading to tissue damage in autoimmune diseases.3 However, the impact of mACHR activation on neutrophils remains understudied.

Objectives: We aimed to determine effects of muscarinic receptor activation on development and functions of neutrophils.

Methods: Neutrophils were isolated from peripheral blood of healthy donors by dextran sedimentation. After one hour in the absence or presence of the natural ligand acetylcholine (Ach) (10nM-100μM) or the muscarinic agonist oxotremorine-m (oxo-m) (10nM-100μM), neutrophil respiratory burst was analyzed by dithyrodhodamine (DHR) flow cytometry assay and migration assessed by transwell assay in response to N-formylmethionyl-leucyl-phenylalanine (fMLP). Cells that migrated were quantified by flow cytometry. To analyze the effects mACHR activation on the development of neutrophils, HL-60 cells were incubated in the presence of DMSO (1%), oxo-m (100μM) or DMSO plus oxo-m. After 6 days, cells were harvested and expression of maturation markers (CD15, CD63 and CD16) as well as mACHR (M1-M5) were measured by flow cytometry.

Results: We observed no effects of mACHR activation on the respiratory burst of neutrophils. However, both Ach and oxo-m inhibited neutrophil migration in a dose-dependent manner, but with peculiar differences. By increasing acetylcholine concentrations, we observed a reduction of neutrophil migration in a directly proportional manner. On the other hand, while the lowest dose (10nM) of oxo-m inhibited migration of HL-60 cells, the increase of oxo-m showed inversely proportional effects on neutrophil migration. Thus, we aimed to investigate, if the highest dose of oxo-m has a different effect on neutrophils ontogeny. In agreement with the results obtained with neutrophils, the incubation of HL-60 cells with the highest dose of oxo-m showed no effect on oxidative burst and migration and induced no changes in the expression of mACHRs (M1-M5), CD16 and CD63 in HL-60 cells. However, we observed that it resulted in significantly increased surface levels of the neutrophilic lineage marker CD15.

Conclusions: Our data indicate a differential activation of mACHR affecting different steps of neutrophil ontogeny. Considering this finding, abnormalities in the activation of muscarinic receptors as have been observed in autoimmune diseases might contribute to neutrophil dysfunction and need further investigation.

SAT0012 | S100A8/A9 INCREASES THE MOBILIZATION OF LY6C HIGH MONOCYTES TO THE SYNOVIAL DURING EXPERIMENTAL OSTEARTHROPATHY

N. Cremers1, E. Geven2, A. Blom2, M. van den Bosch3, P. van der Kraan2, P. van Lent2, Experimental Rheumatology, Radboud university medical center, Nijmegen, Netherlands

Background: It is increasingly recognized that part of the pathology in osteoarthri-
RESULTS: Injection of S10A9 into the knee joints of naive mice resulted in an elevated expression of monocyte-related markers (Ly6C, CCR2, and CX3CR1) within the synovium after 1 and 3 days, suggesting that S10A9/A9 is directly involved in the activation of monocytes. At CioA day 7 in WT mice, numbers of Ly6C+ monocytes, but not Ly6Chigh monocytes, were strongly increased (7.6-fold) in the synovium as compared to saline-injected control joints. In contrast, S10A9 KO mice showed a significant increase in Ly6Chigh monocytes (2-fold), whereas the number of Ly6C+ monocytes remained unaffected. Concurrently, a strong upregulation of several monocyte cell adhesion molecules (ICAM-1, ICAM-2, ICAM-1, KC, and MIP1α) was observed locally in the synovium, of which only the Ly6Chigh mobilization marker CX3CL1 was significantly higher in S10A9 KO mice, corresponding with the increased Ly6Chigh monocytes in the synovium of S10A9 KO mice. This could however not explain the local increased number of Ly6C+ monocytes at CioA day 7 in WT mice, and therefore we next investigated the major source of the monocytes, which is the BM. We observed a decrease of 14% of myeloid cells (consisting partly of Ly6Chigh monocytes) in the BM of WT mice at CioA day 7, whereas there were no changes in the BM of S10A9 KO mice, suggesting that S10A9/A9 affects the release of myeloid populations from the BM. In line with that, expression of adhesion molecules (LFA-1, VCAM, VE-cadherin, PECAM1, and L-selectin) was lower at CioA day 7 in the BM of S10A9 KO mice when compared to WT mice.

Conclusions: Local induction of OA leads to S10A9/A9 production, and therefore we next investigated the main source of the monocytes, which is the BM. We observed a decrease of 14% of myeloid cells (consisting partly of Ly6Chigh monocytes) in the BM of WT mice at CioA day 7, whereas there were no changes in the BM of S10A9 KO mice, suggesting that S10A9/A9 affects the release of myeloid populations from the BM. In line with that, expression of adhesion molecules (LFA-1, VCAM, VE-cadherin, PECAM1, and L-selectin) was lower at CioA day 7 in the BM of S10A9 KO mice when compared to WT mice.

DOI: 10.1136/annrheumdis-2017-eular.6181

Background: Dendritic cell (DC) are a heterogeneous group of antigen presenting cells that can be subdivided into CD1c+ and CD141+ DC. CD141+ DC are a rare population of DC that were first discovered in 2010 in human peripheral blood. Due to their rarity very little is known about the function of these cells in other tissue or in disease. These newly described DC subset have thus never been described in Inflammatory Arthritis (IA) or any of the rheumatic diseases.

Objectives: To identify DC in IA synovium and functionally assess if these cells play a pathogenic role in IA.

Methods: CD141+ DC were magnetically purified from synovial fluid mononuclear cells (SMFC) and peripheral blood mononuclear cells (PBMC) stimulated and stained with a panel of fluorochrome conjugated antibodies for multicolour flow cytometry. CD141+ DC isolated and purified from IA synovial fluid were subsequently cocultured with allogeneic CD3+ T cells for 6d after which intracellular cytokine production was assessed by flow cytometry. Supernatants from this CD141+ DC cell cultures were used to treat synovial fibroblasts & the expression of adhesion molecules, cytokines & MMPs was measured. Finally, using sorted populations of CD141+ DC from SFMC and PBMC, RNA sequencing was performed and differentially expressed genes and interaction network analysis were identified using the DeSeq2 R package, Ingenuity Pathway Analysis (IPA) and Innate and Cytoscape. 78 DC1+ T cells. The IA synovium consists of a complex interplay of multiple cell types. Therefore next we examine the effect of this CD141+ DC-T cell interaction on the key invasive cells in the synovium – synovial fibroblasts. Supernatants from CD141+ activated T cells were cultured with fibroblasts & induced expression of ICAM-1, IL-6, IL-8, MMP1 & MMP3. SF CD141 expressed significantly higher levels of IFNγ and IL-17a. Using the hyperxision TREM1 activation of which induces further expression of CD80, CD86 and CD40. Coculture of these TREM1 activated CD141 with CD3+ T cells increases IFNy and IL-17a production. Finally RNASeq analysis revealed that there are 2089 differentially expressed genes between SF CD141+ DC & WB CD141+ DC. These genes are involved in a number of key pathways such as energy metabolism, chemokine & cytokine signalling. Principal Component Analysis (PCA) revealed that CD141+ DC with the synovium are distinctly different from blood CD141+ DC.

SAT0015 ANCA-ASSOCIATED VASCULITIS- AND SYSTEMIC LUPUS ERYTHEMATOSUS-INDUCED NEUTROPHIL EXTRACELLULAR TRAPS HAVE INTRINSICALLY DIFFERENT FEATURES

L.S. Van Dam 1, T. Kraaij 1, S.W. Kamerling 2, M.C. Avramut 2, C.R. Jost 2, A.J. Koster 2, H.U. Scherer 2, C.D. Pusey 4, A.J. Babelink 1, C. van Kooten 1, Y.K. Teng 1, 1Nephrology; 2Molecular Cell Biology; 3Rheumatology, LUMC, Leiden, Netherlands; 4Renal and Vascular Inflammation, Imperial College, London, United Kingdom

Background: Neutrophil extracellular traps (NETs) are immunogenic, extracellular DNA structures, thought to play an important role in the pathogenesis of many systemic autoimmune diseases including ANCA-associated vasculitis (AAV) and systemic lupus erythematosus (SLE). However, the pathogenic role of NETs is poorly understood. NETs are thought to play a pivotal role in the pathogenesis of many systemic autoimmune diseases including ANCA-associated vasculitis (AAV) and systemic lupus erythematosus (SLE). They are formed by the release of a net-like structure composed of extracellular DNA, histones, and various other proteins. NETs have been shown to be involved in the pathogenesis of various autoimmune and inflammatory diseases, including systemic lupus erythematosus (SLE), rheumatoid arthritis, and lupus nephritis.

Objectives: To investigate the characteristics of NETs induced by sera of AAV and SLE patients.

Methods: The present study involved 101 AAV patients, 59 SLE patients, and 10 healthy controls. Healthy neutrophils were stimulated with 10% serum of these patients to induce NETs. Quantity of NET induction was measured by a novel, highly sensitive NET quantification assay using 3D-confoval laser scanning microscopy. Qualitative characteristics of NETs were investigated by immunofluorescence microscopy that detected co-localisation of several established autoantigens on AAV- and SLE-induced NETs, including citrullinated histone-3 (CitH3), neutrophil elastase (NE), high mobility group box-1 (HMGB1), myeloperoxidase (MPO) and proteinase-3 (PR3).

Results: Quantitative NET induction demonstrated that AAV sera induced significant more NETs (median [Q1 - Q3]: 20.74 [9.56 – 74.14]), compared to SLE sera (5.02 [1.88 – 14.33]). Also qualitatively, NETs induced by AAV or SLE sera were distinct. In both cases, NETs showed co-localisation of MPO and PR3 with extracellular DNA. However, AAV-induced NETs had significantly higher CitH3 expression than SLE-induced NETs. Interestingly, the opposite was observed for other markers as HMGB1 was exclusively expressed on SLE-induced NETs and NE was also higher expressed on SLE-induced NETs compared to AAV-induced NETs. Intriguingly, the distinction between AAV and SLE NETs was further corroborated by live imaging demonstrating differences in morphology and chronology of NET induction: in SLE NET-clusters were induced within the 1st hour while in AAV non-clustered NETs composed of long, thin DNA-fibres were induced in 2–4 hours through lytic effusion.

Conclusions: The present study demonstrates that NET induction in AAV and SLE results in quantitative and qualitative distinct NETs indicating that NET formation in AAV and SLE is likely based on intrinsically different processes. These data increase our understanding of the pathophysiologic relevance of NETs and how they could be considered as a common pathway underpinning different autoimmune diseases.

SAT0016 A NEW SUBSET OF NK CELLS, WITH ENHANCED CYTOTOXIC FUNCTION, IS INCREASED IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

D.J. Cruz González 1, L. Baranda-Cándido 2, C. Abd-Mendoza 2, J. Alcocer-Varela 2, R. González-Amaro 1, D. Gómez-Martín 2, A.E. Monsiváis-Ureña 1, 1Medicina Translacional y Molecular. Centro de Investigación en Salud y Biomedicina; 2Departamento de Reumatología, Hospital Central ‘Ignacio Morones Prieto’, Facultad de Medicina, Universidad Autónoma de San Luis Potosí, San Luis Potosí; 1Departamento de Reumatologia e Inmunologia, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad de México, Mexico

Background: Natural killer cells (NK cells) are granular lymphocytes that belong to the innate immune system. Their primary function is the lysis of virus-infected or tumoral cells. These functions are regulated by activating (NKG2D, NKp46, NKP30, NKG2C, NKP44) and inhibitory (KIRs) receptors. The lysis of tumor cells is mediated by the release of perforin and granzymes, which damage the plasma membrane of target cells.

Objectives: To analyze the phenotype of circulating NK cells as well as its function in SLE patients.

Methods: Sixty SLE patients and fifty-five controls were included in this study. Diagnosis was made according to ACR criteria. Activity of disease was measured by SLEDAI index. The expression of NKG2A, IL-10, NKG2D, NKG2C, NKG2D, NKP30, NKP46, NKP44, CD155, CD16, HLA-DR, CD11c+ was evaluated in NK cells (CD3-CD56+) from peripheral mononuclear cells. NK cell function was assessed by the percentage of monocyte-derived DC lysis by NK cells.

Results: Diminished levels of circulating NK cells were found in SLE patients (p=0.0439) compared to healthy subjects. NK cells from SLE showed higher levels of the inhibitory receptor ILT2 (p=0.0024), and the costimulatory molecules CD86+ (p=0.0113) and CD14+ (p=0.0238); in addition, SLE patients displayed a higher expression of MHC-class II molecule, HLA-DR+ (p<0.0001). Interestingly, higher levels of atypical NK cells CD11c+HLA-DR+ (p=0.0075) were found in SLE patients compared with healthy subjects. Furthermore, we found that SLE patients showed a significant increase level of monocyte-derived DC lysis by NK cells.

Conclusions: In this study, we show for the first time that NK cells in SLE have an altered phenotype, expressing receptors, which are characteristic of dendritic cells (CD134, CD86 and HLA-DR). The expression of these receptors may provide NK cells with the ability to activate T cells, which together with their higher capacity to lyse immature or tolerogenic DCs could contribute to SLE pathogenesis. It is known that NK cells could have a dual role in autoimmune diseases, here we propose that the lysis of DC mediated by NK cells could be important to modulate the pathogenesis in SLE patients. Even more, in this report we identify a new subset of NK cells, CD11c+HLA-DR+, reported previously in a mouse lupus model. It is essential to highlight that these NK cells with DC-like phenotype could be crucial for the development of SLE.

SAT0017 INVESTIGATING NOVEL AUTOANTIBODIES IN PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS

M.C. Baker, N. Lingampalli, W. Robinson. Rheumatology, Stanford University, Palo Alto, United States

Background: Granulomatosis with polyangiitis (GPA) is a disease characterized by inflammation in small blood vessels, leading to significant organ damage and ultimately great morbidity and mortality. The presence of anti-neutrophil cytoplasmatic antibodies (ANCA) is a hallmark of the disease, and thought to directly play a role in pathogenesis by activating primed neutrophils. The two major antigens that ANCA are believed to recognize are myeloperoxidase (MPO) and proteinase 3 (PR3). Although anti-MPO antibodies are directly pathogenic when transferred or induced in animal models, the evidence is less clear for PR3. Clinically, it is debated whether levels of anti-PR3 correlate with disease activity. Therefore, we believe that anti-PR3 antibodies are not the primary drivers of disease in patients with PR3+ ANCA-vasculitis (i.e. GPA), and that novel autoantibodies may play a role in disease pathogenesis.

Objectives: The objective of this work is to identify novel human autoantigen targets of novel autoantibodies identified in GPA, and to test their association with disease. The goal is to discover novel autoantigens that will ultimately lead to new diagnostics and therapeutics.

Methods: Cell-barcode-enabled antibody repertoire sequencing was performed on blood plasmablasts (antibody-producing cells formed during an immune response) from five PR3+ ANCA-vasculitis patients with GPA treated with rituximab in the RAVE trial. Phylogenetic trees were bioinformatically created in order to identify clonal families of plasmablasts. Antibodies representing clonal families of plasmablasts were recombinantly expressed and are being tested using human protein arrays and ELISAs to determine their antigen specificity.

Results: All five PR3+ ANCA-vasculitis patients sequenced from the RAVE trial achieved complete remission but subsequently flared. Plasmablasts were isolated at the baseline flare, at remission and at the post-rituximab flare. Phylograms of the antibody repertoire revealed clonal families of affinity-matured antibodies that share heavy and light chain VJ usage. A total of 24 representative antibodies were selected for recombiant expression, including representative antibodies derived from clonal families: (1) shared across patients at baseline flare and/or post-rituximab flare (n=5), (2) present at baseline flare and post-rituximab flare (n=7) [persistent clone or same clone came back], (3) present at baseline flare or post-rituximab flare (n=6), (4) present in remission and post-rituximab flare (n=5) [achieves remission despite clone presence], (5) present in remission (but not flare) (n=1) [patient in remission despite clone presence]. None of the 24 antibodies bind PR3 in an ELISA and thus these antibodies do not represent...
EFFECTS OF ANTI-TNF ALPHA THERAPY ON B CELLS IN RHETUMOGRHITIS (RA) PATIENTS

O. Pala1, A. Diaz2, B. Auborg1, E. Greidinger1, B.B. Blomberg2, D. Frasca2.

1Rheumatology, 2Microbiology & Immunology, University of Miami, Miami, United States

Background: Our laboratory has previously characterized defects in humoral B cell responses of aged mice and humans. These defects include: the reduction in activation-induced cytokine deaminase (AID), required for the generation of class-switched memory B cells and the reduction in the percentage/number of the subset of switched memory B cells (1). AID and switched memory B cells have been proposed to be effective predictive biomarkers of vaccine responses (2). Moreover, we have shown that aging is characterized by increased systemic inflammatory which induces intrinsic B cell inflammation, measured by intracellular (ic) TNF-α, and this significantly decreases the capacity of the same B cells to make protective antibodies in response to vaccination (3). Other marker of B cell intrinsic inflammation is micro-RNA (miR) expression, particularly miR-16 and miR-155, which is increased in elderly B cells and negatively correlated with B cell function (4).

Objectives: Our goal for this study was to evaluate B cell phenotype and function in RA patients treated Methylxenate (MTX), alone or together with anti-TNF-α. We hypothesized that patients treated with anti-TNF-α will show improved B cell function due to reduction in icTNF-α.

Methods: We recruited 9 RA patients, 5 patients on MTX and 4 on MTX/anti-TNF-α. We measured the relevant B cell subsets in blood (Naive, switched memory, IgM memory and late memory) by flow cytometry. Staining was performed with antibodies specific for CD19, CD27 and IgD. In addition, we isolated blood B cells using magnetic beads, and measured the expression of miR-16 and miR-155 on blood B cells by qPCR.

Results: Preliminary data showed that the percentages of switched memory (IgD-CD27+) B cells are significantly higher (p < 0.003) in patients undergoing MTX/anti-TNF-α therapy. We also observed a significant decrease in naive B cell percentages (p < 0.028). Preliminary results also showed a decrease in the mRNA expression of both miR-16 and miR-155 in patients on combination therapy compared to MTX alone.

Conclusions: These results support the hypothesis that therapy with anti-TNF-α is beneficial for improving B cell function in RA patients, as compared to MTX therapy alone. Future experiments will seek to evaluate intrinsic B cell TNF levels in these patients and correlate them with measurements of B cell function. Treatment with anti-TNF-α may be able to block the excessive amounts of systemic TNF-α and in turn B cell TNF-α which could improve the antibody responses and the risk of infections in RA patients undergoing therapy.

SAT0019 ESTROGEN INFLUENCES THE SIALYLATION PROFILE AND INFLAMMATORY PROPERTIES OF B CELLS – A POTENTIAL EXPLANATION FOR THE SEX DIFFERENCES AND INCREASED RISK FOR RA IN POSTMENOPAUSAL WOMEN

C. Engdahl1,2, J. Raufer1, U. Harre1, A. Bondt1, R. Pfelle1,4, G. Kröneke1,4, H.U. Scherer4, H. Forsblad2,3, G. Schett1, 1Department of Internal Medicine 3, Clinical Immunology, Erlangen, Germany; 2Department of Rheumatology and Inflammation research, CBAR, Institute of Medicine, Gothenburg, Sweden; 3Department of Rheumatology, Lediden University Medical Center, Leiden, Netherlands; 4Klausn-Fiesbiger Center for Molecular Medicine, FAU Erlangen-Nuremberg, Erlangen; 5Department of Internal Medicine 3, Clinical Immunology, Gothenburg, Germany; 6Department of Rheumatology, Lediden University Medical Center, Leiden, Netherlands; 7Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden

Background: Rheumatoid arthritis preferentially affects women. RA has its peak over 50 years coincidencing with the decrease in sex hormones in menopause. Recently, the transition from asymptomatic autoimmunity to RA has been shown to essentially depend on the glycosylation status of antibodies affecting the binding affinity to Fc gamma receptors. Hence a decrease in the sialylation of antibodies resulting from a decrease in the activity of the sialylation enzyme β-galactosidase α2,6-sialyltransferase (ST6GAl1) was shown to trigger the onset of RA.

Objectives: To test whether estrogen influences the glycosylation status of antibodies and ST6GAl1 expression explaining why postmenopausal women are particularly prone to develop RA

Methods: In the experimental part we tested the influence of estrogen on anti-citrullinated protein antibodies (ACPAs) sialylation and ST6GAl1 expression. Ovariectomized mice, which were either left without estrogen supplementation or were supplemented with estrogen (hormone replacement), were immunized with ovalbumin (OVA) to induce antibody production. Immunoglobulin G (IgG) levels were analyzed by ELISA and the glycosylation of the Fc-part of total and OVA-specific IgG was determined using lectin ELISA and MALDI-TOF, respectively. ST6GAl1 expression in plasma cells was determined by RT-PCR and FACS. Inhuman part we measured the effects of estrogen treatment on autoantibody levels and IgG glycosylation in a cohort of postmenopausal RA patients over 2 years.

Results: Ovariectomy and loss of estrogens was associated with a lower sialylation of OVA-specific IgG. Conversely estrogen treatment significantly increased the sialylation level of newly formed OVA-specific and total IgG as well as enhanced the expression of ST6GAl1 enzyme in plasma cells suggesting a shift towards an anti-inflammatory pattern of IgG. These results were confirmed with patients treated protective estrogens and RA patients showing that hormone replacement therapy significantly increased antibody glycosylation, while in a control RA population not exposed to estrogens no such increase in sialylation of IgG was found. Estrogens however, did not influence the CCP autoantibody levels.

Conclusions: These findings indicate that estrogen regulates ST6GAl1 and increases the glycosylation of IgG. Lack of estrogen decreases IgG glycosylation and results in pro-inflammatory properties of IgG which may explain the increase prevalence of RA in postmenopausal women.

Stensballe 1, 1Department of Health Science and Technology, Aalborg University; 2Aalborg; 3Center for Rheumatology and Spine Diseases, Copenhagen University Hospital Herlev; 4Rigshospitalet, Institute for Inflammation Research, Rigshospitalet, Institute for Inflammation Research, Copenhagen; 5Department of Rheumatology, North Denmark Regional Hospital, Aalborg; 6Aarhus University Hospital, Aarhus; 7Aarhus University Hospital, Rigshospitalet, Institute for Inflammation Research, Rigshospitalet, Institute for Inflammation Research, Copenhagen, 8Department of Rheumatology, North Denmark Regional Hospital, Aalborg, Denmark

Background: Protein citrullination is fundamental to several essential processes in apoptosis and antimicrobial defense, however, also linked to multiple pathogenic endpoints. This post-translational modification (PTM), by conversion of arginine to citrulline residues, is mediated by peptidylarginine deiminase (PAD) enzymes found in specific cells and tissues. In polymorphonuclear cells (PMNs) these enzymes enable NETosis, a specialized form of programmed necrosis and the formation of NETs (neutrophil extracellular traps). Also, these enzymes are expressed in the synovium of patients with rheumatoid arthritis (RA) thereby triggering the production of autoantibodies against citrullinated proteins (ACPAs). Objectives: Our objective was to optimize methodology for characterization of this PTM and determine the citrulline in tissue and biofluids of human and mouse origin. The clinical relevance of autoantibodies against citrullinated proteins (OA), Spondyloarthritis (SpA) as well as presence of ACPAs and NETs

Methods: Synovial fluid (SF) and plasma was collected from patients diagnosed with RA, OA, SpA (n=120). Inflammation levels patients were characterized with plasma C-reactive protein (CRP), and circulating anti-CCP levels as well as 10 most relevant proinflammatory cytokines. Intestinal tissue (colon mucosa) from RA patients (n=10) and joint lysate from collagen-induced arthritis mouse model (n=24). All samples were analyzed by citrulline specific sample preparation and high-end mass spectrometric analysis. Follow-up studies were performed by multiple techniques including confocal microscopy and cell-free DNA measurement.

Rheumatoid arthritis (RA) is a chronic autoimmune disease established in vitro in this complex microenvironment has yet to be characterised. Therefore, we investigated the functional relationship linking fibroblasts and T lymphocytes.

Objectives: Our deep proteome based analysis of tissue and biofluids have enabled an extended catalogue of citrullinated proteins and sites relevant to RA patients. Human CD4 T cells were stained with a proliferation-tracking dye after 17a and RANKL after 5 days. Lastly, co-culture of T cells and synovial fibroblasts resulted in proliferation of CD4 T cells (P<0.05), and decreased IgM+CD21-/low memory B cells and Tfh percentage associated with an increase in Tregs frequency (P=0.03), and positively correlated with regulatory T cells (Tregs) (P=0.03), and negatively correlated with B lymphocyte stimulator receptor 3 and programmed death-ligand 1 (35.7% ± 6.1% versus 14.9% ± 3.8%, and 12% ± 1.3% versus 8% ± 0.9%, respectively). B lymphocyte stimulator receptor 3 and programmed death-ligand 1 (35.7% ± 6.1% versus 14.9% ± 3.8%, and 12% ± 1.3% versus 8% ± 0.9%, respectively). B lymphocyte stimulator receptor 3 and programmed death-ligand 1 (35.7% ± 6.1% versus 14.9% ± 3.8%, and 12% ± 1.3% versus 8% ± 0.9%, respectively).

Methods: 27 HCV-CV patients treated with DAA therapy, 12 healthy donors (HD) and 12 HCV were included. We investigated the effects of DAA-based therapy on cellular and cytokine abnormalities in HCV-CV patients by flowcytometry, cytokine/Immunomarker multiplex and ex vivo gene expression.

Results: Compared with HD and HCV, pre-DAA abnormalities in HCV-CV patients.

Conclusions: Our results highlight genes that may drive the pathogenic activity of B cells in RA and suggest shared methylation patterns with SLE.

SAT0022 | EPIGENOME-WIDE ASSOCIATION STUDY OF RHEUMATOID ARTHRITIS IDENTIFIES DIFFERENTIALLY METHYLATED LOCI IN B CELLS

A. Julia1, D. Absher2, M. Lopez-Lasanta1, N. Palau1, A. Pluma1, L. Waite Jones3, J.R. Glossope1, W.E. Farrell1, R.M. Myers1, S. Marsal4, 1Grup de Recerca de Reumatologia, Vall Hebron Research Institute, Barcelona, Spain; 2Absher Lab, HudsonAlpha Institute for Biotechnology, Huntsville, United States; 3Kelee University, Institute for Science and Technology in Medicine, Staffordshire, United Kingdom; 4Grup de Recerca de Reumatologia, Vall Hebron Research Institute, Alabama, Spain

Background: Epigenetic regulation of immune cell types could be critical for the development and maintenance of autoimmune diseases like Rheumatoid Arthritis (RA). B cells are highly relevant in RA, since patients express autoantibodies and depleting this cell type is a successful therapeutic approach. Epigenetic variation, such as DNA methylation, may mediate the pathogenic activity of B cells.

Methods: We performed a genome-wide association study (EWSA) for RA with three different replication cohorts, to identify disease-specific alterations in DNA methylation in B cells.

Results: Genomic DNA from B lymphocytes was assayed on the Illumina HumanMethylation450 BeadChip, assaying ~450,000 different CpG sites. Differential methylated positions (DMPs) were identified in a discovery cohort using a single-point analysis using logistic regression, as well as a pathway-level analysis using a newly developed permutation-based method. A discovery cohort of 50 RA patients and 75 healthy controls from Spain was used to identify the most differentially methylated regions after multiple test correction. Using an independent sample of 15 patients and 15 controls from the same population we performed a replication analysis of the most significant CpG sites and pathways.

Conclusions: Our results highlight genes that may drive the pathogenic activity of B cells in RA and suggest shared methylation patterns with SLE.

SAT0021 | HUMAN CD4 T CELLS AND SYNOVIAL FIBROBLASTS COOPERATE TO PROMOTE INFLAMMATION IN THE RA SYNOVIAL JOINT

A. Petracca1, G. Jameson1, T. McGarry2, D.J. Veale3, U. Fearon2,3, J.M. Fletcher1,2,1School of Biochemistry and Immunology; 2School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin; 3Department of Rheumatology, St. Vincent’s University Hospital, Dublin, Ireland

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterised by synovial tissue proliferation and degradation of articular cartilage. Activated synovial fibroblasts proliferate and express matrix-degrading proteases, adhesion molecules and proinflammatory cytokines, which contribute to cartilage and joint destruction. Moreover, synovial cell activation correlates with infiltration of inflammatory lymphocytes and monocytes which in turn contribute to synovioctye activation, thus further exacerbating inflammation.

Objectives: The functional relationship linking fibroblasts and T lymphocytes in this complex microenvironment has yet to be characterised. Therefore, we established an in vitro model to examine the outcomes of co-cultured activated human CD4 T cells with RA synovial fibroblasts.

Methods: Co-culture assays were carried out using immortalised K4M RA synovial fibroblasts or synovial fibroblast cells derived from arthroscopy biopsies of RA patients. Human CD4 T cells were stained with a proliferation-tracking dye and co-cultured with pre-seeded synovial fibroblasts for 5 days. The resulting cell cultures and supernatants were examined for proliferation, cytokine production, secretion of matrix metalloproteinases and expression of adhesion molecules.

Results: We found that CD4 T cells and K4M RA cells reciprocally induced an increased expression of adhesion molecules ICAM and VCAM. Furthermore, co-culture of CD4 T cells and synovial fibroblasts resulted in proliferation of CD4 T cells expressing increased levels of the proinflammatory cytokines INFγ and IL-17a and RANKL after 5 days. Lastly, co-culture of T cells and synovial fibroblasts resulted in secretion of IL-6, IL-8, INFγ and IL-17a and matrix metalloproteinases MMP-1 and MMP-3.

Conclusions: These results indicate that CD4 T cells work mutually with synovioctyes to create an inflammatory microenvironment likely to promote joint destruction. Future studies will characterise the role of glucose metabolism in these cells and investigate if metabolism is intrinsically coupled to effector functions in both cell types.

SAT0023 | DIRECT-ACTING ANTIVRAL-BASED THERAPY RESTORES IMMUNE TOLERANCE IN HEPATITIS C-INDUCED CRYOGLUBULINEMIA VASCULITIS

C. Comarrond1, M. Garrido2, A-C. Desbois5, M. Costopoulos5, M. Le Garr-Tavernier2, S.N. Si Ahmed4, L. Alric5, H. Fontaine6, B. Beller1, M. Maciejewski2, M. Rosenzweig2, B. Klatzmann7, L. Musset8, T. Poynard9, P. Cacoub10, D. Saadoun10, I. Internal Medicine and Clinical Immunology; 2INSERM, UMR s 959, FRE3632, Hôpital Pitié-Salpêtrière, 3Biological Hematology, Groupe Hospitalier Pitié-Salpêtrière, Paris; 4Hepatology, Hôpital d’Orléans, Orléans; 5Internal Medicine, Centre hospitalier universitaire Purpan, Toulouse; 6Hepatology, CHU Cochin; 7INSERM, UMR s 959, FRE3632; 8Immunology, UFR d’Immunoarchématose et d’autoimmunité, 9Hepatology, 10Internal Medicine and Clinical Immunology, CHU Pitié-Salpêtrière, Paris, France

Objectives: Interferon-free direct-acting antiviral (DAA)-based therapy has proven to be very effective in patients with hepatitis C virus-cryoglobulinemia vasculitis (HCV-CV). However, their mechanisms of action and their effects on cellular immunity remain poorly defined.

Methods: 27 HCV-CV patients treated with DAA therapy, 12 healthy donors (HD) and 12 HCV were included. We investigated the effects of DAA-based therapy on cellular and cytokine abnormalities in HCV-CV patients by flowcytometry, cytokine/Immunomarker multiplex and ex vivo gene expression.

Results: Compared with HD and HCV, pre-DAA abnormalities in HCV-CV patients included a decreased percentage of CD4+CD25+FoxP3+ regulatory T cells (P<0.01) with increases in IgM+CD21+ (P<0.05), CD4+INFγ (P<0.01), CD4+IL17A (P<0.001) and CD4+CXCR5+IL12+ follicular helper T cells (Tfh) (P<0.01), IgM+CD21low memory B cells were negatively correlated with regulatory T cells (Tregs) (P>0.03), and positively correlated with Tfh (P<0.03) and serum cryoglobulin levels (P<0.01). DAA-based therapy was associated with an increase in Treg frequency (1.5% ± 0.18% versus 2% ± 0.18%, and 12% ± 1.3% versus 8% ± 0.9%, respectively). B lymphocyte stimulator receptor 3 and programmed death-ligand 1 staining expression on B cells increased in HCV-CV after DAA-based therapy (MFI 37±2.4 versus 47±2.6, P<0.01; and 29±7.3 versus 48±9.3, P<0.05 respectively).

Conclusions: Our results indicate that DAA-based therapy effectively normalizes many of the disturbances in peripheral B and T lymphocyte homeostasis of HCV-CV patients.

SAT0024 | ALTERATIONS OF PERIPHERAL BLOOD B-CELL SUBSETS IN EARLY RHEUMATOID ARTHRITIS

Background: Alterations of B-cell subgroup have been described in the...
Peripheral blood of rheumatoid arthritis (RA) patients (pts), but differences between B-cell subsets distributions in early and later onset RA (LORA) are still unclear [1,2].

Objectives: To examine B-cell subsets in peripheral blood of healthy donors, early disease duration (<6 months) RA (ERA) and LORA pts by flow cytometry, and to analyze differences between B-cell subsets and RA activity.

Methods: 24 active ERA pts (20F/4M); median age 54 years (range) (38–64); disease duration 5 months (4–6); DAS28 score 5.2 (4.7–5.9); RF+75%, ACCP+87.5% and 20 LORA pts (16F/4M); median age 58 years (range) (44–62); disease duration 12 years (4.5–17.5); DAS28 score 5.3 (4.6–6.2); both RF+ and ACCP+ 80%, were assessed for B-cell subpopulations and laboratory data. In ERA, CRP, LORA pts were treated with DMARDs (anti-TNF-α, Methotrexate), glucocorticoids, and NSAIDS; ERA pts received NSAIDS only. CD19+B cells, memory B cells (CD19+IgD+CD27+), double-negative (CD19+IgD+CD27−), transitional (CD19+IgD+CD10+CD38++CD27−) B cells, and plasmablasts (CD19+CD38+++IgD−CD27−CD20−) were analyzed using multicolor flow cytometry.

Results: The median percentages (range) of non-switched memory B cells (CD19+IgD+CD27+) were lower in ERA and LORA RA cohorts compared to donors: 3.0% (1.6–5.5) and 6.2% (2.4–10.2) vs 7.4% (3.7–11.1), respectively; p<0.05 for both cases. In LORA pts, the median percentages (range) and absolute numbers of switched memory B cells (CD19+IgD+CD27+) were higher compared to ERA pts (CD19+IgD+CD27+), naïve (CD19+IgD–CD27−), double-negative (CD19+IgD+CD27−), transitional (CD19+IgD+CD10+CD38++CD27−) B cells, and plasmablasts (CD19+CD38+++IgD−CD27−CD20−) analyzed were using multicolor flow cytometry.

Conclusions: In ERA pts, immunophenotyping showed increased frequencies of naïve B cells and decreased frequencies and absolute numbers of switched memory B cells compared to LORA cohort.

SAT0029 | B CELL DEPLETION AFFECTS CD8 T CELLS IN ANCA-ASSOCIATED VASCULITIS

A. Naka1,2,3, M. Bucchia2, M. Neele2, M. Rimbert2,4, C. Agard1, M. Hourmant5,

Tilly, M. Yap, F. Perrin1, J. Graveleau1, P. Godmer7, S. Brouard2, C. Bresollette1, F. Fakhouri1,2, M. Hamidou1,2, N. Degauque1,2, Internal Medicine, Nantes University Hospital; 2 U1064, INSERM; 3Pediatrics, *Immunology; *Neurology, Nantes University Hospital; 4 INSERM, Nantes; 5Internal Medicine, CH Bretagne Atlantique, Vannes; 6Virology, Nantes University Hospital, Nantes, France

Background: In anti-neutrophil cytoplasmic antibodies associated vasculitis (AAV), several clues suggest that the efficacy of B cell depletion therapy lies beyond the suppression of ANCA-producing cells and may involve the suppression of B-T cell crosstalk. However little if any data are available regarding the impact of rituximab on CD4, regulatory T and CD8 T cells in this setting.

Objectives: To compare the effects of conventional immunosuppressants (CIS) and rituximab (RTX) on 3 T cell compartments in AAV. To assess the impact of patients B cells and that of B cell depletion on CD8 T cell cytokine production.

Methods: Thorough cross-sectional immunophenotypic analysis of CD4, regulatory T and CD8 cells of 53 patients with AAV, using polychromatic flow cytometry. A marker of endogenous immunosuppressive cytokine/chemokine production of in vitro stimulated CD8 T cells. Active untreated AAV patients’ B cells and/or CD8 T cells were cocultured for 72h with Staphylococcal Enterotoxin (Autoologus and cross-population experiments), and CD8 T cells cytokine production was then assessed by flow cytometry.

Results: Among CD4 T cells, we found that frequency of naive and memory subsets and the expression of CCR5, CCR4 and CD62L were not influenced by maintenance treatment type. Similarly, total Treg frequency and Treg subsets including CD62L+ Helios+ resting (CD45RA+) and memory (CD45RA-FoxP3) Tregs were comparable among RTX and CIS treated patients. By contrast, the type of maintenance treatment markedly influenced the CD8+ T cell compartment. Patient under B cell depletion therapy had less TEMRA (CD45RA+CCR7+) and more TEM cells than those receiving CIS, and resembled those in long term remission off therapy. CMV seropositivity did not explain the observed differences. Longitudinal data confirmed that B cell depletion significantly decreased TEMRA (CD45RA+CCR7-) CD8 T cell frequency (p<0.0001), whereas CIS had the opposite effect. Furthermore, we found that in vitro stimulated CD8 T cells from B cell depleted patients produced less pro-inflammatory cytokine/chemokine than those from patients treated with CIS. In coculture with B cells and SEB, patients CD8 cells coculture produced higher level of inflammatory cytokines than those from controls, but only when they were stimulated with patients’ B cells.

Conclusions: B cell depletion therapy has a significant impact on the CD8 T cell compartment in terms of phenotype and function. B cell can promote pro-inflammatory function of CD8 T cell in vitro. CD8 T cell are found in vasculitides lesions. These observations raise the question whether the disruption of B cell help to CD8 T cells could contribute to the dramatic efficacy of RTX. Further studies are needed to demonstrate the implication of patients’ CD8 T cell in tissue damage.

SAT0030 | BREACH OF AUTORESTRICTIVE B-CELL TOLERANCE BY POST-TRANSLATIONALLY MODIFIED FOREIGN PROTEINS

J. Dekker1, J. Dekker1, J. Merheu1, J. Stoep1, B. Liu2, A. Ioan-Facsinay1, P. van Veelen1, A. de Ru1, G. Janssen1, M. Heggen2, S. R apecki3, T. Huizinga4, L. Trouw4, R. Toes1, Rheumatology, LUMC, Leiden, Netherlands; 2Pfizer, Boston, United States; 3UCB, Slough, United Kingdom; 4LUMC, Leiden, Netherlands

Background: Autoimmunity in Rheumatoid arthritis (RA) patients is characterized by a reduced expression of anti-protein antibody proteins (AMPAs). Much less is known about the occurrence and aetiology of other AMPA responses in RA such as autoantibodies directed against post-translationally modified (PTM) proteins. The best-known AMPA in RA are anti-citrullinated protein antibodies (ACPA). Less is known about the occurrence and aetiology of other AMPA responses in RA such as autoantibodies directed against post-translationally modified (PTM) proteins. The best-known AMPA in RA are anti-citrullinated protein antibodies (ACPA).

DOI: 10.1136/annrheumdis-2017-eular.6894
leading to the formation of these autoantibodies. At present it is unknown how AMPa are generated and how autoreactive B-cell responses against PTM proteins are induced.

Objectives: To investigate how PTM proteins, more specifically carbamylated proteins, could contribute to a breach of B-cell tolerance.

Methods: Proteins towards five different carbamylated proteins was determined for 160 RA-patients and 40 healthy individuals. Anti-CarP antibody cross-reactivity was studied by inhibition experiments. Mass spectrometry was performed to identify carbamylated self-proteins in human rheumatic and osteoarthritic joint tissue. Mice were immunized with carbamylated- or non-modified foreign (Cova) and self-antigens (mouse Albumin). Serum of immunized mice and monoclonal antibodies were analyzed for antigen reactivity.

Results: We show that anti-CarP antibodies in RA are highly cross-reactive towards multiple carbamylated proteins, including modified self- as well as modified non-self proteins. Immunization with carbamylated foreign proteins (Ca-OVA) induced a strong anti-CarP response against both carbamylated foreign- and self-proteins. Similar to murine serum anti-CarP antibodies, murine monoclonal anti-CarP antibodies were highly specific and cross-reactive to multiple carbamylated (auto)antigens. Although citrulline greatly resembles homocitrullines residues in structure, murine anti-CarP antibodies differ in antigen recognition profile from ACa as they are able to discriminate between citrullinated and homocitrullinated forms of the same protein. Interestingly, we were able to identify carbamylated-albumin, in RA synovial tissue, indicating that albumin is present in carbamylated forms in the inflamed joint.

Conclusions: Self-reactive AMPA-responses can be induced by exposure to foreign proteins containing PTM. Our findings show that autoreactive B-cell responses against PTM specific self proteins can be induced by exposure to PTM proteins and provide new insights on the breach of autoreactive B-cell tolerance by foreign proteins.

SAT0031 DETECTION AND ISOLATION OF ANTIGEN-SPECIFIC B CELLS IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Nilsson1, M. Bergquist1, K. Öhnheim1, I.-L. Mårtensson1, J. Viljanen2, E. Lönnblom3, B. Xu4, O. Sarela5, J. Kihlberg2, R. Holmdahl1, L. Gertzoon1

1Rheumatology and Inflammation Research, Gothenburg University, Göteborg; 2Department of Chemistry, BMC, Uppsala University, Uppsala; 3Medical Inflammation Research, Dept of medical Biochemistry and biophysics, Karolinska Institute, Stockholm, Sweden

Background: The majority of autoimmune diseases, e.g. rheumatoid arthritis (RA), are characterized by autoantibodies that are produced by B cells. We have identified several novel post-translationally modified epitopes in collagen type II (CII), a major cartilage constituent that are autoreactive. In mouse models, autoantibodies that bind to these epitopes can either induce or protect against inflammatory arthritis. However, very little is known about the frequencies or phenotype the B cells that produce these autoantibodies in humans.

Objectives: The aim of this project is to study the B cells that produce autoantibodies reactive to these epitopes in patients with RA.

Methods: Clinical data and peripheral blood were collected from patients with RA (n=100). Titres of CII-reactive serum-autoantibodies were determined by Luminex. Titres of CII-reactive serum-autoantibodies were determined by Luminex. The different subsets of B cells that expressed a CII-reactive B cell receptor (n=100). Titres of CII-reactive serum-autoantibodies were determined by Luminex. Serum of immunized mice and monoclonal antibodies were analyzed for antigen reactivity.

Results: We show that anti-CarP antibodies in RA are highly cross-reactive towards multiple carbamylated proteins, including modified self- as well as modified non-self proteins. Immunization with carbamylated foreign proteins (Ca-OVA) induced a strong anti-CarP response against both carbamylated foreign- and self-proteins. Similar to murine serum anti-CarP antibodies, murine monoclonal anti-CarP antibodies were highly specific and cross-reactive to multiple carbamylated (auto)antigens. Although citrulline greatly resembles homocitrullines residues in structure, murine anti-CarP antibodies differ in antigen recognition profile from ACa as they are able to discriminate between citrullinated and homocitrullinated forms of the same protein. Interestingly, we were able to identify carbamylated-albumin, in RA synovial tissue, indicating that albumin is present in carbamylated forms in the inflamed joint.

Conclusions: Self-reactive AMPA-responses can be induced by exposure to foreign proteins containing PTM. Our findings show that autoreactive B-cell responses against PTM specific self proteins can be induced by exposure to PTM proteins and provide new insights on the breach of autoreactive B-cell tolerance by foreign proteins.

SAT0032 EX Vivo ANALYSIS OF AUTOANTIGEN-SPECIFIC T CELL RESPONSES USING A MULTI HLA-CLASS II TETRAMER APPROACH

C. Gerstner1, H. Uchtenhagen1, A. Dubnovitsky2, K. Wkow2, E.A. James3, V. Malmström1, 1Rheumatology Unit, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden; 2Translational Research program, BRI at Virginia Mason, Seattle, United States; 3Department of Clinical Neurosciences, Science for Life Laboratory, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden; 3Tetramer Core, BRI at Virginia Mason, Seattle, United States

Background: HLA class II tetramers allow the direct ex vivo enumeration and phenotypic characterization of antigen-specific T cells and have proven a useful tool in different settings, e.g. allergy and vaccination.

Objectives: Based on flow cytometry we developed a multi HLA-class II tetramer approach that renders it possible to look at numerous specificities simultaneously and is sufficiently sensitive at the same time as auto-reactive T cells are likely to be rare. We focused on validated citrullinated T cell epitopes previously studied in RA, namely a-enolase, fibrinogen and CILP.

To test the robustness and sensitivity of our multi-tetramer assay, we performed repeated experiments on PBMCs of HLA-DRB1*04:01-positive healthy controls and HLA-DRB1*04:01-positive RA patients.

Results: We first, we examined the sensitivity of the panel by assessing PBMC from healthy donors and we could detect low frequencies of auto-reactive T cells in these samples (1–10 per million CD4), mostly displaying a naïve phenotype, which was in sharp contrast to influenza-specific T cells in the same donors which were 10–20 fold higher in numbers. Moreover, we detected the robustness of the panel by running technical repeats of all healthy donor samples, which yielded similar frequencies. Thereafter, we focused on RA patient PBMC obtained from repeated blood draws (2–4 weeks apart). Also in these samples, frequencies ranged between 10–20 tetramer-positive cells per million CD4 T cells, i.e. similar as in healthy controls. Moreover, not all T cell specificities were present in all patients. Still, we found the frequencies to be stable in the repeated blood draws in approximately half of the individuals, implicating that frequencies close to 1 cell per million CD4+ T cells is borderline of what we can stably detect. Importantly, the patient samples utilized were not taken from time points of active disease, where we hypothesize frequencies to be elevated. This may be the case also in synovial fluid and as a proof of principle, we assessed synovial fluid samples of HLA-DRB1*04:01+ RA patients and were able to detect auto-reactive T cells at frequencies comparable to the ones found in peripheral blood.

Conclusions: In conclusion, we developed a sensitive tetramer panel allowing the simultaneous enumeration and phenotypic characterization of antigen-specific T cells in ex vivo samples from RA patients that can be used for monitoring and in-depth studying of these cells during the course of disease and treatment in individual patients.

SAT0033 SMOOKING CONTRIBUTES TO EXHAUSTED STATE OF CD4+ T CELLS IN RHEUMATOID ARTHRITIS

C. Wasen1, M. Turkila1, M. Erlandsson1, K.M. Andersson1, M. Brisslert1, S. Töyrä Silverswärd1, M.I. Bokarewa1, Department of Rheumatology and Inflammation Research, University of Gothenburg, Gothenburg, Sweden

Background: Rheumatoid arthritis (RA) has recently been linked to an exhausted state of CD4+ T cells in peripheral blood of patients [1]. Exhaustion of CD4+ T cells limits their proliferation and increases cell death. In CD8+ T cells smoking counteracts exhaustion, which may lead to increased cytotoxic activity exemplified by targeting of cells with high expression of the anti-apoptotic protein survivin [2]. Exhaustion of CD4+ T cells coincides with expression of interferon (IFN) response genes [3], referred to as the IFN signature. The development of the IFN signature has been linked to smoking status [4].

Objectives: We investigated how smoking affect the CD4+ T cell population in peripheral blood of RA patients with focus on the exhaustion marker programmed cell death-1 (PD-1).

Methods: Blood samples were collected from RA patients and healthy women with different smoking status and analysed for PD-1 and survivin expression using flow cytometry and qPCR. Sorted Th17 cells from peripheral blood were analysed for expression of 18 genes upregulated during exhaustion [3], herein referred to as the exhaustion set, and serum levels of survivin were assessed by ELISA. Peripheral blood CD4+ cells were analysed for their expression of seven IFN response genes [4]. The role of survivin in the formation of exhausted CD4+ T cells was studied in collagen-induced arthritis (CIA), where mice were treated with nicotine or vaccinated with survivin peptides.

Results: High frequency of exhausted PD-1+CD4+ cells was found in smoking RA and the numbers of PD-1+CD4+ cells correlated to the IFN signature expression by cytotoxic CD8+CD107+ cells (r=−0.62, p=0.01). Additionally, the frequency of PD-1+CD4+ cells increased with reduction of the IFN signature population (r=0.71, p=0.002). The IFN signature was found exclusively among smoking RA patients. The patients with the IFN signature all had CD4+ cells with low survivin
analysed. Th17 cells from RA patients with high serum survivin were enriched in genes of the exhaustion set. CD4+ cells with high survivin expression were negative for PD-1, while PD-1+ cells had low expression of survivin. In CIA mice the survivinPD−1− CD4+ cells were reduced by nicotine treatment (p=0.03) or survivin vaccination (p<0.009).

Conclusions: Elevated survivin expression associates with exhaustion of CD4+ T cells in RA by increasing the frequency of PD-1+CD4+ cells and supporting the IFN signature. Balancing T cell exhaustion and preventing the IFN signature are potential future treatment strategies for RA.

SAT0034 ANALYSIS OF THE T-CELL SUBSET COMPOSITION IN ANKYLOSING SPONDYLITIS PATIENTS WITH LONG-STANDING ANTI-TNF THERAPY

S. Dulic1, Z. Vásárhelyi2, A. Bajnok3, B. Szalay4, G. Toldi2, L. Kovács1, A. Bálog1. 1University of Szeged Department of Rheumatology, Szeged; 2First Department of Obstetrics and Gynecology; 3First Department of Pediatrics; 4Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary.

Background: Ankylosing spondylitis (AS) is a chronic, progressive, immune-mediated inflammatory disease, driven primarily by Th1 and Th17 cells. Anti-TNF therapies are successfully used in AS to achieve and maintain remission. However, their influence on the composition of the T-cell repertoire is not clear, and, in particular, the few published studies involve mostly patients with anti-TNF treatment of short duration.

Objectives: We aimed to characterize the changes in several T cell subsets after long-term anti-TNF treatment in AS patients.

Methods: Twenty-two AS patients on long-term anti-TNF therapy were evaluated (15 anti-TNF-responders and 7 non-responders). A wide range of cell subtypes were analysed with flow cytometry and compared with therapy-naive and short-term data.

Results: Key findings include decreased proportions of naive CD4 and CD8 cells, increased frequencies of Th1 and Th17 cells and higher Th1/Th2 and Th17/Treg ratios in the long-term anti-TNF-treated patients (responders, non-responders and total), which was found to be significant not only when compared with healthy controls, but also with therapy-naive and short-term anti-TNF-treated AS patients. We have found several alterations within the various activated T-cell subsets – increase in CD4HLADR cells in responders, in CD8HLADR cells in the whole AS group and in responders, and in CD4CD25 cells in responders, and decrease in CD4CD69 cell percentages in long-term treated patients – becoming evident only after long-term anti-TNF therapy.

Conclusions: This study provides a comprehensive assessment of the impact of anti-TNF therapy on the T cell repertoire in AS, and indicate that these therapies induce profound changes within T-cells. Changes in T cell phenotype seem to develop progressively during therapy, even in inactive disease, and reflect an ongoing effector T-cell differentiation and activation, and a normalization of Tregs development.

SAT0035 INHIBITION OF PROTEIN KINASE C THETA BY THE SELECTIVE INHIBITOR CC-90005 INDUCES T CELL ANERGY

Background: Protein Kinase C theta (PKC-θ), a member of the PKC family of serine/threonine kinases, is essential in T cell receptor (TCR) signaling and T cell activation [1]. Inhibition of PKC-θ activity may provide new therapeutic options for autoimmune diseases with a T effector cell dependent pathology. CC-90005 is a selective inhibitor of PKC-θ and may be a co-expression profile specific to IL-17 expressing T cells. This work was funded in part by the King’s Health Partners R&D Challenge Fund (R140080) and in part by research support from Novartis.

Disclosure of Interest: K. Steel: None declared. E. Chan: None declared. B. Kirkham: MSD, Pfizer, Roche. L. Taams Grant/research support from: Novartis, UCB, Abbvie, Bristol Myer Squibb, Celgene, Janssen, MSD, Pfizer, Roche. L. Taams Grant/research support from: Novartis and UCB.

Results: CC-90005 anergy induction was shown to require only short initial exposures of as little as 2 h and to maintain anergy for as long as 48–96 h post CC-90005 washout. However, T cells pre-treated with the inhibitor in the absence of concomitant TCR stimulation were able to respond to stimulus after as little as 1 h washout, indicating a rapid recovery of PKC-θ activity and T-cell function. CC-90005 upregulated an anergy-related E3 ubiquitin ligase, G质, was a possible downstream mediator of CC-90005 effect on T cell anergy.

Conclusions: CC-90005, a specific inhibitor of PKC-θ, significantly inhibits TCR-mediated T cell activation, proliferation, and cytokine production. Moreover, inhibition of these T-cell functions persists after drug withdrawal and restimulation of T-cells, but only if the primary T cell activation event occurs in the presence of CC-90005. Thus, CC-90005 induces a functional unresponsiveness anergic state in T cells if present during TCR activation, which may have long-term therapeutic benefit in the treatment of T-cell mediated autoimmune and allergic inflammatory conditions.

SAT0036 IL-17+CD8+ T CELLS ENRICHED IN THE SYNOVIAL FLUID OF PSA/SPA PATIENTS EXHIBIT A PRO-INFLAMMATORY CYTOKINE PHENOTYPE

K.J.A. Steel1, E. Chan2, B.W. Kirkham3, L.S. Taams1. 1Centre for Inflammation Biology and Cancer Immunology (CIBIC), Division of Immunology, Infection & Inflammatory Disease (DIIID), King’s College London; 2Department of Rheumatology, Guy’s & St Thomas’ NHS Trust, London, United Kingdom.

Background: Seronegative spondyloarthropathies (SpA) share common clinical and immunological characteristics, including a common association with MHC class I, suggesting a role for CD68+ T cells. In contrast, rheumatoid arthritis (RA) is associated with MHC class II. We previously showed that IL-17+CD8+ T cells are increased in the synovial fluid (SF) of patients with psoriatic arthritis (PsA) but not RA, compared to peripheral blood (PB). This study extends this analysis to other SpA types, and phenotypes the SF IL-17+CD8+ T cells to further elucidate their potential pathogenic role.

Methods: Paired PB and SF were collected from patients with RA, PsA and other SpA types (ankylosing spondylitis (AS), reactive arthritis (ReA), enteropathic arthritis (EA) and peripheral SpA (pSpA)) from Guy’s Hospital Rheumatology clinic with informed consent. PB from healthy controls (HC) was collected at King’s College London. PBMC and SFMC were isolated and stimulated ex vivo with PMA/ionomycin before analysis of surface marker and cytokine expression by flow cytometry.

Results: The percentage of IL-17+CD8+ T (Tc17) cells was increased in the SF of PsA (median 0.9%, p=0.0012, n=13) as well as other SpA patients (0.34%, p=0.0009, n=14), but not RA patients (0.07%, p=0.3, n=7) compared to matched PB (median 0%, n=10, no significant differences between disease and control PB). The percentage of SF IL-17+CD8+ T (Tc17) cells was increased in patients with SpA (2.14%, p=0.004, n=14), RA (2.31%, p=0.016, n=7) and to a lesser extent PsA (0.97%, p=0.057, n=13), compared to PB (median 0.61%, no significant differences between disease and control PB).

Phenotypically, most SF IL-17+CD8+ T cells expressed CD38 (89%, n=7) and CD161 (75%, n=8), known markers of IL-17+CD8+ T cells. A high percentage also expressed CD103 (69%, n=9), which was not observed in the synovial IL-17+CD8+ T cells (2%, n=10). A high frequency of IL-17+CD8+ T cells co-expressed a range of pro-inflammatory cytokines including IFN-γ (72%, n=12), GM-CSF (58%, n=7), TNF-α (48%, n=12) and to a lesser extent IL-21 (20%, n=6) and IL-22 (5%, n=6). IL-10 was usually co-expressed at very low levels (1%, n=7), although 2 samples showed co-expression of IL-10 (33%, n=2). CRCR6, CD161, GM-CSF and IL-21 were not significantly co-expressed by either IL-17A negative CD8+ or IFNγ+CD8+ (Tc1) T cells from the SF, indicating this may be a co-expression profile specific to IL-17 expressing T cells.

Conclusions: These findings confirm the presence of an IL-17A+CD8+ T cell subset in the SF of PsA patients and extend this to other SpA types. The expression of the integrin CD103 by these cells indicates they may represent a tissue resident memory (Trm) population in the synovial joint. In addition to IL-17A, the co-expression of several pro-inflammatory cytokines combined with low expression of IL-10, suggests a pro-inflammatory role for these cells.

SAT0037 | THE EFFECTS OF B CELL DIRECTED THERAPY ON DISEASE RELEVANT BIOMARKERS IN SUBJECTS AT RISK OF RHEUMATOID ARTHRITIS

D. Gerlag1, M. Safy2, K. Majerl2, T. Ramwadhodhe2, S. Tas2, N. de Vries2, M. Starmans-Kool1, A. van Tubergen1, M. Janssen1, S. Eyre6, L. Klareskog7, K. Zwinderman1, P.-P. Tak1, 2Amsterdam Rheumatology and Immunology Center, Amsterdam, Amsterdam, The Netherlands; 2Zuyderland Medical Center, Heerlen, Maastricht Medical Center, Maastricht; 3Fijnstek Hospital, Arnhem, Netherlands; 4Arthritis Research UK Centre for Genetics and Genomics, Manchester, United Kingdom; 5Karolinska Institute, Stockholm, Sweden

Background: Exploration of the mechanism underlying the delay of development of clinical signs of seropositive rheumatoid arthritis (RA) observed after B cell directed therapy in individuals at risk of developing autoantibody positive RA may offer insights into the mechanism of disease and may assist the development of preventive strategies.

Objectives: To explore the effects of a single infusion of rituximab (anti-CD20 antibody) on the observed delay of the onset of clinically manifest arthritis in individuals at risk of developing autoimmune positive RA.

Methods: In a study of 81 subjects positive for both anti-citrullinated protein antibody (ACPA) and rheumatoid factor (RF) with arthralgia who never had clinically manifest arthritis and never used disease-modifying antirheumatic drugs, a 55% reduction of the risk of developing arthritis was observed 12 months after receiving a single iv infusion of 1000 mg rituximab when compared to placebo. In this group there was a delay in the development of arthritis of 12.0 months (12 months placebo vs 24 rituximab group) at the 25% quartile (75% free of arthritis of the arthritis-free survival). Explorative analysis of disease-related biomarkers was performed in subgroups to better understand the mechanisms of the observed delay of clinical disease onset.

Results: Baseline levels of ESR (mm/h; HR 1.03; p=0.016), the total number of B cells in peripheral blood (HR 1.49; p=0.047), the presence of anti-CD45-RO CD45RA+ CD8 memory lymphocytes (HR 1.38; p=0.048), and the percentage of regulatory B cells (HR 1.19; p=0.001) were related to arthritis development over time. Importantly, genetic analysis of 100 RA associated SNPs showed that the top SNP associated with arthritis development in the rituximab-treated group (OR=1.33, confidence interval 1.03-1.71) that is a common polymorphism not associated with arthritis in the placebo group. Explorative analysis showed trends for multiple biomarkers in the B cell compartment that appeared predictive of the development of arthritis.

Conclusions: A single infusion of 1000 mg rituximab significantly affects B cell memory and subsets of memory and regulatory B cells as well as a reduction of disease-related antibodies and immunoglobulin levels in individuals at risk of RA. The changes coincide with a decrease in risk and a delay in development of arthritis in this population. PLC2L2 gene polymorphism was associated with arthritis development in rituximab-treated individuals.

SAT0039 | LARGE TENDER JOINTS HAVE THE GREATEST IMPACT ON LONGITUDINAL TRAJECTORIES OF FUNCTION IN EARLY RHEUMATOID ARTHRITIS

S.H.L. Lim1, O. Schier2, S. Bartlett3, G. Boire4, B. Harauzi5, E. Keystone2, D. Tim1, C. Thorne6, J. Pope7, V. Bykerk8, C. Hitchon1 on behalf of Canadian Early Arthritis Cohort Canada (CATCH) Investigators. 1University of Manitoba, Winnipeg; 2University of Toronto, Toronto; 3McGill University, Montreal; 4Université de Sherbrooke, Sherbrooke; 5Institut de Recherche Robertaud, Montreal, Montreal; 6Southlake Regional Health Center, Newmarket; 7Western University, London, Canada; 8Hospital for Special Surgery, New York, United States

Background: Physical function remains suboptimal in patients with early rheumatoid arthritis (ERA) despite adequate disease control. Hence, factors impacting function need further evaluation. Large weight bearing joints are more likely to influence overall function than small non-weight bearing joints although the magnitude of impact may be task dependent. By weighting large joints more than small joints, the Lansbury Articular Index (LAI) may have stronger associations with function than standard joint counts that give equal weight to small and large joints.

Objectives: 1) To compare the correlations of weighted and non-weighted arthritis joint measures with physical function over time; and 2) to determine the impact of large compared to small joint involvement on the trajectory of HAQ in ERA.

Methods: ERA participants had <1 year symptom duration at enrolment in a 6 joint early Arthritis Cohort and were told nine large joints (time-varying) on the HAQ trajectory were estimated with a series of generalized estimating equations (GEE). GEE models were adjusted for baseline age, sex and education.

Results: ERA subjects (n=2125, 73% female; baseline mean (SD) age 53 (15) years, DAS28 5.1 (1.4)), were followed for median (IQR) 24 (10,48) months. At their last visit 44% were in remission (DAS28 < 2.6). HAQ over time was highly correlated with the following: DAS28 (r=0.83), LT28 (r=0.70), TJC28 (r=0.89), SJC28 (r=0.90) and moderately with the LS28 (r=0.59) and SJC28 (r=0.61) trajectories. Each increase in joint involvement was associated with increase in HAQ: large tender joint (0.110 (95% CI 0.102–0.119)), large swollen joint (0.109 (0.099–0.120)), tender hand joint (0.036 (0.032–0.039)), swollen hand joint (0.035 (0.032–0.039)).

SAT0038 | SERUM B LYMPHOCYTE CHEMOATTRACTANT PROTEIN 13 (CXC13) AND MUSCULOSKELETAL ULTRASONOGRAPHIC FINDINGS IN EARLY RHEUMATOID ARTHRITIS

E. Baraka, S. Egila, G. Hamad, M. Khalil. Rheumatology, Rehabilitation and Physical medicine, Benha Faculty of Medicine, Benha University, Cairo, Egypt

Background: Patients in clinical remission may continue to have synovitis detected by the musculo skeletal ultrasonography (MSUS). Recently B-lymphocyte chemotactic protein (CXCL13) has reported to be upregulated and risen to be a possible new marker of disease inflammation in RA.

Objectives: to detect early synovitis by grey scale and power Doppler MSUS, measure serum levels of CXCL13 and to correlate these levels with both clinical and ultrasonographic disease activity in early RA patients

Methods: CXCL13 serum was assessed by the modified ELISA kit and were follwed for clinical and ultrasonographic disease activities measures (DAS28, tender joint count (TJC28), swollen joint count (SJC28), function (Health Assessment Questionnaire: HAQ) were captured at each visit. The LAI weighted 28 joint count (LT28) and swollen joint count (LS28) were calculated based on the standard 28 joint sites. Correlations of trajectories were calculated using joint modeling for each of the following: DAS28, TJC28,SJC28,LS28 LT28 with the HAQ (2 trajectories/model). Unadjusted effects of large joints (shoulders, elbows, hips, knees, ankles) and hand joints (time-varying) on the HAQ trajectory were estimated with a series of generalized linear mixed models (GEE). GEE models were adjusted for baseline age, sex and education.

Results: ERA subjects (n=2125, 73% female; baseline mean (SD) age 53 (15) years, DAS28 5.1 (1.4)), were followed for median (IQR) 24 (10,48) months. At their last visit 44% were in remission (DAS28 < 2.6). HAQ over time was highly correlated with the following: DAS28 (r=0.83), LT28 (r=0.70), TJC28 (r=0.89), and moderately with the LS28 (r=0.59) and SJC28 (r=0.61) trajectories. Each increase in joint involvement was associated with increase in HAQ: large tender joint (0.110 (95% CI 0.102–0.119)), large swollen joint (0.109 (0.099–0.120)), tender hand joint (0.036 (0.032–0.039)), swollen hand joint (0.035 (0.032–0.039)).
In multivariable modeling, after adjusting for age, sex, and education, large joints had greater effects (tender 0.074 (0.065–0.084), swollen 0.027 (0.014–0.04) on HAQ than hand joints (tender 0.013 (0.009–0.017), swollen 0.008 (0.003–0.013)).

Conclusions: Both Lansbury and standard joint count trajectories correlate similarly with HAQ in ERA. The weighting of large joints in LAI was insufficient to reflect the importance of joint inflammation. Furthermore, HAQ probably bespeaks HAQ questions emphasize large joint activities. The effects of large joint swelling may be under recognized due to difficulty in measuring hip, shoulder or elbow swelling. Overall, tender joints had a greater impact on swollen joints and large tender joints had the most impact on function.

SAT0040 ASSESSING 5-YEAR RADIOGRAPHIC PROGRESSION IN RHEUMATOID ARTHRITIS PATIENTS WITH MODERATE DISEASE: FINDINGS FROM A UK MULTI-CENTRE PROSPECTIVE OBSERVATIONAL STUDY

L. Carpenter1, S. Norton2, E. Nikiphorou3, K. Jayakumar4, D.F. McWilliams5, J. Dixey6, P. Kiely7, D.A. Walsh5, A. Young4 on behalf of ERAS and ERAN.

Objectives: To investigate the long-term progression of radiographic joint damage in these patients and moderate disease activity states can help reduce radiographic progression and consequently joint destruction, minimising the risk of disability in the long-term.

Results: Of 316 and 328 pts in the ADA and ABA groups, respectively, 38 and 45 pts had all specified baseline characteristics (Cohort 1) and 280 and 283 pts had an absence of at least 1 of the specified characteristics (Cohort 2). Overall, the baseline characteristics, including anti-cyclic citrullinated peptide titres, were well balanced between the groups, with the exception of weight. For Cohort 1, the adjusted mean change (95% CI) from baseline DAS28 (CRP) with ADA vs ABA was −2.18 (−2.61, −1.75) vs −1.56 (−2.01, −1.11) at Week 26, −2.58 (−2.99, −2.17) vs −1.68 (−2.10, −1.25) at Week 52 and −2.50 (−2.97, −2.03) vs −2.0 (−2.49, −1.50) at Week 104. Similar trends of increased efficacy with ABA vs ADA were observed for changes from baseline CDAI SDAI, HAQ-DI, pain and fatigue; no differences in radiographic progression were observed. For Cohort 2, no differences in clinical outcomes between ADA and ABA groups were observed. Given the differences in baseline weight between ADA and ABA groups in Cohort 1, sensitivity analyses that excluded pts >100 kg and adjusted for baseline weight were performed and demonstrated minimal effect of weight on treatment efficacy.

Conclusions: This post hoc analysis seems to indicate a trend of increased efficacy for abatacept in pts with seropositive, erosive early RA compared with the TNF inhibitor adalimumab. Given the small sample size, additional pre-specified randomized studies are needed to compare the benefit of biologic DMARDs with different MOAs in pts with early, rapidly progressing RA.

References:

This study provides support on the importance of tight treatment control with early and aggressive therapy according to T2T principles. Preventing sustained moderate disease activity states can help reduce radiographic progression and consequently joint destruction, minimising the risk of disability in the long-term.

SAT0041 EFFICACY OF ABATACEPT VERSUS ADALIMUMAB IN PATIENTS WITH SEROPOSITIVE, EROSIVE EARLY RA: ANALYSIS OF A RANDOMIZED CONTROLLED CLINICAL TRIAL (AMPLE)

Background: Patients (pts) who are anti-citrullinated protein antibody (ACPA) positive tend to develop more severe erosive disease than ACPA-negative pts.1 The presence of seropositivity and erosions have been noted in EULAR treatment guidelines as poor prognostic factors to identify pts with RA who require early and aggressive clinical intervention.2 Since the disease in pts with seropositive, erosive early RA is mostly driven by immunological features, response to RA therapy may vary based on therapeutic mechanism of action (MOA).

Objectives: To investigate the efficacy of abatacept (ABA) vs adalimumab (ADA) in pts with seropositive, erosive early RA.

Methods: AMPLE (NCT00929864) was a 2-year, Phase IIIb study in which biologic-naive pts with RA were randomized 1:1 to either SC ADA 125 mg weekly or SC ADA 40 mg biweekly, both with background MTX. This post hoc analysis of AMPLE compared clinical outcomes between treatment groups in a subgroup of pts with specified baseline criteria: disease duration >6 months, RF or ACPA seropositivity and -1 radiographic erosion. Disease activity and patient-reported outcomes were evaluated at Weeks 26, 52 and 104. Endpoints were compared between ABA and ADA groups using chi-square test for categorical variables, analysis of covariance model (ANCOVA) controlling for baseline covariates and DAS28 (CRP) stratification for continuous variables.

Results: Of 316 and 328 pts in the ADA and ABA groups, respectively, 38 and 45 pts had all specified baseline characteristics (Cohort 1) and 280 and 283 pts had an absence of at least 1 of the specified characteristics (Cohort 2). Overall, the baseline characteristics, including anti-cyclic citrullinated peptide titres, were well balanced between the groups, with the exception of weight. For Cohort 1, the adjusted mean change (95% CI) from baseline DAS28 (CRP) with ADA vs ABA was −2.18 (−2.61, −1.75) vs −1.56 (−2.01, −1.11) at Week 26, −2.58 (−2.99, −2.17) vs −1.68 (−2.10, −1.25) at Week 52 and −2.50 (−2.97, −2.03) vs −2.0 (−2.49, −1.50) at Week 104. Similar trends of increased efficacy with ABA vs ADA were observed for changes from baseline CDAI SDAI, HAQ-DI, pain and fatigue; no differences in radiographic progression were observed. For Cohort 2, no differences in clinical outcomes between ADA and ABA groups were observed. Given the differences in baseline weight between ADA and ABA groups in Cohort 1, sensitivity analyses that excluded pts >100 kg and adjusted for baseline weight were performed and demonstrated minimal effect of weight on treatment efficacy.

Conclusions: This post hoc analysis seems to indicate a trend of increased efficacy for abatacept in pts with seropositive, erosive early RA compared with the TNF inhibitor adalimumab. Given the small sample size, additional pre-specified randomized studies are needed to compare the benefit of biologic DMARDs with different MOAs in pts with early, rapidly progressing RA.

This study provides support on the importance of tight treatment control with early and aggressive therapy according to T2T principles. Preventing sustained moderate disease activity states can help reduce radiographic progression and consequently joint destruction, minimising the risk of disability in the long-term.

This study provides support on the importance of tight treatment control with early and aggressive therapy according to T2T principles. Preventing sustained moderate disease activity states can help reduce radiographic progression and consequently joint destruction, minimising the risk of disability in the long-term.

Conclusions: The present study shows that radiographic destruction over peripheral joints, which directly reflects cumulative inflammatory burden, is a strong independent risk factor for plaque development that is associated with CV events and mortality.

SAT0043 FACTORS AFFECTING THE NEED FOR ORTHOPAEDIC SURGERY IN PATIENTS WITH RHEUMATOID ARTHRITIS. RESULTS FROM 1010 PATIENTS DIAGNOSED WITH RA FROM 1972-2009

B.-T.S. Fjelong1,2, A.M. Fenstad3, O.N. Furnes3,4, T.W. Nystad1,3, 1Dept. of Rheumatology, Haukeland University Hospital; 2Dept. of Clinical Sciences, University of Bergen; 3The Norwegian Arthroplasty Register, Haukeland University Hospital; 4Department of Surgical Sciences, University of Bergen, Bergen, Norway

Background: Surgery still comprises a necessary part of treating RA patients, when medication fail to prevent joint destruction. Orthopaedic corrective procedures are considered a reliable and objective proxy for a destructed joint, and is an important outcome measure in RA.

Objectives: To investigate how patient characteristics, time of diagnosis and treatment affect the need for orthopaedic surgery in patients with rheumatoid arthritis (RA).

Methods: We reviewed the medical history of 1544 patients diagnosed with RA at Haukeland University Hospital in Bergen, Norway from 1972 to 2009, of which 1010 (mean age 57, 69% women) were included in the study. Relevant orthopaedic procedures were obtained from the Norwegian Arthroplasty Register and the hospital’s administrative patient records. 693 procedures (joint synovectomies 22%, arthrodeses 21%, prostheses 41% and forefoot procedures 12%) were performed in 315 patients. Survival analyses were completed to evaluate the impact of age, sex, radiographic changes and year of diagnosis, on the risk of undergoing surgery.

Results: Patients diagnosed in 1972–1985 and 1986–1998 had a relative risk (RR) of 2.4 and 2.2 (p<0.001) respectively, of surgery compared to patients diagnosed in 1999–2009. Radiographic changes at diagnosis and female sex were also significant risk factors. Disease activity at baseline did not affect the outcome. Anti-rheumatic medication was significantly different in the three time periods.

SAT0042 SEVERITY OF RADIOGRAPHIC DESTRUCTION ON PERIPHERAL JOINTS IS A STRONG INDEPENDENT RISK FACTOR FOR CAROTID ATHEROSCLEROSIS

Background: In our previous study, we identified that cumulative inflammatory burden contributes to the development of carotid atherosclerosis through a synergistic interaction with conventional cardiovascular (CV) risk factors in patients with rheumatoid arthritis (RA). However, it is controversial whether the presence of joint destruction which result from inflammatory burden may be a risk factor for carotid atherosclerosis.

Objectives: To investigate whether intima-media thickness (IMT) and plaques of carotid artery are influenced by radiographic joint destruction in patients with RA.

Methods: A total of 186 patients with RA were included in the present study. Plain X-ray of the hands and feet were used to assess the severity of joint destruction. We developed a new radiographic scoring system, named Rheumatoid Arthritis-Radiographic Severity Score (RA-RSS), which scores 21 joint groups with the modified Steinbrocker method. The following joint groups were included: 2 proximal interphalangeal (PIP) joint group, 2 metacarpophalangeal (MCP) joint group, 2 wrist joint group, 2 elbow joint group, 2 shoulder joint group, 1 atlantoaxial joint group, 2 hip joint group, 2 knee joint group, 2 ankle joint group, 2 tarsometatarsal (TMT) joint group, and 2 metatarsophalangeal (MTP) joint group. The grade was determined by the worst changes in each joint group of PIP, MCP, TMT, and MTP joints. RA-RSS groups are assigned as follows: 0 = No radiographic changes; 1 = mild destruction of bone and cartilage; 2 = moderate destruction of bone and cartilage or joint deformities; 3 = Severe destruction of bone and cartilage or bony ankylosis (Score ranges from 0–63). We performed carotid ultrasound to detect the presence of carotid atherosclerosis.

Results: Among 186 patients who were graded using RA-RSS, 110 patients had carotid plaques (59.1%). RA-RSS was significantly higher in patients with plaques compared to patients without plaques (11.2±8.79 vs. 7.6±7.72, p=0.004). Patients were divided into two groups by the cut-off value of plaque development as determined using receiver operating characteristic (ROC) curves: 11.5 (61.8%) patients with RA-RSS ≥10 and 71 (38.2%) with RA-RSS <10. There was a significant difference between the groups with respect to the presence of plaques (48.7% vs. 76.1%, p<0.001), while there was no difference in mean carotid IMT (0.87±0.19 vs. 0.89±0.14, p=0.684). The mean age, the presence of conventional CV risk factors, Korean version of the modified HAQ (mHAQ), DAS28-ESR, and RA-RSS >10 were significantly associated with plaque development. Multivariate logistic regression analysis showed that RA-RSS ≥10 (OR 2.94 [95% CI 1.48–5.84]) and the presence of conventional CV risk factors (OR 2.30 [95% CI 1.21–4.35]) were independent risk factors for plaque development.

A 10-YEAR FOLLOW UP STUDY OF EARLY SERONEGATIVE ARTHRITIS DIAGNOSED AT AN ADULT AGE

K. Paalainen, J. Asikainen, T. Rannio, P. Hannonen, T. Sokka. Rheumatology Department, KSSHJ, Jyväskylä, Finland

Background: Up to 20–30% of patients enrolled into RA cohorts and clinical trials are seronegative. However, in studies examining predictors, prognosis, and response to treatment, seropositive and seronegative groups of patients seem to behave differently. Only a few studies have focused on the long term follow up of seronegative arthritis.

Objective: To investigate long-term outcomes of patients with seronegative arthritis during a 10-year follow-up period including clinical outcomes and reclassification of diagnosis when applicable.

Methods: A total of 1046 patients were classified as early RA in 1997–2005 at single rheumatology center and scheduled for a ten year follow-up, including 434 seronegative patients who are subjects of the present analysis. Follow-up examinations were carried out for at least 2 years and then at 5 and 10 years by the treating specialist including complete clinical examination and patient reported outcomes. In addition, case–reviews were performed, with re-classification of the cases when applicable.

Results: Among the 434 seronegative patients (69.4% women, mean age 58), 271 subjects were seen for the 10 year visit with the mean disease activity index (DAS28 of 2.3 (SD 1.02) and the mean HAQ of 0.71 (SD 0.72). Out of the remaining 146 patients, 88 had died and 53 did not attend the 10-year visit due to altered diagnosis, refusal or mortality. Five patients had dropped out and files of 17 patients were missing. During the follow-up of 10 years, 12/434 (2.7%) patients could be classified as seropositive or erosive RA: 4 turned seropositive (2 for ACPA and 2 for RF [-2x normal level]) and 8 developed erosions typical for RA. Reclassification revealed 70 (16.1%) cases of gout, 24 (5.5%) cases of osteoarthritis without evidence of inflammatory disease, 47 (10.8%) cases of psoriatic arthritis, 9 (2.1%) cases of spondyloarthritides and 16 (3.7%) cases of plausible reactive arthritis. Few cases were reclassified as gout (11 cases (2.5%)) and pseudogout (3 cases (0.7%). Also paraneoplastic arthritis (6 cases (1.4%)), juvenile arthritis (5 cases (1.2%), hemochromatosis (2 cases (0.5%)), ankylosing spondylitis (2 cases (0.5%) and temporal arthritis (2 cases (0.5%)) were revealed during follow up. One case of each reflex sympathetic dystrophy, trauma-induced arthritis, meniscal injury, optional Nasu Hakola disease, microscopic polyangiitis (MPA), granulomatous polyangiitis (GPA), antiphospholipid syndrome and cases of Collins ulcer were also found. The remaining 147 patient (33.8%) could not be reclassified in any clear new diagnosis. A total of 44 of these undifferentiated cases had transient arthritis, 43 cases had features of seronegative spondyloarthritides and 57 cases remained totally unspecified, while three patients had features of inflammatory connective tissue disease (SLE and Sjögren’s syndrome), but they did not meet available classification criteria. In addition, files of 17 (3.9%) patients were missing from the analyses.

Conclusions: Over a 10-year period, 97% of seronegative patients remained seronegative and did not develop RA-like erosions. Reclassification revealed significant heterogeneity in the diagnosis of seronegative RA. Therefore, seronegative arthritis should not be studied as a homogenous disease entity.

11 YEARS’ FOLLOW-UP OF A DANISH 2-YEAR TREAT-TO-TARGET RANDOMIZED CONTROLLED TRIAL IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: BASELINE PREDICTORS OF FUNCTIONAL AND RADIOGRAPHIC OUTCOMES

Background: Up to 20–30% of patients enrolled into RA cohorts and clinical trials are seronegative. However, in studies examining predictors, prognosis, and response to treatment, seropositive and seronegative groups of patients seem to behave differently. Only a few studies have focused on the long term follow up of seronegative arthritis.

Objective: To investigate long-term outcomes of patients with seronegative arthritis during a 10-year follow-up period including clinical outcomes and reclassification of diagnosis when applicable.

Methods: A total of 1046 patients were classified as early RA in 1997–2005 at single rheumatology center and scheduled for a ten year follow-up, including 434 seronegative patients who are subjects of the present analysis. comparison of the data obtained, the adverse events reported for each drug were normalized using the number of treatments for the same period. The reporting odds ratio (OR) and its 95% confidence intervals (CI) were calculated regarding the different categories of adverse events. The incidence of serious adverse events, serious infections, withdrawals due to adverse events and deaths were also evaluated.

**Results:** The EudaVigilance database contains 851,882 adverse events reported for IFX, ETN, and ADA. During this period, the different TNF antagonists have shown almost the same safety profile. The reported adverse events were classified by systems organ class (SOC) and the most frequent were administration site reactions (22.8%) and infections and infestations (11.2%). Safety was not statistically different. The comparison between IFX originator and its biosimilar did not show statistically significant differences in safety (ROR 1.08 (0.80,1.46)) during the initial 3-years after launch for both drugs. However, a small non-significant increase in adverse reactions was noted for IFX-biosimilar, which might reflect increasing attention for this class of drugs.

**Conclusions:** The comparison of reference IFX and IFX-biosimilar did not demonstrate statistically significant differences in safety. This pharmacovigilance study provides the first analysis of TNF antagonists from the EudaVigilance database and offers a framework for safety comparison between originators and biosimilar TNF antagonists.

**Acknowledgements:** We would like to acknowledge EudraVigilance for providing access to the database.

**PREDICTING MAINTENANCE OF RESPONSE BASED ON DISEASE CHARACTERISTICS AND EARLY CLINICAL RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS UPON WITHDRAWAL OF ADALIMUMAB**

J.S. Smolen1, P. Emery2, H. Zhang3, X. Wang4, J. Suboticki3, I. Sainsbury3, A. Kavanaugh4, 1Medical Univ of Vienna, Vienna, Austria; 2Leeds Inst of Rheumatic & Musculoskeletal Medicine, Leeds, United Kingdom; 3AbbVie, N Chicago, IL; 4Univ of California, San Diego, CA, United States

**Background:** Some patients (pts) with rheumatoid arthritis (RA) achieve low disease activity (LDA) after treatment with adalimumab (ADA) plus methotrexate (MTX) and can maintain LDA after ADA withdrawal1. However, others experience a flare in disease activity. The factors associated with loss or maintenance of response are not understood.

**Objectives:** To identify disease characteristics and early clinical responses, which predict maintenance of LDA upon ADA withdrawal in individual RA pts.

**Methods:** Data from the OPTIMA trial were used in this post hoc analysis. In period 1 (P1), pts were treated for 26 weeks (wks) with ADA+MTX or placebo (PBO)-MTX. Pts on ADA+MTX who achieved DAS28-CRP ≤ 3.2 at wks 22 and 26 (responders) were randomized to ADA withdrawal, or ADA+MTX continuation up to Wk 78. Responders to PBO-MTX in P1 continued on PBO-MTX up to Wk 78 (PBO continuation). Data from the ADA withdrawal arm were used to predict LDA at Wk 78 by DAS28-CRP (≤ 3.2) or SDAI (≤ 11). Potential factors including baseline (BL) disease characteristics and Wk 26 responses, including DAS28-CRP, SDAI, ACPA reactivities toward 13 different citrullinated peptides (fillagrin, fibrinogen, alpha-enolase, vimentin, histone) (1).

**Results:** A regression tree method3 was established by the LASSO method, which performs variable selection by penalizing unduly complicated models, with/without incorporating the speed of DAS28-CRP or SDAI response as an individual predictor. Logistic regression on the LASSO-selected factors yielded coefficients used to derive individual scoring equations and prediction scores for Wk 78 outcomes (fig footnote). Prediction score cutoffs were established by the regression tree method. The results were validated in data from the PBO continuation arm.

**Conclusions:** For the prediction of DAS28-CRP LDA at Wk 78, BL physician global assessment (PhGA) and health-assessment questionnaire-disability index (HAQ-DI), and Wk 26 DAS28-CRP, HAQ-DI, SDAI and CRP were selected by LASSO, and used to calculate the prediction score. Including speed of response did not affect the predictors chosen. Of 9 pts predicted not to have DAS28-CRP LDA at Wk 78, 0 had LDA (NPV=100%) (fig 1). Out of 66 pts predicted to have DAS28-CRP LDA at Wk 78, 63 predictions were correct (PPV=96.5%). Results were comparable for most cutoff categories in the validation arm (PPV=82%); however, no pts were predicted to have a non-response at Wk 78. For the prediction of SDAI LDA at Wk 78, the NPV was 86% (1/7 predictions incorrect); PPV was 98% (39/41 predictions correct); in the validation arm, the PPV was 82%.

Background: The rheumatoid arthritis (RA) Treat to Target (T2T) recommendations\(^1\) defined in 2010 aimed to support clinicians to achieve optimal therapeutic outcomes for their patients.

**Objectives:** 38 hospitals prospectively audited management of newly diagnosed RA patients to determine compliance with the T2T recommendations and therapeutic outcomes achieved.

**Methods:** From April 2012 to September 2016 and upon diagnosis of RA, data on disease history, management and clinical outcomes were collected prospectively in a web-based tool. Follow-up to date provides data for up to 24 months from diagnosis (baseline).

**Results:** 1571 patients were recruited in 38 centres, with 12 months’ follow-up for 713 patients and of these 269 also had 24 months’ follow-up. 1021 (65%) patients were followed for the subset of patients with available DAS28 scores at the relevant time points, stratified by those who did/did not achieve their remission target and those with/without sustained remission at 24 months. Of the 108 eligible patients required to receive biologic therapy, according to NICE guidance, 39 (36%) received a biologic within their first 24 months of treatment.

**Conclusions:** The results suggest that more patients with a target set at baseline in 12 months do not appear to affect the proportion of patients in remission at 24 months, but active management in the first 12 months (4 visits, <4 DAS28 scores) does appear to be associated with more patients in remission at 24 months. Thus we conclude that treating RA early and aggressively, in line with the T2T guidelines, leads to sustained clinical improvement.

CITRULLINATION OF ADENOSINE DEAMINASE ISOFORMS IN SYNNOVIAL FLUIDS (SFs) OF RA PATIENTS AND PREDICTION OF TREATMENT SUCCESS

S. Sharoyan 1, L. Karapetyan 1, R. Harutyunyan 2, S. Mardanyan 1, A. Antonyan 1, 2

1 H.C. Buniatian Institute of Biochemistry of Armenian NAS; 2 “Yerevan” Medical Center, Yerevan, Armenia

Background: One of the most important discoveries in rheumatology is the characterization of citrulline containing auto-antigens [1]. The identification of citrullinated proteins as auto-antigens and the development of new assay based on the detection of anti-citrullinated protein antibodies (ACPAs) become a breakthrough in the diagnosis and treatment of rheumatoid arthritis (RA). Matsui and coauthors in vitro identified adenosine deaminase (ADA) as an ACPA antigen [2]. Earlier we have reported the enhanced ADA activity in synovial fluids (SFs) of RA patients [3]. This increasing was in correlation with the ratio of small isoenzyme (SADA) from SFs with high ADA activity (100–190 IU/L) were used. Earlier we demonstrated a negligible level of SADA at activity can serve as new citrulline containing ACPA antigen. This finding can be used as an independent predictor of disease activity. In our cohort, 105 (30.1%) ERA patients were treated with biological disease modifying anti-rheumatic drugs (bDMARDs) over time. Biotechnological therapy was less frequently started by subjects in CDC, both after 12 months (p=0.003) and at the time of last FU (p=0.0001). At the multivariate analysis, not achieving CDC at the 12th month of FU [OR (95% CI): 2.69 (1.59–4.57)] and a normal BMI (95% CI): 2.05 (1.23–3.42) were the variables significantly associated to bDMARD therapy over time.

Conclusions: The simultaneous achievement of symptom control, inhibition of radiographic progression and normalization of function, is a feasible target in real world EAC. Having a VERA and a normal weight are associated to a high chance of “deep” remission.

SAT0053 THE INCIDENT IMMUNOLOGICAL STATUS PREDICTS DRUG-FREE DISEASE FLARE IN RHEUMATOID ARTHRITIS PATIENTS ACHIEVING STRINGENT CLINICAL AND ULTRASONOGRAPHIC CONTROL OF THE PERIPHERAL INFLAMMATORY PROCESS

A. Manzo, S. Bugatti, F. Benaglio, B. Vitolo, G. Sakellariou, R. Caporali, C. Montecucco, Rheumatology and Translational Immunology Research Laboratories (LaRIT), Division of Rheumatology, IRCCS Policlinico San Matteo Foundation/University of Pavia, Pavia, Italy

Background: The development of predictive tools to evaluate health risks and make the optimized health plans in patients with rheumatoid arthritis (RA) achieving remission still represents a major unmet need. In this perspective, the relative weight of clinical, ultrasound and immunological assessment of disease characteristics for predicting recurrence of the inflammatory process under drug-free conditions remains unclear.

Objectives: To investigate the predictive value of baseline clinical remission stringency, synovial power Doppler (PD) ultrasound indices and the incident autoimmune status, as predictors of flare under drug-free conditions after a DAS28-driven treatment strategy with methotrexate (MTX) in early RA.

Methods: 85 RA patients achieving remission and candidate to MTX withdrawal were recruited according to the following criteria: 1) introduction of MTX within 12 months from symptoms onset, 2) at least 24 months of MTX treatment with a DAS28-driven protocol targeting low disease activity (LDA), 3) DAS28 ≤ 2.6 for ≥ 6 months in the absence of corticosteroids. Following treatment withdrawal, patients were followed for three months intervals across 24 months through clinical, ultrasound (hands-feet-axillary lymph nodes), radiographic and immunologic screenings (ACPAs, CRP status, CXC1L3 circulating levels and FACS analysis for quantification of KB67/ regulatory-T B cell subsets). Treatment was re-introduced in case of DAS28 > 3.2 or stable LDA.

Discipline: Other
DOI: 10.1136/annrheumdis-2017-eular.1433
Results: At baseline, 84% of the patients were in remission according to the SDAI (median 84.8 vs. 205.6 ng/mL, p=0.0006), and in the dead group than in the alive group. Univariate analyses revealed that age ≥ 75 years and those who died after AE (dead group), and identified variables significantly associated with AE occurrence and survival using Cox hazard analyses. A rapid and meaningful reduction in pain is important to quality of life in patients (pts) with rheumatoid arthritis (RA). Baricitinib (bari) is a selective inhibitor of Janus kinase (JAK) 1/2 in development for pts with active RA, regardless of the pt population. Significant improvements in pain for bari vs PBO and bari vs ADA were sustained through week 24.

Conclusions:

Background: Acute exacerbation (AE) is recently recognized as deterioration of respiratory status in idiopathic pulmonary fibrosis. It is reported that AE also occurs in other interstitial lung diseases (ILD) such as collagen vascular diseases associated ILD (CVID-ILD). However, the characteristics and risk factors of AE in CVID-ILD are not clearly identified.

Objectives: To clarify the characteristics of patients with rheumatoid arthritis-associated interstitial pneumonia (RA-IP) and to investigate the risk factors associated with AE and its survival of RA-IP.

Methods: We examined the clinical features of 60 RA-IP patients admitted to our hospital between July 2010 and September 2016. We compared the characteristics between patients who developed AE (AE group) and those who did not (non-AE group), and between patients who survived after AE (alive group) and those who died after AE (dead group), and identified variables significantly associated with AE occurrence and survival using Cox hazards analyses.

Results: Thirty-six (60%) were female. Twenty-two (36.7%) developed AE and 22 (36.7%) died after AE. The mean age at RA diagnosis was 61.1 ± 16.3 years in the AE group and 61.5 ± 13.1 years in the non-AE group. Sex, smoking habit and high-resolution computed tomography (HRCT) pattern were not significantly different between two groups. Although there was no significant difference, more patients in the AE group received methotrexate (MTX) treatment than those in non-AE group (40.9% vs. 18.9%, p=0.12), and MTX use was significantly associated with occurrence of AE in a Cox hazard analysis (Hazard ratio [HR] 1.09, 95% confidence interval [CI] 1.01–1.18). Further, age (median 70 vs. 82 years, p=0.002) and matrix metalloproteinase-3 (MMP-3) level (median 84.8 vs. 205.6 ng/mL, p=0.003) on admission were significantly higher in dead group than in alive group. Univariate analyses revealed that age ≥ 75 years (HR 10.53, 95% CI 1.26–88.15), MMP-3 ≥ 200 ng/mL (HR 15.58, 95% CI 1.38–175.8), and 3L or more oxygen use (HR 8.46, 95% CI 1.02–70.49) on admission were significantly associated with death (Table 1).

Baricitinib showed rapid and greater reduction in pain compared to adalimumab or placebo in patients with rheumatoid arthritis

P. Taylor1, B. Zhu1, C. Gaich1, X. Zhang2, A.M. DeLozier2, D. Schlichting2, R. Patash1, F. Durand1, B. Faurel1. 1University of Oxford, Oxford, United Kingdom; 2Eli Lilly and Company, Indianapolis, United States; 3University Pierre et Marie Curie, Paris, France

Background: A rapid and meaningful reduction in pain is important to quality of life in patients (pts) with rheumatoid arthritis (RA). Baricitinib (bari) is a selective inhibitor of Janus kinase (JAK) 1/2 in development for pts with active RA.

Objectives: To evaluate the effect of bari treatment on pain reduction compared to adalimumab (ADA) or placebo (PBO) in pts with inadequate response to methotrexate (MTX) or biologic disease-modifying antirheumatic drugs (bDMARDs).

Methods: In RA-BEAM (NCT01710358), 1305 pts with inadequate response to MTX were randomised 3:3:2 to PBO QD, bari 4 mg once daily (QD), or ADA 40 mg biweekly. In RA-BEACON (NCT01721044), 527 pts with inadequate response or intolerance to bDMARDs were randomised 1:1:1 to PBO or bari (2 or 4 mg) QD. This post-hoc analysis reports the pts’ assessment of pain using a visual analogue scale (VAS, range: 0 to 100 mm). The proportion of pts who achieved ≥30% pain improvement of ≥30%, ≥50%, and ≥70% on their baseline pain score, baseline joint erosion status (RA- BEAM only), and history of bDMARD at screening (RA-BEACON only). Missing data were imputed using modified last observation carried forward.

Results: Mean baseline pain scores were 60, 62, and 61 for PBO, bari 4 mg, and ADA, respectively, in RA-BEAM and 65, 62, and 66 for PBO, bari 2 mg, and bari 4 mg, respectively, in RA-BEACON. A significantly greater proportion of pts treated with bari 4 mg achieved ≥30%, ≥50%, and ≥70% pain improvement as early as week 1 compared to PBO (both studies) and as early as week 4 compared to ADA (RA-BEAM) (Table). A significant pain improvement of ≥70% was achieved at week 12 for pts treated with bari 4 mg compared to PBO (both studies) and ADA (RA-BEAM). Pain improvement of ≥30%, ≥50%, and ≥70% with bari 2 mg was significant compared to PBO by week 12 (RA-BEACON). Significant improvements in pain for bari vs PBO and bari vs ADA were sustained through week 24.

**SAT0056** RHEUMATOID ARTHRITIS MAGNETIC RESONANCE IMAGING SCORE (RAMRIS) CAN PREDICT DAS28 THERAPY RESPONSE AFTER 6 MONTHS: RESULTS OF THE GERMAN ARTHROMARK COHORT

P. Sewerin1, S. Vordenbäumen1, C. Schleich2, R. Sengewein2, R. Brinks3, G. Pongratz2, J. Lesch2, L. Le4, U. Mansmann1, M. Schneider1, B. Ostendorf1 on behalf of ArthroMark Studygroup. 1Department for Rheumatology; 2Department for Diagnostic and Interventional Radiology; 3Hilger-Research-Center for Rheumatology, University Hospital Düsseldorf, Düsseldorf; 4Institute for Medical Information Sciences, Biometry and Epidemiology, Ludwig Maximilian University of Munich, Munich, Germany

Background: Remission is the ultimate goal in rheumatoid arthritis (RA). The absence of rheumatoid factors (RF) and/or anti-citrullinated protein (CCP) antibodies, no morning stiffness, low conventional disease activity and no erosions are considered to have low disease activity, and early therapeutic intervention are established good prognostic markers. Magnetic resonance imaging (MRI) is a well evaluated imaging technique and is increasingly used in daily practice. In this study, we prospectively investigated the prognostic performance of high-field MRI and serological biomarkers 6 months after initiation of methotrexate in patients with early RA (eRA).

Objectives: To evaluate the value of high-resolution MRI of the hand as a prognostic marker for EULAR-response and remission after 6 month of MTX therapy in early RA patients.

Methods: Prospective study on the ArthroMark cohort using 3T MRI of the hand at baseline (V0) before initiating an MTX-therapy in eRA patients, after 3 months (V3) and after six months (V6). 28 patients (Ø 56.8 years) with RF and/or CCP positive RA and a disease duration ≤6 months (mean±16.3 weeks) fulfilling the 2010 ACR/EULAR criteria were examined. EULAR core set of variables were recorded: patient’s global assessment of disease activity, number of tender and swollen joints, ESR and CRP. The following biomarkers were assessed by ELISA: Dkk-1, Osteoprotegerin, IL-22, MMP-3, TNF-Alpha and Neopteriptide-Y. Remission was defined as DAS28 <2.6 according to the ACR/EULAR remission criteria. MRI-scan was performed by using the OMERACT RA-MRI scoring system (RAMRIS) to assess disease activity.

Results: A low RAMRIS subscore for erosions (p=0.019) or total RAMRIS score (p=0.0001) were significant results found for the MRI markers assessed for response prediction at either V3 or V6. Concerning remission, low levels of RAMRIS at baseline were significantly associated with EULAR remission at V6 (p=0.033). The other markers assessed did not show significant results at either V3 or V6. In multivariate analyses, response was predicted more accurately with the inclusion of either RAMRIS (p value LR-test =0.035), RAMRIS synovitis subscore at MCP-2 (p value LR-test =0.035) or a combination of the two (p value LR-test =0.042). Remission was more accurately predicted when RANKL was considered with low RANKL improving the chance of remission. In contrast to response-prediction, MRI did not significantly add to the prediction model for remission.

Conclusions: Low RAMRIS scores or RAMRIS synovitis subscorer at MCP-2 were predictive for therapy response after 6 months in our generalised mixed model. Baseline RAMRIS was able to significantly predict remission. Our data suggests that MRI and/or serological markers may did disease activity prediction and facilitate patient selection for intensified therapy in the future.

**SAT0058** EFFECTS OF BARICITINIB ON PATIENTS WHO STOP METHOTREXATE MONOTHERAPY AND SWITCH TO BARICITINIB MONOTHERAPY

R. Fleischmann1, T. Takeuchi2, M. Schiff2, D. Schlichting3, L. Xie4, M. Issa4, I. Stolykov4, J.R. Lisse4, R. Martinez-Osuna5, T. Rooney4, C.A. Zerin5, U. Tews6, SW Medical Center, Dallas, United States; 2Keio University, Tokyo, Japan; 3Univ Colorado Hospital, Colorado, United States; 4Eli Lilly and Company, Indianapolis, United States; 5Univ Sao Paolo, Sao Paulo, Brazil

Background: Baricitinib (bari) is a reversible oral Janus kinase (JAK) inhibitor with selectivity for JAK1/JAK2 in development for treatment of patients (pts) with active rheumatoid arthritis (RA). In the 52-week (wk) Phase 3 RA-BEGIN study of MTX-naïve pts, there were 3 arms: bari 4 mg once daily (QD), meloxicam (MET) 7.5 mg QD, up to 20 mg weekly (QW), and the combination of bari plus MTX (bari+MTX). Nonresponders were rescued from week 24 onwards by receiving bari+MTX, regardless of original treatment. Bari monotherapy showed superior efficacy compared to MTX monotherapy and similar clinical efficacy to bari+MTX.

Methods: In RA-BEGIN, 588 pts were randomised 4:3:4 to MTX, bari monotherapy 4 mg QD and bari+MTX. At wk 24, 27% of pts who had entered the LTE; all pts received bari 4 mg monotherapy, MTX could be added in the LTE by investigator decision. Seventy-seven percent of pts (451/588) enrolled in the LTE, of whom 423 had not been rescued in RA-BEGIN. This post hoc analysis evaluated clinical efficacy of pts who continued bari monotherapy compared to those in whom MTX was added within the first 24 wks of the LTE.

Results: Of these 423 pts, 202 (47%) remained on monotherapy at Wk 24 of the LTE and 223 pts started on MTX before wk 24. Most (193) had initiated MTX within 4 wks of starting the LTE study, evenly balanced from the 3 original arms. Acros stance of pts who had MTX added in the LTE had worse disease control upon entry and during the LTE. Through 24 wks, statistically significant improvement in disease state was observed in the MTX-to-bari-group regardless of whether or not MTX was added back. In the bari-to-bari monotherapy group, the addition of MTX led to lowered disease activity, which was statistically significant. No statistically significant changes in disease activity were observed in the pts who were switched from bari+MTX to bari monotherapy regardless of additional MTX therapy (Table 1). Exposure-adjusted incidence rates for total treatment-emergent adverse events, including non-serious infections, were lowest in the MTX-to-bari group. Clinically significant or consistent differences in SIE,
SAEs, or AEs leading to study drug discontinuation were not seen in any of the arms, whether MTX was added or not.

Conclusions: Switching from MTX to bari monotherapy, maintaining bari monotherapy was associated with improvements in depths of disease control during the initial 24 wks post-switch. Disease control did not significantly change after withdrawal of MTX from combination therapy. Pts who entered the LTE with suboptimal disease control after treatment with bari monotherapy may benefit from the addition of MTX. Discontinuation of MTX in pts treated with combination during the index study was associated with maintenance of response. There were no differences in important measures of safety including events that are serious or led to discontinuation.

Background: In rheumatoid arthritis (RA), several autoantibody characteristics, including specificity, levels and isotypes, may influence their pathogenic properties and clinical and laboratory outcomes of the disease (1,2). Furthermore, particular, classical IgM rheumatoid factor (RF) may boost inflammation triggered by anti-citrullinated protein antibodies (ACPAs) (3).

Objectives: To investigate whether RF impacts on disease characteristics and response to therapy in ACPA-positive early RA patients treated with conventional synthetic disease modifying drugs (csDMARDs).

Methods: 574 early RA patients consecutively enrolled in our Early Arthritis Clinic between 2005 and 2014 were included. Patients had symptoms’ duration ≤12 months, were glucocorticoid- and DMARD-naive, and fulfilled RA criteria at inclusion. IgM RF and IgG ACPA were determined in baseline sera by immunonephelometry and a second-generation ELIA CCP assay respectively. Autoantibody levels were considered high when >3 times the upper limit of normal (ULN). Patients were treated with incremental doses of methotrexate according to a treat-to-target strategy aiming at low disease activity (LDA, DAS28<3.2). The associations between autoantibody specificity and levels and the achievement of LDA and disease remission (DAS28<2.6) over 6 months were investigated by Cox regression.

Conclusions: High peak radiographic progression is a rear phenomenon that gets less frequent in patients over the last years of observation. This may be an effect of modern therapy. Among the patients with high radiographic progression, (1) a greater delay between diagnosis and first symptoms was found and (2) the use of biologic agents was less frequent. These data suggest that the decreasing frequency of very high radiographic peak progression in the Swiss RA patients reflect a more effective therapeutic approach in the last years.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.4232
selected for outcome analyses. Among seropositive patients, both LDA and remission were less frequently achieved in case of RF-potency. Relevantly, in ACQA-positive patients (n=273), the co-occurrence of RF dose-dependently influenced clinical outcomes. After 6 months of treatment, LDA and disease remission were achieved respectively by 69.6% and 47.8% of single ACPA-positive patients (chi-square for trend p=0.18 for LDA; p=0.05 for remission). After adjusting for confounders (age, gender, symptoms’ duration, baseline disease activity, use of prednisone, recruitment period), high levels of RF independently predicted failure to achieve LDA with an HR (95% CI) of 0.61 (0.39 to 0.95) and failure to achieve remission with an HR (95% CI) of 0.63 (0.35 to 0.99) (Figure 1). In contrast, ACQA levels did not show any significant predictive value, neither for thresholds of -3 ULN nor >100 U.

Conclusions: Among ACQA-positive RA patients, disease characteristics may vary in association with the extent of overall humoral autoimmunity. In particular, the concomitant presence of high levels of IgM RF seems associated with lower response rates to csDMARDs. Collectively, these findings highlight the importance of further subclassifying patients with autoantibody-positive RA in order get deeper insights into disease mechanisms and clinical outcomes.

SAT0061  | HAQ SCORE IS AN INDEPENDENT PREDICTOR OF SUSTAINED REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

S.-S. Lee 1, 2, J.-H. Kang, J.-E. Kim, K.-E. Lee, D.-J. Park, Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic Of

Objectives: We compared remission rates, according to different definitions of remission in rheumatoid arthritis (RA) and investigated the potential predictors of sustained remission at the 2-year follow-up.

Methods: We obtained data on 291 RA outpatients, seen from July 2009 to September 2012. Sociodemographic data and answers to questionnaires were collected at each interview. Remission was defined according to the Disease Activity Score in 28 joints (DAS28-ESR), DAS28-CRP, Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), and ACR/EULARARLar definition. Sustained remission was defined as when the patient fulfilled the definitions at two consecutive annual assessments. Predictors of sustained remission according to the DAS28-CRP were assessed by univariate and multivariate analyses.

Results: For the 291 RA patents, the remission rates of RA were 17.9% (DAS28-ESR), 54.3% (DAS28-CRP), 10.3% (SDAI), 10.0% (CDAI), and 8.6% (Boolean). On follow-up for 2 years, the sustained remission rates of RA were 46.5% (DAS28), 55.0% (DAS28-CRP), 37.5% (SDAI), 32.0% (CDAI), and 30.8% (Boolean). RA patients who achieved sustained remission according to the DAS28-CRP were younger, and had more education, higher monthly income, lower patient global assessment, lower patient pain assessment, and had less joints with grade 3 signals (p=0.04). Specifically, patients with a low CRP, and a high 14–3-3 level had a higher likelihood of flaring versus those with a low 14–3-3, 22% versus 12%.

Conclusions: Baseline 14–3-3 and increases in its levels are associated with worse radiographic outcomes in patients who achieve clinical remission and discontinue ADA. To reduce the risk of flare in patients who are candidates for discontinuation of ADA, CRP and 14–3-3 measurements should be considered in combination as markers of flare prediction.

SAT0063  | A PROSPECTIVE STUDY ON COMPARISON OF COMPOSITE INDICES WITH ULTRASOUND FOR DETECTING REMISSION AND PREDICTION OF FLARE IN 2 YEARS

1Department of Numerical Medicine, 2Rheumatology, Istanbul Medeniyet University School of Medicine, Istanbul, Turkey; 3Rheumatology, University of Ottawa, Faculty of Medicine, Ottawa, Canada; 4Allergy and Immunology, 5Koc University, School of Medicine, Istanbul, Turkey

Background: Treat-to-target (T2T) approach suggests using a composite index patient’s remission status. To compare two ultrasound indices for RA patients in remission taking Ultrasound Global Synovitis Score (GLOESS) as a gold standard and their predictive value for flares in 2 years.

Methods: RA patients who were considered to be in clinical remission according to the clinician were recruited. Disease activity was assessed using DAS28-CRP, CDAI, SDAI and Rapid-3 and 38 joints from 2007 to 2011. The total GLOESS score was calculated in 2 consecutive visits of the following 2 years, whenever available.

Results: Ninety-six consecutive patients (80.2% females) were recruited. Patients were more frequently categorized as being in remission using DAS28 (80%) as compared to CDAI (50%), SDAI (45.2%) and Rapid-3 (37.5%). Patients that were in remission according to CDAI had lower GLOESS scores on 28 joints (p=0.05) and had less joints with ≥2 signals (p=0.04) (table). For SDAI patients in remission had less number less number of joints with grade ≥2 signals (p=0.03) than to have lower GLOESS scores on 28 joints as well as lower number of joints with ≥2 signals (p=0.06). None of the US scores were able to differentiate different disease states according to DAS28-CRP or Rapid. Flare data was available in 76 patients, 22 of whom had flares. Patients that had flare had higher GLOESS scores on 28 joints at baseline (p=0.03) and tend to have higher number of joints with grade ≥3 signals (p=0.06). Although numerically higher, none of the clinical indices were able to predict flares based on remission status (remission vs non remission: CDAI: 22.5% vs 36.1, p=0.2; SDAI: 22.9 vs 38.6, p=0.2; DAS28: 25.4% vs 50%, p=0.1; RAPID3: 20% vs 34.8%, p=0.2).

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.2363
Background: Anti-citrullinated protein/peptide antibodies (ACPA) have been suggested to identify a more severe phenotype of rheumatoid arthritis (RA).

Objectives: In this study in a recruitment cohort of early RA we have assessed a number of antibodies against different citrullinated and/or mutated peptides using a multiplex platform in relation to the patients disease inflammation and radiological disease progression.

Methods: Patients with early RA (<12 m of symptoms) fulfilling the 1987 ARA criteria (n=1022, 629/393, mean age 56.7±14.0 years) were sampled at the time of diagnosis and assessed using disease activity score (DAS28) at baseline, 1, 2, 12 and 18 months. Radiographs were graded using Larsen score (baseline and at 24 m). Plasma sampled at baseline was analysed for presence of antibody reactivities against 21 different citrullinated and mutated peptides/proteins; Fibronectin (Fib), -α2 (36–52), -β2 (573, Fib)-α2, Fib-α2, Fib β2 (62–78, 72), Fib-β2 (78–72), Filaggrin (Fil307–324), -α-Enolase peptide 5–21 (CEP-1), Vimentin ( Vim) 2–17, Vim60–75, F4-R-Cit, F4-Cit-Cit, F4-Cit-R, or mutated proteins (Blaz2, Pept1, Pept5, Pept21, Pept22) and type II Collagen citrullinated or not using a custom-made microarray assay based on the ImmunoCAP ISAC system (Phadia AB, Sweden). Cut-off levels were at the 98th percentile of controls (n=477). Anti-CCP2 was analysed using ELISA (EuroDiagnostic, Sweden).

Results: The most frequent appearing ACPA were: Fib-β2 (60–74) (56.6%), Fib-β2 (536–52) (55%); Fib-β2 (573, Fib)-α2 (54.9%), Fil307–324 (51.7%); CEP-1 (53.7%) and Pept5 (52.0%). Antibodies against CEP1 (76%), Fib-β2 (62–78) (72%), Fil307–324, F4-R-Cit antibodies with significant correlation between radiological progression and antibodies against Vim-2–17, Fib-β2 (36–52), CEP1, Fib-β2 (621–635) and CCPRP and between DAS28 and Vim60–75, F4-R-Cit, Pept21 (74%, F4-R-Cit antibodies vs. being negative).

Conclusions: Analyses at baseline, of the ACPA specificity profiles allowed different patterns of disease activity and radiological progression during the first 24 months of the disease to be identified.

UPIA, Rheumatoid Arthritis (RA), Spondyloarthritis (SpA) or Psoriatic Arthritis (PsA), respectively.

Results: During the follow-up (6 (14.3%) UPIA reached a defined diagnosis (2 RA, 2 SpA and 2 PsA, respectively). At baseline, UPIA who differentiated had higher GSUS (p=0.01) and PDUS scores (p=0.02) compared to patients who remained as UPIA. At follow-up 1 year, UPIA who differentiated to arthritis had higher histological scores for lining and sublining CD68⁺ (p=0.005 and p=0.04 for lining and sublining, respectively), sublining CD3⁺ cells (p=0.002) and CD31⁺ vessels count (p<0.001) than patients who remained as UPIA. In addition, there were direct correlations between baseline GSUS and PDUS scores with lining CD68⁺ cells scores (p<0.001 for GSUS and p=0.02 for PDUS scores respectively), sublining CD68⁺ cells scores (p=0.02 for GSUS and p=0.03 for PDUS scores respectively), sublining CD3⁺ cells score (p=0.02 for GSUS and p=0.002 for PDUS scores respectively) and CD31⁺ vessels count (p<0.001 for CD31⁺, p<0.001 for GSUS scores respectively). Finally, the areas under the receiver operating characteristic (ROC) curves CD31⁺ vessels count (cut-off value: 24.3), GS score (cut-off value: 1.5) and PDUS score (cut-off value: 1.5) were calculated to assess the best cut-off points to identify the differentiation likelihood during the follow-up in UPIA patients. The logistic regression analysis, demonstrated that having baseline GSUS and PDUS scores >1.5 [OR:13.64 (95% CI: 0.98–242.59); p=0.05] and CD31⁺ vessels count >24.3 [OR:51.13 (95% CI: 3.15–829.16); p=0.01] were independent factors associated with the achievement of defined arthritis.

Conclusions: Histological and US assessment may help in the identification of patients with seronegative UPIA with high likelihood of clinical differentiation towards defined arthritis.

FURTHER TREATMENT INTENSIFICATIONS IN UNDIFFERENTIATED AND RHEUMATOID ARTHRITIS PATIENTS OVER TIME. PATIENTS IN LOW DISEASE ACTIVITY HAVE LIMITED BENEFIT TOWARDS PHYSICAL FUNCTIONING

S.A. Bengts1, O. Olivar2, A. Gakdemir1, N. Rijiayi3, Q. Collée3, J.H. Van Groenendael4, R.B. Landewé4,5,6, C.F. Allaart1,1, R. Rheumatology, LUMC, Leiden, Netherlands; 2Rheumatology, Hospital Universitario 12 de Octubre, Madrid, Spain; 3Medical Center Haaglanden, The Hague; 4Reumazorg Southwest Netherlands, Bergen op Zoom; 5Amsterdam Rheumatology & Immunology Center, Amsterdam Medical Centre, and Medical Center, Heerlen, Netherlands

Background: It is recommended to optimize treatment as long as a predefined treatment target is not met, but should we aim at remission if patients are in low disease activity (LDA)?

Objectives: To assess if RA or undifferentiated arthritis (UA) patients who achieved LDA benefit with better functional ability from treatment intensification aimed at DAS remission.

Methods: In the IMPROVED study 610 patients with early RA (ACR 2010) or UA were “treated to target” aimed at DAS remission, assessed 4-monthly. Initial treatment was methotrexate (MTX) + tapered high dose prednisone. Patients with DAS ≤ 1.6 tapered treatment. Patients with DAS > 1.6 were randomized to MTX + tapered high dose prednisone or to MTX + adalimumab. Over 5 years, patients with DAS > 1.6 were required to increase, change or restart medication. HAQ was measured 4-monthly. A linear mixed model analysis with confounders.

Results: Overall, over 5 years DAS (baseline mean (SD): 3.2 (1.7) and HAQ (1.2 (0.7)) showed a statistically significant and clinically relevant decrease (ΔHAQ -0.59, 95% CI -0.61; -0.57; ΔDAS -1.77, 95% CI -1.79; -1.75). The number of patients in LDA per visit ranged from 88 to 146, of which 26% to 73% (increasing over time) had no treatment change due to protocol violations. We found a statistically significant but not clinically relevant effect of treatment change on ΔHAQ, corrected for baseline HAQ, age, gender and treatment arm (model 1, β -0.085, 95% CI -0.13; -0.044). When ΔDAS was added (model 2), the effect of treatment change was partly explained by ΔDAS and no longer statistically significant (β -0.002; 95% CI -0.006; 0.015). The effect of treatment intensification on HAQ improvement became less over time, as demonstrated by a statistically significant interaction between change in HAQ and time in follow-up model 3 (β 0.0098, 95% CI 0.0010; 0.019) (table 1).

Conclusions: Treatment intensification in early RA or UA patients who already achieved low disease activity is associated with a statistically significant decrease in HAQ, but not with a clinically meaningful improvement in functional ability. The effect on ΔHAQ decreased with increasing follow-up time. Therefore not remission or low disease activity, but good functional ability may be the optimal treatment target at which to steer treatment adjustments. These results suggest that, whereas remission may be the optimal goal, when patients in low disease activity have acceptably low HAQ, further treatment intensification may only have downsides such as side effects and costs.

THE TIME UNTIL PERFORMING TIGHT CONTROL AS A TREAT-TO-TARGET STRATEGY AND THE TOLERABILITY OF METHOTREXATE STRONGLY INFLUENCE THE ACHIEVEMENT OF CLINICAL REMISSION IN RHEUMATOID ARTHRITIS

T. Hagiwara, K. Kamada, N. Namura, Rheumatology, Takarazuka City Hospital, Takarazuka, Japan

Background: Clinical remission (CR) is the first targeted outcome of early treatment for rheumatoid arthritis (RA). Therefore, a consensus is needed for achieving CR by using the treat-to-target (T2T) strategy in RA treatment. However, in patients who received long-term insufficient treatment for RA, achievement of CR becomes increasingly difficult, especially if there is delay in the treatment. We believe that making primary-care physicians aware of treatment results will increase the remission rate of RA.

Methods: We examined 388 patients with RA who were observed between January and October 2016 and who had not received new disease-modifying anti-rheumatic drugs (DMARDs) more than 3 months before the observation day. We investigated their age at RA onset, sex, Steinerbrock radiographic stage and functional class, activity level, rheumatoid factor (RF), the anti-cyclic citrullinated peptide antibody and DMARDs prescribed at the first consultation (Prescribed Before), disease activity, status of methotrexate (MTX), glucocorticoids (GCs), and biologic agent use at the last observational day.

Results: We analysed the assumed remissions by using the Boolean-based definition (Boolean remission) as a purpose variable for these factors. Furthermore, we examined the odds ratio (OR) and 95% confidence interval (95% CI) by using a multiple logistic regression analysis for the statistically significantly different factors.

As for the time-related factor, we recognized that each factor had distinct multiplex collinear characteristics. Therefore, we adopted the time required for the first consultation as disease duration with the most effective values as the analysis object. The representative factor for the functional assessment adopted class according to the number of effective analyses.

Results: We recognised the statistically significant differences in disease duration, stage, class at the time of the first medical examination, RF, Prescribed Before, and state of MTX and GCs use at the last observation day for the achievement of Boolean remission.

We examined the multiple logistic regression analysis with the previously mentioned results and obtained the following results.

- Disease duration (per 1 year); OR 1.110, 95% CI 1.048–1.175, p<0.001.
- MTX (state; using vs no using); OR 2.522, 95% CI 1.560–4.076, p<0.001.
- GCs (state; no using vs using); OR 1.803, 95% CI 0.912–3.565, p=0.090.
- Disease duration (≥ 1.605y vs > 1.605y); OR 2.233, 95% CI 1.437–3.470, p<0.001.
- MTX (state; using vs no using); OR 2.566, 95% CI 1.644–4.291, p<0.001.
- Class at 1st interview; OR 1.589, 95% CI 1.181–2.136, p=0.01.
- Class at 1st visit; OR 1.512, 95% CI 1.126–2.029, p<0.01.
- GCs (state; no using vs using); OR 1.883, 95% CI 0.956–3.711, p=0.067.

Conclusions: Our results indicated the importance of the time required for consultation facilities with the T2T strategy treatment, tolerability for MTX use, and mild dysfunction at the first interview. The window of opportunity to achieve remission for patients with RA has less time than expected. Therefore, we recommend that physicians should introduce patients with RA to a rheumatologist following the T2T strategy promptly when the primary care provided by the family physician is insufficient.
A RAPID3-LIKE INDEX DOCUMENTS SUPERIOR EFFICACY OF BARICITINIB VERSUS ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Pincus1, B. Zhu2, C.J. Larmore2, J.D. Bradley2, N. Patel2, C.L. Gaich2, A.E. Koch2.
1Rush University Medical Center, Chicago; 2Eli Lilly and Company, Indianapolis, United States

Background: RAPID3 (Routine Assessment of Patient Index Data) indicates differences in efficacy of active versus control treatments at levels similar to DAS28 and CDAI (Disease Activity Score 28-Erythrocyte Sedimentation Rate) and CDAI (Clinical Disease Activity Index) in clinical trials of adalimumab, abatacept, certolizumab.

Objectives: To compare improvement according to RAPID3, DAS 28-ESR, and CDAI in the RA-BEAM trial of baricitinib vs adalimumab and placebo.

Methods: Post-hoc analyses were performed of the RA-BEAM trial, in which patients with moderately to severely active rheumatoid arthritis and an inadequate response to methotrexate (MTX) were randomized to baricitinib, adalimumab, or placebo. All patients were to continue stable background MTX and other DMARDs, as well as stable low-dose prednisone and/or NSAIDs, if indicated. A RAPID3-like index was computed from 3 measures: physical function (FN), pain (PN), and patient global assessment (PATGL). FN on a HAQ (Health Assessment Questionnaire) of 20 items [rather than MDHAQ (multidimensional HAQ) of 10 items] was recalculated from 0–3 to 0–10; PN and PATGL (visual analog scales) were recalculated from 0–100 to 0–10, for a 0–30 total score, hence “RAPID3-like”.

Conclusions: RAPID3-like documented greater efficacy of baricitinib versus adalimumab and placebo in the RA-BEAM trial, with results in similar ranges to DAS28-ESR and CDAI. RAPID3 is feasible to provide quantitative, standard medical history data; almost of the time and effort is by the patient rather than a health professional, assuring quantitative data in the infrastructure of usual clinical care.

SAT0071 RHEUMATOID ARTHRITIS (RA) REGISTRY IN AKITA PREFECTURE, WHERE AGING IS THE MOST ADVANCED IN JAPAN

T. Aizawa, K. Tsuchikawa, Y. Miyaki, Y. Shimada, and K. Inoue, Department of Orthopedic Surgery, Kitakita Municipal Hospital, 1, Kitakita City, Akita, Japan.

Background: The rate of aging (percentage of population aged 65 years and over) in Akita Prefecture is 33.8% (26.6% for the whole of Japan), the highest throughout Japan. The Akita Orthopaedic Group on Rheumatoid Arthritis (AORA) was established in 2010. Since then, patients have been enrolled every year to prepare the registry.

Objectives: To compare patient characteristics as well as clinical effectiveness between the treatments with and without use of methotrexate (MTX) and a biological (BIO) using the data of the AORA registry.

Methods: The subjects were 2,016 patients enrolled in the Akita registry in 2015. The subjects included 403 men and 1,613 women. According to the use of MTX and BIO, 2,016 patients were divided into the group treated with no use of MTX or BIO (group A), that treated with BIO, but no use of MTX (group B), that treated with MTX, but no use of BIO (group C), and that treated with MTX and BIO (group D).

Results: The subjects were grouped into group A (n=873), B (n=153), C (n=805), and D (n=385). MTX was used in 59.2% and BIO was used in 26.7% of all patients. The mean ages were 69.6 years (group A), 67.5 years (group B), 65.6 years (group C), and 62.6 years (group D). The aging rates were 67.9% (group A), 55.6% (group B), 56.8% (group C), and 48.3% (group D), which shows that aging was more advanced in group A.

The results of patients with a complication of hypertension, diabetes, respiratory disease, cerebrovascular disease, heart disease or malignant tumour were 52.0% (group A), 54.2% (group B), 45.3% (group C), and 40.8% (group D). The incidence of complication was the lowest in group D.

The rates of patients who received one or more of conventional synthetic disease-modifying antirheumatic drugs (cs DMARDs) other than MTX were 79.0% (group A), 42.5% (group B), 39.9% (group C), and 19.2% (group D). Although bucillamine and salazosulfapyridine were frequently used in any group, concomitant use of tocilizumab was remarkable in group A, and C, while that of iguratimod was remarkable in groups C and D. The rate of use of a prednisolone (PSL), was significantly higher in group B. The dose of PSL was significantly higher in group A. In regard to BIO, three drugs of etanercept, tocilizumab, and abatacept accounted for 90% in group B. In group D, etanercept and tocilizumab were also frequently used, followed by infliximab, adalimumab, golimumab and abatacept. In DAS28ESR, the rate of combined low disease activity and remission was significantly higher in group D. The mean values of C-reactive protein (CRP) (mg/dL) were 0.61 (group A), 0.52 (group B), 0.47 (group C), and 0.35 (group D), which shows that the mean value was significantly higher in group A than group D.

Conclusions: Using the AORA registry, we compared patient characteristics as well as clinical effectiveness between the treatments with and without use of MTX and BIO. Since in group A, neither MTX nor BIO could be used in most patients, one had to practically rely on PSL. The study suggests that remission needs to be achieved prior to increase in complication due to aging.

or remission. Rescue rates were 7.3% for bari 4mg, 17.1% for bari 2mg. Most rescued patients could regain LDA or remission. Dose reduction was associated with a lower rate of non-serious infections; rates of SAEs and AEs leading to discontinuation were consistently seen with dose reduction from 4mg to 2mg in well-controlled pts. However, after step-down most pts could maintain LDA or remission, or recapture control with return to 4mg if needed. Attempted dose taper may be a reasonable consideration for some pts following induction of sustained disease control with bar 4mg.

**SAT0074 PERSISTENCE WITH METFORMIN TREATMENT AND ONSET OF RHEUMATOID ARTHRITIS**

M.E. Naffaa 1, V. Rosenberg 2, G. Chodick 2,3, V. Shalev 2,3, S. Tiosano 3,4, H. Amital 3,4, 1Rheumatology unit, Galilee Medical Center, Nahariya; 2Maccabi Healthcare Services; 3Sacker Faculty of Medicine, Tel-Aviv University, Tel-Aviv; 4Internal Medicine B’, Sheba Medical Center, Ramat-Gan, Israel

**Background:** Several studies have suggested that metformin, an oral hypoglycemic agent, possess an anti-inflammatory property and may have a role in the treatment of rheumatoid arthritis (RA)1,2, but little is known on its preventive effects.

**Objectives:** To examine the association between persistence with metformin and the onset of RA.

**Methods:** Using the computerized medical database of a large health organization in Israel (Maccabi Healthcare Services, MHS) we have identified incident RA cases among new users of metformin between 1998 and 2014. Included were patients aged 18 or above with one year of follow up before and after the therapy initiation. RA was defined according to physician diagnoses. Participants were followed until the earliest of the following dates: onset of RA, leaving MHS, death, end of follow up (1.1.2016). Persistence with metformin was assessed by calculating the mean proportion of follow-up days covered (PDC) with metformin during the study period.

**Results:** A total of 113,749 eligible patients were included. During the study follow up period (794,386 person-years) we identified 600 incident cases (incidence rate of 75 cases per 100,000 PY). The incidence of RA in women (111 per 100,000 PY) was higher compared to men (42 per 100,000 PY). In a multivariable model, persistence with metformin (PDC≥80%) was associated with lower risk of RA (hazard ratio (HR) 0.66; 95% confidence interval (CI) 0.53–0.82) compared to non-persistent participants (PDC<80%). Figure 1 shows the hazard function according to persistence with metformin treatment. Similar risk reduction was observed among men but did not reach statistical significance (HR=0.85; 95% CI 0.54–1.32).

**Conclusion:** In the present study, we observed an association between high persistence to metformin therapy and reduced risk of developing RA in women.
Doe Early Remission Lead to Better 5-Year Outcomes Than Low Disease Activity? Results from the Real Life Nor-Dmard Study

Background: When initiating therapy with synthetic disease-modifying anti-rheumatic drugs (sDMARDs) in patients with rheumatoid arthritis (RA), the recommended target is remission or low disease activity (LDA). Limited data exist on the impacts of reaching remission rather than LDA on long-term outcomes. Objectives: To compare RA-patients who achieved Simplified Disease Activity Index (SDAI) remission versus LDA 6 months after initiating sDMARD therapy, with regard to physical function, Health Related Quality of Life (HRQoL) and disease activity during 5 years of follow-up in a routine clinical setting. Methods: Data were provided NOR-DMARD, a prospective multicentre longitudinal observational study. We selected DMARD-naive patients with RA enrolled between December 2000 and April 2009 who had a registered visit with available SDAI status 6 months after initiating sDMARD therapy. Data on each patient were collected at baseline, after 3, 6 and 12 months, and yearly thereafter, including the Modified Health Assessment Questionnaire (MHAQ), the Medical Outcomes Study 36-item Short-Form Health Survey (SF-36) with Physical and Mental Components Summary scores (PCS and MCS, respectively) and SF-6D, and assessments that allowed the calculation of the composite disease activity scores SDAI, Clinical Disease Activity Index (CDAI) and the Disease Activity Score based on 28 joint counts (DAS28), Multivariate linear mixed models were used to explore the effect of SDAI status at 6 months on physical function (MHAQ), HRQoL (SF-36 PCS and MCS, SF-6D) and disease activity (SDAI, CDAI, DAS28) during 5 year follow-up. The statistical models were adjusted for age, gender, disease duration and baseline disease activity. Furthermore, we performed mixed model analyses separately for patients in LDA, MDA and HDA at baseline, exploring the impact of SDAI status at 6 months on long-term disease activity in each sub-group. Results: Of 1148 eligible patients, 867 patients (75.5%) started with methotrexate in monotherapy and 281 (24.5%) started with another sDMARD or sDMARD combination. Patients in SDAI remission (n=145; 16.6%) rather than LDA (n=454; 39.5%) 6 months after initiating therapy had better physical function (MHAQ), estimated mean difference 0.11–0.20, p<0.002, higher SF-36 PCS (4.13–8.16, p<0.003) and SF-6D (0.06–0.12, p<0.0001), and lower disease activity (SDAI, DAS28, CDAI, DAS28) 5 years after follow-up. The statistical models were adjusted for age, gender, disease duration and baseline disease activity. Furthermore, we performed mixed model analyses separately for patients in LDA, MDA and HDA at baseline, exploring the impact of SDAI status at 6 months on long-term disease activity in each sub-group. Conclusions: The achievement of SDAI remission 6 months after initiating DMARD-therapy was associated with favourable long-term outcomes compared with the achievement of SDAI low disease activity. The results from the study support that stringent remission is the optimal treatment target in patients with RA.

Serum Level of Syndecan-4 And Its Correlation With Clinical Parameters In Rheumatoid Arthritis Patients

X. Ye, J. Zhao, Z. Zhang. Rheumatology and Clinical Immunology Department, Peking University First Hospital, Beijing, China

Background: Heparan sulfate proteoglycan syndecan-4 plays an important role in inflammation. However, the role of syndecan-4 in rheumatoid arthritis (RA) has not yet been elucidated. Objectives: To detect serum level of syndecan-4 in RA patients and investigate its correlation with RA clinical parameters. Methods: The concentration of serum syndecan-4 was assayed by enzyme-linked immunosorbent assay (ELISA). 43 patients' serum samples from our RA cohort study between 2014 and 2016, and 20 age- and gender-matched osteoarthritis (OA) patients' serum samples were collected and analyzed. Compared the serum syndecan-4 levels in RA patients with DAS28 ≥3.2 and DAS28 ≥3.2 by Wilcoxon signed rank test. The relationships between serum syndecan-4 levels and RA clinical parameters (DAS28, rheumatoid factor (RF), erythrocyte sedimentation rate, C-reactive protein, etc.) were analyzed. Results: Baseline serum syndecan-4 levels of RA patients were significantly higher than the matched OA patients (1101.56 pg/mL vs 281.41 pg/mL, p<0.0001). In RA patients who had sera both at the point of DAS28 ≥3.2 and DAS28 ≥3.2 (n=13), we found that the former syndecan-4 levels were higher than the latter (1666.22 pg/mL vs 1378.34 pg/mL, p<0.05). The levels of serum syndecan-4 and RF were significantly and positively correlated in RA patients (r=0.696, p=0.008). Furthermore, there is a tendency that serum syndecan-4 levels were higher in the RF-positive (n=31) than in the RF-negative (n=12) RA patients (1344.43 pg/mL vs 971.27 pg/mL, p=0.078).

Conclusions: Compared with age- and gender- matched OA patients, serum syndecan-4 concentration is significantly higher in RA patients. Serum syndecan-4 level is positively correlated with RF. Syndecan-4 may play an important role in the pathogenesis of RA. Further investigation is required to study the mechanism of syndecan-4 in RA.

Clinical Features and Perforin A91V Gene Analysis in SOJA Children With Macrophage Activation Syndrome

X. Chen, H. Zeng. 1 Department of Pediatric Allergy, Immunology and Rheumatology; 2 Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children’s Medical Center, Guangzhou, China

Objectives: Macrophage activation syndrome (MAS) is a severe, potentially life-threatening syndrome. Here we aim to review the precipitating events, clinical features, treatment, outcome and perform A91V gene analysis in systemic onset juvenile idiopathic arthritis (SoJIA) children with MAS.

Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.3874
Methods: Retrospective review of cases of MAS from a collected database of fourteen children with SoJIA from 2003 to 2008. Gene-specific polymersase chain reaction (PCR) primers were used to analyze the perforin A91V gene polymorphism.

Results: Fourteen patients (nine boys) were considered to have evidence of MAS, with age ranged from 4 months to 12 years. The primary diagnosis was systemic onset juvenile idiopathic arthritis. No medication was identified as trigger. Eleven had infections prior to MAS, specific infectious agents were identified in four. High fever, new onset hepatosplenomegaly, lymphadenopathy, liver dysfunction, abnormal lipid metabolism and hemophagocytosis were common clinical features. Two cases were with acute respiratory distress syndrome (ARDS), multiple organ failure (MOF) in three and three died. The perforin A91V (NCBI:SNP rs35947132) variant gene was detected in seven systemic onset juvenile idiopathic arthritis complicated with MAS cases, but no mutation were found. Glucocorticoid, intravenous immunoglobulin, immunocompressive therapy were effective and HP (Plasmasphere) used in one serious case was also effective.

Conclusions: MAS is a rare and potentially fatal complication of childhood rheumatoid diseases, especially systemic onset juvenile idiopathic arthritis. Most of our patients were male, and most cases were preceded by infection. Bone marrow studies support the diagnosis. MOF may be a poor prognostic sign. Aggressive early therapy is essential.

SAT0078 MAGNETIC RESONANCE IMAGING OF THE HANDS IN RHEUMATOID ARTHRITIS: UNILATERAL OR BILATERAL?

1Rheumatology; 2Radiology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University; 3Zhongshan School of Medicine, Guangzhou, China

Background: MRI had higher sensitivity of detecting inflammation than physical examination and higher examination of detecting bone damage than X-rays. Physical examination and X-rays are usually performed on bilateral hands of RA patients, however, MRI evaluation of unilateral hand was recommended by OMERACT at the very beginning when RA MRI score (RAMRIS) was validated in the databases.

Objectives: To explore the advantages of bilateral hands MRI on RA.

Methods: Consecutive hospitalized RA patients were recruited from April 2014 to April 2016 at Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University. Together with assessing swelling and tenderness of 28 joints essential for DAS28, bilateral wrists and MCPJ2–5 of each patient were scanned simultaneously on 3.0T MRI system. MRI synovitis, osteitis and bone erosion were scored referred to the definitions and atlas of RAMRIS system.

Results: (1) Among 120 RA patients were included, 79% were female, age (median and IQR, similarly hereinafter) was 52 (44–61) years, disease duration was 48 (12–120) months and DAS28-crp was 5.9 (4.7–6.9). The mean imaging time for the entire MRI examinations including the time of patient positioning and contrast agent injection was 23 minutes. The mean scoring time was 10 minutes for RAMRISbilateralhands and 7 minutes for RAMRIS unilateral-hand. Interreader ICC for RAMRIS_bilateral_hands was 0.852 in synovitis, 0.739 in osteitis and 0.815 in bone erosion. (2) The mean imaging evaluation time was 23 minutes. The other 50 patients had equally severe involvement at physical examination. (3) Of wrists with MRI synovitis, osteitis and bone erosion per joint or bone were shown in figure 1A. For MCPJ2–5, 27%–42% of RA patients showed unilateral synovitis, 45%–53% showed unilateral osteitis and 51%–69% showed unilateral bone erosion (Figure 1B).

Conclusions: Performing MRI of bilateral hands yields additive information compared with imaging only unilateral hand.

SAT0079 ASSOCIATION OF ALCOHOL CONSUMPTION AND DISEASE ACTIVITY IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: ANALYSIS OF THE IORRA COHORT

Y. Shimizu1, E. Tanaka1, E. Inoue1,2, M. Ochiai1, R. Yamaguchi1, N. Sugimoto1, A. Nakajima1, K. Ikarı1, A. Taniguchi1, H. Yamanaoka1, 1Tokyo Women’s Medical University Institute of Rheumatology; 2National Center for Child Health and Development Center for Clinical Research for Development, Tokyo, Japan

Background: While the results of several observational studies suggest that light-to-moderate alcohol consumption may decrease the risk of susceptibility to or severity of rheumatoid arthritis (RA) (1–3), findings regarding the effect of alcohol consumption on RA disease activity are conflicting. Furthermore, there are few reports of longitudinal studies regarding the effect of alcohol consumption on RA disease activity. In addition, although alcohol consumption in the Japanese general population was lower than that in European countries, according to the 2011 World Health Organization’s Global Status Report on Alcohol and Health, there are few reports specifically concerning alcohol consumption in Japanese RA patients.

Objectives: To examine the longitudinal relationship between alcohol consumption and changes in disease activity in patients with RA using the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort database.

Methods: Subjects were RA patients who participated in the IORRA cohort study between October 2014 and October 2015. Patients were assigned to one of 5 groups according to alcohol-drinking status at baseline: the non-drinking group, drinking group 1 (0 g < Alco-drink ≤ 14 g), drinking group 2 (14 g < Alco-drink ≤ 28 g), drinking group 3 (28 g < Alco-drink ≤ 50 g), and drinking group 4 (50 g < Alco-drink). Multiple regression analyses were used to examine the relationship between alcohol consumption and baseline DAS28, and change in DAS28 between baseline and 1 year.

Results: Data from a total of 4,695 Japanese patients with RA (female: 86.6%, mean age: 61.3 years old, mean disease duration: 15.2 years, and mean DAS28: 2.5) were utilized. The main characteristics of the database were: male, mean age, mean disease duration, mean DAS28 at baseline/after 1 year in the non-drinking group, and drinking groups 1, 2, 3, and 4 were 2.735 (92.8%, 64.0 years old, 16.1 years, 2.7/2.7), 646 (89.9%, 58.7 years old, 14.8 years, 2.4/2.5), 497 (82.5%, 56.7 years old, 13.8 years, 2.3/2.3), 444 (71.6%, 56.4 years old, 13.0 years, 2.3/2.3) and 373 (58.2%, 57.5 years old, 13.7 years, 2.2/2.3), respectively. Baseline DAS28 in drinking groups 2 (p=0.02), 3 (p<0.01), and 4 (p<0.01) was significantly lower than that in the nondrinking group. Multivariate regression analysis revealed that there was no association between alcohol-drinking status and the change in DAS28 at 1 year, after adjusting for DAS28 at baseline.
SAT0080 | CLINICAL SIGNIFICANCE OF SOLUBLE CD163 IN REFRACTORY SYSTEMIC-ONSET IDIOPATHIC ARTHRITIS

Y. Cui 1, H. Zeng 2.

1Department of Pediatric Allergy, Immunology and Rheumatology; 2Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children’s Medical Center, Guangzhou, China

Objectives: The present study explored the correlation of soluble CD163 with refractory systemic-onset juvenile idiopathic arthritis (refractory So-JIA) as well as the clinical significance of soluble CD163 in (refractory So-JIA).

Methods: A total of 33 young patients diagnosed with So-JIA in the active period and 30 young patients diagnosed with So-JIA in the inactive period at Guangzhou Women and Children's Medical Center (Guangzhou, China) from January 2010 to January 2012 as well as 40 age-matched healthy individuals, who had visited the hospital for medical examination in the same time-period were enrolled in the present study. Flow cytometry was used to determine the lymphocyte count and ELISA was adopted for determining the levels of soluble CD163 in serum

Results: The levels of soluble CD163 and their correlation with indexes of disease activity were observed. In patients with So-JIA in the active period, the levels of soluble CD163 and the TOEL count were significantly higher than those in the inactive So-JIA and healthy individuals (P < 0.05). Furthermore, the levels of soluble CD163 were positively correlated with C-reactive protein, ferritin, erythrocyte sedimentation rate, white blood cell count and immunoglobulin E as indexes of disease activity (P < 0.05).

Conclusions: Soluble CD163 is a more valuable index for early recognition refractory active So-JIA, which can provide a basis for active period development and clinical observation. Disclosure of Interest: None declared

SAT0082 | THE INVESTIGATION FOR THE INFLUENCE OF SILASTIC ARTHROPLASTY OF METACARPOPHALANGEAL JOINT ON THE ACTIVE EXTENSION RANGE OF PROXIMAL INTERPHALANGEAL JOINT IN THE RHEUMATOID HAND

Orthopedic Surgery, Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan

Background: The ulnar deviation (UD) deformity of the metacarpophalangeal (MCP) joints is a typical deformity in the patients of rheumatoid arthritis (RA). Joint replacement arthroplasty can be indicated for the treatment of severe UD deformity, silastic prostheses being widely used with generally good results [1]. There are few, however, previous reports focusing on the relationship between the range of motion (ROM) of the MCP and PIP joints after the surgery.

Objectives: The objective of this study was to investigate the relationship of silastic replacement arthroplasty of MCP joint replacement on post-operative extension range of PIP joint of the same finger.

Methods: RA patients who underwent silastic replacement arthroplasty of at least 1 MCP for the treatment of UD deformity were reviewed. There were 80 hands of 65 patients, average age of whom was 70.1 (32.4 - 86.1) years old, 56 patients being female and 9 being men. The ROM of the PIP joints before and after surgery was recorded from the medical records, and the relationship between the post-operative change of ROM in PIP joints and post-operative ROM of the MCP joint of same finger was examined. Paired t-test and the correlation coefficient were used for statistical analysis.

Results: The mean active extension range of PIP joints in index to little finger changed from -0.68° (-56.3-30.0) to 0.92° (-52.3-30.0) [P < 0.05], -6.4° (-104.0 to -30.0) to 8.41° (-56.3-112.0) [P < 0.05]. Non-PIP joint (T1FI as reference) changed from 0.29° (0-30.0) to 0.12° (-76.0-30.0) [P < 0.05]. Methotrexate use 0.084 0.12 0.51

Conclusions: In our multicenter study using a linear mixed-effect model including between-institution variation as a random effect, RF positivity, in addition to some well-known variables, was found to be independently associated with decreased effects of bDMARDs treatment in bio-naive RA patients. Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.1508

SAT0081 | RELATIONSHIP BETWEEN RHEUMATOID FACTOR POSITIVITY AND TREATMENT EFFECT WITH A FIRST BIOLOGIC AGENT IN RHEUMATOID ARTHRITIS: MULTICENTER STUDY USING A MIXED-EFFECT MODEL

Y. Ogawa 1, N. Takahashi 2, N. Ishiguro 2, T. Kojima 2, 1Sakasihiga Hospital, Nakatsugawa; 2Nagoya University Graduate School of Medicine, Nagoya, Japan

Background: Although the presence of rheumatoid factor (RF) may be a risk factor for the onset and progression of rheumatoid arthritis (RA), sufficient literature does not exist to support the clinical relationship between RF positivity and the effects of treatment with biologic disease-modifying antirheumatic drugs (bDMARDs). This multicenter study aims to explore the association of RF positivity with the effects of bDMARDs treatment in bio-naive RA patients using a linear mixed-effect model.

Objectives: In a multicenter study, patients are clustered within institutions, therefore results of adjustment models are likely to be biased by random, unobserved between-institution differences. Such bias could lead to inaccurate prediction and interpretation of outcomes. We used a linear mixed-effect model including between-institution variation as a random effect, which would improve the performance of this multicenter study.

Methods: In total, 625 bio-naive RA patients registered in the Tsurumai Biologics Cooperative Clinical Registry (biologics Japan), a multi-institution registry of 15 affiliated institutions in Japan, who received bDMARDs treatment during the study period (2006–2016) were eligible for inclusion. Demographic information and disease characteristics were assessed at baseline. DAS28 using erythrocyte sedimentation rate was recorded at baseline and following 24 weeks of therapy, in order to predict DAS28 improvement at 24 weeks, a linear mixed-effect model including between-institution variation as a random effect, controlling for RF positivity, age, sex, stage, methotrexate (MTX) use, prednisolone (PSL) use, tumor necrosis factor inhibitor (TNFi) or non-TNFi, and DAS28 at baseline, was developed.

Results: Of the 625 patients, 513 showed RF positivity and 112 were antibody negative. Mean ± SD age at baseline was 56.9±14.0 years; 509 patients were women (81.4%). The mean ± SD DAS28 score at baseline was 5.9±1.24. Proportion of MTX and PSL use were 79.3% and 58.1%, respectively. Following adjustment for relevant covariates, RF positivity was associated with a decrease biologic treatment effect (β = −0.33±0.12, p < 0.05). In another model including an additional interaction term of RF status and TNFi or non-TNFi, the influence of RF status on treatment effect was persistent (β = −0.26±0.14, p < 0.01). These two models had comparable AIC. A model excluding RF positivity term had larger AIC than these two models, suggesting that RF positivity is crucial for predicting the effect of bDMARDs treatment.

Conclusions: In our multicenter study using a linear mixed-effect model including between-institution variation as a random effect, RF positivity, in addition to some well-known variables, was found to be independently associated with decreased effects of bDMARDs treatment in bio-naive RA patients. Disclosure of Interest: None declared

SAT0083  TOCLIZUMAB INDUCED CLINICAL REMISSION IN RHEUMATOID ARTHRITIS PATIENTS: RESIDUAL DOPPLER SIGNALS IN COMPARISON WITH OTHER BIOLOGICS

Y. Hara, Y. Ishida, Y. Yamaguchi, Y. Yoshimine, T. Wibowo, Y. Manabe, M. Yaga, K. Kawamoto, H. Nakahara, S. Higa, T. Igarashi, K. Maeda, A. Ogata. Department of Allergy, Rheumatology and Connective Tissue Diseases, Department of Internal Medicine, Respiratory Medicine, Department of Internal Medicine, West Osaka Medical Hospital, Osaka, Japan.

Objective: To study the residual Power Doppler (PD) signals for assessing synovitis in CRP negative patients with rheumatoid arthritis (RA) treated with biological agents.

Methods: Biologics treated RA patients who were maintained normal CRP for more than 6 months (34 TNF inhibitors, 37 Tocilizumab, 23 Abatacept) were assessed by ultrasonography. Residual PD signals were assessed in MCP, PIP, and wrist joints with both hands. We assumed patients who had any PD signals in assessed joints were “residual PD signals”.

Results: All treated patients with biologics maintained normal CRP for a half year (n=94). 35.1% of patients treated with biologics had positive PD signals. The remission rates of DAS28-ESR, CDAI, and Boolean were 68.7%, 62.8%, and 48.9% respectively. 28.1% of patients who achieved DAS28-ESR remission had residual PD signals, 22.0% in CDAI, and 21.7% in Boolean. 23.8% of patients treated by TNF inhibitors who achieved DAS28-ESR remission had residual PD signals, 34.6% in Tocilizumab, and 20.0% in Abatacept. In case of setting the DAS28-ESR remission less than 3.0, 30.2% of patients who achieved DAS28-ESR remission had residual PD signals, 29.0% in less than 2.0, and 12.5% in less than 1.5. The patients who have no tender or swollen joints and the excellent patient oriented global health assessment (VAS score was zero) had fewer residual PD signals (23.4% vs 68.6% in tender joints, 26.7% vs 66.7% in swollen joints, and 13.3% vs 44.4% in patient VAS).

*TNF inhibitors (Infliximab n=6), Eularcept (n=14), Adalimumab (n=7), Golimumab (n=4), Certolizumab pegol (n=3). ** Residual PD signals: patients who had any PD signals in assessed joints. ***Achieved: remission rate in biologics treated patients who were maintained normal CRP for a half year.

Conclusions: The patients who achieved clinical remission had residual PD signals. Patients with Tocilizumab induced remission had more residual PD signals compared with TNF inhibitor or Abatacept induced remission. More strict criteria of clinical remission may reduce residual PD signals in patients treated by Tocilizumab.

SAT0084 A STUDY ON CHARACTERISTICS OF RHEUMATOID ARTHRITIS PATIENTS ACHIEVING DEPRESSION REMISSION WITH 6 MONTHS OF BIOLOGIC AGENT TREATMENT

Y. Miwa, N. Najima, T. Isozaki, R. Takahashi, Y. Miura, Y. Ikari, M. Hatako, T. Hayashi, T. Kasama, K. Sanada. on behalf of ASHURA Registry Group. Division of Rheumatology, Department of Medicine; Department of Psychiatry, Showa University School of Medicine, Tokyo, Japan.

Background: Approximately 15% of RA patients also suffer from depression, with an odds ratio of 1.42 (95% CI 1.3 - 1.5) compared to the general population [1]. A previous study reported that biological agents can improve the depression status in RA patients [2]. Although previous studies have been cross-sectional, there were no reports that analyzed factors that led to depression remission.

Objective: To examine the relationship between baseline factors and depression remission after six-month biologic agent treatment in rheumatoid arthritis (RA) patients.

Methods: The subjects were 384 RA patients treated with biologic agents. The following patient’s characteristics were investigated: age, gender, number of visits, disease duration, previous biologic agents, baseline steroid dosage, methotrexate dosage and serum matrix metalloproteinase-3 (MMP-3) levels. For evaluation, we used the Simplified Disease Activity Index for RA disease activity; the Health Assessment Questionnaire Disability Index (HAQ-DI) score for activities of daily living; the Short Form-36 for non-specific health-related quality of life; and the Hospital Anxiety Depression Scale (HAD-S) scores.

Depression remission was defined by HAM-D <7 after 6 months of treatment. The subjects were divided into two groups according to the presence or absence of depression, and a retrospective study was performed.

Results: We included 152 patients in the analysis. Two hundred thirty-two

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.2498
patients were excluded due to primary and secondary failure, complications, loss to 6-month follow-up, incomplete data, etc. Compared with a group of RA patients with depression remission (n=124), a group of patients with no depression remission (n=126) (regression coefficient 1.35; 95% CI 0.39–2.31; p=0.006).

Conclusions: Our results demonstrated that the rate of discontinuation due to adverse events by biologics was significantly high in RA patients over 75 years and above.

SAT0088 | HDL CHOLESTEROL EFFLUX CAPACITY IN RHEUMATOID ARTHRITIS PATIENTS: CONTRIBUTING FACTORS AND RELATIONSHIP WITH SUBCLINICAL ATHEROSCLEROSIS

B. Tejera Segura 1, M. Macía-Díaz 2, J.O. Machado 3, A. de Vera-González 3, A. González-Delgado 1, J.M. Omlos 3, J.L. Hernández 1, F. Díaz-González 3, M.A. González-Gay 3, I. Fernández-Amaro 1

1Division of Rheumatology; 2Pharmacology Department; 3Central Laboratory Division, Hospital Universitario de Canarias, Tenerife; 4Department of Internal Medicine; 5Rheumatology Department, Hospital Universitario Marqués de Valdecilla-IDIVAL, Santander, Spain

Background: Lipid profiles appear to be altered in rheumatoid arthritis (RA) patients due to disease activity and inflammation. Cholesterol efflux capacity (CEC) has not only been linked to cardiovascular events in the general population, but also to be impaired in RA patients.

Objectives: To analyze whether CEC is related to subclinical atherosclerosis, as determined by the presence of carotid plaque or increased levels of carotid intima-media thickness (cIMT) in RA patients. Secondarily, we aimed to describe the disease-contributing factors that are related to CEC as an expression of the abnormalities in the lipid profile associated with the disease.

Methods: Cross-sectional study that encompassed 401 individuals; 178 patients and 223 sex-matched controls. CEC was measured using an in vitro assay, lipoproteins serum concentrations, and standard lipid profile were assessed in patients and controls. Carotid intima-media thickness and carotid plaques were assessed in RA patients. A multivariable analysis was performed to evaluate the relation of CEC with RA-related data, lipid profile and subclinical carotid atherosclerosis.

Results: Mean CEC was not significantly different between RA patients (18.9 ± 5.90) and controls (18.6 ± 10.44), p=0.11. Demographic variables were not associated with CEC except for a correlation with male gender that was only found in RA patients, but not in controls. Systolic blood pressure inversely correlated with CEC in controls (beta coefficient -0.01 [0.20–0.01], p=0.025). In RA patients, a similar trend was found although a statistically significant difference was not reached. Neither the traditional cardiovascular risk factors nor the cardiovascular co-morbidity-related data were associated with CEC. Similarly, lipid profile did not show any relationship with CEC in patients or controls. ESR tended to be associated with a lower CEC although it did not reach statistical significance. RA patients with low (beta coeff. -5.2 [-10.0–0.3], p=0.039) and moderate disease activity (beta coeff. -4.6 [-8.5–0.7], p=0.020) were associated with inferior levels of CEC when compared to patients in remission. CEC was not found to be associated with cIMT in RA patients. However, higher CEC was associated with a protective effect for the presence of carotid plaque in RA patients. This relationship was maintained even after multivariate analysis (OR 0.94 [0.93–0.99], p=0.015).

Conclusions: Our study, which includes the largest series of RA patients ever assessed for CEC, reveals for the first time that CEC is related to subclinical atherosclerosis in RA patients. The fact that CEC is also associated with disease activity reinforces the idea that CEC may be a mediator between disease activity and subclinical atherosclerosis.

SAT0089 | COMPARATIVE CARDIOVASCULAR SAFETY OF ABATACEPT AND TUMOR NECROSIS FACTOR INHIBITORS IN RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT TYPE 2 DIABETES: A POPULATION-BASED COHORT STUDY

E.H. Kang 1,2, Y.P. Jin 2, J.G. Bril 2, J.P. Lewey 1,3, E.P. Patorno 1, R. Desai 1, S.C. Kim 1

1Division of Pharmacoeconomics and Pharmacoeconomics, Harvard Medical School and Brigham and Women’s Hospital, Boston, United States; 2Division of Rheumatology, Department of Medicine, National University Bundang Hospital, Seongnam, Korea, Republic of; 3University of Pennsylvania, Philadelphia, United States

Background: Patients with rheumatoid arthritis (RA) are at high risk of developing cardiovascular disease (CVD) and may benefit from potent disease-modifying anti-inflammatory drugs such as biologics. Since diabetes mellitus (DM) is a major risk factor for CVD, RA patients with DM constitute a high CVD risk subgroup calling for particular attention. However, there is a lack of knowledge on the comparative cardiovascular safety of different biologics in RA patients with DM.

Objectives: To examine the comparative cardiovascular safety of abatacept versus TNF inhibitors in RA patients with and without DM.

Methods: RA patients enrolled in both public (Medicare) and commercial (Truven MarketScan) health plans in the U.S. who newly initiated abatacept or TNF inhibitors were eligible. The primary outcome of interest was a composite CVD endpoint of myocardial infarction (MI), stroke/transient ischemic attack (TIA), and coronary revascularization. The secondary outcomes included each component of the composite CVD endpoint and heart failure (HF). After 1 year of exposure, Cox proportional score (PS) matching between two exposure groups, Cox proportional hazard model was used to estimate the hazard ratio (HR) and 95% confidence interval (CI) for each outcome, comparing abatacept to TNF inhibitors. PS matching was separately done in subgroups with or without baseline DM in each database. PS-matched hazard ratios were compared between the two databases were pooled using an inverse variance–weighted fixed-effect model.

Results: We identified 31,899 Medicare enrollees (6,107 new users of abatacept and 25,792 new users of TNF inhibitors) and 71,956 commercial enrollees (6,942 new users of abatacept and 65,464 new users of TNF inhibitors) with RA. Among RA patients, abatacept may be associated with a reduced risk of coronary events compared to TNF inhibitors, particularly in patients with DM. The risk of HF was not different between these two groups.

Conclusions: Among RA patients, abatacept may be associated with a reduced risk of coronary events compared to TNF inhibitors, particularly in patients with DM. The risk of HF was not different between these two groups.

Clinical arthritis is always preceded by subclinical inflammation? A longitudinal study at joint level in patients with arthralgia that developed arthritis.

Rheumatology, Leiden University Medical Centre, Leiden, Netherlands

**Background:** The clinical phase of Rheumatoid arthritis (RA) is preceded by a phase with subclinical inflammation. MRI can detect subclinical inflammation and, at patient level, this is predictive for the development of clinical arthritis. However, at joint level it is unknown how arthritis develops. It is unknown how frequently joints with subclinical inflammation progress to clinical arthritis, and vice versa, how often joints that developed clinical arthritis had local subclinical inflammation during the preceding phase of arthralgia. A longitudinal MRI study in patients that developed arthritis can unravel if arthritis development is restricted to some locations in which the severity of inflammation increases over time or, alternatively, if the process is more generalized with a weak association between the locations of subclinical inflammation and subsequent clinical arthritis.

**Objectives:** This longitudinal study at joint level during progression from pre-RA to RA determined the relation between the location of subclinical inflammation and clinical arthritis over time.

**Methods:** 290 small joints (4 MCPs, 1 wrist, 5 MTPs per person) of 29 patients that presented with arthralgia and developed clinical arthritis were studied with 1.5T MRI at both time-points. MRIs were evaluated for BME, synovitis and tenosynovitis by three readers (ICCs 0.98, 0.96 and 0.97) that were blind to clinical data and the time in order. Subclinical inflammations was defined as presence of BME, synovitis and/or tenosynovitis.

**Results:** The median time between presentation with arthralgia and clinical arthritis development was 17 weeks. At presentation with arthralgia 68 joints had subclinical inflammation and no significant association was found between joint tenderness and the presence of local MRI-detected subclinical inflammation (OR 0.98; 95% CI 0.48–1.9). Over time, 21% of 68 joints had resolution of subclinical inflammation, 60% had persistent subclinical inflammation and 19% developed clinical arthritis. At arthritis development 37 joints were swollen. Of these, 24 (65%) had no prior subclinical inflammation at the time of presentation with arthralgia (Figure).

**Conclusions:** This first longitudinal MRI-study on joint level in pre-RA suggested that the majority of joints that developed clinical arthritis had no (long-lasting) preceding phase with subclinical inflammation.

poorly understood. The study of lipid profiles in RA has been biased towards lipoprotein levels, whereas those of triglycerides (TG) and lipoprotein functionality have been neglected.

Objectives: since recent findings point to an emerging role for TG and TG-rich lipoproteins (TRL) on inflammation, we aimed to evaluate a combined lipid profile clustering. How high TG and low HDL levels (TGhighHDLlow) in RA.

Methods: lipid profiles were analyzed in 113 RA patients, 113 healthy controls (HC) and 27 dyslipemic subjects (DL). A group of 13 biological-naïve RA patients was prospectively followed for 3 months upon TNFα-blockade. Serum levels of inflammatory mediators were assessed by immunoassays. PON1 activity and Total Antioxidant Capacity (TAC) were quantified in serum. PON1 rs662 status was evaluated by RT-PCR.

Results: the prevalence of the TGhighHDLlow profile was similar among RA patients (29/113), HC (30/113) and DL (11/27), linked to higher TRL levels in all groups. However, this profile was associated with increased CRP (p=0.012), TNFα (p=0.004), MCP-1 (p=0.004), IP-10 (p=0.018) and leptin (p<0.001) serum levels in RA, where decreased PON1 activity and TAC were found (both p<0.001). TRL serum levels were positively correlated to inflammatory mediators, whereas a negative association was found for PON1 activity (r=-0.203, p=0.036). These findings remain after excluding patients with previous CV events or those under statins. No associations were observed in the HC and DL groups. When RA patients were stratified by PON1 rs662 status, these associations were restricted to the low activity genotype (QQ) (TNFα: p<0.002, MCP-1: p=0.013, EGF: p=0.047, IP-10: p<0.018 and leptin: p<0.002), whereas no effect of the lipid profile was observed in the QQ/patients harboring the TC or CC genotypes (all p>0.205). As expected, QQ-patients exhibited a lower PON1 activity compared to the other genetic variants (both p<0.010). The TGhighHDLlow prevalence was related to a decreased anti-TNFα usage in the cross-sectional sample (p=0.004). A poor clinical response was associated with an increased TRL levels (p<0.042).

Conclusions: the TGhighHDLlow profile is associated with systemic inflammation, increased TRL levels, decreased PON1 activity and a poor clinical outcome upon TNFα-blockade in RA. Overall, these findings support the link between inflammation and lipid profile, oxidative status and TRL having a pivotal role. The TGhighHDLlow profile can be proposed as a surrogate marker of HDL dysfunction in RA.

SAT0094 METABOLIC AND CARDIO-VASCULAR BENEFITS OF HYDROXYCHLOROQUINE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS
C. Rempenault1, B. Combe1, T. Barnetche2, C. Gaujoux-Viala3, C. Lukas4, J. Morel1, C. Hua1, 1Reumatología, University Hospital La measuring and Montpellier; 2Reumatología, University Hospital Pellegrin, Bordeaux; 3Rheumatology, University Hospital Carémeau, Nimes, France

Background: Cardiovascular disease (CVD) is the leading cause of mortality in rheumatoid arthritis (RA) patients (1). Hydroxychloroquine (HCQ) has been shown to improve major outcomes like survival rates in other inflammatory diseases, like systemic lupus (2).

Objectives: The aim of our study was to access currently available literature on the cardiovascular impact of hydroxychloroquine (HCQ) in patients with RA.

Methods: We systematically searched literature (via PubMed, Embase and abstracts from recent ACR and EULAR congresses) for studies evaluating the effects of HCQ, either in monotherapy or in combination with other conventional synthetic disease modifying antirheumatic drugs (csDMARDs) on cardiovascular outcomes or known risk factors for CVD in RA patients (lipid profiles, diabetes incidence and vascular events), and incidence of CVD). A meta-analysis was performed with Review Manager Software, with random effects models, whenever methodologically possible and relevant. Data were extracted by one investigator and independently checked by another.

Results: The IL discussed the 185 articles and abstracts of potential interest, and further examination resulted in 16 studies fulfilling required criteria for pre-planned analyses regarding the cardiovascular impact of HCQ in RA. For lipid profiles, the mean difference (mg/dL) between HCQ users versus nonusers was -9.82 (95% confidence interval [95% CI] 14.03, 5.60) for total cholesterol, -10.61 [14.17, -7.04] for low density lipoprotein, -18.15 [27.20, 11.10] for triglycerides and +4.13 [2.22, 6.04] for high density lipoprotein (figure 1); with respectively a decrease (mg/dL) of 13.15 [20.96; 5.34], 12.35 [10.14; 4.36], 12.54 [28.94; 3.86] and an increase of 1.67 [0.96, 4.31] after HCQ initiation. Diabetes incidence was reduced in HCQ ever users versus patients who never used HCQ (with a hazard ratio of 0.59 [0.49; 0.70]). In addition, HCQ seems to decrease insulin resistance and incidence of cardiovascular events but data were too scarce for meta-analysis.

Conclusions: Beside its limited efficacy on disease activity, this study supports the interest of HCQ on lipid profiles, and diabetes incidence, and to a lesser extent on cardio-vascular events and insulin resistance in RA patients. These data strongly suggest that HCQ may be of some interest in RA, in combination with other csDMARDs.

Background: Rheumatoid arthritis (RA) patients have higher levels of resistance to the action of insulin (IR) compared to healthy subjects. The increase in IR, is related to beta-cell dysfunction and it can be a consequence of chronic low-grade inflammation, and insulin resistant state that is in turn a risk factor for atherosclerosis. The increase in IR is associated with increased CRP (p=0.010), IP-10: p=0.018, and leptin: p=0.002), whereas no effect of the lipid profile was observed in the QQ/patients harboring the TC or CC genotypes (all p>0.205). As expected, QQ-patients exhibited a lower PON1 activity compared to the other genetic variants (both p<0.010). The TGhighHDLlow prevalence was related to a decreased anti-TNFα usage in the cross-sectional sample (p=0.004). A poor clinical response was associated with an increased TRL levels (p<0.042).

Conclusions: the TGhighHDLlow profile is associated with systemic inflammation, increased TRL levels, decreased PON1 activity and a poor clinical outcome upon TNFα-blockade in RA. Overall, these findings support the link between inflammation and lipid profile, oxidative status and TRL having a pivotal role. The TGhighHDLlow profile can be proposed as a surrogate marker of HDL dysfunction in RA.

Figure 1. Forest plot for the mean difference (mg/dL) between HCQ users and non-users of total cholesterol (A), low-density-lipoprotein (B), high-density-lipoproteins (C), and triglycerides (D).

In RA patients, biventricular systolic-diastolic function of the heart was impaired compared to FM (Table 2). Over the study period, myocardial function improved (Table 2) and DAS28-CRP declined (3.5±1.1 vs 2.3±1.0; p<0.001). Only RA patients had LGE, with no improvement over time (67%).

Conclusions: Myocardial function was impaired in RA patients with active RA compared to FM controls, although the latter group had worse classical CV risk factor profile. After one-year DMARD-treatment targeting to remission, myocardial function improved in parallel with decreasing RA activity. Inflammation seems to be deleterious to the myocardium. Tight control of RA activity may improve myocardial function.

POLYPHARMACY IS ASSOCIATED WITH AN INCREASED RISK OF ADVERSE OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS

A.D. Amarilla Vallejo, A. Rutherford, M. Filkova, M. Molokhia,

E. Nikphorou, S. Norton, K. Hyrich, J. Galloway

Background: In the general population, polypharmacy (PP) is associated with increased risk of adverse events. The relationship between adverse outcomes and PP in Rheumatoid Arthritis (RA) has not been studied in depth. The mantra of RA management encourages PP through combination therapy to deal with the comorbidity associated with RA. The aim of this study was to study the relationship between PP and adverse events in RA, including the influence of DMARDs within the PP count.

Methods: Data from the British Society for Rheumatology Biologics Register were analysed. PP was defined as number of drugs co-prescribed at baseline, with two models: (1) including DMARDs (excluding DMARDs from the medication count). PP was stratified by 0–5, 6–9 and >10. Patients were studied from initiation of at least one biologic until 1st serious adverse event (SAE), 3 years of follow up, or last available visit, whichever came first. A Cox-proportional hazard model was used, with adjustment for a priori selected confounders.

Results: This study included 15,004 patients commencing biologics. The demographics are shown in Table 1. Excluding DMARDs from the PP cohort comprised patients who previously or concurrently started TMP-SMX with biologic treatment with biologics. PP is common in patients with RA and is associated with adverse events especially when patients are on >10 drugs. Excluding or including DMARDs from the PP model had negligible impact on findings. The relationship between PP and comorbidity is worthy of further research, as PP represents a potentially simple but valuable predictor of adverse outcomes, and a suitable surrogate for comorbidity in epidemiological analyses.

ACPA AND ABDOMINAL ADIPOSITY ARE INDEPENDENT PREDICTORS OF INCREMENTS IN BASAL INSULIN IN PATIENTS WITH RA

C. A. Rutherford, M. Filkova, M. Molokhia

Results: We retrospectively analyzed patients classified with RA per ACR 1987 and ACR/EULAR 2010 criteria with at least one year of follow-up in a cohort of RA patients without comorbidities from Hospital Civil ‘Juan I. Menchaca’. Patients who developed IR during follow-up had a mean increase of DAS-28 of 1.27 (P < 0.005 vs patients who improved or never developed IR). Patients positive for ACPA had a greater increase in IR during follow-up. Multivariate analysis revealed that ACPA, increments in WHR and ST4 were independent predictors of basal insulin increases during follow-up.

Conclusions: ACPA and abdominal adiposity (WHR) are independent predictors of IR development in RA

POSSIBILITY OF BACTERIAL INFECTION PROPHYLAXIS OF TRIMETHOPRIM-SULFAMETHOXAZOLE IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS UNDERGOING TREATMENT WITH BIOLOGICS: A SINGLE-CENTER, RETROSPECTIVE, CASE-CONTROL STUDY

E. Kikuchi, N. Aoki, T. Yoshioka, T. Okai

Center for Rheumatology and Joint Surgery, Kawakita General Hospital, Tokyo, Japan

Background: Trimethoprim-sulfamethoxazole (TMP-SMX) is widely used for the prophylaxis of Pneumocystis jiroveci pneumonia (PCP) in immunocompromised patients, but data about the prophylactic effect of TMP-SMX against bacterial infections are insufficient.

Objectives: To analyze the prophylactic effect of TMP-SMX against severe bacterial infections in elderly patients with rheumatoid arthritis undergoing treatment with biologics.

Methods: Data were retrospectively collected from the medical records of patients with rheumatoid arthritis at our center. We divided the elderly patients (65 years or above) who took biologic agents into two groups. The first group (TMP-SMX+) comprised patients who previously or concurrently started TMP-SMX with biologic

agents for the purpose of PCP prophylaxis and continued with it throughout the treatment with biologics. The second group (TMP-SMX+) comprised patients who were not prescribed TMP-SMX throughout the treatment with biologics. We analyzed the retention rate of each group by Kaplan-Meier curves and the Wilcoxon test. The primary end point was the 18-month retention rate of biologics without severe infection (defined as hospitalization or multiple days of intravenous antibiotic treatment in the clinic, including suspected cases).

**Results:** The TMP-SMX+ group included 30 patients with a mean age of 76.7±7.0 years. The rate of ACPA positivity was 80.0%, MTX use was 73.3%, oral steroid use was 43.3%, and bio-naive patients was 73.3%. The number of patients treated with abatacept, certolizumab pegol, etanercept, golimumab, infliximab, and tocilizumab was 13, 7, 7, 1, and 1, respectively. The cumulative retention rates at 12 and 18 months were 1.000 and 0.941, respectively. Prophylactic doses of TMP-SMX were between TMX 20mg/SMX 100mg/day and TMX 91mg/SMX 457mg/day.

The TMP-SMX- group included 113 patients with a mean age of 73.6±5.6 years. The rate of ACPA positivity was 79.3%, MTX use was 70.8%, oral steroid use was 54.9%, and bio-naive patients was 80.5%. The number of patients treated with abatacept, adalimumab, certolizumab pegol, etanercept, golimumab, infliximab, and tocilizumab was 15, 15, 4, 41, 7, 18, and 13, respectively. The cumulative retention rates at 12 and 18 months were 0.812 and 0.790, respectively. There was a significant difference between the retention rates in the two groups (p =0.038, Wilcoxon test). Five patients were enrolled in both groups because another biologic agent was used in different periods.

In the TMP-SMX+ group, only one patient was hospitalized for probable bacterial pneumonia (causative bacteria not detected). In the TMP-SMX- group, nine patients were hospitalized for pneumonia, three for septic arthritis, two for urinary tract infection, and two for soft tissue infection. The causative bacteria were Escherichia coli, Klebsiella oxytoca, Enterococcus faecalis and others.

Furthermore, seven patients in the TMP-SMX- group were treated for PCP, whereas no patients contracted PCP in the TMP-SMX+ group. Furthermore, seven patients in the TMP-SMX+ group were treated for PCP, whereas no patients contracted PCP in the TMP-SMX+ group.

**Conclusions:** Prophylactic administration of TMP-SMX may reduce the risk of bacterial infection in elderly patients with rheumatoid arthritis undergoing treatment with biologics.

**THE EFFECT OF LACTATION ON THE ACTIVITY OF RHEUMATOID ARTHRITIS**

E. Matianova, N. Kosheleva. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

**Background:** It has been reported that rheumatoid arthritis (RA) onset in females is often associated with post-partum period and lactation. Moreover, flares of disease were more frequent, than in non-breastfeeding women during 3 to 6 months period of the follow-up (FUP). RA exacerbations were more frequent in lactating women than in non-breastfeeding women during 3 to 6 months period of the FUP. RA flare was documented based on changes in DAS28CRP score values vs the previous visit following EULAR recommendations.

**Objective:** To assess the prevalence of nocturnal hypertension and its associations in patients with RA.

**Methods:** 62 patients with RA (EULAR 2010) without known cardiovascular disease were examined (73% females, age 58.5±15.4 (M±SD) years, 13% months post-partum. Pts’ median age was 29 (20–37) years, disease duration 8 (1–28) years. RF (62.1%) and ACPA (58.6%) seropositive, of radiographic stage 2–3 (72.4%) and functional class 1–2 (86.2%) prevailed. At each control visit DAS28CRP score and the number of between the visits flares were obtained among breastfeeding and non-breastfeeding women. RA flare was documented based on changes in DAS28CRP score values vs the previous visit following EULAR recommendations.

**Results:** 6 pts were lost for follow up (FUP; the 1 after Mo 37, 5 after Mo 5–6 post-partum). Lactation immediately after birth was suppressed in 5 (15.6%) pts. 27 (84.4%) pts were breast-feeding their babies for the period from 2 weeks to 16 months (Mo=2.5 [1.6] months). All relevant data on the study population during the FUP is summarized in the Table1.

**Conclusions:** Lactation and breastfeeding is associated with 4-fold higher risk of RA exacerbation as compared to non-breastfeeding population (RR=4; 95% CI=1.8;9.2; p=0.0002). Increased RA exacerbation rates among nursing mothers is partially explained by postponement of active therapy. The majority of pts refused initiation of therapy for the sake of breastfeeding.

Approaches to breastfeeding practices in RA mothers should be individual. Nursing is acceptable during RA remission or low disease activity given the patient continues on the recommended drugs, compatible with breast-feeding.
smokers, 61% with AH, 34% with dyslipidemia). Median duration of RA was 8 years (IQR 3–17), Seropositive RA was diagnosed in 69% of patients. Median CRP was 12.1 mg/l (IQR 2.2–23.4 mg/dl), median rheumatoid factor (RF) was 32.5 IU/ml (IQR 8.3–173 IU/ml). All patients received disease-modifying antirheumatic drugs, 22% (38%) - biological treatment. Median duration of AH was 6.1 years (IQR 0–10) years. All patients with AH received antihypertensive treatment. 24h peripheral and central BP monitoring was performed (BenLab Vasotens, “Petr Telegin”). Arterial stiffness was assessed by applanation tonometry (Sphygmocor, AtCor). P<0.05 was considered significant.

Results: Mean office BP was 130±15/82±10 mmHg. Mean pulse wave velocity (PWV) was 8.6±2.8 m/s. Reverse dipping state was as follows: non-dipping in 37% (62.9%) patients, dipping in 7 (11.3%), extreme dipping – in 5 (8.1%) and reverse dipping in 11 (17.7%). Median of nocturnal fall in systolic BP was 3.5% (IQR 0–9%). Isolated nocturnal AH was observed in 12 (19.4%) pts. Patients were divided in three groups according to nocturnal fall of BP: G1 (non-dipping >10%) – 42 (67.7%) pts and G2 (dipping <10%) – 16 (32.3%) pts. Non-dippers were older (56.7±16.2 vs 49±12.5 years), more often were smokers (20 vs 0%), had higher BMI (25.4±6.0 vs 22.3±5.1 kg/m²), median duration of AH (1.5, IQR 0–11 vs 0; min, max 1 year), median duration of RA (10, IQR 7–19 vs 2.5; IQR 2–6.5 years), PWV (8.6±2.8 vs 7.2±2.1 m/s), nocturnal BP (120.4±12.6/69.8±10.4 vs 103.8±8.2/55.4±4.4 mmHg), <0.05 for trend. Spearman analysis revealed significant correlations between nocturnal fall in SBP and RA duration (r=-0.3), reverse dipping and age (r=0.21), age and CRP (r=0.21), and disease duration and prednisone dose. Conclusion: The majority of patients with rheumatoid arthritis are characterized by non-dipping state. Diastolic nocturnal hypertension is a significant predictor of non-dipping in this patient population.

SAT0104 | THE IMPACT OF DISEASE ACTIVITY ON PATIENT REPORTED COGNITIVE Dysfunction (“brain fog”) IN RHEUMATOID ARTHRITIS

G.W. Reed1, L.R. Harrold1, O. Pala2, J.M. Kremer1
1University of Massachusetts, Worcester; 2University of Miami, Miami; 3Albany Medical College and The Center for Rheumatology, Albany, United States

Background: Rheumatoid arthritis (RA) is a systemic, inflammatory disease and its burden extends beyond joint disease. In recent years, there has been significant advances in treating joint disease but we need a greater understanding of physical and especially psychosocial comorbidities to improve quality of life in RA patients. In particular, patients often report “brain fog” meaning a diminished ability to think, learn, remember and perform other mental tasks. Doctors have long recognized that patients with certain physical conditions can experience cognitive dysfunction. Limited information is available in the literature with regard to the prevalence of cognitive dysfunction and factors associated with the condition in RA.

Objectives: To characterize the association of disease activity with patient reported cognitive dysfunction in patients with RA overall and stratified by age.

Methods: We identified patients with RA aged ≥ 18 years who were enrolled in the Canadian registry who were rheumatoid arthritis naïve at their last follow-up visit (October 2010–June 2016). We compared those who reported cognitive dysfunction (responded “yes” to the question asking if they had “problems with thinking”) to those who did not with respect to disease activity based on the Clinical Disease Activity Index (CDAI). Unadjusted and adjusted logistic regression models controlling for demographic (age, gender, race, education), comorbidity/lifestyle (diabetes, fibromyalgia, body mass index, smoking) and RA disease characteristics (disease duration, disability and prednisone dose) were conducted. We further examined whether the relationship between disease activity and cognitive dysfunction varied based on patients age (≤ 55 vs > 55 years) testing the modest effect using a likelihood ratio test.

Results: There were 10,401 patients who met inclusion criteria of whom 883 (8%) reported cognitive dysfunction. Those who reported cognitive dysfunction were more likely to be women (83% vs. 73%, p<0.001), younger (62 vs 64 years, p<0.001), disabled (16% vs. 11%, p<0.001) with higher levels of disease activity based on the CDAI (51% vs. 31%, p<0.001). In adjusted models, the likelihood of cognitive dysfunction increased with higher levels of disease activity in the total population (Table). The impact was more pronounced in those age ≤ 55 (p=0.007; Table).

Conclusions: HBV occult infection seems to influence negatively the effectiveness

SAT0107 FURTHER “WELLNESS” CAN BE ACHIEVED BY SURGICAL INTERVENTION IN THE IMPAIRED HAND EVEN FOR PATIENTS WITH WELL-CONTROLLED RHEUMATOID ARTHRITIS
H. Ishikawa 1, A. Abe 1, Y. Nomura 1, S. Ito 1, T. Kojima 2, M. Kojima 3, N. Ishiguro 1, A. Murasawa 1.
1Rheumatology, Nagata Rheumatic Center, Shibata; 2Orthopedic Surgery, Nagoya University Hospital; 3Medical Education, Nagoya City University Graduate School of Medicine, Nagoya, Japan

Background: The hand is the most frequently involved site in rheumatoid arthritis (RA). The treatment aim of RA is achieving and maintaining remission (REM) or low disease activity (LDA) via tight medical control. However, despite remarkable advances in medication, progressive deterioration and/or deformity of the hand, if adequate medication is not administered in the early stage. Surgical reconstruction is still required in hands with functional loss and/or a grotesque appearance caused by joint deterioration or tendon rupture. Recently, patients have expressed a desire to achieve functional REM with a higher quality of life (QOL) and wellness.

Objectives: The objective of this study was to clarify the systemic effects of surgical intervention in the impaired hand, even in patients with well-controlled disease who have achieved REM or LDA.

Methods: A prospective cohort study was performed in 119 hands of 119 patients with functional loss and/or a grotesque appearance due to RA who underwent primary elective surgery between October 2012 and September 2014. A total of 42 hands in 42 patients (males: 2; females: 40) had a disease activity of REM or LDA just before surgery. In the REM/LDA group, the average (range) age was 61 (29–82) years, and the average (range) disease duration was 15 (2–35) years. The procedures performed included Darrach procedure (ulnar head resection) in 17 hands, radiolunate arthrodesis in 10, extensor tendon reconstruction in 6, thumb/index metacarpophalangeal joint arthroplasty (Swanson) in 14, proximal interphalangeal (interphalangeal) joint fusion in 4, and thumb CM joint arthroplasty (Thompson) in 4 and so on. The patient-reported outcome (PRO) was assessed using the Health Assessment Questionnaire-Disability Index (HAQ-DI), EuroQol-5 Dimensions (EQ-5D), Beck Depression Inventory-II (BDI-II), Patient’s General analogue scale (PS-VAS), modified Health Assessment Questionnaire Disability Index (mHAQ). Drugs administered for patient had been checked at the time of consultation.

Results: On the whole, the physical function (HAQ-DI, DASH, GP), QOL (HAQ-DI, EQ-5D, Pt-GH), mental wellness (BDI-II, Pt-GH), and disease activity (DAS28-CRP) were significantly improved at 6 and 12 months after surgery compared to baseline (p < 0.05). In the REM/LDA group, a significant improvement was noted in the upper-extremity function (DASH), QOL (EQ-5D), and disease activity (DAS28-CRP) at 6 and 12 months after surgery; however, we did not observe any significant changes in any other items (Table 1).

Table 1: Outcome of surgical intervention in the impaired hand for patients with rheumatoid arthritis

Mean(SD); *p<0.05 compared to baseline, **p<0.01 compared to baseline

Conclusions: Achieving REM or LDA is not the ultimate goal of treatment for patients with functional loss and/or a grotesque appearance of their hands. Further “wellness” can be achieved by surgical intervention in the affected hand, even for patients with well-controlled RA. Such intervention can also ameliorate the disease activity.

SAT0108 CLINICAL SIGNIFICANCE OF ANTI-ACTIN ANTIBODIES IN AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES
I. Ayadi 1, L. Laadhari, M. Kallel-Sellami. Immunology, la Rabta Hospital, Tunis, Tunisia

Background: Anti-actin antibodies (AAA) are well-described as the major component of smooth muscle autoantibodies (microfilament antibodies). They are specially detected in patients with chronic active hepatitis (CAH) and celiac disease (CD). AAA have also been found less frequently in various other autoimmune disorders including systemic lupus erythematosus (SLE), Sjogren’s syndrome, and myasthenia gravis, as well as in primary biliary cirrhosis and alcoholic liver disease.

Objectives: to study clinicobiological characteristics of patients with AAA in autoimmune inflammatory rheumatic diseases (AIRD).

Methods: From January to December 2016, we have collected all cases of patients with AAA presenting for symptomatology of AIRD. The presence of AAA was detected fortuitously by indirect immunofluorescence (IF) in accordance with its characteristic fluorescence pattern in Hep2 cells (BioRad®). The specificity for F-actin was confirmed by IIF on rat liver-kidney-stomach sections (Biosystem®) and/or Immunodot (Euroimmun). Coeliac disease related antibodies were performed in all patients with AAA.

Results: Six patients were included: 5 women and a man with a mean age of 43.5 years. AIRD have been suspected in these patients and the mean clinical features were inflammatory polyarthritis and fever. AIRD was diagnosed in three (50%), SLE and five (75%) in patients with rheumatoid arthritis (RA). Hepatic function was disturbed with elevated serum ALT and AST activities in one case highly suspected of CAH. CD was diagnosed in one case. The sixth patient had positive antinuclear antibodies, hypocomplementemia and anti-Ro52, anti-SSB and anti-DFS antibodies associated with FR but didn’t
fulfilled SLE criteria. The immunological tests showed anti-nuclear antibodies among all patients with high titre and anti-DNA antibodies in SLE and CAH patients respectively. One RA patient had anti-Ro60 antibodies.

**Conclusions:** During our study, AAA were found fortuitously in AIRD. This association is rarely described in the literature. Hepatic involvement can be seen as fibromyalgia, depression, etc.). However, DAM and STR may affect clinical management and outcomes of treatment in many RA patients. For example, an RA patient with well-controlled INF who has secondary fibromyalgia may have 0 swollen joints (SJc) and an ESR<15, but nonetheless have a DAS28 of 5.1, CDAD of ≥22, and RAPID3 of ≥16 (indicating high activity), based on 14/28 tender joints and a patient global assessment of 80/100. Therefore, quantitative estimates of DAM, and STR, as well as INF may clarify patient status and clinical management decisions.

**Objectives:** To analyze physician quantitative estimates for the proportion of management decisions attributed to INF, DAM, or STR (total=100%) in RA patients seen in routine care.

**Methods:** At one academic rheumatology center, the rheumatologist completes 0–10 visual analog scales (VAS) for overall global assessment (DOCGL), tender joints and a patient global assessment of 80/100. Therefore, quantitative estimates of DAM, and STR, as well as INF may clarify patient status and clinical management decisions.

**Results:** Among the 77 RA patients, >40% of clinical management decisions were attributed to INF in only 31 (40%), versus >40% to DAM in 33 (43%), and >40% to STR in 17 (22%) (Table). No category of INF+DAM or INF+STR included >60% attributed to INF. Cross-tabulations were computed for various phenotypes in 5 INF+DAM and INF+STR categories, 0, 1–20%, 21–40%, 41–60%, and 61–100%.

**Conclusions:** Physician quantitative estimates of the proportion of clinical management decisions attributed INF, DAM, and STR may help clarify RA patient status and document a basis for clinical decisions. High levels of DAM and/or STR may explain in part why a target of RA remission often is not met in many patients seen in routine clinical care.

**References:**

value -0.05 and \( t = -0.486 \), \( p \) value <0.01 respectively), depressed bronchial resistance SGaw (\( t > 0.773 \), \( p \) value <0.01) and increased RV (\( t = -0.736 \), \( p \) value <0.01), which determined BO severity.

**Conclusions:** More than half of patients with RA have BO predominantly in terminal bronchioles. Accepting significant decrease of Clara cell protein CC16 in patients with RA we suppose pathogenic relationship between functional depression of Clara cell anti-inflammatory activity and BO in this category of patients.

**SAT0112 PREVALENCE AND INCIDENCE OVER 3 YEARS OF DIFFERENT COMORBIDITIES IN RHEUMATOID ARTHRITIS (RA): A 3 YEAR LONGITUDINAL STUDY IN 769 ESTABLISHED RA PATIENTS**

**COMEDRA working group, Paris, France**

**Background:** Comorbidities including cardiovascular (CV) risk, cancer and osteoporosis are frequent in RA.

**Objectives:** To quantify at baseline and 3 years later, the prevalence (at baseline) and incidence (over 3 years) of some selected comorbidities.

**Methods:** This was an open long term (3 years) extension of the COMEDRA 6-month randomized controlled trial in which patients with definite, stable RA were visiting a nurse for comorbidity counselling.[2] Comorbidity status was assessed through face-to-face interviews and nurses provided advice on screening and management, at baseline and 3 years later. The frequency of comorbidities was assessed at both timepoints and incidence of new cases was assessed as overall % of patients and as relative increase in the given comorbidity.

**Results:** Of the 970 recruited patients, 776 (80%) were followed up at 2–4 years (15, 1.5%, had died) and 769 (79%) had available data for comorbidities at both timepoints: at baseline, mean (±SD) age 57 (±11) years, mean disease duration (14, ±10) years; 614 (80%) were women and 538 (70%) were receiving a biologic.

**Table:** frequency of comorbidities at baseline and 3 years later

**Conclusions:** Comorbidities are frequent in RA though screening does not always address the most frequent or severe comorbidities. Efforts must be pursued to improve comorbidity screening and prevention.

**SAT0113 OBESITY AND METABOLIC SYNDROME INFLUENCE ON N-TERMINAL PRO-BRAIN NATRIURETIC PEPTIDE LEVELS IN RHEUMATOID ARTHRITIS PATIENTS**

L. Kondratyeva, T. Popkova, I. Kirillova, D. Novikova, A. Novikov, E. Alexandrova, E. Nasonov. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** N-terminal pro-brain natriuretic peptide (NT-proBNP) is a recognized myocardial injury marker, a known predictor of heart failure and cardiovascular death. Rheumatoid arthritis (RA) patients (pts) were shown to have higher than in general population NT-proBNP concentrations, proportional to serum C-reactive protein (CRP) levels.

**Objectives:** To find out whether obesity/overweight or MS may modify NT-proBNP levels in RA pts.

**Methods:** A total of 68 early RA pts (72% females, 28% males) was enrolled in the study. Mean disease duration was 6 [4;8] months, and RA activity using DAS28 calculator was 5.6 [5.1;6.4] scores. The majority of pts had positive RF (87%) and ACPA (88%). All pts were glucocorticoid and disease-modifying antirheumatic drugs - naïve prior to inclusion. The overweight/obesity was determined by WHO criteria in patients with body mass index (BMI) >25 kg/m2. National Cholesterol Education Program/Adult Treatment Panel III criteria were used to confirm MS. Serum levels of NT-proBNP (pg/mL) were measured using electrochemiluminescence test Elecsys proBNP II (Roche Diagnostics, Switzerland).

**Results:** Overweight and obesity were established in 54,4% RA pts. Overweight/obese RA pts were older than pts with normal BMI (57 [53;61] years vs 48 [34;61] years, \( p <0.02 \)), had higher DAS28 scores (5.65 [5.20;6.57] vs 5.28 [4.76;5.69], \( p <0.01 \)), higher CRP (38.8 [14.3;47.9] mg/L vs 12.8 [2;22.8] mg/L, \( p <0.01 \)). Elevated NT-proBNP concentrations were found in 62.2% overweight/obese pts vs 29.0% pts with normal weight (\( p <0.01 \)). Median NT-proBNP concentrations in overweight/obese pts were 153 [75;226.8] pg/mL vs 72.2 [40;147.4] pg/mL, respectively (\( p <0.02 \)). MS was established in 62.2% pts with BMI >25 kg/m2 and in 25.8% pts with BMI <25 kg/m2 (\( p >0.01 \)). Median NT-proBNP concentrations did not vary significantly in pts with and without MS, whether they were overweight/obese (\( p >0.75 \)), or had normal BMI (\( p >0.27 \)). In 2011, we started a cardiovascular (CV) risk management program for rheumatoid arthritis (RA) patients visiting Reade in the Netherlands. We previously reported the presence of under treatment of hypercholesterolemia and hypertension [1].

**Objectives:** To assess the effectiveness of our CV risk management program in RA patients, using new CV risk stratification tools.

**Methods:** CV risk screening was performed at baseline and informed the general practitioner (GP) about the results, including advices regarding the initiation of cardio preventive drugs. In high risk patients, antihypertensives were prescribed and, if indicated, lipid-lowering drugs. In low risk patients, preventive medication was left to the GP. CV risk screening was repeated after 12 months.

**Results:** Of the 266 patients 202 (76%) were female, the mean age was 58±11 years. After one year, 88 out of 134 patients who received inadequate or no treatment at baseline were still untreated or undertreated. Of the 188 (71%) patients who were at high CV risk and who did have an indication to start therapy, only 7.5% was contacted by their GP and another 6.8% arranged an appointment themselves. While the 10-year CV risk did not decrease in the whole population, a risk reduction was found in the patients that started medication. Remarkably, 42% of patients reported lifestyle changes, including more exercise (20%), diet adaption (16%) and weight loss (9%).

**Conclusions:** It is striking that one year after the introduction of our CV risk management program for rheumatoid arthritis (RA) patients visiting Reade in the Netherlands, we previously reported the presence of under treatment of hypercholesterolemia and hypertension [1].

**Disclosure of Interest:** None declared

**Conclusions:** It is striking that one year after the introduction of our CV risk management program for rheumatoid arthritis (RA) patients visiting Reade in the Netherlands, we previously reported the presence of under treatment of hypercholesterolemia and hypertension [1].
**SA0115** EFFECT OF BIOLOGICAL DISEASE MODIFYING ANTI-RHEUMATIC DRUGS (bDMARDS) ON CARDIOVASCULAR DISEASE (CVD) RISK IN RA PATIENTS: THREE YEARS RESULTS FROM A CANADIAN COHORT

K. Hirose, C. Moro, A. Lewis. 1Rheumatology, Memorial University of Newfoundland, St. John’s, Canada; 2Rheumatology, Mainline Rheumatology Lankenau Medical Center, Philadelphia, United States; 3Epidemiology, Memorial University of Newfoundland, St. John’s, Canada

**Background:** RA patients have a higher risk for developing CV Diseases (e.g. IHD and stroke) than the general population. We reported previously (ACR, EULAR) the results CV risk in our patients treated with bDMARDS for 1 & 2 years.

**Objective:** To assess the effect of bDMARDS treatment on 10-year CV disease risk in patients with RA after 36 months and evaluate the impact of their use on the incidence of CV events.

**Methods:** A cohort of RA patients was followed prospectively. Demographics, disease activity parameters, inflammatory markers, CV events, CVD 10 year risk assessment (Framingham Risk Score (FRS)) were ascertained at the baseline and every six months, up to 36 months. Statistical analysis utilized SPSS (IBM version 24) software.

**Results:** 321 patients were included, of those 270 patients were followed for three years. Eight bDMARDS were included evaluating their effect on disease activity and CV risk in 233 patients who continued on their prospective biologic for the three years.

Significant overall reduction in disease activity in all groups was obtained as compared to baseline. The whole group DAS improved from 3.996 to 3.118.

The HAQ also improved significantly (1.201 to 0.857) and the CRP improved significantly (12.91 mg/L to 7.3).

Overall, Total cholesterol (TC) changed from 5.195 mmol/L at baseline to 4.992 (P 0.001). High Density Lipoprotein Cholesterol (HDL-C) decreased significantly at 36 months from 1.336 to 1.376. The Atherogenic Index (AI) for the whole cohort changed from 3.636 to 3.845. The overall 10 year risk of cardiovascular event increased from 12.878 to 13.8.

The cohort included 321 patients. Eight bDMARDS were evaluated to assess their effect on disease activity and CV risk. The outcomes in 233 patients who continued their prospective biologic for the three years were reported (Table). 77% were females, median RA duration was 11 yrs. Significant reduction in disease activity in all groups was achieved vs. baseline. The DAS improved from 3.996 to 3.118, the HAQ improved significantly (1.201 to 0.857) and the CRP also improved significantly (12.91 mg/L to 7.3).

**Conclusions:** The bDMARDS studied were effective in controlling the disease activity of RA. Although the overall CV risk was not reduced in the group as a whole at 36 months, bDMARDS may still play a role in reducing the CV risk in these patients.

DOI: 10.1136/annrheumdis-2017-eular.3188
Conclusions: Pain is a frequent and relentless suffering during the long-term course of rheumatoid arthritis. In this study, 34% of the patients had unacceptable pain 15 years after diagnosis indicating unsatisfactory treatment. Unacceptable pain also occurred in patients in remission indicating that pain in RA is multifactorial. Therefore, the cause of pain should be identified and treatment initiated accordingly.

SAT0117 RETENTION RATES OF ADAHILUMAB, ETANERCEPT, AND INFLIXIMAB AS 1ST OR 2ND-LINE BIOThERAPY FOR RHEUMATOID ARTHRITIS PATIENTS IN DAILY PRACTICE IN AUVERGNE

M. Soubrier1, B. Pereira2, T. Frayssac1, A. Fan1, M. Couderc3, S. Malochet-Guinamand1, S. Mathieu1, Z. Tatar1, A. Tournadre3, J.-J. Dubost1.

Methods: We have conducted a retrospective cohort study among patients to investigate the safety and efficacy of an alternate-day corticosteroids (CORT) as first-line therapy for rheumatoid arthritis (RA) and is as effective as a daily corticosteroid dose for treating rheumatoid arthritis. The retention rates of the initial anti-TNF treatment (etanercept [ETN], adalimumab [ADA], and infliximab [IFX]) initiated as first-line biotherapy for rheumatoid arthritis (RA) and is as effective as a daily corticosteroid dose for treating rheumatoid arthritis.

Results: Among the 346 patients analyzed, 201 received ETN, 82 ADA, and 63 IFX. The first anti-TNF was interrupted in 151 cases. The retention rates were 82.8%, 67.6%, 46.5%, 28.1%, and 22.5% at 1, 2, 5, 10, and 15 years, respectively, with a median retention duration of 59.2 months (ETN: 59.3 [19.1–104.2], ADA: 79.9 [19.3–136.2], and IFX: 72.7 [17.5–134.5]). The predictive factors of discontinuation were active RA (DAS28-CRP HR: 1.22 [1.03–1.45]), inflammatory syndrome (ESR HR: 1.01 [1.00–1.02], CRP HR: 1.00 [1.00–1.01]), absence of MTX treatment (HR: 0.60 [0.43–0.83]), and corticosteroid use (HR: 1.91 [1.31–2.78]). The patients who switched to another anti-TNF treatment had an inferior retention than those who switched to a non-anti-TNF treatment (HR: 0.39 [0.17–0.87]; p=0.02).

Conclusions: In real-life conditions, the retention rates of the initial anti-TNF treatment (etanercept [ETN], adalimumab [ADA], and infliximab [IFX]) initiated as first-line biotherapy for rheumatoid arthritis (RA) and is as effective as a daily corticosteroid dose for treating rheumatoid arthritis.

SAT0118 SAFETY AND EFFICACY OF ALTERNATE-DAY CORTICOSTEROIDS AS ADJUNCTIVE THERAPY IN RHEUMATOID ARTHRITIS

M. Suda1, S. Ohde2, T. Tsuda1, M. Kishimoto1, M. Okada1.

1Immuno-Rheumatology Center, St. Luke’s International Hospital; 2Center for Clinical Epidemiology, St. Luke’s International University, Tokyo, Japan

Background: Corticosteroids are often used for treating rheumatoid arthritis. However, minimizing adverse events while maximizing efficacy remains challenging. An alternate-day corticosteroid dose is known to decrease adverse events.

Objectives: To investigate the safety and efficacy of an alternate-day corticosteroid dose for treating rheumatoid arthritis.

Methods: We have conducted a retrospective cohort study among patients over 18-year-old who started oral corticosteroids (prednisolone and methylprednisolone) as treatment of rheumatoid arthritis from 2005 to 2014 at St. Luke’s International Hospital, a tertiary-level community teaching hospital in Tokyo, Japan. Patients were included if they met the American College of Rheumatology/European League Against Rheumatism 2010 classification criteria for rheumatoid arthritis, and had positive anti-cyclic citrullinated peptide antibody. They were excluded for a history of corticosteroid use for other diseases, or if they were lost to follow-up within 1 year after starting corticosteroids. We divided patients into a daily corticosteroid group (QD) and an alternate-day corticosteroid group (QOD). Patients received both daily and alternate-day corticosteroids were assigned to the daily group. We investigated the percentage of patients without any infection within 1 year after starting corticosteroids. We have conducted multivariate logistic regression model analysis to calculate adjusted odds ratio for QD/QOD to the outcome. We also investigated the mean decrease in C-reactive protein (CRP) at 1 month as a marker of short-term effectiveness, and the percentage of patients free from corticosteroid at one year, using student’s t-test.

Results: In total, 139 patients were analyzed (69 in the QD group, 70 in the QOD group). The maximum dose of corticosteroid in one year was not significantly different in both groups. However, the percentage of patients without any infection within 1 year after starting corticosteroids was 82.8%, 67.6%, 46.5%, 28.1%, and 22.5% at 1, 2, 5, 10, and 15 years, respectively, and the mean daily dose of corticosteroid in one year was significantly higher in the QD group (6.1±4.4 mg/day vs 3.9±1.7 mg/day; P<0.01). The percentage of patients without any infection within 1 year after starting corticosteroids at one year was 26.1% in QD group, and 58.6% in QOD group (P<0.01). Kaplan-Meier plot showed that QD group patients were more difficult to become free from corticosteroid (log-rank test: P<0.01).

Conclusions: Alternate-day corticosteroid dose has a lower adverse event rate and is as effective as a daily corticosteroid dose for treating rheumatoid arthritis.

DOI: 10.1136/annrheumdis-2017-eular.4160
was more common in women with RA, but did not differ significantly between pregnancies prior to and after RA diagnosis. A total of 41% of the post-RA pregnancies had an adverse pregnancy outcome (miscarriage, preterm delivery, or infant abnormalities), compared to 13% of pre-RA pregnancies (p<0.01) and 20% of control pregnancies (p=0.01).

Conclusions: Women with RA, overall, had similar rates of miscarriage, stillbirth, and ectopic pregnancy compared to healthy women, but pregnancies that occurred after RA diagnosis had higher rates of these adverse outcomes. More pregnancies in women with RA were planned, leading to a lower rate of elective termination.

**SAT0120 EVALUATION OF THE RISK OF OVERALL MALIGNANCY AND MALIGNANT LYMPHOMA WITH METOTREXATE AND BIOLOGICAL AGENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS BASED ON THE IORRA COHORT DURING A 14-YEAR OBSERVATION PERIOD**

N. Sugimoto1, E. Tanaka1, E. Inoue1,2, M. Kawano1, M. Ochiai1, Y. Shimizu1, R. Yamaguchi1, K. Ikari1, A. Nakajima1, H. Yamanaka1, 1Institute of Rheumatology, Tokyo Women’s Medical University; 2Center for Clinical Research for Development, National Center for Child Health and Development, Tokyo, Japan

Background: While dramatic progress has been made in this decade with treatments for rheumatoid arthritis (RA), such as methotrexate (MTX) and biological agents, concern about the safety, including the occurrence of malignancy, of these highly effective drugs still exists in daily clinical practice. There has not been an evident association between the use of biological agents and the occurrence of malignancy in most reports from clinical trials1 and observational studies2, although MTX use might be associated with the development of malignant lymphoma, called MTX-associated lymphoproliferative disorder3, in patients with RA. In an analysis of risk factors for overall and site-specific malignancies in Japanese patients with RA, higher disease activity was identified to be a risk factor for overall malignancies (hazard ratio [HR] 1.10, 95% CI 1.02–1.19), suggesting that tight control of RA disease activity would reduce the occurrence of malignancies in patients who were on MTX therapy4,5. However, it is still uncertain whether MTX and biological agents were risk factors for overall malignancy and malignant lymphoma using a marginal structural Cox proportional hazards model5 confirmed by medical records. Data for malignancies occurring in patients who were on biological agents) in a large observational cohort of Japanese patients with RA over a long-term period.

Methods: Among Japanese patients with RA enrolled in the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort from April 2000 to September 2013, data for all malignancies were extracted from patients’ self-reports and confirmed by medical records. Data for malignancies occurring in patients who died of other causes during the study were also collected from medical information from affiliated hospitals. We analysed whether MTX and biological agents were risk factors for overall malignancy and malignant lymphoma using a marginal structural Cox proportional hazards model5 adjusted for age, gender, smoking history, body mass index, RA disease duration, rheumatoid factor positivity and disease activity (28-joint disease activity score).

Results: Among 11,106 Japanese patients with RA representing 68,483 person-years, 507 overall malignancies, including 68 malignant lymphomas, were confirmed. Neither MTX nor biological agent use was a significant risk factor for overall malignancy with a HR (95% CI) of 1.18 (0.77–1.81) and 1.01 (0.69–1.53), respectively, or for malignant lymphoma, with a HR (95% CI) of 1.17 (0.55–2.48) and 1.26 (0.43–3.64), respectively.

Conclusions: The use of MTX and biological agents was not significantly associated with the occurrence of overall malignancy or malignant lymphoma during long-term longitudinal observation of Japanese patients with RA.

**SAT0121 COMORBIDITIES AND DISEASE ACTIVITY ARE RELEVANT FOR FUNCTIONAL DISABILITY IN RHEUMATOID ARTHRITIS**

N. Andrade1, A.M. Kakehashi1, C. Machado2, K. Gomes3, M.F. Guimarães4, S. Kramp1, C. Rodrigues5, C. Brenol6, 1Federal University of Rio Grande do Sul, Porto Alegre; 2Universidade Federal de Minas Gerais, Belo Horizonte; 3University of Fortaleza, Fortaleza, Brazil; 4University of Fortaleza, Fortaleza, Brazil

Background: Health status in rheumatoid arthritis (RA), as measured by Health Assessment Questionnaire - Disability Index (HAQ-DI), has been established as a relevant quantitative measure to assess and monitor the disease (1). Current RA therapy has shown improvement in patient-reported outcomes, but more data on specific factors influencing health status are needed (2).

Objectives: To assess the relationship between functional disability and clinical factors in patients with RA, using the HAQ score.

Methods: Cross-sectional study in patients with RA according to the ACR classification criteria from three Brazilian University Hospitals. Demographic and comprehensive clinical data, including components of metabolic profile were collected at the time of assessment. Blood pressure, weight and height were determined in the assessment visit and recent laboratory data were assessed from medical records. Disease activity was evaluated by the Disease Activity Score in 28 joints (DAS28) and functional disability was assessed by the HAQ-DI, considering an index < 0.5 as disability. All analyses were performed using Stata for MAC 12.0 software. Variables that achieved a p-value < 0.05 in the univariate analysis were considered as candidates to take part of a multivariate binominal logistic model, and in this model, variables were considered as statistically significant at the 0.05 level (3).

Results: 453 patients were included, 380 (83.9%) women, mean age 55.7 ±12 years, 356 (79.1%) Caucasian, and mean disease duration of 13.3 ±9 years. Methotrexate were used by 73.5% of the sample. Mean DAS28 was 3.9 ±1.4, mean HAQ score was 1.11 ±0.77, and 23.9% of the patients had HAQ score >0.5. Dyslipidemia, high blood pressure (HBP) and family history of premature cardiovascular disease occurred in 28.6%, 12.8%, 51% and 21.4% of the patients, respectively. Mean body mass index (BMI) was 27.1 ±4.9 kg/m². In multivariate analysis age, DAS28, tobacco use, and diabetes mellitus were independently associated with HAQ >0.5 (TABLE 1).

DAS28 – disease activity score in 28 joints; BMI – body mass index; OR – odds ratio.

Conclusions: Our results depicted that distinct factors could reflect in the functional status response in RA patients. This is relevant since it may influence the clinically important difference when evaluating the HAQ response in populations with diverse cultural features and different comorbidities prevalence.
WHICH MULTIMORBID CONDITIONS ARE MORE PREVALENT AROUND THE TIME OF EARLY RA DIAGNOSIS AND HAVE THE GREATEST IMPACT ON TRAJECTORIES OF DISEASE ACTIVITY IN THE FIRST YEAR? RESULTS FROM THE CANADIAN EARLY ARTHRITIS COHORT

O. Schieir 1, S.J. Bartlett 1,2,3, C. Hitchon 4, J. Pope 5, G. Boire 6, B. Harraoui 7, E. Keystone 1, D. Tin 8, C. Thorne 8, V.P. Bykerk 1,9 on behalf of Canadian Early Arthritis Cohort (CATCH) Investigators. 1University of Toronto, Toronto; 2McGill University, Montreal, Canada; 3Johns Hopkins University, Baltimore, United States; 4University of Manitoba, Winnipeg; 5Western University, London, United States; 6Université de Sherbrooke, Sherbrooke; 7Institut de Rhumatologie de Montreal, Montreal; 8Southlake Regional Health Center, Newmarket, Canada; 9Hospital for Special Surgery, New York, United States.

Background: Multimorbidity (MM) is highly prevalent in early RA (ERA), and higher counts of conditions are associated with poorer disease control 1. It is important to understand the number of, and which specific conditions most affect disease presentation, early therapies and disease activity over time.

Objectives: To estimate the prevalence of MM conditions at the time of ERA diagnosis and associations with ERA clinical characteristics, early treatment, and trajectory of disease activity in the 1st year of follow up.

Methods: Data were from ERA patients (<1-year of symptoms) enrolled in CATCH (Canadian Early Arthritis Cohort) who met 1987 or 2010 RA criteria, and had at least two DAS28 measures in the first year. We examined baseline prevalence of: 1) cardiovascular disease (CVD), 2) diabetes, 3) cancer, 4) pulmonary disease, 5) bowel disease, 6) other rheumatic diseases, and 7) psoriasis, obtained from patient-reports of physician-diagnosed medical conditions, 8) obesity (BMI ≥30), and 9) depressive symptoms (RAND-12 <42). We compared baseline demographic and clinical characteristics in ERA + each condition vs. ERA alone. We estimated adjusted effects of each condition on early use of RA therapies with logistic regression and adjusted effects of each condition on DAS28 trajectory over the first year of follow up with linear growth models.

Results: The sample included 1,595 patients, 1,153 (72%) were female, with a mean (sd) age of 54 (15) years and 6 (3) months of symptoms. At baseline, 1,434 (92%) were treated with conventional DMARDs (mostly methotrexate (76%) and 33 (2%) with a biologic. More than 70% of ERA patients reported at least one MM, and over 30% reported 2+ MMs. Patients with MM were often older and had higher disease activity at baseline, with variations by condition. Patients with RA+CVD or depressive symptoms had a 60% and 90% higher adjusted odds of baseline steroid use, respectively (p <0.01). In fully adjusted growth models, relative to patients with ERA only, patients with: a) diabetes, other rheumatic diseases or depressive symptoms had higher baseline DAS28 scores and less improvement over time; b) pulmonary disease, bowel disease, psoriasis or obesity had similar baseline DAS28 scores but less improvement over time; and c) CVD or cancer had higher baseline DAS28 scores but similar improvement over time (all p<0.05).

Conclusions: Multimorbidity is common in ERA patients seen in routine practice and associated with higher disease activity at baseline, less improvement over time, or both, and a greater likelihood of prescribing steroids for certain conditions. Integrating MM in to current RA care strategies may help achieve better patient outcomes.

SAT0123 MULTIDIMENSIONAL EVALUATION OF PAIN IN RHEUMATOID ARTHRITIS

P. Verenge-Salle 1, S. Poupin 2, A. Bera-Louville 3, M. Soubrier 4, C. Richez 5, R.-M. Javel 6, S. Perrot 7, P. Bertin 1,2, Rheumatology, University Hospital Limoges; 3Rheumatology, University Hospital Rouen; 4Rheumatology, University Hospital Lille; 5Rheumatology, University Hospital, Clermont-Ferrand; 6Rheumatology, University Hospital, Bordeaux; 7Rheumatology, University Hospital, Strasbourg; 9Pain center, University Hospital, Paris, France

Background: Although pain in rheumatoid arthritis (RA) is frequently thought to be inflammatory in nature, some studies reported clinically significant pain despite relatively low rheumatoid arthritis (RA) disease activity. Less than 50% of patients are satisfied by the management of pain.

Objectives: to report a recent multidimensional evaluation of pain in a large RA population.

Methods: Patients with RA were enrolled in 7 French Rheumatology Centers during a visit or a hospitalization in a transversal observational study. Socio-demographic data, previous and prescribed medications, disease duration, immunologic status, DAS28 score were assessed. Patients completed the multidimensional pain questionnaire from french health autority, the health assessment questionnaire (HAQ), the Beck depression scale and the anxiety scale STAI. Joint damage was evaluated by a simple erosion narrowing score.

Results: Of the 299 screened patients, 296 were included with a mean age of 58.4±11.7 years, 80.3% of female, a mean disease duration of 13.2±9.6 years, positivity of rheumatoid factors in 76.4%, anti-citrullin antibodies in 74% of cases. Concerning medications, 42.7% were treated by corticoids (mean dose=6.4 mg/d), 66% by analgesics drugs (64.1% with acetaminophen, 45.6% weak opioids, 7.1% strong opioids) and 24.4% with NSAID. The RA treatments were DMARDs in 69.1% and biotherapies in 82.7% of cases. The mean DAS28 score was 3.1±1.3 with 38.7% of patients in remission and 15.4% in low disease activity. The verbal scale for satisfaction about pain management showed that a third of patients was very satisfied, the half satisfied, 16% weakly or not satisfied. The mean pain visual analog scale (VAS) for the last 8 days was 33.6 ±26.5/100. 39% of patients had a pain VAS >40 mm/100. The Beck scale showed a moderate to severe depression in 34.3% of patients. Anxiety was present in 57.5%. The impact of pain on daily behaviors were more important on work. The pain VAS for the 8 days was correlated with the score of depression et with the DAS28 score (p=0.0001). The population with a pain VAS >40 mm had a significant more important Beck score, anxiety score, HAQ, DAS28 score and had more impacts of pain on daily behaviors.

Discussion: there was no difference between the populations with VAS ≤40 or >40 mm in terms of IL-6, IL-17 and IL-33 serum levels. The multidimensional evaluation of pain wasn’t different between treatment groups (DMARDs, biotherapies) and between the different biotherapies. Multivariate analysis with principal component analysis
found statistically significant associations between pain VAS and depression score, impacts of pain on daily behaviors and between pain VAS and DAS-28.

Conclusions: Almost 40% of patients had moderate to severe pain in a population of severe RA followed in hospital centers and treated with biotherapies in more than 80% of cases. Therefore, pain is still a major outcome to consider in RA. But a low proportion of patients with moderate to severe pain is less important than that one published by Taylor et al. Pain is associated with the DAS-28 score, but also with the depression score.

SAT0124 HIGHER BMI AND SHORTER DISEASE DURATION ARE ASSOCIATED WITH “FIBROMYALGIC” RHEUMATOID ARTHRITIS – EVALUATION USING POWER DOPLPER ULTRASONOGRAPHY

P. Cheung, M. Lahir. Rheumatology, National University Hospital, Singapore, Singapore

Background: Power Doppler ultrasonography (PDUS) can differentiate RA patients who truly have active disease. Patients with persistent joint tenderness may not necessarily have true inflammation; yet composite disease activity indices remain high, leading to treatment escalation. These patients are often referred to have “fibromyalgic RA” where tender joints far exceed that of swollen joints.

Objectives: We evaluated the predictors of “fibromyalgic RA” (FMRA), defined as patient-reported tender joint count (TJC) at least 7 greater than PDUS joint count. Methods: Consecutive RA patients were recruited in a tertiary rheumatology centre in Singapore. Patients self-assessed 28 joints for tenderness, followed by blinded PDUS assessment of the corresponding joints. Patients were grouped into either, (i) PDUS joint count > patient-reported TJC, (ii) PDUS joint count = patient-reported TJC (iii) patient-reported TJC > PDUS joint count, (difference >7). Group (iv) defined as FMRA. Predictors of FMRA were evaluated by multinomial logistic regression.

Results: Of the 101 patients, 81% were female, 72% Chinese, median age of 52 (IQR 48-59) and mean disease duration of 6.2 (1.9-8.8) years. Median BMI was 23.6 (8.0-27.0) and DAS28 was 3.2 (2.5-4.2). FMRA patients (15%) had a high median patient-reported TJC of 13 (10-18) but low median PDUS joint count of 1 (0-4). Compared to the other groups, they had higher median DAS28 of 4.6 (3.3-5.2), shorter mean disease duration of 2.3 (0.4-6.8) years, and higher median BMI of 26.9 (23.7-32.2). No differences in mean ESR or proportion of patients with serositis disease were observed. Using Group (i) as the reference, patients with FMRA were more likely to have a higher BMI (adjusted OR=1.6, 95%CI 1.2; 2.1,p=0.001 for every unit increase) and shorter disease duration (adjusted OR=0.8, 95% CI 0.7;0.98,p=0.03 for every additional year). Age, gender, ethnicity, disease activity (PDUS score) and serositis were not significant predictors of FMRA.

Conclusions: Higher BMI and shorter disease duration were independent predictors of FMRA. Use of PDUS would be useful in this group, rather than becoming treatment escalation on composite disease activity indices alone.

SAT0125 TENOSYNOVITIS IN RHEUMATOID ARTHRITIS: PREVALENCE AND DETERMINANTS OF TENOSYNOVITIS DETECTED IN THE SONAR-ULTRASONOGRAPHY EXAMINATION IN THE SCQM COHORT

R. Micherell1, A. Scherrer2, L. Brulhardt2, L. Ziswiler4, P. Zufferey5, B. Möller6, R. Micheroli7

Background: Tenosynovitis is one of the common features of rheumatoid arthritis (RA). The diagnosis of tenosynovitis is frequently made clinically and erosive progression in RA is more sensitive. US and MRI detected tenosynovitis is a predictor for unstable remission and erosive progression in RA.

Objectives: The aim of this study was to assess the prevalence and determinants of TS detected in the SONAR (Swiss Sonography Group in Arthritis and Rheumatism) examination in patients with Rheumatoid Arthritis in the SCQM Cohort.

Methods: The SONAR ultrasound examination consists of a semi-quantitative score employing both multiplanar grey scale (B-mode) and Doppler-mode (PWo) and a TS composite score (grade 0–3). Pathologic TS was defined as TS grade 2–3. Characteristics of patients with and without TS are shown using standard descriptive methods. In a longitudinal sub-group the change in TS from no TS to pathologic TS or vice versa and DAS28 over time was categorized as “worse”, “same” and “better” (ΔDAS28 >2.1). The correlation between change DAS28 and in tenosynovitis was evaluated.

Results: 941 RA patients with TS score were available. 20% of included patients showed signs of TS. The presence of TS was associated with male gender and higher values of disease activity and physical function disability. Furthermore, 15% of patients in DAS28 Remission had sonographic TS. TS was less frequently observed in patients on biologic therapies (Table 1). The longitudinal subgroup consisted of 348 patients. The correlation between change in DAS28 and change in TS was poor (polychoric correlation 0.28 [0.14, 0.43]).

SAT0126 MENTAL HEALTH BENEFITS ASSOCIATED WITH REDUCTION IN DISEASE ACTIVITY AMONG RHEUMATOID ARTHRITIS PATIENTS: A SYSTEMATIC REVIEW OF THE LITERATURE

V. Strand1, R. Rendas-Baum2, M. Kosinski3, D. Brooks4, R. Ganguly4

Background: The association between physical functioning and rheumatoid arthritis (RA) disease activity is well established. In randomized controlled trials (RCTs) of RA treatment, reductions in disease activity result in improved physical functioning. The mental health benefits associated with reductions in disease activity are less well recognized.

Objectives: Investigate the association between reductions in RA disease activity and measures of mental health status.

Methods: A systematic review of the published literature of RCTs in RA was conducted. The search was limited to those published in the last 10 years that included the Short-Form (SF)-36 Health Survey as an outcome measure.

Results: The search strategy yielded 77 articles of which 38 were excluded for the following reasons: not RCT (23); focus exclusively on early RA (9); psychometric evaluation (4); review study (1); and off topic (1). Of the 39 articles reporting mean changes in scores on the SF-36 mental health (MH) and role emotional (RE) domain, treatment by group analysis also presented these changes in association with reductions in RA disease activity measures.1-3 In relation to American College of Rheumatology (ACR) response criteria, small to moderate (0.2–0.5 standard deviation [SD]) effect size changes in RE and MH domain scores were observed among RA patients whose ACR responses ranged from 20–49%. Moderate to large effect sizes (0.5–0.8 SD) were reported in RE and MH domain change scores among ACR50 responders. Similar changes in RE and MH domain scores were reported by patients with reductions in Simplified Disease Activity Index (SDAI) of ≤10 points.

Conclusions: The benefits of clinically meaningful reductions in disease activity among RA patients not only include improved physical functioning but also meaningful improvements in overall mental health status. The improvement in mental health is positively associated with reduction in disease activity, with only small to moderate improvements associated with less than ACR responses. Additional work is needed to investigate the incremental effects of RA therapies on mental health beyond the effects related to reductions in disease activity.

**SAT0127**

**UNFAVORABLE BODY COMPOSITION ALREADY AT THE ONSET OF CLINICAL ARTHRITIS**

S.A. Turk, D. van Schaardenburg, M. Boers, S. de Boer, C. Fokker, W.F. Lems, M.T. Nurmosahmed, Amsterdam Rheumatology and Immunology Center; Reade; Amsterdam Rheumatology and Immunology Center; Academic Medical Center; Amsterdam Rheumatology and Immunology Center; VU University Medical Center, Amsterdam, Netherlands

**Background:** Rheumatoid arthritis is associated with an increased cardiovascular (CV) risk. There is mounting evidence that inflammation is involved in the pathogenesis thereof (1). An unfavorable body composition is, independently, associated with an increased CV risk, and often present in established arthritis patients. This unfavorable composition is a loss of muscle mass (sarcopenia), in the presence of a stable or even increased (abdominal) fat mass (sarcopenic obesity). However, their applicability in ethnic RA subsets is unknown.

**Objectives:** Currently it is unknown when this unfavorable body composition develops. Therefore, we compared body composition in DmARD-naive early arthritis patients with non-arthritis controls and explored the association with disease activity and traditional CV risk factors.

**Methods:** A total of 317 consecutive early arthritis patients and 1268 age, gender and ethnicity matched non-arthritis controls (3) had a Dual-energy X-ray absorptiometry scan to assess lean (muscle) mass index (LMI), fat mass index (FMI), fat mass distribution (arms and legs versus trunk) and android to gynoid fat mass ratio. For the obesity definition, the cut offs based on the control group were applied (mean minus two times SD). In addition, a disease activity score, erythrocyte sedimentation rate, lipid profile (total cholesterol, LDL, HDL, triglycerides) and blood pressure assessments were done.

**Results:** Early arthritis patients (84% fulfilling the 2010 ACR/EULAR criteria) had a significantly lower mean LMI (p < 0.01) compared with controls. Female patients had a higher mean BMI (p = 0.01) and more fat was distributed to the trunk in patients (females p = 0.01, males p = 0.07) (table). The prevalence of an unfavorable body composition (i.e. sarcopenia and sarcopenic obesity) was higher than in controls, for females 5.0% versus 1.3%, OR: 4.2, p < 0.01 and for males 8.2% versus 1.5%, OR: 5.7, p < 0.01 (figure). A higher BMI, more android fat and more fat distributed to the trunk were associated with higher blood pressure and lipid levels (and lower HDL levels). There was no clear relationship between body composition parameters and disease activity.

**SAT0128**

**CLINICAL FEATURES AND EVOLUTION OF PULMONARY FUNCTION IN A SINGLE-CENTER COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS RELATED INTERSTITIAL LUNG DISEASE**

**Background:** Interstitial lung disease (ILD) is an extra-articular manifestation of Rheumatoid Arthritis (RA), has been related with a poor prognosis. However, there is a lack of clinical data regarding its evolution with different treatment approaches.

**Objectives:** Our aim was to assess clinical features and evolution of ILD in a cohort of RA patients from a tertiary hospital

**Methods:** Single-centre retrospective observational study including all patients diagnosed with ILD with a previous or posterior diagnosis of RA evaluated from January 2007 to December 2016 in the Rheumatology Department of a university hospital.

**Results:** Twenty-one patients (18 women) were included, mean age 68.4±11.9, mean RA duration 12.3±8.2 years. 9.5% were current smokers and 33.3% former smokers. 61.9% were ACPA+ (52.4% with high basal titers, median ACPA titers: 699; IQR 321–811) RF+ (47.3%), with high titers (median RF: 71.4%) 68% had extra-articular manifestations, mainly rheumatoid nodules. RA diagnosis was made after that of ILD in 4 patients; mean elapsed time 1.56±1.26 years. In the other 17 patients, the mean duration of RA until ILD diagnosis was 11.2±7.2 years. Currently 17 subjects (85%) receive GC; 4 (19%) in monotherapy and 11 (57.9%) synthetic DmARDs (5 methotrexate, 3 leflunomide (LEF), 1 hydroxychloroquine (HCQ) and 2 with double therapy (HCQ/AZA and HCQ/LEF)).

Four patients are currently treated with biological therapy (2 abacetap (ABA), 1 infliximab and 1 etanercept (ETN), all of them in monotherapy. Five patients received TNFI prior to ILD diagnosis (3 ETN, 1 infliximab and 1 adalimumab). Biological therapy was withdrawn in 3 cases and switched to ABA in the two remaining ones.

The median duration of EPID was 2.5 (range 0.7–11.9) years. HRCT patterns were: non-specific interstitial pneumonia (NSIP) 52.9%, usual interstitial pneumonia (UIP) 17.6%, cryptogenic organized pneumonia (COP) 11.8%, and other patterns 17.7%.

1 patient had baseline and follow-up PFT; 9 (64.3%) remained stable; 3 (21.4%) improved and 2 (14.3%) worsened (1 had received previous ETN). There was a trend for worsening of PFT in patients with UIP pattern.

No patient died from ILD during this period

**Conclusions:** In our RA-ILD cohort, NSIP was the most common HRCT pattern and PFT remained stable in most patients during follow-up. Five patients (23.8%) had received TNFI prior to ILD diagnosis and only one of them showed worsening of PFT during ETN treatment, with clinical improvement after withdrawal.

**SAT0129**

**EXPLORATION OF COMORBIDITY INDICES IN AN ETHNIC RHEUMATOID ARTHRITIS SUBSET**

S. Dowell, G. Kerr, C. Swearingen, M. Quinones, J. Berrian, S. Hochberg, on behalf of EMRAC Working Group. Rheumatology, Howard University Hospital; Rheumatology, Washington VAMC, Washington; NYU, New York, United States

**Background:** Comorbidity is common in ethnic patients with rheumatoid arthritis (RA) and often impact choice of DMARD therapy and clinical outcomes. In addition to the complex sum of comorbidities, comorbidity indices have been proposed as better predictors of poor clinical outcomes in patients with rheumatoid arthritis. However, their applicability in ethnic RA subsets is unknown.

**Objectives:** To compare composite to mean comorbidity indices in ethnic subsets with rheumatoid arthritis.

**Methods:** Patients enrolled in the Ethnic Minority RA Consortium (EMRAC), with at least 6 months of follow-up data were analyzed. At enrollment, sociodemographic data and RA disease status, rheumatic disease comorbidity index (RCDI) and comorbidity count (COUNT) were analyzed amongst ethnic subsets. Spearman correlation was estimated between RCDI and COUNT while Poisson regression
was used to model the differences in the comorbidity indices between race groups.

Results: 453 EMRAC subjects were analyzed; 342 (81.4%) were female, average age was 58.9 (±15.1) years, average duration 13.3 (±11.1) years and average follow-up length 2.1 (±1.4) years. Individual comorbid frequencies as well as comorbid associations included in Table 1. The median nerve thickness was overall RDCI and COUNT was 0.90 (95% CI [0.88, 0.91], P <0.001). Hispanics, however, had significantly lower comorbidity indices scores than other race groups (RDCI Hispanic vs White P=0.003, Hispanic vs Black P=0.004, Hispanic vs Other P=0.038; COUNT Hispanic vs White P=0.012, Hispanic vs Black P=0.004, Hispanic vs Other P=0.157).

Objectives: To establish the median nerve thickness (measured by ultrasound) in RA and its relation to renal impairment.

Methods: 120 RA patients were recruited through a specialized rheumatology clinic. The US measurements were performed by the same person. Patients were sitting with their forearms resting in a supinated position on a small table. The US probe (an 8–16 MHz linear array transducer) was held as lightly as possible to avoid disturbing the anatomy of the nerve. The median nerve was examined at the entrance of the carpal tunnel, between the pisiform bone and the tubercle of the scaphoid bone, where the distal volar carse is an external pisiform landmark. A continuous trace was made just within the hyperechogenic boundary of the nerve. The cross-sectional area of the median nerve was calculated directly by the software of the US equipment. Each median nerve was measured three times, and the mean value was used for further analyses. Modification of Diet in Renal Disease (MDRD) equation used to estimate the Glomerular Filtration Rate (GFR). The average of the right and the left areas of the median nerve were used when exploring bivariate correlations to the renal variables (Pearson’s correlation coefficients). All statistics were performed using USTAT program.

Results: the average median nerve thickness was 9.72±2.6 mm² (Range 1.5–22.25). The average GFR was 122±20 ml/min (95.6–248). Thickness of the median nerve was positively associated with the age of the participants (p=0.03, CI: 0.00, 0.08), body mass index (p=0.04, CI: 0.00, 0.21), uric acid level (p=0.033, CI: 0.00, 0.01), and urine microalbumin (p=0.04, CI 0.00, 0.01). GFR showed no significant relation the thickness of the median nerve.

Conclusions: RA patients without symptoms or clinical signs have a median nerve thickness that is positively correlated to the level of microalbumin and uric acid. Whether sonographic examination of the median nerve would be helpful in predicting who is going to have a deteriorated renal function need to be explored in a larger study.

Background: Disease flares in RA are common. The RA Flare Questionnaire (RA-FQ) can be used to identify and quantify flares in rheumatoid arthritis (RA).

Objectives: To further explore the psychometric properties of RA-FQ, we used Rasch analysis and reviewed results with RA patients research partners (PRPs) to gain additional insight into the interpretability, meaningfulness, and utility of results. Ten PRPs first completed the questionnaire for the robust psychometric properties of the RA-FQ. RUMM2030 was used to evaluate unidimensionality, targeting of items to people, reliability, response options, redundancy, local dependence, and model fit was excellent ($\chi^2 = 31.6$, df=45; $p=0.935$). There was little evidence of differential item functioning by sex, age, or country/language. Items suggest flare symptoms and impacts increased together showing a consistent story of how individuals experience worsening RA disease activity. Among PRPs, scores ranged from 10 to 41. There was unanimous agreement from the patients that the RA-FQ could also enhance communication between doctors and patients at routine visits. Several noted potential applicability in monitoring day-to-day status and with self management. Thresholds for clinically important worsening to identify flare varied by setting, patient population, and context of use.

Conclusions: Taken together, results from classical and Rasch analyses support for the robust psychometric properties of the RA-FQ. The 5-item measure is easy to complete and simple to score. Feedback from RA PRPs and clinicians increase confidence in the relevance, meaningfulness, and easy interpretation of RA-FQ results for clinicians, researchers, and patients.

DOI: 10.1136/annrheumdis-2017-eular.5593
conventional cardiovascular risk factors. Exclusion criteria were smoking, diabetes mellitus, symptomatic AH, cardiovascular diseases (except AH). DMAS was measured by using the BPlab with technology VASOTENSE (Russian). An index of arterial stiffness (ASI), a daily index of arterial stiffness (AASI), an aortic pulse wave velocity (PWVao), augmentation index (Alx) were measured. All indexes were estimated at day and night hours. Statistics was performed with STATISTICA 7.0 (StatSoft, USA).

**Results:** Hypertensive RA patients and AH patients without RA had comparable DMAS parameters (ASI, PWVao, Alx). The AASI index was higher in RA patients without AH versus controls (0.48±0.2 and 0.29±0.17, respectively, p=0.00001) and the AASI index was higher in hypertensive RA patients versus AH patients (0.5±0.2 and 0.38±0.15, respectively, p=0.01). AASI >0.77 revealed at RA patients more often than in controls: at 13.15% of hypertensive RA patients and at 16.6% of RA patients without AH, respectively, p<0.05. The increase of PWVao observed at RA patients frequently than in controls (p<0.05). Daily index ASI100 was higher in RA patients without AH than in healthy controls (121 [109.5; 139] mmHg vs. 107 [103; 115] mmHg, p=0.014). The increased of Alx75 was registered in 25% of RA patients without AH and in 9.09% of controls (p=0.08). PWVao and average Alx75 correlates with ESR (r =0.38 and r =0.36, respectively, p<0.05) in RA patients with AH; AASI correlates with level C-reactive protein (r=0.36, p<0.05). ASI and AASI in RA patients with AH correlates with age (Spearman's r =-0.41 and r =-0.36, respectively, p<0.05), systolic blood pressure (r =0.76 and r =0.65, respectively, p<0.05); pulse blood pressure (r =0.77 and r =-0.43, respectively, p<0.05).

**Conclusions:** Arterial stiffness, according to daily monitoring, in RA patients is higher than in hypertensive patients without RA and healthy controls. Arterial stiffness in patients with RA and AH is higher than in patients with RA without AH. Age, systolic blood pressure, pulse blood pressure, high levels of ESR and C-reactive protein associated with increased arterial stiffness in RA patients.

**SAT0136** ASSOCIATION OF GENOTYPES FOR BCLI POLYMORPHISM IN THE GLUCOCORTICOID RECEPTOR GENE WITH ISCHEMIC HEART DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

V.S.S.U. Knytya, O. Savchenko, L. Prystupa. Internal Medicine Department, 4682, Sumy, Ukraine

**Objectives:** The objective is to study associations of genotypes for Bc1I polymorphism in the glucocorticoid receptor (GR) gene with ischemic heart disease (IHD) in patients with rheumatoid arthritis (RA).

**Methods:** 161 subjects with rheumatoid arthritis aged 40 years and older were examined by means of instrumental, clinical and laboratory examinations. Rheumatoid arthritis was diagnosed according to ACR/EULAR Classification Criteria (2010). The IHD diagnosis was verified by means of ACC/AHA guidelines (2012). BCL1 polymorphism in exon 2 was identified using polymerase chain reaction with subsequent analysis of restriction fragment length polymorphism by Fevery I. et al. (venous blood was used as the material for the study). Statistical analysis was performed using SPSS-17 program.

**Results:** It was revealed that 76 (47.2%) patients had isolated RA (group I), while 85 (52.8%) individuals had RA with concomitant IHD (group II). In group I, there were 29 (38.2%) patients with C/C genotype, 39 (51.3%) – with C/G genotype, and 8 (10.5%) – with G/G genotype. The distribution in group II was as following: 16 were homozygous for the C allele (18.8%), 40 were heterozygous (47.1%) and 29 were homozygous for the G allele (34.1%) (χ²=15.23; p<0.02). It was established that the risk of ischemic heart disease was 6.57 times higher in homozygotes for the G allele (OR=6.57; 95% CI=2.44–17.73; p<0.001) as compared with homozygotes for the C allele.

**Conclusions:** It was established that G/G genotype prevailed in RA patients with ischemic heart disease, while C/C genotype prevailed in patients with isolated RA. The risk of IHD development in patients with RA was associated with G/G genotype for Bc1I polymorphism in the GR gene.

**SAT0137** BONE MINERAL DENSITY MEASUREMENT INTERVALS FOR SEROPOSITIVE RHEUMATOID ARTHRITIS PATIENTS NOT TREATED FOR OSTEOPOROSIS

W. Park, K.-H. Jung, S.-R. Kwon, M.-J. Lim, S.-G. Park, M.-J. Jo. In-Ha University Hospital, Incheon, Korea, Republic Of

**Background:** Osteoporosis occurs more frequently in rheumatoid arthritis (RA) patients than in healthy individuals. However the appropriate interval for the bone mineral density (BMD) measurement in RA patients is not well established.

**Objectives:** This study investigated the effective BMD measurement interval and the risk factors associated with the development of osteoporosis for RA patients.

**Methods:** A retrospective study was performed on 511 RA patients aged more than 40 years old who had undergone BMD (DXA, GE LUNAR PRODIGY ADVANCE) testing more than once and who had normal BMD or osteopenia at the baseline BMD test and no history of any fracture of the spine or femur. The subjects were categorized into four subgroups: normal BMD (T-score > -1), mild (1 > T-score > -1.5), moderate (1.5 > T-score > -2), and advanced (≥ 2 T-score > -2.5) osteopenia. The BMD testing interval was defined as the estimated time for 10% of the RA patients to make the transition into osteoporosis without osteoporotic fracture or the administration of any osteoporosis drug.

**Results:** The observation period was 2,214 patient-years, with an average of 4.3 years. The estimated BMD testing interval was more than 10 years for normal, 4.3 years for mild, 2.5 years for moderate, and 1.5 years for advanced osteoarthritis in estimated the time for 10% of the RA patients to make the transition into osteoporosis without osteoporotic fracture or the administration of any osteoporosis drug.

**Conclusions:** Our study indicated that in normal or osteopenic RA groups, a baseline BMD T-score is the most important factor in estimating the interval in which osteoporosis is predicted to occur. In addition, we recommend that the BMD measuring interval should be greater than 10 years in normal BMD RA
SAT0138  OPTIMIZING TARGETED THERAPY: CAN PROMS FILL THE GAP BETWEEN PATIENTS’ AND PHYSICIAN-PERCEIVED REMISSION IN RHEUMATOID ARTHRITIS

1Rheumatology, Darlington Valley Hospital, Darlington, United Kingdom; 2Community and Public Health; 3Rheumatology and Rehabilitation, Ain Shams University, Cairo, Egypt; 4Rheumatology, North Middlesex University Hospital, London, United Kingdom

Objectives: 1. To compare the patient perspective on remission in RA in comparison to the rheumatologist perceived remission perspectives. 2. To determine the value of Patient Reported outcomes in identifying specific symptoms and aspects of disease ability to define remission in RA from the patient perspective.

Methods: RA patients diagnosed according to ACR/EULAR criteria were treated with biologics. Remission was measured in two ways: 1) patient perceived remission using the question “Would you say that, at this moment, your disease activity is as good as gone? (yes/no)”; and 2) Physician perceived remission was defined as a physician global assessment <1 on a 0–10 VAS, phrased as “How active do you think the rheumatoid arthritis of your patient is today?” The study included 188 RA patients (76 males, 112 females; mean age 52.4±11 years) and 87 rheumatologists (30 males, 57 females; mean age 48.7±11.7 years). All participants were asked to complete a questionnaire which was composed of all domains identified in relation to the disease remission. 10 cm visual analogue scale (scored 0–10) was used to illustrate the importance of each factor in an individual opinion. The list included joint pain, functional ability, quality of life, absence of morning stiffness, absence of fatigue, normal laboratory tests, no comorbidity risk, radiological remission. Disease Activity score and ability to work. In addition, patients were asked to complete a copy of the PROMs [1]. One-way analysis of variance was used for the comparison of independent variables. Spearman correlation coefficient was used to assess the correlation between variables.

Results: There were no significant differences in questionnaire answers in relation to patients’ demographics and present disease activity. Regarding the patient perceived remission, the top 4 were: pain (76%), functional ability (71%), quality of life (69%) and fatigue (43%). Regarding the physician perceived remission, the following factors were rated more relevant by rheumatologists than the patients (p<0.001): low disease activity score (88%), radiological remission and progression of erosions (76%), lab measurements (ESR/CRP) (57%) followed by difficulties in performing paid work (49%).

Conclusions: We observed that enthesis involvement was not seldom in patients with seronegative RA. Furthermore there were also similar frequency of enthesitis involvement in seropositive patients with RA. The value of enthesis sites evaluation for the differential diagnosis of patients with seronegative RA should be further investigated and the assessment of enthesis sites in seronegative and seropositive RA patients can be important to detect active and chronic changes in the enthesis region.

SAT0139  ASSESSING ENTHESITIS BY ULTRASONOGRAPHY IN PATIENTS WITH SERONEGATIVE RHEUMATOID ARTHRITIS

Z. Erturk1, T. Ösoz2, I. Yağcı2, Y. Yaçınıkaya1, Ü. Gazi1, P. Ataşgündüz1, H. Direkeli1, N. İnan1, Z. Erturk1, T. Ösoz2, I. Yağcı2, Y. Yaçınıkaya1, Ü. Gazi1, P. Ataşgündüz1, H. Direkeli1, N. İnan1
1Rheumatology; 2Physical Therapy and Rehabilitation, Marmara University, Istanbul, Turkey

Background: In patients with seronegative rheumatoid arthritis (RA) there is a difficulty to make the differential diagnosis with the spondyloarthropathies. Objectives: To assess the presence of enthesitis in patients with seronegative rheumatoid arthritis in comparison with the healthy controls, patients with seropositive rheumatoid arthritis and ankylosing spondylitis.

Methods: In this cross-sectional study, seronegative and seropositive rheumatoid arthritis patients, who fulfilled the 2010 ACR/EULAR criteria, patients with ankylosing spondylitis and healthy controls have been assessed by grey scale and power doppler ultrasonography for the presence of enthesopathy at the achill, plantar fascia, proximal patella, distal patella, quadriceps, tibialis anterior, triceps, common flexor and extensor tendons. Clinical assessment of the patient groups included demographic findings, health assessment questionnaire and disease activity score.

Results: In our study, we recruited age and sex matched 27 seronegative RA, 17 healthy controls, 20 seropositive RA and 12 ankylosing spondylitis patients. We performed and analysed both right and left sides of the enthesis regions separately which have been indicated in the methods section. The mean DSAS28, mean ESR and mean CRP of the patients with seronegative RA were 3.6±1.28, 32.2±21.2 and 12.37±27.77 respectively (Table 1).

Median of Madrid sonographic enthesis index (MASEI) was 5 in patients with seronegative RA. 4 patients have severe scores. There were significant differences between seronegative RA and healthy controls (5, p=0.014) but no differences has been observed between seronegative seropositive RA (6) and ankylosing spondylitis (7) in MASEI scores.

Conclusions: We observed the presence of enthesitis involvement was not seldom in patients with seronegative RA. Furthermore there were also similar frequency of enthesitis involvement in seropositive patients with RA. The value of enthesis sites evaluation for the differential diagnosis of patients with seronegative RA should be further investigated and the assessment of enthesis sites in seronegative and seropositive RA patients can be important to detect active and chronic changes in the enthesis region.

Rheumatoid arthritis - anti-TNF therapy

SAT0140  EFFECT OF OBESITY IN RESPONSE TO BIOLOGICS IN RHEUMATOID ARTHRITIS

A. Khan1, S. Sukumaran2, M. Kanikula1, A.-S. Zafar2, S. Shah2, S. Adnan2
1Department of Rheumatology, Queen Elizabeth Queen Mother Hospital, Margate; 2Department of Rheumatology, William Harvey Hospital, Ashford, United Kingdom

Background: Obesity epidemic has impacted practically every area of health including care of patients with RA. Adipose tissue is an active organ that produces pro-inflammatory molecules. A significant treatment challenge remains is the standard dose of RA medications may not attain same concentrations at sites of inflammation in obese vs non-obese patients thus making them less effective.

Objectives: The study aim was to determine whether obesity represents a risk factor for a poor remission in RA requiring biologic therapies. Obesity may be associated with more severe and refractory inflammation through increased levels of inflammatory adipocytokines leptin, resistin or visfatin or decreased levels of the anti-inflammatory adipocytokine adiponectin. We retrospectively analysed 178 patients diagnosed with RA at East Kent University Hospitals.

Methods: Data analysed for age, sex, disease duration, prior DMARD, positivity RF and CCP antibodies, median 28 (5-84) at diagnosis and at 6 months were analysed. Median of MPH was 28 (5-84) at diagnosis and at 6 months were analysed. Main aim was to analyse any difference between obese and non-obese patients in terms of their response to treatment. Obese patients were defined with a BMI of 30 or above.

Results: See Table 1.
Results suggested that there were significant differences between two groups for sex, duration of disease, RA and CRP. There was also some evidence of difference between groups in terms of their age and pre-treatment DAS28 score but these differences were only of borderline statistical significance. There was smaller proportion of males in the obese group with 20% male compared to 36% of non-obese patients. Obese patients had on average a longer disease duration with a median of 12 years compared to a median of 8 years for the non-obese group. The RA status also varied between groups with a much higher proportion of patients in the negative category for the obese group. CRP values were significantly lower in the obese group with a median of 24 compared to 35 in the non-obese group.

### Table 2. EULAR response between obese and non-obese patients

<table>
<thead>
<tr>
<th>EULAR response</th>
<th>Non-Obese N (%)</th>
<th>Obese N (%)</th>
<th>P-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>No response</td>
<td>9 (9%)</td>
<td>32 (39%)</td>
<td>&lt;0.001</td>
</tr>
<tr>
<td>Moderate response</td>
<td>40 (42%)</td>
<td>36 (43%)</td>
<td></td>
</tr>
<tr>
<td>Good response</td>
<td>46 (48%)</td>
<td>15 (18%)</td>
<td>&lt;0.001</td>
</tr>
</tbody>
</table>

Non-obese had the best response with 48% good response compared to 18% of the non-obese group with post treatment mean DAS28 score of 3.2 and mean reduction of 2.4.

**Conclusions:** Obesity is important factor that impacts treatment and outcome in RA. Further clinical studies to elucidate the pharmacokinetics of specific biologic agents in relation to BMI should provide further clinical guidance.

**SAT0141**

**OPTIMAL CIRCULATING ADALEUMAB LEVELS RANGE ASSOCIATED WITH GOOD CLINICAL RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS**

A. Jochems, A. Martinez-Feito, C. Plasencia, B. Hernández-Breijo, A. Mezcúa, A. Villalba, I. Monjo, P. Nozal, A. Balza, M.D. Pascual-Salcedo, I. Immuno-Rheumatology Research Group; Immunology Unit, University Hospital la Paz, Madrid, Spain

**Background:** TNF inhibitors have become an important part of healthcare worldwide for inflammatory diseases such as RA. Many publications show that responders (pts) have higher Adalimumab (Ada) serum trough levels (ATL) than non-responders. These factors are influenced by age, weight, gender or other factors that may predict a poor response to MTX.

**Objectives:** To identify predictors of MTX insufficient response (IR) and rapid radiographic progression (RRP) among pts with RA receiving 6 months of MTX therapy.

**Methods:** In OPTIMA, pts with RA -1 year were randomized to receive either adalimumab (ADA) 40 mg every other wk (EOW) + MTX weekly (wkly) or placebo (PBO) EOW + MTX wkly for 26 wks. In PREMIER, pts with RA -3 years were randomized to receive ADA 40 mg EOW + MTX wkly, ADA 40 mg EOW + PBO wkly, or PBO EOW + MTX wkly for 2 years. This post hoc analysis compared MTX-IR pts, defined as not reaching stable low disease activity at wks 22 and 26 in OPTIMA and wks 20 and 24 in PREMIER, with pts who responded to initial MTX monotherapy. Comparisons were also made between pts who did and did not have RRP and assessed by an increase in modified Total Sharp Score (mTSS) of >1.5 from baseline (BL) to 6 mos. In pts with available data, backward logistic regression was used to identify potential predictors of MTX-IR and RRP. Candidate predictors included BL demographics, time-averaged disease parameters for 3 time periods (through 4 wks, 8 wks, and 12 wks of MTX exposure), and BL disease characteristics for the 12-wk interval. Time-averaged variables were calculated as area under the curve standardized for length of time interval.

**Results:** This analysis included 525 MTX-IR and 162 MTX responders. Mean disease duration at BL was 6 mo for both groups. The mean Disease Activity Score 28 (DAS28) was 5.6 ± 1.5 for MTX-IR and 5.2 ± 1.4 for MTX responders. The mean mTSS at BL was 20.7 for pts who experienced RRP vs those who did not (12.4). Predictors of MTX-IR and RRP at 6 mos are shown in the Figure. Time-averaged HAQ-DI and DAS28 (CRP) through 12 wks were the strongest predictors of both MTX-IR and RRP. Additionally, early clinical response (time-averaged DAS28[CRP]) at both 4 and 8 wks was predictive of both MTX-IR and RRP; however, time-averaged HAQ-DI was not predictive until wk 12.

**Conclusions:** In the OPTIMA and PREMIER trials, post-BL measures of RA activity were predictive of MTX-IR and RRP. Pts who are likely to progress on MTX or have RRP may be good candidates for switching to earlier step-up therapy to reduce the likelihood of permanent bone damage.

SAT0144 | TUMOR NECROSIS FACTOR-ALPHA INHIBITORS AND PSYCHIATRIC SIDE EFFECTS: RESULTS FROM THE FRENCH PHARMACOVIGILANCE DATABASE

C. M. Yelnik 1, L. Gaboriau 2, N. Petitpain 3, H. Théophile 4, C. Scalbert 5, E. Delaporte 5, S. Gautier 5, M. Lambert 1, Internal Medicine Department, University of Lille, UFR Medicine, University Hospital Center of Lille; 2Regional Pharmacovigilance center of Hauts-de-France, Lille; 3Regional Pharmacovigilance center of Hauts-de-France, Lille; 4Regional Pharmacovigilance center of Hauts-de-France, Lille; 5Dermatology department, University of Lille, UFR Medicine, University Hospital Center of Lille, Lille, France

Background: Although Tumor Necrosis Factor alpha (TNF-α) is a major proinflammatory cytokine in the brain, potential psychiatric side effects of TNF-α inhibitors have been little investigated. Manic and psychotic disorders are not recognized as TNF-α inhibitors’ side effects even though few reports of such complications have been reported.

Objectives: This study reports cases with psychiatric symptoms (in the spectrum of psychotic and manic disorders) that occur during treatment with tumor necrosis factor alpha (TNF-α) inhibitors and aims to evaluate the role of these agents as causative factors.

Methods: We searched the French Pharmacovigilance Database for consecutive cases of positive psychiatric side effects reported during treatment with TNF-α inhibitors. Major psychiatric symptoms were defined according to DSM-V, as mania and psychosis, and minor psychiatric symptoms as psychomotor agitation, euphoria, hallucinations, personality distortion, and increased libido. Each case had one major symptom or at least one minor symptom.

Results: Among 7912 consecutive cases of side effects registered in the database for TNF-α inhibitors, 184 reported psychiatric symptoms, and of these, 71 met inclusion criteria, whereas 113 met an exclusion criterion. Depression was the most frequent cause for exclusion. TNF-α inhibitors were the only medication suspected in 56 cases (79%). The time between beginning TNF-α inhibitors and onset of symptoms varied from hours to months with a median time of 49 days (IQR=156); initial symptoms mostly worsened under treatment. TNF-α inhibitors were withdrawn in 42 (61%) cases. The improvement of symptoms was significant associated with treatment withdrawal (78% versus 22%, p<0.01). Relapses occurred after rechallenge of TNF-α inhibitors in three of four patients.

Conclusions: We report the first cohort of 71 cases with psychiatric symptoms in the spectrum of manic and psychotic disorders during treatment with TNF-α inhibitors. Our experience suggests that anti-TNFα therapy may cause manic or psychiatric side effects.

SAT0143 | COMPARISON OF TREATMENT WITH GOLIMUMAB AND CERTOLIZUMAB-PEGOL IN ARTHRITIS- RESULTS FROM THE SOUTH SWEDISH ARTHRITIS TREATMENT GROUP (SSATG) REGISTER

C. Rosenma, E. Lindqvist, P. Geborek, M. C. Kapetanovic. Section of Rheumatology, Lund University. Department of Clinical Sciences Lund, Skåne University Hospital, Lund, Sweden

Background: “Head to head” studies comparing the efficacy and tolerability of different TNF inhibitors are scarce, in particular the comparison between certolizumab pegol and golimumab.

Objectives: To compare the efficaciousness, drug survival and tolerability of certolizumab-pegol and golimumab in adult patients with establish arthritis (RA, JIA, SpA or unspecified polyarthritis) starting these treatments between February 2010 and December 2013 at outpatient unit at the Skåne University Hospital, Department of Rheumatology Lund/Malmö and two associated private rheumatology units.

Methods: All patients starting treatment with biologics were consecutively included in the South Swedish Arthritis Treatment Group (SSATG) register and regularly followed up according the standard protocol including: SJC/TJC, CRP, ESR, physicians global assessment of disease activity, patients’ assessment of disease activity and pain (VAS global and VAS pain) and HAQ. Last follow up date was October 17th 2016. Kaplan–Meier survival analysis was used to estimate the drug survival. Possible predictors of drug survival were analysed using Cox regression model.

Results: In total, 352 patients (71% women, mean age 51 years, mean disease duration 12 years) started these treatments during study period. Of these, 168 received golimumab and 184 certulizumab-pegol. Mean treatment time was 31 months (range 0–77). Percentage of patients with RA, SpA, JIA and unspecified arthritis were 58.4%, 16.4%, 5.7%, and 19.5% respectively. Certolizumab-pegol was more used in RA (67% vs 49%) and JIA (8% vs 2%) while golimumab was more frequent among patients with SpA (21% and 12%) or PsA (23% and 10%, respectively). Only 7% of golimumab and 10% of certolizumab-pegol patients received these drugs as first biologic treatment and approximately 50% of patients received these drugs as ≥ 3 biological treatment.

In golimumab treated patients mean DAS28 decreased from 4.3 (baseline) to 3.3 (3 months); 2.8 (6 months) and 2.7 (12 months) but levelled off at 36 months follow up. Corresponding mean DAS28 levels in certulizumab-pegol treated patients were 4.6 (baseline); 3.2 (3 months); 2.8 (6 months) and 2.6 (12 months). The similar pattern was seen in changes in HAQ and CDAI over the study time. There were no statistically significant differences in DAS, HAQ or CDAI between treatments at any follow up visit. At the end of follow up 68% with golimumab and 60% (32%) of certulizumab-pegol patients remained on their treatment. No significant difference in drug survival was seen between the treatments (Figure). Patients with spondyloarthropathy had significantly better survival on golimumab compared to RA patients (p=0.005) which remained after adjustment for age, gender, CRP, number of previous biologics and concomitant methotrexate at baseline.
Influence of body mass index (BMI) on the disease

Randomised double-blind study shows comparable

long-term efficacy and safety between rituximab

biosimilar CT-P10 and innovator rituximab in

patients with rheumatoid arthritis: 48-week results

1 Ajou University School of Medicine, Suwon, Korea, Republic Of; 2 Clinica Internacional, Lima, Peru; 3 Centro de Estudios Reumatologicos, Santiago, Chile; 4 Centro de Investigacion en Artritis y Ostesarropia, Mexico, Mexico; 5 KrasSMU, Krasnoyarsk, Russian Federation; 6 Biologics Especializados SA, Mexico City, Mexico; 7 Medical University, Wroclaw; 8 2nd University Hospital, CM UMK, Bydgoszcz, Poland; 9 Clinica San Borja, Lima, Peru; 10 Rheumatology Medical Center, Halle/Saale, Germany; 11 Poznanska University of Medical Sciences, Poznan, Poland; 12 Tampere Medical University, Tampere, Finland; 13 Centro Integral de Reumatologia del Caribe, Bananquilla, Colombia; 14 Reumatika - Centrum Reumatologii, Warszawa; 15 Medical University of Lublin, Lublin, Poland; 16 IN-HA University, School of Medicine, Incheon; 17 Chungnam National University Hospital, Daejeon; 18 Celltrion, Inc., Incheon; 19 Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic Of

Background: In phase 1 trials (NCT01534884 and NCT01873443), pharmacokinetic equivalence of CT-P10, biosimilar of rituximab, to innovator rituximab (RTX) was demonstrated. In the phase 3 study, equivalence of PK and efficacy up to week 24 were achieved between CT-P10 and RTX (US and EU sourced) 12. Objectives: To investigate the long-term efficacy, pharmacodynamics, immunogenicity and safety of CT-P10 up to week 48.

Methods: Patients with rheumatoid arthritis were randomly assigned to CT-P10, US-RTX or EU-RTX, in combination with MTX. The patients received 2 treatment courses at Week 0 and 24, each consisting of 2 infusions of 1000mg study drug every 2-week interval.

Results: A total of 372 patients were randomised, and 330 patients completed the 2nd course treatment. DAS28 scores through Week 48 were comparable between CT-P10 and US/EU-RTX (Figure), as well as the proportion of ACR responses at Week 48 between the CT-P10 and combined rituximab groups; 81.3% and 79.8% for ACR 20, 55.4% and 53.9% for ACR50, and 31.7% and 33.7% for ACR 70, respectively.

Figure 1. Efficacy Results – DAS28.

B-cell depletion was comparable from after the 1st infusion and up to Week 48. Number (%) of patients with positive anti-drug antibodies in the CT-P10, US-RTX, and EU-RTX was 7 (4.9), 13 (9.4), and 5 (8.6), respectively at Week 48. The safety profile was also similar across groups (Table).
SAT0147 | SERUM LEVELS OF THE ANTI-TNF BIOLOGICS CORRELATE WITH CLINICAL EFFICACY IN PATIENTS WITH INFLAMMATORY ARTHRITIS

C. C. Mok 1, B. Fong 1, L. Y. Ho 1, H. C. To 1, 2.

Background: The risk of infections, especially severe infections (SI), remains of particular interest in rheumatoid arthritis (RA), both defective immune response and therapeutic immunosuppression being responsible. The RABBIT Risk Score (RRS), an instrument developed and validated in the German Biologics Register RABBIT and replicated in other RA settings (British Register), allows the estimation of SI occurring during 12 months according to local guidelines, enveloped between 2008 and 2016 in a single academic center. Along with disease activity and therapeutic response, baseline RRS (http://www.biologika-register.de/en/home/risk-score/) was applied for each case, to evaluate the predictive value of the RRS. The study included patients with spondyloarthritis (SpA) and psoriatic arthritis (PSA) and were commenced on antitumor necrosis factor (anti-TNF) biologic according to the trough levels of the drugs. Low drug concentrations were significantly more patients withdrew treatment due to inefficacy at month 12 in this group of patients (33% vs 75%; p<0.001 by log rank test).

Results: The performance of RRS was previously established in a pilot study on 181 RA. Currently, the RRS was considered in 144 RA recruited to the first group and 128 to the second. The prescription pattern significantly changed (p<0.05 for patients enrolled in last years: RA were more likely to receive earlier biDMARDs, for lower activity and functional status; moreover, lower corticosteroids (dose, duration) and fewer synthetic DMARDS before starting biologics were reported (p<0.05).

Methods: Longitudinal study on 272 consecutive RA with moderate-to-severe active disease at baseline (defined as the BASDAI >4, CRP >5 mg/L and tender joint count >7), recruited at 32 academic centers from 2011 to 2014. The RABBIT Risk Score is a simple risk tool that allows the estimation of SI occurring during 12 months according to the baseline RRS.

Conclusions: The RABBIT Risk Score is a simple tool, able to predict serious infections in Romanian RA receiving biological therapy (TNF and non-TNF drugs), optimizing the selection of appropriate medication based of individual infectious risk profile in routine practice.

SAT0148 | COMPARATIVE EFFECTIVENESS OF TOFACITINIB, BIOLOGIC DRUGS AND TRADITIONAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS IN RHEUMATOID ARTHRITIS

C. M. Moura 1, M. A. Machado 1, H. Behloul 1, J. R. Curtis 2, M. Abrahamowicz 1, S. Bernatsky 1.

Background: Most rheumatoid arthritis (RA) patients initiate therapy with methotrexate (MTX), but 1/3 will have low disease activity with this agent alone. Several therapeutic options are available for patients with MTX-resistant RA, including new Janus kinase (JAK) inhibitors (e.g. tofacitinib). Objectives: To compare the effectiveness of traditional disease-modifying antirheumatic drugs (DMARDs), biologic DMARDs and tofacitinib for RA patients with inadequate response to MTX.

Methods: We used MarketScan® databases (2011–2014) to study adult RA individuals previously treated with methotrexate (oral or SQ) and newly prescribed one of the medications under study. The date of first filled prescription or infusion drug was defined as the cohort entry and a 12-month pre-period was used to exclude prior users of biologics or tofacitinib. We required subjects to be continuously enrolled in the medical and pharmacy plan 12 months before and after the cohort entry. Effectiveness was access through an algorithm previously validated, based on the following criteria: 1) non-adherence; 2) switching/adding a new biologic or tofacitinib; 3) switching/adding a new DMARD; 4) increasing of the dose of the starting therapy; 5) use of glucocorticoid joint injections; and 6) increasing the dose of oral glucocorticoid. A patient’s therapy was defined as not effective if at least one of the criterion occurred during the first year of follow-up.

Results: 16,305 RA patients were included; 2,879 began therapy with DMARD, 13,345 with biologics and 81 with tofacitinib. Among all patients, 77.5% were female and the mean age was 56.2 years (standard deviation 12.6). Table 1 shows the proportion of patients that meet the individual criterion and that achieved effectiveness at the end of the 12-month follow-up.

Conclusions: Similar rates of therapy effectiveness were observed among groups, although the rates for the individual criteria differed. Fewer patients initiating biologic agents were non-adherent compared to DMARD and tofacitinib therapy, but switching/adding and injections tended to be higher in this group.

SAT0152 REAL-LIFE INFliximab AND ADALIMUMAB TROUGH LEVEL AND ANTI-DRUG ANTIBODY MEASUREMENTS IN RHEUMATOLOGY: THE FINNISH EXPERIENCE
D. Ho1, S. Valtanen2, M. Hanna2, L. Krøger3, K. Eklund4, S. Jokiranta1,2
1Research Programs Unit, Immunobiology, University of Helsinki; 2United Medix Laboratories Ltd, Helsinki; 3Pediatric Rheumatology, Kuopio University Hospital, Kuopio; 4Rheumatology, Helsinki University and Helsinki University Hospital, Helsinki, Finland

Background: Therapeutic drug monitoring of TNF inhibitors (TNFi) may optimize clinical benefits while at the same time reducing financial costs and risk of adverse events1,2. Monitoring the TNFi trough levels (TLS) and the anti-drug antibodies (ADAbs) can provide relevant information to make rational adjustments to therapy if indicated.

Objectives: To identify distributions and trends in infliximab (IFX) and adalimumab (ADL) TLSs and ADAbs from clinically requested, real-life samples from Finnish patients with rheumatoid arthritis (RA), spondyloarthropathies (SpA), or juvenile idiopathic arthritis (JIA).

Methods: Samples for TL and ADAbs were taken on a clinical basis in daily practice from four university hospitals and 15 central hospitals in Finland and sent for analysis to United Medix Laboratories. Samples were collected and analyzed from January 2012 to February 2016. TL measurements were performed by enzyme-linked immunosorbent assay (either at Sanquin laboratories, Amsterdam, The Netherlands, or in Helsinki, Finland). Adalimumab, TLS from 2–10 μg/ml (IFX) or 5–10 μg/ml (ADL) were considered as general target ranges. ADAbs measurements were performed by radioimmunoassay (Sanquin). 1762 TL (1241 patients), 1598 ADAB (1203 patients), and 860 combined TL and ADAB samples (716 patients) were analyzed. Statistical analyses were performed by SPSS (IBM, Armonk, NY). p < 0.05 was considered statistically significant.

Results: The highest proportions of samples with very low TLS (< 0.1 μg/ml) were found in IFX-treated RA patients (14.5%) and ADL-treated SpA patients (12.6%). The proportion of all samples in the general target range was 51.3% (IFX) and 33.4% (ADL). Compared to reported data of RA and SpA samples had possibly supratherapeutic (<10 μg/ml) TLSs (RA: ADL, 22.9% vs IFX, 10.4%, p < 0.001 and SpA; ADL, 21.4% vs IFX, 15.0%, p < 0.05). A greater proportion of ADL JIA patients had TLS >10 μg/ml (ADL, 54.5% vs IFX, 36.3%, p < 0.001). Proportions of samples with ADAbs (≥12 AU/ml) ranged from 18.0% (IFX RA) to 28.6% (ADL, SpA). A greater proportion of ADL samples with TLS of 2–5 μg/ml and detectable ADAbs (≥12 AU/ml) (RA: ADL, 3.3% vs IFX, 0%; SpA: ADL, 5.6% vs IFX, 0%; JIA: ADL, 3.4% vs IFX, 0.9%) was observed.

Conclusions: IFX RA and ADL samples had the highest proportions of very low TLS and compared to IFX much greater proportions of ADL samples in IFX RA and ADL SpA had been reported through different ADL RA and SpA samples had possibly supratherapeutic (<10 μg/ml) TLSs. Furthermore, ADL ADAbs were lower compared to IFX ADAbs. RA and SpA patients monitored by IFX and ADL had TLS and ADAbs that differed considerably from the expected model. RA patients had higher TLS and ADAbs compared to SpA. RA ADAbs were lower compared to SpA ADAbs.

SAT0154 EFFECTIVENESS AND SAFETY OF CT-P13 IN PATIENTS WITH RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS, PSORIATIC ARTHRITIS AND PLACQUE PSORIASIS: OBSERVATIONAL STUDY IN REPUBLIC OF KOREA
D.-W. Kim1, T.-H. Kim1, S.R. Kwon2, E.Y. Lee3, C.-N. Son4, Y.S. Kim5, S.H. Kim7, Y.-B. Park8, J.-W. Hur9, H.-S. Lee10, S.J. Lee11, S.H. Lee11, 1Inje University Busan Paik Hospital, Busan; 2Hanyang University Hospital for Rheumatic Diseases, Seoul; 3Inha University Hospital, Incheon; 4Seoul National University College of Medicine, Seoul; 5Keimyung University Dongsan Medical Center, Daegu; 6Chosun University Hospital, Gwangju; 7Gwangmyeonggaeng Saeum Hospital, Gyeonggi-do; 8Yonsei University Severance Hospital; 9Eulji University Seongdong Hospital, Seoul; 10Hanyang University Guri Hospital, Gyeonggi-do; 11Celltrion Inc., Incheon, Korea, Republic Of

Background: CT-P13 is approved as a biosimilar of innovator infliximab for rheumatoid arthritis (RA), ankylosing Spondylitis (AS), Psoriatic Arthritis (PsA) and Plaque Psoriasis (Ps)

Objectives: To evaluate the effectiveness and safety of CT-P13 under routine care in Republic of Korea.

Methods: This observational study included both biologic naïve patients (Naïve group) and patients who switched from other anti-tumor necrosis factor (TNFi) to CT-P13 (Switch group). Effectiveness was evaluated based on remission (DAS28≤2.6 in RA, BASDAI≤3 in AS and absence of swollen and tender joint counts in PsA), and response (BASDAI 20/50/75 in AS and PASI 50/75 in Ps). Adverse events (AEs) were collected over 6 month period.

Results: Total 940 patients (400 with RA, 531 with AS, 3 with PsA and 6 with Ps) were registered and 338 (36.0%) patients (108 with RA, 228 with AS, 2 with PsA) who switched to CT-P13 were included.

The proportion of patients achieving remission was similar between Naïve and Switch groups in both RA and AS during post-baseline visits (Table 1). In RA, the proportion of patients achieving each disease activity category by DAS28 was similar between Naïve and Switch groups (Figure 1). The proportion of patients significantly younger (53.3 vs 59.7 years), with lower disease duration of RA (8.8 vs 11.2 years) compared to low dose MTX group. Patients in the high dose group also had higher disease activity (mean CDAI: 20.8 vs 15.4) and more likely to be biologic-naïve (71.3% vs 55.4%), compared to the low dose group (all p < 0.05). Unadjusted and adjusted analyses found no sufficient evidence that patients on high dose MTX had a better improvement in the outcomes selected (table). Persistency of ADA did not differ between the two groups.

Table: Outcomes at 6 months among ADA plus low (<152 mg) vs high (≥152 mg) combination MTX therapy

<table>
<thead>
<tr>
<th>Outcome</th>
<th>Low MTX (n=114)</th>
<th>High MTX (n=105)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Achievement of Remission (DAS28≤2.6)</td>
<td>7.1 (15.7%)</td>

who achieved BASDAI 20/50/70 response gradually increased from week 6 to week 24 or 30 in Naive group with AS (Figure 1).

Fifty percent of naïve patients with PsA achieved clinical remission. The proportions of both PASI 50 and 75 responses were 50% at Week 22 in Naive group and were 100% and 50% in Switch group, respectively during post-baseline visit in 23 patients. Throughout this study, treatment-emergent adverse events (TEAE) and treatment-emergent serious adverse events (TSEAE) were reported as Table 2. Only 11% of patients experienced infection.

Conclusions: MTX administered in combination with biologics, like ADA, leads to superior outcomes vs monotherapy. For pts who can’t tolerate MTX, non-MTX csDMARDs, specifically HCO and SSZ but not LIF, may be good alternatives, as outcomes were largely comparable with those of pts receiving MTX when combined with ADA. The limited sample size examined in this analysis should be confirmed in a larger pt population.

DOI: 10.1136/annrheumdis-2017-eular.1597
Our findings confirm specific CD4+ and CD8+ T-cell responses from patients with latent form of tuberculosis (LTBI) and active tuberculosis (TB) subjects, in which INF-γ in the tubes TB1 and TB2 was observed in 16 individuals and 15 non-responder individuals, respectively in 27.3% and 23.9% RA patients, and 27.4% and 23.5% PsA patients. MTX was not associated with an increased drug survival in both RA (p=0.09) and PsA patients (p=0.50), where 50% of MTX users survived for 2 years, compared to 48% of ADA treated patients achieving remission or low disease activity (LDA). Reasons for discontinuation were not associated with different ADA clinical response, as well as concomitant MTX.

**EFFICACY OF SWITCHING FROM ETANERCEPT TO ADALIMUMAB IN RHEUMATOID ARTHRITIS AND PSORIATIC ARTHRITIS PATIENTS WHO EXPERIENCED A FIRST-LINE BIOLOGIC THERAPY FAILURE: THE FEARLESS STUDY**

F. G. Favalli, A. Becciolini, A. Carletto, F. Conti, G. Amato, E. Fusaro, L. Quattrocchio, A. Lo Monaco, M. Benucchi, F. Salaffi, A. Semeraro, M. Biggogiglio, S. Parisi, F. Ceccarelli, I. Piazza, R. Foti.

**Department of Rheumatology, Gaetano Pini Institute, Milano; 2Rheumatology Unit, AOUI, Vittorio Emanuele, Catania; 3Rheumatology, Azienda Ospedaliero Universitaria Città della Salute and della Scienza, Torino; 4Clinica di reumatologia, Dipartimento di scienze mediche e biologiche, ASULID, Udine; 5UOC di Reumatologia, Azienda Ospedaliero-Universitaria Sant’Anna Cona-Ferrara, Ferrara; 6SOS Reumatologia, Ospedale S. Giovanni di Dio, Firenze; 7Clinica Reumatologica, Università Politecnica delle Marche, Ancona; 8U.O.Rheumatico, ASL Taranto-PF OLO SS. Annunziata Taranto e Valle d’Itria, Taranto; 9Department of Clinical Sciences and Community Health, Division of Rheumatology, University of Milano and Gaetano Pini Institute, Milano, Italy.

**Background:** The strategy for the choice of the second biologic agent after the failure of the first TNF inhibitor (TNFi) is still an unclear aspect in the treatment of both rheumatoid arthritis (RA) and psoriatic arthritis (PsA). Switching between structurally different TNFis (from etanercept [ETN] to monoclonal antibody [mAb] or vice versa) has been proposed as a more effective procedure than switching among different mAbs, but to date no study has been specifically focused on exploring this topic.

**Objectives:** To evaluate the comparative 2-year retention rate and the 12-month efficacy of adalimumab (ADA) as second biologic agent in etanercept (ETN) non-responder RA and PsA patients in a multicentre retrospective study.

**Methods:** All RA and PsA patients from 11 Italian Rheumatology Units treated with ADA after a first-course ETN failure and with at least 12-month follow-up were retrospectively collected in a multicentre registry. Data analysis was limited to the period from January 2002 to May 2016. Two-year ADA retention rate was calculated by Kaplan-Meier method. 12-month ADA response was defined as achievement of disease activity score 28 calculated by using erythrocyte sedimentation rate (DAS28-ESR) <2.6 (remission) or >2.6 and <3.2 (low disease activity, LDA). Sub-analyses according to reason for ETN discontinuation and concomitant methotrexate use in RA and PsA patients have been performed.

**Results:** The study population (219 patients) included 117 RA (female 85.5%, mean [± standard deviation, SD] age 53.2±13.5 years, mean [±SD] disease duration 10.1±7.7, positive rheumatoid factor 70.2%; positive anti-citrullinated peptide antibodies (ACPA) 59.6%; mean [±SD] baseline DAS28-ESR 4.97±1.3; MTX users 64.9% and 102 PsA patients [female 63.7%; mean [±SD] age 51.7±10.6; mean [±SD] disease duration 7.1±5.1; mean [±SD] baseline DAS28-ESR 4.4±1.1; MTX users 50%). The 2-year retention rate was 48.2% in RA and 56.5% in PsA patients, irrespective of reason for ETN discontinuation. Similarly, concomitant MTX was not associated with an increased drug survival in both RA (p=0.09) and PsA patients (p=0.50), where 50% of MTX users survived for 2 years, compared to 48% of ADA treated patients achieving remission or LDA. Reasons for ETN discontinuation were not associated with different ADA clinical response, as well as concomitant MTX.

**IMPACT OF PARTICIPATION IN THE ADALIMUMAB PATIENT SUPPORT PROGRAM ON FUNCTIONAL AND CLINICAL OUTCOMES AMONG PATIENTS WITH RHEUMATOID ARTHRITIS: PASSION STUDY**

**Department of Medicine, University of British Columbia; 2Addenbrooke’s Hospital, Cambridge, United Kingdom; 3Rheumatazentrum, Ratingen, Germany; 4AbbVie Inc., North Chicago, United States; 5AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany.

**Background:** Patients (pt) with Rheumatoid arthritis (RA) who are treated with adalimumab (ADA) are offered participation in the Support Program for Patients (PSP) to access a wide variety of services. To date, no prospective study has been conducted to analyze the acceptance and the impact of these PSPs on treatment effectiveness and pt satisfaction.

**Objectives:** The purpose of this study was to examine the effectiveness of ADA in patients with rheumatoid arthritis (RA) attending a course in the context of PSP participation. **Methods:** PASSION (NCT01383421) was a 78-week (wk) post-marketing observational study of pts with RA receiving ADA in routine clinical care. Pts from the EU, Israel, Mexico, Puerto Rico, and Australia with an insufficient response to ≥ 1 disease-modifying antirheumatic drug (DMARD) newly initiating ADA (1 prior...
biologic DMARD was allowed) were enrolled. The primary endpoint was the % of pts achieving the minimal clinically important difference (MCID; improvement of ≥0.22 compared to baseline [BL] in the Health Assessment Questionnaire Disability Index (HAQ-DI) at wk 78. Non-responder imputation (NRI) was used to account for the missing values. Secondary clinical parameters included % of pts achieving MCID in HAQ-DI at wks 24, 52 and changes in the 28-joint DAS based on CRP (DAS28(CRP)), Simplified Disease Activity Index (SDAI), and Clinical Disease Activity Index (CDAI) at wks 24, 52, and 78 vs BL. Pts were categorized based on their participation in the PSP: ever (PSP users) vs never (PSP non-users) and outcomes were compared after adjusting for corresponding BL values.

Results: Overall, the primary endpoint, percentage of pts achieving the MCID for HAQ-DI, was achieved by 72.1% (as observed) and 42.8% (NRI) of pts at week 78 with the percentage of pts achieving the MCID for HAQ-DI significantly higher in PSP users vs PSP non-users (48.1% vs 37.8% [NRI]; P<0.001). From 1,025 pts, 48.7% pts were PSP users (BL: mean age, 54.3 years; % female, 77.1%; mean RA duration, 7.8 y; mean HAQ-DI, 1.5; mean DAS28(CRP), 5.3; mean SDAI, 35.6; mean CDAI, 33.3; 17.8% pts had received prior biologic DMARD. Significant changes (P<0.05) from BL to wk 78 were observed for pts using the PSP vs PSP non-users in HAQ-DI (0.53 vs 0.39), DAS28(CRP) (−2.33 vs −1.97), SDAI (−24.5 vs −19.8), and CDAI (−22.66 vs −18.55) scores (Figure). Study discontinuation rates were significantly (P=0.001) lower among PSP-users vs PSP non-users (25.5% vs 41.6%). Reasons for discontinuations are listed in the Table.

Figures: Changes from baseline in DAS28 (CRP) (A), SDAI (B), CDAI (C), and HAQ-DI (D) over time between PSP users and PSP non-users.

Significantly different between PSP users and PSP non-users (P<0.05). Log rank test (Mantel-Cox) for comparison of survival curves.

Table: All reasons for study discontinuation by PSP utilization category

Conclusions: The final study results showed that, in pts with moderate to severe RA who initiated ADA, significantly better improvement in functional and clinical outcomes was achieved in the PSP users vs the PSP non-users. Improvements were achieved at early timepoints and continued to increase throughout the study.

Results: We screened 255 articles by title and abstract and 7 publications fulfilled our inclusion criteria. Three meeting abstracts were also included. Six studies assessed infliximab biosimilars (CT-P13 and SB2), three studies assessed etanercept biosimilars (SB4 and GP2015) and one study assessed an adalimumab biosimilar (ABP 501). All but two concerned phase III trials and seven were performed on rheumatoid arthritis patients. All biosimilars had comparable immunogenicity profiles in respect to their reference drugs, except for the etanercept biosimilar SB4, which presented significantly less ADA than the etanercept when compared to reference etanercept (0.7% vs 13.1% at 24 weeks and 1.0% vs 13.2% at 52 weeks, p<0.001 for both). As expected, infliximab had the highest incidence of ADA; the proportion of ADA in studies of infliximab and adalimumab was higher when compared to historical data. Only 4 studies reported nADA, which were highest in the infliximab biosimilar CT-P13 54-week study in ankylosing spondylitis patients. Electrochemiluminescence immunoassay was the preferred method to measure ADA. Table 1 summarizes the main findings in the included studies.

Table 1. Immunogenicity of biosimilars approved for the treatment of inflammatory rheumatic diseases. ADA: antidrug antibody; NA: not available; nADA: neutralizing antidrug antibody. *The EGAILITY study presented a four-arm design in which two arms were continuously treated with either reference etanercept or GP2015 and the other two arms were systematically switched. The results presented in this table concern the groups continuously treated with reference etanercept or GP2015.

Conclusions: Currently approved biosimilars for the treatment of rheumatic diseases have comparable immunogenicity profiles in respect to their reference drugs. The discrepancy in ADA between SB4 and reference etanercept did not correlate with efficacy or safety and did not preclude biosimilarity, according to the regulatory agencies. The higher proportion of ADA compared to historical data may be explained by the greater sensitivity of current immunogenicity assays, such as electrochemiluminescence immunoassay.

**SAT0161**  PRELIMINARY REAL WORLD DATA ON SWITCHING PATTERNS BETWEEN ETANECETP, ITS RECENTLY MARKETED BIOSIMILAR COUNTERPART AND ITS COMPETITOR ADALIMUMAB, USING SWEDISH PRESCRIPTION REGISTRY

R. Alten1, P. Neregård1, H. Jones3, E. Singh3, C. Curiale4, T. Meng5, L. Luchesse6, C. Miglio6, J. Young7, G. J. Bergman7,1, Schlosspark-Klinik, Berlin, Germany;7Pfizer, Stockholm, Sweden;7Pfizer, Collegeville, United States;7Pfizer, Rome, Italy;7Pfizer, Berlin, Germany;7QuintilesMS, London, United Kingdom;7QuintilesMS, Solna, Sweden

**Background:** The increasing availability of biologic treatments over the past 10 years has revolutionized the management of chronic inflammatory autoimmune diseases such as rheumatic diseases. In April 2016, the first etanercept biosimilar (EtnBS) was launched in Sweden, which may represent a cheaper option to its innovator adalimumab (EtnI) against anti-TNF and other biologic agents. In this study, we evaluate early observations and investigate the reasons for switching back.

**Objective:** The objective of this study was to describe the position of etanercept innovator (EtnI) within the Swedish biologic market for rheumatic diseases, before and after the launch of its biosimilar. The study also provides early real-world data on the market penetration of EtnBS by evaluating switching dynamics to and from this drug since the date of launch.

**Methods:** The overall biologic market share across all type of rheumatic diseases was monthly tracked over the last year of available data in the Swedish Prescription Registry (100% coverage). The proportion of patients receiving a rheumatologists prescription for any biologic in each month, from November 2015 to October 2016 was recorded. In addition, switching dynamics of patients initiating EtnBS treatment between April 2016 and October 2016 were studied. The proportion of patients receiving no biologic treatment (naive) and of those on treatment with EtnI, adalimumab and other biologic agents in the 12 months prior to initiate EtnBS treatment was reported. Furthermore, patients who switched from EtnBS back to EtnI or adalimumab and the mean time to this second switch were also evaluated.

**Results:** EtnI and adalimumab dominate the biologic market for rheumatic diseases in Sweden, holding the 40% and 28% of market share, respectively, up to April 2016. However, in the 6 months after EtnBS was launched, the share of EtnI decreased constantly, dropping to 31% in October 2016 (Figure 1). Since April 2016, we identified in total 2,439 patients receiving first prescription of EtnBS by a rheumatologist. Of these, 977 (40.1%) were naïve to biologic, 1,179 (48.3%) had prior treatment with EtnI, 107 (4.4%) with adalimumab, 176 (7.2%) with other biologics. Among the patients who changed to EtnBS from prior EtnI, the 7% switched back to EtnI after an average time of 43 days. Similarly, of those who were on previous adalimumab treatment, 6% switched back to adalimumab, after an average, 57 days.

**Conclusions:** Many patients changed from EtnI to its biosimilar treatment since its launch in Sweden. However, this study showed that 7% of these patients switched back to their original treatment after short time. Despite the change from a brand biologic to the biosimilar is very likely made for economic reasons, the reasons for switching back to the innovator are not clear and may imply patients’ preference or biologic to the biosimilar is very likely made for economic reasons, the reasons for switching back to the innovator are not clear and may imply patients’ preference or clinical reasons. Interestingly, the same pattern is observed for patients changing from adalimumab to EtnBS. Long-term studies are required to confirm these early observations and investigate the reasons for switching back.

SAT0164 ASSOCIATION BETWEEN FLARE AND RADIOGRAPHIC PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

J.S. Smolen 1, H. Jones 2, E. Mahgoub 2, R. Pedersen 2, L. Marshall 2, 1Medical University of Vienna, Vienna, Austria; 2Pfizer, Collegeville, United States

Background: Biologic therapy has improved RA management, enabling some patients to achieve remission. Many clinicians decrease the biologic dose for patients in low disease activity (LDA) or remission. However, it is unclear which patients may flare and if flare contributes to radiographic progression.

Objectives: To assess whether patients who flared had a higher incidence of radiographic progression, and to compare patients with and without flares.

Methods: PRESERVE (ClinicalTrials.gov: NCT00565409) was a 2-period trial in patients with moderate RA despite MTX. Period 1 was open-label, single treatment induction with etanercept (ETN) 50mg+MTX weekly (QW) for 36 wks. Patients in LDA or remission (disease activity score for 28 joints [DAS28] ≤3.2) during wks 12 to 36 were randomized to Period 2, the randomized, double-blind phase, to evaluate maintenance of LDA/remission. Patients were randomized to ETN 50mg+MTX QW, ETN 25mg+MTX QW, or placebo+MTX QW to wk 88. This post hoc analysis evaluated flare and radiographic progression at wk 88. Flare was defined as 2 ways: 1) loss of LDA with/without DAS28 change of 0.6; and 2) relapse (DAS28-5.1 or DAS28-3.2 at ≥2 time points). Radiographic progression was evaluated according to 4 levels of stringency: 1) minimally clinically important difference (modified total Sharp score [mTSS] change ≥0.5); 2) smallest detectable difference (mTSS change ≥2.3); 3) mTSS change ≥0.5; and 4) mTSS change >0. Baseline [BL] characteristics were compared for patients with vs without flare defined as loss of LDA and DAS28 change of 0.6. Analysis of covariance and chi-square test compared continuous and categorical outcomes, respectively.

Results: Age, race, BMI, and disease duration did not differ significantly for flare vs non-flare, total N=531. BL DAS28 was higher for flare vs non-flare (p=0.289 and p=0.271, respectively).

SAT0165 REAL-WORLD UTILIZATION OF CONCOMITANT MEDICATIONS IN PATIENTS INITIATING ETANERCEPT: A RETROSPECTIVE COHORT STUDY OF CANADIAN CLAIMS-LEVEL DATA

M. Khraiishi 1, Y. Zhang 2, J. Ivanovic 3, B. Millson 2, M.-J. Brabant 4, E. Singh 5, J. Woolcott 6, H. Jones 7, 1Faculty of Medicine, Memorial University of Newfoundland, St. Johns; 2Health Access & Outcomes, QuintilesIMS, Kanata, Canada; 3Inflammation and Immunology, Global Medical Affairs, Pfizer Inc., Collegeville, United States; 4Health Economics and Outcomes Research, Pfizer Inc., Kirkland, Canada

Background: Methotrexate (MTX) and prednisone (pred) are immune suppressants frequently used to treat immune-mediated inflammatory diseases (IMIDs). Etanercept is a soluble TNF receptor (humanized protein) indicated for the treatment of IMIDs, including rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), and arthritis associated with ulcerative colitis (UC). Limited information exists on how MTX or pred use changes in patients who initiate etanercept in real-world settings.

Objectives: To evaluate whether initiation of etanercept impacts use of co-therapy with MTX or pred in Canadian patients with IMIDs.

Methods: A retrospective cohort study was conducted using claims-level data from QuintilesIMS Private Drug Plan database, Ontario Public Drug Plan database, and Quebec Public Drug Plan database. Bio-naive patients initiating etanercept between 07/2013 and 06/2015, were identified and their claims made for MTX or pred were analyzed. Patients' utilization of MTX or pred was calculated as average weekly dose in mg, and then compared in the 6-months pre versus 12-months post initiation of etanercept using a paired t-test. Differences in the presence of concomitant medications pre and post- etanercept were also examined using a paired t-test.

Results: The study captured 3,745 etanercept patients (61% female, 77% aged between 18 and 65, 84% rheumatic diseases, and 15% PsO) across Canada in the selection period. Of selected patients, 33% used MTX (n=1,244) and 14% (n=523) used pred pre and post initiation of etanercept. In concomitant MTX patients, the average weekly dose dispensed was 25.0mg in the 6 months prior to initiation of etanercept, and 25.0mg in the 12 months following the first claim of etanercept (p=0.4793). In concomitant prednisone patients, the average weekly dose dispensed reduced from 123mg pre- etanercept to 108mg post- etanercept initiation (p=0.2316). 19% of patients stopped MTX (n=287) use post-etanercept initiation, compared to 36% who stopped pred use (n=289).

Conclusions: In this real-world setting, approximately 1/3 of patients stopped or reduced co-therapy of MTX, and 1/3 of patients stopped or reduced co-therapy of pred following initiation of etanercept; however, those patients who remained on co-therapy showed non-significant changes in their average consumption. Further research is needed to understand the impact on overall patient outcomes and safety.

SAT0166 MARKERS OF RESPONSE TO INFlixIMAB IN RHEUMATOID ARTHRITIS – THE PLACE OF ANTI-NUCLEAR ANTIBODY AND NUCLEASE SERUM ACTIVITY

M. Volkava 1, A. Kundzner 1, I. Generalov 2, D. Petrovich 1, 1Cardiology and Rheumatology, BeilAPGE, Minsk; 2Clinical Microbiology, VSMU, Vitebsk, Belarus

Background: It is important to study new potential markers of response to treatment in rheumatoid arthritis (RA), because up to 40% patients don't achieve...
remission even using biological therapy. DNase activity of the blood serum and antinuclear antibody may be useful in this context. Changes of serum DNase activity in the RA treatment by biological agents previously have been not investigated.

**Objectives:** The aim of this work is to study the dynamics clinical and laboratory parameters of DNAse serum activity in RA patients treated by infliximab (INF) and assess the prognostic potential of them in prediction of response to INF.

**Methods:** 24 RA patients were involved in the study. All patients fulfilled the EULAR/ACR 2010 RA criteria. 22/24 patients received 6 infusions of INF at a dose of 3 mg/kg according to standard protocol: at 0h, 2h, 6h and then every 8 weeks. 2/24 patient received 4 infusions of INF. All patients received synthetic DMARDs therapy by metotrexate (10–17.5 mg weekly), 18/24 patients received glucocorticoids (methylprednisolone 4–8 mg daily) and non-steroidal anti-inflammatory drugs. Prior to treatment by INF patients did not receive any biological agents. All patients had high disease activity before INF treatment (DAS28≥5.1).

ANA determination was performed by indirect immunofluorescence on Hep-2 cells using digital system AKLIDES. ANA was measured in serum samples before 1st INF administration, at 22–30 weeks after the 1st INF administration. To determine the DNase activity of serum the method of rivanol clot was used. DNase activity was measured in serum samples before 1st INF administration, 6 weeks after the 1st INF administration, at 30 week of treatment.

**Results:** At week 30, ACR70 improvement reached 5/22 of the patients, ACR50 - 9/22 of the patients, ACR20 - 14/22 of the patients. At 30 weeks of treatment INF 2/22 of patients achieved remission (SDAI<3.3), 10/22 - a low disease activity (3.3–SDAI<11). 13/24 patients were ANA-positive before INF treatment, 12/22 - after 24 weeks of treatment.

Levels of serum DNase activity did not differ before and during the INF treatment (p>0.05). For assessment prognostic value of laboratory signs in INF response prediction logistic regression was used. Prognostic model, which included changes in ANA (ΔANA) and DNase serum activity level (ΔDNAse) to INF was applied. Anti-CCP- and RF-negativity was better (p=0.02) (area under ROC-curve =1,0; 95% CI 0,844–1,00 p=0,0001) than the model, which included only anti-CCP- and RF-negativity (area under ROC-curve =0,795; 95% CI 0,597–0,924, p=0,014).

**Conclusions:** The study confirmed the efficacy of RA treatment by INF for anti-CCP- and RF negative patients. DNAse serum activity and ANA may be used as additional prognostic biomarker of INF response. For the assessment DNase activity as marker of response to therapy is needed further investigations with more number of patients.

**SAT0167**

**CAN INFlixIMAB EFFICACY BE PREDICTED BASED ON BLOOD CONCENTRATION AT THE FOURTH DOSE?**

M. Sato 1, M. Takemura2, T. Tani1, T. Ohashi1, 1Rheumatology, Ohashi and Tani Orthopedics, Gifu; 2Advanced Diagnostic System Research Laboratory, Fujita Health University Graduate School of Health Sciences, Toyoaka, Japan

**Background:** Biological drugs exhibit excellent efficacy and continuity in the treatment of rheumatoid arthritis (RA) and play an important role in RA treatment. Blood concentration is an important factor in the efficacy of biological drugs, particularly antibody drugs. Infliximab (IFX) is an antibody drug against TNF-α and is required to reach a blood concentration of ≥1 μg/mL to be effective.

**Objectives:** To investigate whether clinical efficacy can be predicted based on blood concentrations at the fourth dose of IFX in patients with RA.

**Methods:** This study included 56 patients with RA who were treated with IFX. Patients included 13 men and 43 women aged from 26 to 81 years (mean: 56.3±14.7 years). The IFX concentration was measured immediately before administering the fourth IFX dose (8 weeks after administering the third dose). We then investigated the relationship between subsequent IFX efficacy and IFX concentration immediately before the fourth dose of IFX in these patients with RA. Concentrations were measured in stored frozen serum by using the ELISA method.

**Results:** The IFX concentration immediately before the fourth dose was ≥1 μg/mL in 32 patients (57.1 μg/mL group) and <1 μg/mL in 24 patients (1.1 μg/mL group). At the fourth dose, IFX was effective in 30 patients (93.8%) in the ≥1 μg/mL group, at a mean concentration of 5.18 μg/mL, while the mean concentration was 5.69 μg/mL for the remaining 2 non-responders. IFX was also effective in 21 patients (87.5%) in the <1 μg/mL group but did not elicit any response in the other 3 patients. At this point, all 5 non-responders patients were primary non-responders, 41.2% were in the ≥1 μg/mL group and 41.2% were in the <1 μg/mL group. Based on the data, we observed no relationship between efficacy and IFX concentration. After 1 year of IFX treatment, 36 of the 56 patients were responsive and 20 were non-responders. In the 2 groups, 26 responsive patients (63.9%) and 9 non-responders (45.0%) had an IFX concentration of ≥1 μg/mL immediately before the fourth dose.

**Conclusions:** At the fourth dose, many of the patients with an IFX concentration of <1 μg/mL were also responsive to the treatment, so future efficacy was difficult to predict based on IFX concentration. In other words, during clinical evaluation, measurement of IFX concentrations is not necessary in responsive patients. However, IFX concentrations should be measured in non-responsive patients or patients with a diminished response. If the concentration is <1 μg/mL, IFX efficacy should be restored by increasing the dose or shortening the administration interval.

**DISCONTINUATION OF FIRST BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS: MAIN CAUSES AND CORRELATION BETWEEN SECONDARY INEFFICACY AND DEVELOPMENT OF IMMUNOGENICITY**

P. Bogas1, C. Plascencia1, D. Pascual-Salcedo2, G. Bonilla1, E. Morai1, C. Tornero1, L. Nuño1, A. VillaIba1, D. Peiteado1, A. Martínez2, B. Hernández4, A. Balza1, 1Rheumatology; 2Immunology; 3Hospital Universitario la Paz, Madrid, Spain

**Background:** Biologic therapy has been a major change in Rheumatoid Arthritis (RA) prognosis, but around 40% of patients (pts) fail to respond. Part of this treatment failure can be explained by the development of anti-drug antibodies (ADA), but the ADA-associated secondary inefficacies rate is currently unclear.

**Objectives:** To assess in our RA cohort treated with Adalimumab (Ada), Infliximab (Ixfx), etanercept (Entn), certolizumab (Czp), tocilizumab (Tcz) and Abatacept (Abt) as 1st biologic agent, the frequency of drug suspension as well as the main causes for discontinuation and the secondary inefficacy rate associated with the development of immunogenicity.

**Methods:** From the RA cohort that initiated their 1st biologic agent at Hospital La Paz between 2005 and 2016, only those who had suspended their drugs were included, and causes for suspension were collected. Clinical activity was measured by DAS28 and Delta-DAS28 at 6 months of treatment to classify discontinuation by primary or secondary inefficacy. Drug levels (DL) and/or ADA were also measured by ELISA at 6 months since initiating the biologic agent in 43 pts and at drug discontinuation in 59 pts. Primary inefficacy was defined as DAS28≥3.2 and delta-DAS28 <1.2 at 6 months with DL present. Secondary inefficacy was defined as DAS28≥3.2 plus delta-DAS28 <1.2 at 6 months with ADA+. Delta-DAS28≥1.2 or Delta-DAS28 <3.2 at 6 months with subsequent loss of efficacy. Statistical analysis was performed using SPSS version 20.0.

**Results:** From the 246 pts who started their first biologic therapy, 144 (58%) pts who had definitively discontinued were included. [Ixf (n 35, 24%), Ada (n 40, 28%), Entn (n 30, 21%), Czp (n 23, 16%), Tcz (n 10, 7%) y Abt (n 6, 4%)]. 116 (80.6%) were women. The mean age was 56.3±14.7 years. From the global cohort, 18 (12.5%) drop out of the treatment due to primary inefficacy, 41 (28.5%) to secondary inefficacy, 57 (39.6%) to adverse effects (AE), 11 (7.6%) to remission and 17 (11.8%) to other causes (surgery, pregnancy, etc.). 12.5% pts who discontinued due to AE or other causes had also a primary or secondary inefficacy; by including those pts in these last causes for suspension, a total of 20 pts (14%) failed due to primary inefficacy and 57 pts (39.6%) to secondary inefficacy. The most frequent AEs were: infections (35%), cutaneous AEs (psoriasis, rash, etc. (10.5%), infusions reactions (9%) and neoplasia (9%). Of the 59 pts who had DL/ADA measured at drug discontinuation, 42.4% were ADA+. Within the group that failed due to secondary inefficacy and had DL/ADA determined, 50% were ADA+; nevertheless this rate was smaller in suspensions due to other causes. Likewise, in the ADA+ pts, 73% suspended due to secondary inefficacy.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.6072
discontinuation. These data suggest that the development of ADA is a frequent cause of secondary inefficacy in our RA pts.

**SAT0169** MAINTENANCE AND IMPROVEMENT IN CLINICAL EFFICACY BETWEEN WEEK 12 AND 24 IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SB4 OR REFERENCE ETANERCEPT

P. Emery1, J. Vencovsky2, E. Keystone3, J. Ghi4, S.Y. Cheong5, E.E. Hong6. 1Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 2Institute of Rheumatology, Prague, Czech Republic; 3Mount Sinai Hospital, Toronto, Canada; 4Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of

**Background:** SB4 is approved by the European Commission as a biosimilar of the reference etanercept (ETN).

**Objectives:** To evaluate the maintenance and improvement in clinical efficacy between week 12 and 24 in patients with rheumatoid arthritis (RA) treated with SB4 or ETN from a post-hoc analysis of phase III trials.

**Methods:** Patients with RA were randomised to receive 50 mg/week of either SB4 or ETN with background methotrexate. American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) responses were compared at week 12 and week 24. At week 12, patients w 24 available-case subset results were categorised as ACR responders or ACR non-responders and EULAR responders (patients with moderate or good EULAR response) or EULAR non-responders. The same was assessed for week 24 and patients with missing data at week 24 were regarded as non-responders.

**Results:** A total of 551 patients (283 patients from SB4 and 268 patients from ETN) completed 24 weeks of the study. In both treatment groups, efficacy was well maintained between week 12 and week 24. Among patients who were ACR20, 50, or 70 responders at week 12, 90.8% vs. 91.4%, 80.5% vs. 80.6%, and 74.6% vs. 77.5% of patients from SB4 and ETN, respectively, maintained their responses at week 24. Likewise, EULAR response was maintained by 93.1% vs. 92.6% of patients who had a good or moderate response at week 12. (Table). The improvement in ACR responses between week 12 and 24 was comparable between SB4 and ETN group (Table). In SB4 and ETN, respectively, 42.1% vs. 50.5% of 12-week ACR20 non-responders became ACR20 responders at week 24. Similarly, 20.9% vs. 21.9% of 12-week ACR50 non-responders became ACR50 responders and 13.0% vs. 11.4% of 12-week ACR70 non-responders became ACR70 responders. The improvement in EULAR responses was also comparable between SB4 and ETN. 43.2% vs. 52.2% of 12-week EULAR non-responders in SB4 and ETN, respectively, became EULAR responders at week 24.

**Conclusions:** Efficacy of SB4 and ETN was well maintained and the maintenance rate was comparable between week 12 and week 24. In addition, a similar and considerable proportion of patients in SB4 and ETN who did not achieve a clinical response at week 12 reached clinical response at week 24. These results suggest that etanercept non-responders at week 12 may benefit from continuing treatment up to 24 weeks.

**SAT0170** B-CELL PHENOTYPE AND IGD-CD27- MEMORY B CELLS ARE AFFECTED BY TNF-INHIBITORS AND TOCILIZUMAB TREATMENT IN RHEUMATOID ARTHRITIS

R.A. Moura1, C. Quaresma1, A.R. Vieira1, M.J. Gonçalves1, 2, J. Polido-Pereira1,2, V.C. Romão2, N. Martins3, H. Canhão1, J.E. Fonseca1, 2. 1Rheumatology Research Unit, Instituto de Medicina Molecular; 2Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon, Portugal

**Background:** The use of TNF-inhibitors and/or the IL-6 receptor antagonist, tocilizumab, in rheumatoid arthritis (RA) have pleiotropic effects that also involve circulating B-cells.

**Objectives:** The main goal of this study was to assess the effect of TNF-inhibitors and tocilizumab on B-cell phenotype and gene expression in RA.

**Methods:** Blood samples were collected from untreated early RA (ERA) patients (<1 year of disease duration), established RA patients under methotrexate treatment, established RA patients before and after treatment with TNF-inhibitors and tocilizumab, and healthy donors. B-cell subpopulations were characterized by flow cytometry and B-cell gene expression was analyzed by real-time PCR on isolated B-cells. Serum levels of BAFF, CXCL13 and sCD23 were determined by ELISA.

**Results:** The frequency of total CD19+ B-cells in circulation was similar between controls and all RA groups, irrespective of treatment, but double negative (DN) IgD-CD27- memory B-cells were significantly increased in ERA and established RA when compared to controls. Treatment with TNF-inhibitors and tocilizumab restored the frequency of IgD-CD27- B-cells to normal levels, but did not affect other B-cell subpopulations. TACI, CD95, CD5, HLA-DR and TLR9 expression on B-cells significantly increased after treatment with either TNF-inhibitors and/or tocilizumab, but no significant changes were observed in BAFF-R, BCMA, CD69, CD86, CXCR5, CD25, CD38 and IgM expression on B-cells when comparing baseline with post-treatment follow-ups. Alterations in B-cell gene expression of BAFF-R, TACI, TLR9, FcγRIB, BCL-2, BLMIP-1 and p2M were found in ERA and established RA patients, but no significant differences were observed after TNF-inhibitors and tocilizumab treatment when comparing baseline and follow-ups. Serum levels of CXCL13, sCD23 and BAFF were not significantly affected by treatment with TNF-inhibitors and tocilizumab.

**Conclusions:** In RA, treatment with either TNF-inhibitors or tocilizumab affects B-cell phenotype and the frequency of memory B-cell subpopulations in peripheral blood, particularly DN (IgD-CD27-) B-cells, but not B-cell gene expression or serum levels of CXCL13, sCD23 and BAFF, when comparing baseline with post-treatment follow up. Overall, our results suggest that TNF-inhibitors and tocilizumab inhibit B-cell trafficking towards inflammatory sites, thus supporting active B-cell recirculation from tissues through blood and lymphatic systems.

**SAT0171** ABP 501 BIOSIMILAR TO ADALUMAB: FINAL SAFETY, IMMUNOGENICITY, AND EFFICACY RESULTS FROM AN OPEN-LABEL EXTENSION STUDY

S. Cohen1, J.L. Pablos2, H. Wang3, G.A. Müller4, A. Kivitz5, A. Matsumoto6, E. Krishnan7, 1Metroplex Clinical Research Center, Dallas, United States; 2Instituto de Investigación Sanitaria. Madrid, Spain; 3Spanish Rheumatology Network, S. P. I. D. A.; 4Department, Centro Hospitalar de Lisboa Norte, EPE, Lisbon, Portugal; 5Alltoona Center for Clinical Research, Duncansville, 6Arthritis and Rheumatism Associates, Wheeling, United States

**Background:** ABP 501 has been approved by the US FDA as the first biosimilar to the fully human recombinant monoclonal antibody, adalimumab. Totality of evidence to date suggests that ABP 501 is highly similar to adalimumab. Subjects receiving either ABP 501 or adalimumab in the active-controlled, comparative, pivotal phase 3 study in rheumatoid arthritis (parent study) continued on this open-label extension (OLE) study if they had completed the final week 26 visit of that study.

**Objectives:** To describe the safety, immunogenicity, and efficacy outcomes of ABP 501 in the OLE study.

**Methods:** Subjects who completed the parent study were screened and were included if they met the eligibility requirements. All subjects included in the OLE were treated with ABP 501 40 mg subcutaneously every other week for 70 weeks and the follow-up safety assessment at week 72 (or early termination). Data were summarized descriptively and no inferential analyses were performed.

**Results:** Of the 467 subjects enrolled in the OLE study, 466 were treated with ABP 501. Of these, 237 transitioned from the adalimumab arm of the parent study; 412/467 completed the study. Demographics and disease characteristics were balanced between subjects who transitioned from adalimumab and those who continued on ABP 501 from the parent study. Overall, the incidence of treatment-emergent adverse events (TEAEs) was 63.7% (297/466) and that of grade ≥3 TEAEs was 9.0% (42/466); incidence of TEAEs leading to discontinuation of investigational product was 3.6% (17/466). TEAEs with incidence ≥5% were nasopharyngitis (9.2%), upper respiratory tract infection (8.6%), bronchitis (8.4%), rheumatoid arthritis (6.2%), hypertension (4.7%), and pharyngitis (4.1%). The incidence of serious adverse events was 9.9% (46/466). Most common
SAT0172 ECONOMIC OUTCOMES, TREATMENT PATTERNS, AND ADVERSE EVENTS AND REACTIONS FOR PATIENTS PRESCRIBED INFLIXIMAB OR CT-P13 IN THE TURKISH POPULATION

K. Phillips1, T. Juday2, Q. Zhang3, A. Keshishian3. 1Vanderbilt University Medical Center, Nashville; 2AbbVie Inc., North Chicago; 3STATinMED Research, Affiliated to, United States

Background: CT-P13, a biosimilar drug product to infliximab, was approved and marketed in July 2014 in Turkey. There is little information on the costs, treatment discontinuation and adverse events and reactions between patients who switched from infliximab to CT-P13 and patients who continued infliximab.

Objectives: The study objective was to evaluate health care costs, treatment discontinuation, and adverse events and reactions between patients who switched from infliximab to CT-P13 and patients who continued infliximab in the Turkish population.

Methods: Adult patients with ≥1 claim for infliximab or CT-P13 were identified in a Turkish healthcare administrative database representing 80% of the Turkish population during the identification period (16 July 2014–31 Aug 2015). Patients were required to continuously use infliximab for ≥6 months with no hospitalizations. Eligible patients either continued on infliximab (index date: date of first infliximab prescription), or switched from infliximab to CT-P13 (index date: switch date). Patients were excluded if they had ≥1 condition with an indication for infliximab during the baseline period. Patients who switched to CT-P13 were 1:1 matched to patients who continued infliximab based on the length of infliximab use prior to the index date. Demographics and clinical characteristics were measured 12 months pre-index date. Generalized linear models were used to compare adjusted health care costs, continued use was used to evaluate the adjusted risk of discontinuation, and Poisson regression was used to evaluate the adjusted risk of adverse events and reactions.

Results: The study included 1,524 patients, of whom 1,388 were continuous infliximab users and 136 switched to CT-P13. Ankylosing spondylitis and rheumatoid arthritis were the most common conditions indicated for infliximab and CT-P13; however, patients were much less likely to be switched to CT-P13 for other conditions. After adjusting for demographics and clinical characteristics, patients who switched to CT-P13 had higher outpatient ([Turkish lira] TL 289 vs TL 181; p<0.001), inpatient (TL 64 vs TL 29; p=0.313), and pharmacy costs (TL 1,473 vs TL 1,329; p=0.371), which resulted in significantly higher total health care costs (TL 2,209 vs TL 1,640; p=0.046) compared to patients who continued infliximab. Additionally, patients who switched to CT-P13 were more likely to discontinue infliximab users and 13% of patients compared to those who continued infliximab. Of patients who discontinued CT-P13, 79% switched back to infliximab. After adjusting for baseline characteristics, patients who switched to CT-P13 were significantly more likely to discontinue treatment compared to those who continued infliximab (HR=5.53; 95% CI: 4.01–7.63). There was no difference in the incident rate ratio (IRR) between the cohorts for adverse events (IRR=0.67; 95% CI: 0.19–2.30) and reactions (IRR=0.84; 95% CI: 0.55–1.27).

Conclusions: Patients who switched to CT-P13 had significantly higher health care costs and were more likely to discontinue treatment compared to those who continued infliximab. However, there was no difference in the rate of adverse events and reactions.

SAT0173 SWITCHING FROM REFERENCE PRODUCT ETANERCEPT TO THE BIOSIMILAR SB4 IN A REAL-LIFE SETTING: FOLLOW-UP OF 147 PATIENTS

V. Sigurðardóttir1,2, T. Husmark1, A. Svírd1,2. 1Reumatologikliniken, Falun, Sweden; 2Centre of Clinical Research Dalarna, Falun, Sweden

Background: The etanercept biosimilar SB4 was introduced in Sweden in early 2016. SB4 has been shown in a randomized controlled trial to be equivalent to its etanercept reference product (ERP) in terms of efficacy and safety in subjects with active rheumatoid arthritis (RA) (1). In light of this, and the fact that biosimilars offer considerable cost savings, all patients being treated with ERP at our clinic were switched to treatment with SB4 in April 2016.

Objectives: To describe the clinical experiences of switching patients on treatment with ERP to SB4 at our clinic.

Methods: All patients using ERP 50 mg at our clinic were identified using the Swedish Rheumatology Quality Register (SRQ). The patients were issued prescriptions for SB4 50 mg and were sent a letter encouraging them to switch to SB4 when they ran out of ERP. The process of switching was started 21st. However, the actual date of starting treatment with SB4 might have been 0–90 days from April 20th for individual patients, as prescriptions are written in 3 month increments.

Patients were followed up clinically and in the SRQ as planned at the last visit before switching.

Results: A total of 147 RA patients and 136 psoriatic arthritis (PsA) patients from the last visit preceding the switch and the last visit after the switch registered up to January 2017 were collected from the SRQ. The paired T-test was used to compare mean DAS28 before and after switching.

At the end of January 2017, 126 patients (86%) were still on SB4. Since the switch, 9 patients have requested to be switched back to ERP, 2 made the request before initiating treatment with SB4. No objective evidence for lack of efficacy was seen in these 9 patients. Seven patients have stopped treatment with SB4 because of inactive disease. Five patients have been switched to a non-etanercept biologic because of lack of efficacy; these patients also had lack of efficacy when on ERP.

The 76 RA patients had a mean disease duration of 17 years and had been on ERP for a mean duration of 4.7 years. As of January 2017, 60 of the RA patients had been on a follow-up visit and 54 of these had available DAS28 data from both the last visit before and after switching. For the RA patients DAS28 was 2.80 before and 2.79 after switching. p=0.960. Complete DAS28 data was available for 23 of the 28 PsA patients, mean DAS28 was 2.54 before switching and 2.06 after, p<0.161. The mean duration since switching at follow-up was 22 weeks for the RA and PsA patients.

Conclusions: Switching from the etanercept reference product to the biosimilar SB4 was acceptable to most of our patients. Low mean disease activity has been maintained in the RA and PsA group after the switch.

SAT0174 USE OF A 8-WEEK OBSERVATIONAL PERIOD FOR PREDICTING REMISSION AND LOW DISEASE ACTIVITY AT 52 WEEKS IN RA PATIENTS TREATED WITH CERTOLIZUMAB PEGOL – A MULTICENTER STUDY

Y. Kanaanya1, A. Kaneko2, N. Takahashi3, T. Kato4, M. Hayashi5, Y. Hattori2, N. Asai3, N. Ishiguro2, T. Kojima2. 1Reumatologikliniken, Falun, Sweden; 2Orthopedic Surgery and Rheumatology, Toyota Kosei Hospital, Toyota; 3Orthopedic Surgery and Rheumatology, Nagoya Medical Center; 4Orthopedic Surgery, Nagoya University Graduate school of Medicine, Nagoya; 5Orthopedic Surgery, Kato clinic, Okazaki; 6Orthopedic Surgery and Rheumatology, Nagano Red Cross Hospital, Nagano, Japan

Background: Certolizumab pegol (CZP) is a polyethylene glycol (PEGylated Fc-fn new anti-TNFα agent. However few data still reported clinical efficacy of CZP treatment in the routine setting.

Objectives: This study aimed to provide clinical evidence of an adequate observational period for predicting remission and low disease activity (LDA) achievement at 52 weeks in RA patients treated with Certolizumab pegol (CZP).

Methods: Patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria who had been prescribed CZP from Tsurumi Biomail Communications Registry (TBCR) between May 2013 and October 2015 were enrolled. The final study cohort of 98 Japanese RA patients. We reviewed the methods about the improvement of DAS28-ESR and SDAI which was an index of disease activity of RA using Wilcoxon signed-rank test and the rate of remission and LDA patients at
from IFX to CT-P13 (Switchers cohort; SC) during the identification period; had
continuous medical/pharmacy benefit enrollment ≥120 days after the index date (date of switch for SC and a random IFX prescription
for CC); had a prescription claim for IFX within 16 weeks of the index date
and 12 months after the index date (date of switch for SC and a random IFX prescription
date for CC); had a prescription claim for CT-P13 following availability of CT-P13
(120 days after the index date for SC, and a random IFX prescription date for CC).

Conclusions: This study shows switching from IFX to CT-P13 was infrequent. However, in those switching to CT-P13, a high percentage (82%) of CT-P13
discontinuation was observed and the majority returned to IFX. Further studies
are needed to understand the reasons for these observations.

SAT0176 PATTERNS OF BIOLOGIC DMARD MONOTHERAPY IN A LARGE NATIONWIDE RHEUMATOID ARTHRITIS COHORT: DATA FROM 1036 PATIENTS

Rheumatoid arthritis - other biologic treatment

SAT0175 A DESCRIPTIVE ANALYSIS OF REAL-WORLD TREATMENT PATTERNS IN A TURKISH RHEUMATOLOGY POPULATION

1New York University Hospital for Joint Diseases, New York; 2STATinMED Research Inc, Ann Arbor; 3Janssen Scientific Affairs, LLC, Horsham, United States; 4Guven Hospital, Ankara, Turkey

Objectives: This study examined treatment patterns in a rheumatology patient (pt)
population initially prescribed innovator infliximab (IFX) that either switched to
biosimilar infliximab (CT-P13) or continued on IFX following availability of CT-P13
in the Turkish healthcare system.

Methods: Adult pts with ≥1 diagnosis code (ICD-10-CM M05.X; M06.X) for
rheumatoid arthritis (RA) and a prescription for IFX were identified in a national
Turkish health care database during the study period (01DEC2010-01DEC2015).

Eligible pts were those who continued on IFX (Continuers cohort; CC) or switched

to another biologic with 94% of these returning to IFX.

Conclusions: The new TNF-antagonist therapy of CZP was effective early and
rapidly in patients with active Japanese RA. This study suggested that eight
weeks is an adequate optimal period to judge whether the achieved remission or
not at Week 52.

SAT0176 PATTERNS OF BIOLOGIC DMARD MONOTHERAPY IN A LARGE NATIONWIDE RHEUMATOID ARTHRITIS COHORT: DATA FROM 1036 PATIENTS

Rheumatoid arthritis - other biologic treatment
Background: There are limited literature data regarding the characteristics of rheumatoid arthritis (RA) patients treated with biologic DMARD (bDMARD) monotherapy.

Objectives: To evaluate the disease and treatment characteristics of RA patients treated with bDMARD monotherapy.

Methods: Multicenter, cross-sectional RA epidemiological study in Greece (06/2015–05/2016, ERE RA Study Group). Demographics, disease characteristics, treatment and co-morbidity data were collected via a web-based platform.

Results: 1036 RA patients treated with bDMARDs were identified during the one year recruitment period (female: 82%, mean age: 61.5±13 years, mean disease duration: 12.5±8.9 years, mean DAS28-ESR: 3.4±5.3). 26% (n=273) were receiving bDMARDs as monotherapy and 8% (n=23) of them had never tried conventional synthetic DMARDs (csDMARDs) before; The latter group (n=23) compared to the csDMARD-exposed (92%, n=250) group, had more often co-morbidities (cardiovascular disease (22% vs. 8%, p=0.029), chronic hepatitis (13% vs. 3%, p<0.001), hypertension (57% vs. 38%, p=0.008), COPD (13% vs. 4.4%, p=0.07)) or were active smokers (41% vs. 14%, p<0.001). csDMARD discontinuation was mainly due to adverse events (AEs) (58%) followed by inadequate response (IR) (44%). Compared to the cs- and b-DMARD combination therapy group, monotherapy treated patients were more frequently seropositive (64% vs. 57%, p<0.005), had lower DAS28-ESR (3.2 vs. 3.5, p=0.009) and were more likely to have discontinued csDMARDs for AEs (58% vs. 21%, p<0.001) or IR (44% vs. 27%, p=0.001). Tocilizumab (22.3% vs. 12.7%, p<0.001) and rituximab (19.8% vs. 13.5%, p<0.03) were utilized more often, whereas adalimumab less often (8.8% vs. 14.8%, p=0.012) as monotherapy compared to as part of combination therapy.

Conclusions: In our large RA cohort, one out of four bDMARD treated patients, were receiving bDMARDs as monotherapy. Co-morbidities rather than RA characteristics influence the initial decision for bDMARD monotherapy whereas among those starting combination cs- and b-DMARD therapy, the majority discontinue csDMARDs due to AEs.

SAT0177 SAFETY EVENTS ARE SIMILAR WITH ABATACEPT VS PLACEBO TREATMENT IN RA: RESULTS FROM INTEGRATED DATA ANALYSIS FROM NINE CLINICAL TRIALS

B. Soule 1, M. Hochberg 2, D. Fleming 1, A. Torbeys 1, T. Simon 1, S. Banerjee 1, M. Boers 3, Bristol-Myers Squibb, Princeton; 2University of Maryland, Baltimore, United States; 3VU University Medical Center, Amsterdam, Netherlands

Background: Abatacept is a selective co-stimulation modulator that consists of the extracellular domain of human cytotoxic T lymphocyte-associated antigen-4 linked to the Fc portion of human immunoglobulin G1 and is approved initially for the treatment of RA in 2005. The integrated safety database for abatacept in adult RA comprises data from short- and long-term periods of 16 open-label and double-blind RA clinical trials, and combines studies of both IV and SC abatacept involving 7044 total patients. Of these, data from the 9 double-blind, placebo-controlled studies involving 4138 total patients were included in this analysis. The most recent overall safety analysis was performed in 2012 and reported IV and SC results separately.

Objectives: To provide an update of the overall abatacept safety profile based on data analysis from both IV and SC trials.

Methods: This evaluation included all patients with RA enrolled in 9 key double-blind, placebo-controlled clinical trials of IV and/or SC abatacept. The safety analysis includes all serious adverse events (SAEs), as well as AEs of interest including infections, malignancies and autoimmune diseases.

Results: In total, 2653 patients were exposed to abatacept and 1485 received placebo. During the double-blind, controlled period, the mean (SD) duration of exposure was 10.3 (3.5) months for the placebo group and 10.8 (3.3) months for the abatacept group for a total exposure of 2357 and 1254 patient years, respectively (Table 1). The proportion of patients as well as incidence rates for serious adverse events (SAEs), malignancies and infections were similar in both groups. Table 2 compares AEs and infections in the abatacept and placebo treatment groups.

Conclusion: In a large RA clinical trial database, safety events including deaths, serious infections, opportunistic infections, malignancies and autoimmune diseases occurred at similar frequencies and rates in the abatacept and placebo treatment groups.

THE ASP358ALA VARIANT IN THE IL6R GENE IS SIGNIFICANTLY ASSOCIATED WITH DIFFERENCES IN SOLUBLE IL-6R LEVELS BUT NOT WITH DIFFERENCES IN SARILUMAB RESPONSE IN RHEUMATOID ARTHRITIS (RA) PATIENTS

A. Damask1, A. Boyapati1, J.D. Hamilton1, S. Hamon1, C. Paccard2, J. Parrino1, J. van Adelsberg1, N.M. Graham1, J. Penn1, A. Lopez1, J. Reid1, J. Overton1, A. Baras1, A.R. Shuldiner1, C. Paulding2, J. Parrino1, J. Hamilton Shareholder of: Regeneron Pharmaceuticals, Inc, Employee of: Regeneron Pharmaceuticals, Inc, Tarrytown, United States; 2Sanofi R&D, Chilly-Mazarin, France

Background: Sarilumab is a human mAb that blocks IL-6 from binding to both membrane-bound and soluble IL-6Rs (sIL-6R). A missense variant in the IL6R gene, Asp358Ala (rs2228145), falls within a proteolytic cleavage site and individuals with an alanine at this position have increased sIL-6R in circulation.1 In addition, this variant has been associated with several diseases including RA.2

Objectives: To determine the impact of the Asp358Ala variant on sIL-6R concentrations and response of RA patients to sarilumab.

Methods: DNA was collected from patients enrolled in the MOBILITY study (NCT01061736) that evaluated the efficacy and safety of sarilumab + methotrexate (MTX) in RA patients with inadequate response to MTX. The pharmacogenetic analysis was conducted on 599 Caucasian patients (396 sarilumab 150 or 200 mg q2w + MTX, 203 placebo + MTX).

Results: Concentrations of sIL-6R were strongly associated with the Asp358Ala genotypes at baseline (p=4.2 x 10⁻⁴). The difference in sIL-6R concentrations between genotype groups continued to increase in sarilumab-treated patients through the end of treatment, particularly for the CC genotype (Figure; p=7.8 x 10⁻⁷). There was a modest association for change in sIL-6R in placebo + MTX–treated patients (p=0.0052). Variation in Asp358Ala was not associated with sarilumab efficacy, including mTSS at week 52 and ACR scores (Table).

Conclusions: The Asp358Ala variant in the IL6R gene is significantly associated with differences in sIL-6R levels at baseline and after sarilumab treatment. The differences across genotypes may be due to increases in sIL-6R production. Importantly, this variant was not associated with differences in sarilumab treatment response. These data suggest that the sarilumab doses used for this clinical study saturate both the membrane and soluble forms of IL-6R and effectively block IL-6 signaling. Sarilumab provides therapeutic benefit for RA patients irrespective of their Asp358Ala genotype status.

Efficacy and Safety of Sarilumab 200 mg q2w Administered as Combination Therapy or Monotherapy in Different Patient Populations with Active RA

M.C. Genovese1, R. Fleischmann2, H. van Hoogstraten3, E.K. Mangan4, S. Jayawardena5, G.R. Burmester2, 1Stanford University Medical Center, Palo Alto; 2Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas; 3Sanofi Genzyme, Bridgewater; 4Regeneron Pharmaceuticals, Inc, Tarrytown, United States; 5Charité - University Medicine Berlin, Free University and Humboldt University of Berlin, Berlin, Germany

Background: Sarilumab, a human mAb blocking the IL-6Rα, was evaluated in 3 pivotal clinical trials.

Objectives: To assess efficacy and safety of sarilumab 200 mg q2w + csDMARDs or as monotherapy (MONARCH) in adults with active RA and inadequate response or intolerance to MTX (MOBILITY/MONARCH) or TNFi (TARGET).

Methods: MOBILITY (NCT01061736) was a 52-wk study; TARGET (NCT01709578) and MONARCH (NCT02332590) were 24-wk studies. Patients were randomized to placebo (Pbo) or SC sarilumab 150 or 200 mg q2w + MTX (MOBILITY) or csDMARDs (TARGET), MONARCH patients were randomized to SC monotherapy with adalimumab 40 mg q2w or sarilumab 200 mg q2w. Efficacy endpoints assessed in all 3 studies will be presented.

Results: Within studies, baseline demographic and disease characteristics were similar among treatment groups. Sarilumab 200 mg q2w improved ACR responses, HAQ-DI, DAS28-CRP, and CDAI (Table). Treatment response with sarilumab + csDMARDs was similar in MTX-IR and TNF-IR patients and with sarilumab monotherapy. Incidence of TEAEs and SAEs with sarilumab was more frequent vs Pbo (MOBILITY, TARGET) and similar to adalimumab (MONARCH). The most common TEAEs included infections, neutropenia, and injection site reactions and occurred more often with sarilumab vs Pbo (MOBILITY, TARGET). In MONARCH, rates of infection were similar with sarilumab and adalimumab.

Conclusions: The Asp358Ala variant in the IL6R gene is significantly associated with differences in sIL-6R levels at baseline and after sarilumab treatment. The differences across genotypes may be due to increases in sIL-6R production. Importantly, this variant was not associated with differences in sarilumab treatment response. These data suggest that the sarilumab doses used for this clinical study saturate both the membrane and soluble forms of IL-6R and effectively block IL-6 signaling. Sarilumab provides therapeutic benefit for RA patients irrespective of their Asp358Ala genotype status.

although neutropenia was more frequent with sarilumab. Safety of sarilumab was generally comparable in monotherapy and combination studies; monotherapy was associated with fewer ALT elevations >3×ULN compared with combination therapy: MONARCH, 3%; MOBILITY, 8%; TARGET, 4%.

Conclusions: Sarilumab 200 mg q2w + csDMARDs significantly reduced disease activity compared with placebo in a similar extent regardless of population (MTX-IR or TNF-IR) and as monotherapy. Safety profile of sarilumab was generally comparable across all 3 trials, with monotherapy resulting in fewer ALT elevations.

SAT0181 | LOW DOSE INTERLEUKIN-2 COMBINED WITH TOCILIZUMAB SELECTIVELY INCREASES REGULATORY T CELLS HELPING REFRACTORY RHEUMATOID ARTHRITIS PATIENTS ACHIEVE REMISSION MORE RAPIDLY
Z. Sheng-Xiao1, M. Xiao-Wen2, L. Xiao-Qing3, M. Miao1, W. Xiao-Yan1, R. Hong-Zhong4, W. Caogong, L. Xiao-Feng1. 1. The Second Hospital of Shanxi Medical University, Taiyuan, China

Background: Rheumatoid arthritis (RA) is a prevalent chronic autoimmune inflammatory disease. Its pathogenesis is closely associated with a failure of endogenous immune tolerance that caused by the imbalance of pro-inflammatory T helper 17 (Th17) cells and anti-inflammatory regulatory T (Treg) cells. Low-dose Interleukin-2 (IL-2) has been showed to induce both Th17 and Treg cells expansion and activation while IL-6 antagonist Tocilizumab suppresses the differentiation of Th17, which is expected to control the development of RA.

Objectives: To study the influence of the combination of IL-2 and Tocilizumab on T cells subgroups and their clinical efficacy and safety on refractory RA.

Methods: Total 50 RA patients with low Treg cells, who had been treated with glucocorticoids and DMARDs for over 6 months, were divided into three groups randomly. Patients in non-IL-2 group (n=15) were still given conventional glucocorticoids and DMARDs. Patients in IL-2 group (n=26) were not only given those treatments, but injected subcutaneously human IL-2 (aldesleukin) at 50 WIU per day for 5 days course. Patients in IL-2 and Tocilizumab group (n=9) were not only received the treatment like IL-2 group, but also treated with Tocilizumab at the dosage of 160mg during the day 1 and day 3. The demographic features, clinical manifestations and laboratory indicators were compared before and after the treatment.

Results: There was no difference among all groups in gender, age and course of the disease (p>0.05). The ratios of Th1/Th2 and Th17/Treg were significantly associated with a failure of endogenous immune tolerance that caused by the imbalance of pro-inflammatory Th1 helper 17 (Th17) cells and anti-inflammatory regulatory T (Treg) cells. Low-dose Interleukin-2 (IL-2) has been showed to induce both Th17 and Treg cells expansion and activation while IL-6 antagonist Tocilizumab suppresses the differentiation of Th17, which is expected to control the development of RA.

SAT0182 | SIRUKUMAB LEADS TO SIGNIFICANT AND CLINICALLY MEANINGFUL IMPROVEMENTS IN HEALTH-RELATED QUALITY OF LIFE THAT MEET OR EXCEED NORMATIVE VALUES IN PATIENTS WITH RHEUMATOID ARTHRITIS REFRACtory TO TNF INHIBITORS IN POST-HOC ANALYSES OF A PHASE 3 TRIAL
V. Strand1, R. Ganguly2, N. Li3, K. McQuarrie4, 1. Stanford University, Palo Alto, CA; 2. GlaxoSmithKline, Collegeville, PA; 3. Janssen Research & Development, LLC, Spring House, PA, United States

Background: Patients (pts) with rheumatoid arthritis (RA) experience reduced health-related quality of life (HRQoL). Sarilumab (SIR) is an anti-interleukin-6 (IL-6) monoclonal antibody.

Objectives: These post hoc analyses evaluated improvements over time in HRQoL relative to an age/gender-matched normative population in RA pts with inadequate responses to tumor necrosis factor inhibitors (TNF-IR) from the phase 3 SIRROUND-T trial.

Methods: 878 pts received SIR 50mg every 4 weeks (q4w), SIR 100mg every 2 weeks (q2w), or placebo (pbo) q2w. Health-related physical/emotional well-being were measured at baseline (BL) and Wk 24 by the 36-item Short Form Questionnaire (SF-36), fatigue by Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue (FACIT-F), and physical function by Health Assessment Questionnaire-Disability Index (HAQ-DI).

Results: SF-36 physical and mental component summary (PCS and MCS) mean scores at BL for pbo, SIR 50mg q2w, and 100mg q2w indicated substantial impairment (PCS: 33.2, 31.8, and 32.4; MCS: 41.9, 41.2, and 42.1). Significantly greater improvements from BL were reported at Wk 24 with SIR 50mg q4w and 100mg q2w vs pbo in PCS (4.8 and 5.1 vs 1.7) and MCS (3.4 and 4.0 vs 1.1) mean scores (all P<0.001) exceeding the minimum clinically important difference (MCID) of 2.5. Significantly greater least squares mean changes in the 8 SF-36 domain raw scores were reported with both doses of SIR vs pbo at Wk 24: all were >MCID of 5.0 (Table; Figure). More pts receiving SIR 50mg q4w or 100mg q2w reported SF-36 domain scores >normative values (ranges: 11–34% and 13–42%) vs pbo (range: 6–29%). For pbo, SIR 50mg q4w, and SIR 100mg q2w, BL FACIT-F scores were 26.0, 24.2, and 25.2; clinically meaningful improvements >MCID (4 points) were reported by 54.3 and 51.4% of pts receiving SIR 50mg q4w and 100mg q2w vs 33.7% with pbo (P<0.001). Numerically greater percentages of pts reported scores >normative values with both doses of SIR vs pbo (27 and 28% vs 16%). BL HAQ-DI scores were 1.57, 1.65, and 1.61 with pbo, SIR 50mg q4w, and 100mg q2w, and 100mg q2w. Clinically meaningful improvements (change of <0.22) were reported by significantly higher proportions of pts receiving SIR 50mg q4w (52.2%) or 100mg q4w (54.8%) vs pbo (37.4%, P<0.001). Numerically more pts reported HAQ-DI scores >normative values with SIR 50mg q4w and 100mg q2w vs pbo (13 and 16% vs 9%).

SAT0183 CLINICAL REMISSION IN SUBJECTS WITH RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS TOCILIZUMAB AS MONOTHERAPY OR IN COMBINATION WITH METHOTREXATE OR OTHER SYNTHEtic DMARDs: A REAL-WORLD CLINICAL TRIAL (TOSPACE)

R. Sanmartín, E. Martín Molá, J.E. Fonseca, D.J. Veale, A. Escudero, C. González, R. Sanmartín, C. González on behalf of ToSpace Study group.

DOI: 10.1136/annrheumdis-2017-eular.3904

Background: Subcutaneous tocilizumab (TCZ-SC) has demonstrated non-inferiority to TCZ-IV and superiority to placebo

Objectives: The primary objective of this study was to assess the 24-week efficacy and safety of subcutaneous (SC) tocilizumab (TCZ) 162 mg weekly (qw) or every 2 weeks (q2w) as monotherapy or in combination with methotrexate (MTX) or other synthetic (s) DMARDs in patients with active rheumatoid arthritis (RA) in the real world setting

Methods: This multinational (Spain, Ireland, Portugal), multicenter, phase IIIb study. Subjects ≥18 years of age with active RA (DAS 28-ESR < 3.2) who have had inadequate response or intolerance to sDMARDs or to a first anti-TNF drug. The study comprised a phase 1 with open-label design in which patients received TCZ-SC 162 mg qw (+/- oral/SC MTX or other sDMARDs) for 24-weeks and the main outcome was the percentage of patients achieving sustained clinical remission (DAS 28-ESR <2.6) at Week 20 and Week 24 (primary outcome of the study); and a phase 2 where patients achieving sustained clinical remission during the phase 1 were randomized to receive TCZ-SC 162 mg qw or TCZ-SC 162 mg q2w (+/- oral/SC MTX or other sDMARDs) for an additional 24 weeks; the main outcome of the phase 2 was the percentage of patients who maintained the remission at week 48 (i.e. DAS 28-ESR <2.6)

Results: 401 patients were included in the phase 1, 74 patients received TCZ-SC monotherapy and 327 patients received TCZ-SC in combination with oral/SC MTX or other sDMARDs. Sustained clinical remission rates were comparable between the mono- and combination-therapy groups at 24 week (48.4% vs. 52.9%, p=0.523). Of the 179 patients who achieved sustained clinical remission during the phase 1, 89 were randomly assigned to receive TCZ-SC 162 mg qw and 90 to receive TCZ-SC 162 mg q2w. At the end of phase 2, the percentage of patients who maintained the remission at week 48 was 91.5% with TCZ-SC qw and 73.9% with TCZ-SC q2w (p=0.002). Main efficacy outcomes for both phases of the study are presented in the table. Rates of serious adverse events (AEs) and rates of AEs leading to drug discontinuation were similar in patients treated with mono or combination therapy, and in patients treated with TCZ-SC qw or TCZ-SC q2w.

Conclusions: In the real-world setting, treatment with TCZ-SC 162 mg qw weekly in patients with active RA is associated with rate of sustained clinical remission of approximately 50% regardless it is administered as monotherapy or in combination with a sDMARD. The proportion of patients who remained in clinical remission at week 48 was significantly higher with TCZ-SC qw than with TCZ-SC q2w. The safety profile of TCZ-SC was consistent with previous studies of TCZ-SC and TCZ-IV

SAT0185  BIO-HOLIDAY THERAPY WITH A TIGHT CONTROL STRATEGY IN RHEUMATOID ARTHRITIS PATIENTS WITH CLINICAL DISEASE ACTIVITY INDEX REMISSION ENABLES MAINTENANCE OF BONE METABOLISM STATUS

E. Torikai, M. Suzuki, Y. Matsuyma. Orthopaedic Surgery, Hamamatsu University School of Medicine, Hamamatsu, Japan

Background: The cost of Bio therapy has become a major problem in health economics and is unaffordable for some patients. Thus, it is important to consider whether we should discontinue or extend the interval of Bio. At EULAR 2016, we reported that, if disease activity (DA), radiographic progression, and biochemical function via Bio-holiday therapy in rheumatoid arthritis (RA) patients with clinical disease activity index (CDAI) remission under a tight control strategy is possible. Osteoporosis is another issue for RA patients. RA patients generally develop osteoporosis more frequently than healthy individuals because of increased bone resorption and inhibited bone formation.

Methods: To investigate bone metabolism markers and bone mass index of RA patients with CDAI remission who underwent Bio-holiday therapy. Methods: Sixty-four RA patients with CDAI remission were included and were classified into two groups. Bio-holiday group (group H) comprised 34 patients (golimumab (GLM) and tocilizumab (TCZ), 18 and 16 patients, respectively) and in which patients were taken off Bio if they achieved CDAI remission. Patients were classified into 3 groups: 1) those who achieved CDAI remission maintained their therapy because of adverse events. Besides one patient who dropped out because of RA flare-up, no patients in either group discontinued their therapy because of financial constraints in the in the groups H and C, respectively. One patient in each group dropped out because of RA flare-up. No patients in either group discontinued their therapy because of adverse events. Besides one patient who dropped out because of RA flare-up, all remaining patients in the group H were able to achieve CDAI remission without delay. There were no statistical differences in the change in bone metabolism makers [urine type I collagen cross-linked N-telopeptide (NTX), serum tartrate-resistant acid phosphatase 5b (TRACP5b), serum bone-specific alkaline phosphatase (BAP), and serum osteocalcin (OC)] and bone mineral density (BMD) of lumbar spine (L-spine) and femoral neck (FN) between both groups for 2 years.

Results: The mean withdrawal periods were 12.1 and 8.8 months with GLM and TCZ, respectively. Three and four patients dropped out because of financial constraints in the in the groups H and C, respectively. One patient in each group dropped out because of RA flare-up. No patients in either group discontinued their therapy because of adverse events. Besides one patient who dropped out because of RA flare-up, all remaining patients in the group H were able to achieve CDAI remission without delay. There were no statistical differences in the change in bone metabolism makers [urine type I collagen cross-linked N-telopeptide (NTX), serum tartrate-resistant acid phosphatase 5b (TRACP5b), serum bone-specific alkaline phosphatase (BAP), and serum osteocalcin (OC)] and bone mineral density (BMD) of lumbar spine (L-spine) and femoral neck (FN) between both groups for 2 years.

Conclusions: We conclude that maintaining disease activity bone metabolism status via Bio-holiday therapy for RA patients with CDAI remission under a tight control strategy is possible. Given that the flare-up rate in RA patients with deep remission is not high, it is not difficult to resume Bio therapy and gain CDAI remission. Furthermore, this treatment is financially durable. Therefore, we recommend Bio-holiday therapy.

SAT0186  EFFECTS OF DENOSUMAB, A SUBCUTANEOUS RANK INHIBITOR, ON THE PROGRESSION OF STRUCTURAL DAMAGE IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH csDMARD: RESULTS FROM THE 12-MONTH DOUBLE BLIND PHASE 3, DESIRABLE STUDY

T. Takeuchi1, Y. Tanaka2, S. Soen3, H. Yamanaka4, T. Yoneda5, S. Tanaka6, T. Nitta7, N. Okubo7, H.K. Genant8, D. van der Heijde9. 1Keio University School of Medicine, Tokyo, Japan; 2University of Occupational and Environmental Health, Kitakyushu; 3Kindai University Nara Hospital, Iruma; 4Institute of Rheumatology Tokyo Women's Medical University, Tokyo, Japan; 5Indiana University School of Medicine, Indianapolis, United States; 6The University of Tokyo, 7Daichi Sankyo Co. Ltd, Tokyo, Japan; 8University of California, San Francisco, United States; 9Leiden University Medical Center, Leiden, Netherlands

Background: Denosumab is a fully human monoclonal antibody (IgG2 subclass) that inhibits bone resorption and inhibiting RANKL, a key mediator of osteoclast formation, function, and survival.

Methods: Denosumab (60 mg every 6 months (Q6M)) was compared with placebo (PBO) in a 12-month, randomized, double-blind, placebo-controlled, parallel-group study in RA patients receiving csDMARD treatment. Subjects fulfilling the 1987 ACR criteria or 2010 ACR-EULAR criteria were randomized (1:1:1) to denosumab 60 mg Q6M, denosumab 60 mg Q3M, or placebo. The primary endpoint is the change in mTSS between baseline and 12 months in the value of patients modified total Sharp score (mTSS). Radiographs of hands and feet at baseline, 6 months and 12 months were scored with blinded time order by 2 readers independently. Average score of the 2 readers was used for the analysis. Comparisons of each denosumab group with placebo for the change from baseline were performed using van Elteren stratified rank test adjusting for baseline glucocorticoid use. Missing scores were imputed using linear extrapolation/interpolation.

Results: Among 679 patients randomized, 667 (placebo, n=223; Q6M, n=222; Q3M, n=222) received at least one dose of study drug, and 60 (placebo n=15; Q6M, n=23; Q3M, n=22) were withdrawn during the study. Demographic and baseline characteristics were similar across the groups (Table 1). Mean change from baseline in mTSS and erosion score (ES) at 12 months was significantly lower with both denosumab 60 mg Q6M and Q3M compared with placebo, with no obvious evidence of an effect on joint space narrowing (JSN) score for denosumab (Table 2).

Consistently, the percent of nonprogressors (ie, mTSS change ≤0.5) at 12 months was significantly greater with denosumab 60 mg Q6M (75.6%, p=0.010) and Q3M (78.1%, p=0.001) compared with placebo (64.2%). Incidence of adverse events (AEs), serious AEs, and AEs leading to discontinuation of study drug were similar across treatment groups. No events of osteonecrosis of the jaw or atypical femoral fracture were observed.

Conclusions: Denosumab inhibited the progression of joint destruction significantly more than placebo and was generally well tolerated in Japanese patients with RA on csDMARDs. Denosumab has potential Utility as a new therapeutic option to inhibit structural progression for patients with RA.

DOI: 10.1136/annrheumdis-2017-eular.1208

SAFETY, PHARMACOKINETICS AND EFFICACY OF E6011, AN ANTI-FRACTALKINE MONOCLONAL ANTIBODY, IN A FIRST-IN-PATIENT PHASE 1/2 STUDY IN RHEUMATOID ARTHRITIS; ADDITIONAL DATA OF 400 MG COHORT

Background: Fractalkine (CX3CL1, designated as FKN hereafter) is the sole member of the CX3C-chemokine which leads to dual actions, chemotaxis and cell adhesion for leukocytes expressing the cognate receptor, CX3CR1, during their migration. Accumulating evidence is telling that FKN–CX3CR1 axis plays a pivotal role in leukocyte/lymphocyte accumulation in inflamed tissues in RA1. Last year, we presented an interim report (up to 200 mg cohort) of Phase 1/2 study [1].

Objectives: To evaluate safety, pharmacokinetics and efficacy of E6011 with the dosage up to 400 mg in a Phase 1/2, open-label, multiple ascending dose study in RA patients (n=18) (NCT02196558).

Methods: Active RA patients with inadequate response (IR) to MTX or TNF inhibitors (TNFi) were received 7 consecutive doses (subcutaneous) of E6011 at week 0, 1, 2 and thereafter every 2 weeks up to week 10. The safety, pharmacokinetics and efficacy up to week 12 were evaluated.

Results: Twelve, 15 and 10 subjects were enrolled in the cohort of 100, 200 and 400 mg dosage, respectively, in total 37 subjects received repeated subcutaneous (SC) administrations of E6011. As a result, repeated dose of E6011 was found safe and well tolerated. The incidence of adverse event (AE), treatment-related AE and serious AE were 56.8%, 29.7% and 5.4%, respectively. AEs occurring in ≥2 subjects were nasopharyngitis, injection site erythema, headache and oropharyngeal pain, among which there were no severe AEs, serious infections and deaths. No significant differences were observed in the incidence or severity of AEs across the cohorts.

After starting multiple SC injection of E6011, serum E6011 concentration reached steady-state at week 2, and its level was maintained up to week 12 in all cohorts. Clinical outcome was also available in the study in which response rates of ACR20, 50 and 70 at week 12 were evaluated. The percentage of patients categorized “good response” with the EULAR response criteria at week 12 (NRI) were 16.7% in 100 mg cohort, 20% in 200 mg cohort and 40% in 400 mg cohort.

Conclusions: E6011 was safe and well tolerated, and the study demonstrated a promising efficacy of E6011 in active RA patients with MTX- or TNFi-IR. The results obtained suggest that a novel approach to target FKN/CX3CR1 interaction will be clinically beneficial for RA, and support to conduct phase 2 clinical trials in which the efficacy and safety should be confirmed in a placebo controlled double-blind manner.

SAT0188 FIRST-LINE TREATMENT PATTERNS OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO ARE ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODY POSITIVE VersUS NEGATIVE

K. Price 1, Y. Doleh 1, M. Eaddy 2, A. Ogbonnaya 2, H.-C. Shih 2, H. Ahmad 1, L. Lamerato 3, A. Szymbalski 1, 3-British-Myers Squibb, Princeton; 2-Xcenda, LLC, Palm Harbor; 3-Henry Ford Health System, Detroit, United States

Background: Patients with RA who are at a higher risk for progressive and destructive arthritis could be identified using anti-cyclic citrullinated peptide antibodies (anti-CCP) levels. Treatment guidelines recommend the use of non-biologic DMARDs as initial treatment in RA; but, if warranted, biologic (b)DMARDs could be considered in early treatment of RA. Real-world data describing treatment patterns based on anti-CCP designations are limited.

Objectives: This study evaluated treatment patterns of patients with RA who are anti-CCP positive (+) or negative (−).

Methods: This retrospective study was based on electronic medical record (EMR) data with a supplemental chart review from a large integrated delivery system. Patients newly diagnosed with RA (International Classification of Diseases, Ninth Revision, Clinical Modification diagnosis code 714.0) were identified between 1 January 2009 and 31 December 2014. The first RA diagnosis date was designated as the index date. Patients were required to have 12 months of continuous activity in the EMR (6 months pre- and 6 months post-index). Based on the baseline anti-CCP test results, patients were categorized as anti-CCP+ (>7.0 U) or anti-CCP− (<7.0 U). First-line therapy (time to treatment initiation, treatment change, treatment change, treatment changes and response to treatment) was evaluated in the post-index period. Response to treatment was determined based on physicians’ notes.

Results: Overall, 217 anti-CCP+ and 191 anti-CCP− patients with RA were included in this study. A higher proportion of anti-CCP+ (153, 70.5%) than anti-CCP− patients (44, 23.0%; p=0.0001) initiated treatment, generally within 1 month after diagnosis (anti-CCP+, mean [SD]: 31.1 [42.1] days and anti-CCP−, 28.1 [37.4] days; p=0.6538). MTX was most commonly used as first-line therapy. More anti-CCP+ than anti-CCP− patients received MTX (73.2 vs 56.8%; p=0.0374), while more anti-CCP– than anti-CCP+ patients received hydroxychloroquine (48 vs 13.1%; p=0.0037). Only three anti-CCP+ and no anti-CCP− patients were treated with a bDMARD. Response to treatment was similar between the cohorts (p=0.2444); 22.9% of anti-CCP+ and 18.2% of anti-CCP− patients had a complete response to the first-line therapy, and 33.3% of anti-CCP+ and 25.0% of anti-CCP− patients had a partial response to the first-line therapy. Treatment change, however, significantly differed between the two cohorts (p=0.0058); 11.1 and 9.1% of patients discontinued, 9.8 and 9.1% of patients switched, and 3.9 and 9.1% of patients augmented in the anti-CCP+ and anti-CCP− cohorts, respectively. Treatment changes occurred approximately 3 months after diagnosis (anti-CCP+, 82.0 [49.7] days and anti-CCP−, 83.8 [52.7] days; p=0.9178).

Conclusions: After diagnosis of RA, patients who are anti-CCP+ were more likely to start therapy, indicating that physicians were more aggressive in treating this cohort. Patients were treated according to guidelines with non-biologic DMARDs, predominantly MTX. Patterns of treatment change differed between the cohorts; however, treatment response was similar with a complete response rate of 20%.

SAT0189 | FACTORS INFLUENCING THE PRESCRIPTION OF TOCILIZUMAB ALONE OR IN COMBINATION WITH DMARDs IN RHEUMATOID ARTHRITIS PATIENTS IN A REAL LIFE SETTING. POOLING ANALYSIS OF 3 OBSERVATIONAL STUDIES

A. Sarau1, A. Cantargre2, B. Combe3, R.-M. Filpo4, I. Idier5, C. Bafie6, J. Tebb7, T. Rheumatology, University Hospital, Brest; 2Rheumatology, University Hospital, Toulouse; 3Rheumatology, University Hospital, Montpellier; 4Rheumatology, University Hospital, Lille; 5Medical, Chugai Pharma France, Fréjus la Dole; 6Statistics, Roche SAS, Boulogne; 7Rheumatology, University Hospital, Lyon, France

Background: Tocilizumab (TCZ) as monotherapy (Mono) is nowadays a standard treatment in rheumatoid arthritis (RA) for patients in whom methotrexate (MTX) is inappropriate.

Objectives: To describe factors influencing the use of TCZ in Mono or in combination with DMARDs (Combo) in real-life practice in RA patients (pts).

Methods: Analysis: pooled data of 3 prospective, multicentre, observational studies (PEPS n=610, Spare-1 n=307, Act-solo n=577). Patients: RA pts requiring TCZ treatment according to their physician. Treatment: TCZ as prescribed in real life. Endpoint: Evaluation of factors influencing the use of TCZ in Mono or in Combo. Results: The baseline characteristics and the different mechanisms of clinical and antidestructive effects of anti-B-cell therapies are often discussed. The aim of this study is to assess clinical and antidestructive effect of Rituximab (RTX) in patients with rheumatoid arthritis (RA). Objectives: to assess clinical and antidestructive effect of Rituximab (RTX) in patients with rheumatoid arthritis (RA). Methods: 108 patients (pts) with RA, most of them were middle-age women with high disease activity (mean DAS28 6.1±1.04, RF-positive 77%, ACCP-positive 83%) treated with RTX (1000 mgx2 or 500 mgx2). Clinical effect was evaluated by EULAR criteria; radiological progression by SLE data. Results: 104 patients were treated by RTX (500 x2 or 1000 x2), had good response: after 48 week of treatment clinical improvement was achieved in 65% pts, good and moderate response by EULAR criteria in 23% and 42% pts accordingly. Noteworthy, after 12 months of treatment RTX radiological progression was absent in 50% pts with high disease activity.

Conclusions: RTX treatment slowed joint damage without clinical improvement. Clinical and antidestructive results did not always coincide which suggests different mechanisms of clinical and antidestructive effects of anti-B-cell therapy.
Germansprachspraxis, Magdeburg; 8 Rheumatologie, Chugai Pharma Europe Ltd., Frankfurt; 9 Rheumatologie, Roche Pharma AG, Grenzach-Wyhlen; 10 Rheumatologie/Immunologie der Medizinischen Klinik und Poliklinik II, Universitätsklinikum Wuerzburg, Wuerzburg; 11 Rheumapraxis, Osnabrueck, Germany

Background: According to WHO definition approximately 15% of all patients with rheumatoid arthritis (RA) suffer from anaemia (hemoglobin <13 g/dl for men and <12 g/dl for women). Interleukin 6 (IL-6) takes an active part in the pathogenesis of this inflammatory anaemia.

Objectives: The 6th interim analysis of the non-interventional ICHIBAN study (NCT01194401) evaluated the occurrence of inflammatory anaemia, characterized the patient population with anaemia, and observed the response during intravenous Tocilizumab therapy (TCZ i.v.). Patients were subgrouped according to their anemic/non-anemic status at baseline.

Methods: Since 2010 the ICHIBAN study collects clinical data of the routine use of TCZ i.v. in RA patients. The observation period for each patient is up to two years. At the due date of the current interim analysis (Dec 10, 2015) 2999 patients were enrolled. 902 patients have completed the maximal 104 weeks observation period (Group W104).

Results: At baseline, the proportion of patients with anaemia (acc. to WHO definition) was 21.4% (men) and 22.0% (women) in the group W104. On comparison, RA patients with anaemia showed, amongst others, increased inflammation parameters, a higher disease activity and higher rates of comorbidities. Already after 4 weeks with TCZ i.v. the proportion of patients with anaemia improved to 12.1% (men) and 12.7% (women). After 104 weeks therapy the proportion of patients with anaemia reduced further to 7.4% (men) and 8.4% (women). The relevant response parameters and laboratory values are shown in Table 1.

Conclusion: Despite the higher disease activity at baseline for anaemic patients, the benefit was comparable for patients with and without anaemia. DAS28-ESR values decreased on average by 2.9 (women) and 3.1 (men) in RA patients with anaemia and by 2.7 (women) and 2.8 (men) in RA patients without, resulting in similar disease scores at the end of the observational period.

The effectiveness of TCZ i.v. was also confirmed by patient reported outcomes (PROs) via visual analogue scales (VAS). In particular, a reduction of the intensity of pain (<50%) and a reduction of fatigue (<38%) was observed (Table 1).

Conclusions: At start of therapy, approximately one out of five patients documented in ICHIBAN showed anaemia according to the WHO definition. During TCZ i.v. therapy a noticeable decrease in the rate of anaemia and improved hemoglobin values were observed. These effects can already been seen after four weeks of treatment and continue up to the end of this study (i.e. 2 years). Despite the higher burden of disease at baseline in RA patients with anaemia, TCZ i.v. therapy resulted in good clinical response rates and PROs.

SIRUKUMAB INTEGRATED SAFETY IN RHEUMATOID ARTHRITIS PATIENTS: ANALYSIS OF THE SIRROUND PHASE 3 DATA

D. Aletaha 1, C. Thorne 2, M. Schiff 3, M. Harigai 4, R. Rao 5, N. Goldstein 6, B. Cheng 6, C. Cohen 1, B. Hsu 6, K. Brown 1, 1Medical University of Vienna, Vienna, Austria; 2University of Toronto and Southlake Regional Health Centre, Newmarket, ON, Canada; 3University of Colorado School of Medicine, Denver, CO, United States; 4Tokyo Women’s Medical University, Tokyo, Japan; 5GSK Medicines Research Centre, Hertfordshire, United Kingdom; 6Janssen Research & Development, LLC, Spring House, PA; 7GlaxoSmithKline, Collegeville, PA, United States

Background: Sirukumab (SIR), a human monoclonal antibody that selectively binds the IL-6 cytokine, is in development for the treatment of rheumatoid arthritis (RA). Efficacy of SIR was shown in several phase 3 trials in RA patients (pts; SIRROUND program).

Objectives: To analyze safety data from completed/ongoing studies in the SIRROUND program.

Methods: Safety comparisons included SIR 50mg q4w and 100mg q2w doses vs placebo (pbo) in the pbo-controlled period (Wk 0–18) of 2 phase 3 studies. A long-term comparison of the safety of SIR 50mg q4w and 100mg q2w for the entire program was also performed.

Results: In phase 3 studies, 2026 pts received SIR for up to 3.4y (median duration, 1.46y). During Wk 0–18, there were more adverse events (AEs), AEs leading to discontinuation, and serious AEs (SAEs) with SIR vs pbo, with cumulative rates of SAEs remaining constant over time (Table). In general, no dose effect with SIR was observed in the 18-wk or long-term analysis. Mortality rates were similar across treatment groups through 18 wks and remained stable in long-term analysis. Serious infections were more frequent in SIR-treated pts vs pbo during Wk 0–18, with similar rates through long-term analysis. Rates of gastrointestinal (GI) perforations and malignancies were low and similar across groups during the 18-wk and long-term analysis; major adverse cardiovascular event (MACE) rates were similar through 18 wks and numerically higher with SIR 50mg q4w vs 100mg q2w in long-term analysis.

Conclusions: SIR is well tolerated in pts with moderately to severely active RA. Overall, no dose relationship was observed between SIR 50mg q4w and 100mg q2w for types or frequencies of AEs.

but recent registry data point to better responses and retention if a drug with a different mode of action is prescribed.

**Objectives:** Assess the long-term retention of rituximab (RTX) and TNFi following first biologic (b)DMARD inadequate response in RHUMADATA® registry patients (pts) with RA.

**Methods:** Data from RHUMADATA® pts with RA prescribed either RTX or TNFi as the second bDMARD after 1 January 2006 were analysed. Pts were followed until treatment discontinuation or 9 January 2017 cut-off. Pt characteristics were compared using descriptive statistics, bDMARD discontinuation rates using Kaplan-Meier methods, and proportional hazard models were used to identify predictors of treatment discontinuation.

**Results:** Data for 53 and 194 pts prescribed RTX or a TNFi, respectively, as second-line treatment were extracted. No clinically significant differences in baseline characteristics were noted between treatment groups. Most pts were women (74.9%), average age (SD) was 45.2 (12.9) years at diagnosis and disease duration 10.5 (8.7) years. Most pts were stopping an anti-TNF agent: 100% of those who were switched to RTX and 83% of those who were prescribed a second anti-TNF. Overall, 77.3% of pts stopped their first bDMARD after >6 months of treatment (secondary failure). Significant differences in retention between RTX and TNFi groups (log-rank p< 0.001) were observed (Table, Figure). Results remained unchanged for pts treated with TNFi only in first line, and primary/secondary failure of the first bDMARD did not affect sustainability of the second agent. Lack of efficacy (54.4%) and AE’s (16.5%) were the most commonly cited reasons for treatment discontinuation.

**Conclusions:** Rituximab has better sustainability over a second line TNFi in RA patients having failed one prior bDMARD.

TREATMENT OUTCOMES WITH ANTI-TNF AND NON-ANTI-TNF DISEASE-MODIFYING THERAPY BY BASELINE BODY MASS INDEX

E. Alemao 1, Z. Guo 1, C. Iannaccone 2, M. Frits 3, M. Weinblatt 2, N. Shadick 2. 1Bristol-Myers Squibb, Princeton; 2B Brigham and Women’s Hospital, Boston, United States

**Background:** Recent studies have indicated that being overweight or obese could reduce the effect of anti-TNF treatment in patients (pts) with RA. 1-3 Other data show that certain biologic (b)DMARDs, such as abatacept, work independently of BMI. 4 Additional data on the role of BMI on treatment outcomes in clinical practice settings is required to inform clinical practice.

**Objectives:** To evaluate the impact of BMI on outcomes of disease activity in pts with RA treated with TNF and non-TNF agents (conventional or other bDMARDs).

**Methods:** Pts enrolled in a tertiary care RA registry, established in 2003, were analysed. The registry mostly comprises pts with established RA who were evaluated semi-annually for multiple clinical patient-reported outcomes and resource utilization parameters, and annually for composite disease activity measures such as DAS28 (CRP), CDAI and SDAI. The current analysis is based on pts enrolled in the RA registry with BMI values at time of enrolment. Pts were classified into groups based on BMI: normal (BMI < 25 kg/m²), overweight (BMI ≥ 25 to <30 kg/m²) and obese (BMI ≥30 kg/m²). Outcomes evaluated included change from baseline in DAS28 (CRP), CDAI, SDAI and joint counts at 12 months.

**Conclusions:** Retreatment with rituximab infusions was not associated with a higher rate of SIEs in this study. Patients who experienced an SIE had a higher prevalence of risk factors for infections.

**References:**

**Acknowledgements:** This study is sponsored by Corrona, LLC. Corrona, LLC has been supported through contracted subscriptions in the last 2 years by AbbVie, Amgen, BMS, Crescendo, Eli Lilly, Genentech, GSK, Horizon Pharma USA, Janssen, Momenta Pharmaceuticals, Novartis, Pfizer, Roche and UCB.
from treatment exposure. Treatments were categorized into TNF and non-TNF, which included conventional DMARDs and other non-TNF biologics. Multivariate linear regression analyses were used to evaluate impact of BMI on treatment outcomes controlling for baseline covariates of age, sex, disease duration, comorbidities, baseline disease activity and serostatus. Separate models were run for the TNF and non-TNF groups.

**Results:** A total of 997 (78%) pts in the registry had baseline BMI values and were included in the analysis. Around 37% (n=371) had TNF exposure and were included in the TNF cohort; the remainder (63%; n=626) were included in the non-TNF cohort. Proportions of pts in the normal, overweight and obese groups for the TNF cohort were 45.5% (n=168), 27.5% (n=102) and 27.0% (n=100), respectively. For the non-TNF cohort, these were 41.7% (n=261), 33.1% (n=207) and 25.2% (n=158), respectively. In both cohorts, pts with normal BMIs were younger vs the overweight and obese BMI groups. However, obese BMI pts had higher disease activity measures at baseline (mean [SD] CDAI: 22.6 [17.8] for TNF and 24.9 [17.3] for non-TNF) vs the normal BMI pts (17.5 [15.9] for TNF and 20.5 [15.0] for non-TNF). Adjusted mean change from baseline in disease activity in the TNF cohort was significantly reduced across all disease activity measures for the normal BMI group (p < 0.05), but not for the overweight and obese groups (Fig). There were significant reductions in disease activity measures for all BMI groups (all p < 0.05) in the non-TNF cohort (Fig).

**Conclusions:** Independent of BMI, non-anti-TNF therapy demonstrated similar outcomes in pts with RA. However, obese and overweight pts with RA (vs normal weight) had less improvement in disease activity (as measured by DAS28 [CRP]) with anti-TNF therapy.

TOCLIZUMAB FOR THE MANAGEMENT OF RHEUMATOID ARTHRITIS: DISCONTINUATION DUE TO INEFFICACY AND TOXICITY – EXPERIENCE FROM A LARGE TEACHING HOSPITAL

E. Byrne, P. Mark, S. Khalid, K.-P. Kuet, R. Kilding, K. Graves, J. Maxwell, M. Akil. Rheumatology, Sheffield Teaching Hospitals, Sheffield, United Kingdom

**Background:** Tocilizumab (TCZ) is a humanised anti interleukin-6 receptor antibody licensed for use for the treatment of moderate to severe Rheumatoid Arthritis (RA) as monotherapy or in combination with methotrexate (MTX).

**Objectives:** To describe the use of TCZ for RA in a large UK teaching centre and examine reasons for treatment discontinuation.

**Methods:** A retrospective case note review of all adult patients receiving TCZ either alone or in combination with DMARDs, for the treatment of RA between April 2009 and January 2017 in Sheffield, UK.

**Results:** 132 patients received TCZ for RA. 71% were female. 61% were CCP positive. Mean disease duration was 15.6 years (range 1.5–43). 46 (34.6%) received TCZ as monotherapy. 55 (42.1%) in combination with MTX and 31 (23.3%) other DMARDs. 23% of patients received concomitant oral prednisolone.

**Discussion:** Median duration of TCZ treatment was 27 months across the whole cohort, and 19 months in those who discontinued treatment.

**Conclusions:** Our real world data on the use of TCZ in the treatment of adult patients with RA is consistent with clinical trial data for efficacy and safety and is similar to other biological drugs used in the treatment of RA. We have seen a relatively low rate of withdrawal due to primary and secondary treatment failure.

**Disclosure of Interest:** None declared DOI: 10.1136/annrheumdis-2017-eular.5105

SUBCUTANEOUS TOCLIZUMAB MONOTHERAPY OR COMBINED WITH A CSDMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS: TOZURA, A POOLED ANALYSIS OF PHASE IV STUDIES IN 22 COUNTRIES

E. Choy1, R. Caporali2, R. Xavier3, B. Fautrel4, R. Sanmarti5, C. Bernasconi6, A. Peth-Piringer7, 1Cardiff University, Cardiff, United Kingdom; 2University of Pavia, Pavia, Italy; 3Universidade Federal do Rio Grande do Sul Porto Alegre, Rio Grande do Sul, Brazil; 4Pierre and Marie Curie University, Paris, France; 5Universitat de Barcelona, Barcelona, Spain; 6F. Hoffmann-La Roche AG, Basel, Switzerland

**Background:** Tocilizumab administered subcutaneously (TCZ-SC) has been approved for the treatment of rheumatoid arthritis (RA) both as mono- and combination therapy.

**Objectives:** To evaluate the efficacy and safety of TCZ-SC 162 mg once weekly (qw) as monotherapy or in combination with conventional synthetic DMARDs (csDMARDs) over 24 weeks in adult patients (pts) with moderate to severe RA.

**Methods:** TOZURA is a multinational, open-label, single-arm umbrella program comprising 7 single-country and 4 regional multicountry protocols (total 22 countries). Pts enrolled were inadequate responders to DMARD, and previous biologic DMARDs were allowed in 8 of 11 protocols. Pts received TCZ-SC 162 mg qw for 24 weeks administered at the investigator’s discretion as monotherapy or in combination with a csDMARD. Stable oral NSAIDs and corticosteroids (CS), ≤10 mg/day prednisone or equivalent, were allowed. Efficacy and safety were evaluated at weeks 1, 2, 4 and every 4 weeks for 24 weeks (plus 4 weeks for safety). Propensity score-based matching was used for between-group tests.

**Results:** Of 1804 pts treated, 353 (19.6%) received monotherapy (mono) and 1451 (80.4%) combination therapy (combo). 349 pts (19.3%) received a prior biologic DMARD. Background characteristics: 81.6% female; mean age, 54.1

*To date.

**Conclusions:** Our real world data on the use of TCZ in the treatment of adult patients with RA is consistent with clinical trial data for efficacy and safety and is similar to other biological drugs used in the treatment of RA. We have seen a relatively low rate of withdrawal due to primary and secondary treatment failure.

**Disclosure of Interest:** None declared DOI: 10.1136/annrheumdis-2017-eular.5105
years; mean RA duration, 7.7 years; and 82.7% seropositive—similar between treatment groups. Baseline CS was less frequent in the mono vs combo group (41.1% vs 51.2%); however, the mean prednisone equivalent daily dose was similar (6.6 vs 6.5 mg/day, respectively). Pts who continued TCZ to week 24 based on Kaplan-Meier estimates (95% CI) were 79.3% (74.7%–83.2%) for mono and 84.3% (80.9%–87.3%) for combo. DAS28 scores decreased comparably from baseline to week 24 in both groups (mean change: mono −3.40 and combo −3.46), with no significant difference between groups (P = 0.61). Results were similar for the Clinical Disease Activity Index (CDAI, mean change by week 24: −23.5 and −23.8, with no significant difference between groups; P = 0.42). The proportion of pts who achieved DAS28 or CDAI-based remission, low disease activity or ACR20/50/70/90 responses was similar between groups (Figure 1). In all, 18.2% of pts withdrew; 6.4% did so for safety reasons (mono 9.1%, combo 5.8%), AE rates were similar between groups (Table). Serious AE (SAE) rates were 21.0/100 PY (mono: 22.8/100 PY, combo: 12.8/100 PY). Serious infection and infestation rates were 3.6/100 PY (mono: 4.0/100 PY, combo: 3.5/100 PY) — similar between groups. Six deaths occurred (0.64/100 PY, 1 in the monotherapy group (0.57/100 PY) and 5 in the combination (0.65/100 PY) group.

**Conclusions:** TCZ-SC demonstrated convincing and comparable efficacy as mono- and combination therapy in pts with RA as was previously observed with TCZ-IV. The safety profile of TCZ-SC is consistent with the known safety profile of TCZ as monotherapy and in combination with csDMARDs.

**BIOLOGIC THERAPY RETENTION IN RHEUMATOID ARTHRITIS (RA) PATIENTS (PTS) ACCORDING TO THE MOSCOW ARTHRITIS REGISTRY (MAR)**

G. Lukina1, E. Koltsova2, E. Schmidt3, E. Zhilyaev4. 1, E. V.A. Nasonova Research Institute of Rheumatology, Moscow Clinical Scientific Center; 2, Research Institute of the Organization of health and healthcare management; 3, City Clinical Hospital 1 named after N.I. Pirogov; 4, Russian Medical Academy of continuing professional education, CUSC “European Medical Center”, Moscow, Russian Federation

**Background:** The use of biologics significantly improved the results of the therapy of RA pts who did not respond to the target disease activity level on traditional DMARDs treatment. However the biologic therapy is in many cases withdrawn due to inefficacy or side effects (rarely because of sustained remission). Retention on treatment is a good integral index of efficacy and safety of biologics used in the real clinical practice.

**Objectives:** To assess the treatment survival of various biologics in RA pts in the real clinical practice.

**Methods:** Patients from MAR with RA receiving biologics were enrolled. Cases with missed results were excluded. A Cox proportional hazards regression model was used to determine predictors of the patient discontinuation risk. Comparison of biologics retention rates for different biologics was performed by means of Kaplan-Meier survival curves. Bonferroni adjustment was applied because of multiplicity of comparisons.

**Results:** 306 RA pts (mean age 54.5 years, mean age of disease onset 39.6 years; 86.2% women, 18.1% smokers, RF-positive 83.7%) were included in the study and 394 treatment courses (263 retrospective and 131 prospective) were analyzed. It was shown that significant independent predictors of discontinuation risk were: the biologic drug, the sequence number of the biologic drug in the patient and the age of RA onset. Risk of withdrawal was minimal by the use of the first biologic and increased by administration of the next ones. It also increased in pts with late onset of RA. Mass body index, age of the patient and the dose of methotrexate did not show significant correlations. Abatacept (ABA) demonstrated significant superior efficacy over adalimumab (ADA) (p < 0.001), infliximab (INF) (p < 0.001), rituximab (RTM) (p = 0.004) and etanercept (ETA) (p = 0.003) when they was used as the first biologic drug. The treatment survival of tocilizumab was significantly higher compared to INF (p = 0.02). As a second-line biological therapy ADA was maintained significantly longer than the INF (p = 0.048).

**Conclusions:** Results of the real clinical practice trial showed the significant differences in the retention rates of some biologics. It is reasonable to take these differences into consideration by the planning of the biologic treatment of RA pts.

**Disclosure of Interest:** None declared

**ABATACEPT BUT NOT TNF INHIBITORS BLOCK AUTOANTIBODY-MEDIATED CYTOKINE PRODUCTION BY MONOCYTES**

A. Bozec1, Y. Luo2, C. Engdahl1, C. Figueiredo3, H. Bang4, G. Schett1

1University of Erlangen-Nuremberg, Erlangen, Germany; 2University of Chengdu, Chengdu, China; 3Universidade de São Paulo, São Paulo, Brazil; 4Oncology, Inc., Mainz, Germany

**Background:** The anti-inflammatory effect of abatacept (CTLA4-Ig) is most pronounced in patients with high-titer autoantibodies (including anti-citrullinated protein antibodies, ACPA, and rheumatoid factor, RF) even exceeding the effect of TNF inhibitors (TNFi)1. Considering that autoantibodies trigger inflammatory cytokine production by monocytes2 and that abatacept binds to monocytes influencing their functional state3 we hypothesized that abatacept, in contrast to TNFi, may effectively inhibit the production of several different cytokines by ACPA-or RF-challenged monocytes.

**Objectives:** (i) To test whether abatacept inhibits the production of TNFα, IL-1b, IL-6 and IL-8 by monocytes exposed to ACPA or RF; (ii) to compare these effects of abatacept with those of TNFi and (iii) to investigate whether the effect of abatacept on cytokine production is based on IDO induction in monocytes.

**Methods:** CD14+ monocytes were isolated from peripheral blood and stimulated with MCSF for 24 hours before exposing them to random IgG alone (negative control), 10mg/mL purified anti-citrullinated vimentin antibodies (ACPA), 10mg/mL of TNF inhibitors (TNFi) with or without IDO inhibitor 1-MT. Supernatants were analyzed for four key pro-inflammatory cytokines TNFα, IL-1b, IL-6 and IL-8 by cytokine array (R&D Systems, MN). Results of the real clinical practice trial show the significant differences in the retention rates of some biologics. It is reasonable to take these differences into consideration by the planning of the biologic treatment of RA pts.

**Conclusions:** Results, of the real clinical practice trial show the significant differences in the retention rates of some biologics. It is reasonable to take these differences into consideration by the planning of the biologic treatment of RA pts.
effectors cytokines are inhibited simultaneously may explain the strong anti-inflammatory effect of abatacept in RA patients with high-titer ACPA and RF.

SAT0202 EFFICACY AND SAFETY OF SARILUMAB MONOTHERAPY VERSUS ADAлимABUM MONOTHERAPY IN PATIENTS WITH ACTIVE RHUMATOID ARTHRITIS IN THE PHASE 3 MONARCH STUDY, INCLUDING SUBPOPULATIONS

Conclusions: Sarilumab monotherapy demonstrated superiority to adalimumab monotherapy in the ITT population in change from baseline in DAS28-ESR. The extent of treatment effect with sarilumab vs adalimumab was generally consistent across subpopulations. Overall incidences of AEs and serious AEs and rates of infection and serious infection were similar between groups.

SAT0203 SIGNIFICANCE OF EXTENSION OF TOCILIZUMAB INFUSION INTERVALS FROM 4 WEEKS TO 6 WEEKS IN RA PATIENTS WHO HAD SHOWN GOOD RESPONSE TO 4 WEEK INTERVALS

H. Uda1, K. Shigematsu2, O. Saiki3, Rheumatology; 2Orthopedics, Higashiosaka City Medical Center, Higashiosaka; 3Internal Medicine, Shiraiishi Hospital, Imabari, Japan

Background: A period of 4 weeks (w) has been recommended as tocilizumab (TCZ, 8mg/kg) infusions. However, we found that 5 or 6w intervals were also effective in more than 90% of RA patients with low disease activity (LDA) at 4w intervals (1).

Objectives: We conducted the study to investigate the significance of extension of intervals from 4w to 6w. We compared, in the same patients, the clinical features such as diseases activity, major and minor side reactions between at 4w and 6w. Moreover, we also considered the mechanisms.

Methods: This was a retrospective observational study. Among RA patients who had shown LDA with TCZ infusions at 4w intervals, the patients who could extend the intervals from 4w to 6w with LDA for more than 2 years without changing the doses of oral medicines were enrolled. In the same patients, we compared the events of serious and common side reactions between at 4w and 6w intervals. We examined the course of the levels of total cholesterol (TCHO), triglyceride (TG), and platelet (PLT) counts. We also examined the levels of serum trough TCZ and IL-6.

Results: Among 120 patients who maintained LDA at 4w intervals, more than 60% of patients maintained LDA at 6w intervals. When we compared the disease activity of 6w-responders between at 4w and 6w-intervals, all parameters reflecting the disease activities such as CRP and DAS28CRP score at 6w intervals were elevated significantly, but were still within LDA. At 4w intervals, serious adverse events were occurred as much as 11 cases during 2 years. At 6w intervals, however, they were decreased to 3 cases only in the same period. The common adverse reactions such as general fatigue, nausea, and dizziness occurred frequently at 4w intervals in most of the patients. At 6w intervals, these common adverse reactions were decreased significantly. At 4w intervals, the levels of TCHO and TG were elevated significantly. At 5w and 6w intervals, however, they were decreased accordingly. At 6w intervals, they were within normal limits. In most of patients, the levels of PLT counts were decreased significantly at 4w intervals. At 5w and 6w intervals, however, they were increased gradually. When TCZ were infused at 4w intervals, the serum trough TCZ levels were around 10 µg/mL. In contrast, they became undetectable when extended to 5w, and it is obvious that the trough TCZ levels of 6w were lower than 5w. The levels of IL-6 were significantly high at 4w-intervals, but the levels of IL-6 were decreased to less than 10 pg/mL at 5w-intervals.

Conclusions: The present study provide evidence that more than half of RA patients who showed good response at 4w could extend response to TCZ infusions at 6w intervals. Overall, the extension of intervals from 4w to 6w, major and minor side reactions were reduced significantly, and the levels of TCHO and PLT were also normalized with sustaining LDA, suggesting that the dose of TCZ (8mg/kg) at 4w intervals might be excessive in some patients. Taken together, we should be careful for deciding the intervals of TCZ infusion for each patient.

ABATACEPT SURVIVAL IN RHEUMATOID ARTHRITIS: PATIENTS AT 2 YEARS IS 59%: ITS USE AS A 2ND LINE BIOLOGIC AGENT AND LOWER BASELINE HAQ PREDICT BETTER SURVIVAL IN CLINICAL PRACTICE: A PROSPECTIVE, OBSERVATIONAL SINGLE CENTER STUDY

I.D. Flouri1, 2, A. Repa1, N. Argoustidi1, N. Kougas1, A. Fanourakis1, I. Papapoliopoulos1, G. Adamichou1, P. Kypionidou1, E. Kampouraki1, M. Terizaki1, D.T. Bourmpas2, G. Bertisias1, P. Sidipoulos1, I.D. Flouri1, Rheumatology, Clinical Immunology and Allergy, Faculty of Medicine-University of Crete, Heraklion-Crete; 4th Internal Medicine Department, Attikon University Hospital, Athens, Greece

Background: Long-term prospective observational studies are complementary to controlled clinical trials to explore effectiveness and safety of biological therapies in real practice.

Objectives: To study abatacept survival, reasons of discontinuation and clinical responses in everyday clinical practice of patients with rheumatoid arthritis (RA).

Methods: Prospective, observational single center study at the Rheumatology Clinic, University Hospital of Heraklion, Crete. At baseline, patient demographics, co-morbidities and disease characteristics are being recorded, while during follow-up, discontinuations, disease activity and adverse events are collected. For this analysis, all patients who received Abatacept intravenously from 6/2007 till 6/2016 were included. Kaplan-Meier curves and Cox regression analysis were used to determine drug survival and predictors thereof. Linear regression was used to compare DAS difference at 12 months between different lines of bDMARD therapy.

Results: A total of 224 patients (women: 87%, seropositive: 34%) were included. Median (IQR) age was 63 (56–70) years, disease duration 7.4 (4–13.4) years and baseline DAS28 5.9 (5.2–6.5). Abatacept was the 1st bDMARD in 59 (26%) patients, 2nd in 71 (32%) and ≥3rd in 94 (42%) patients. During follow-up (total: 508 patient-years, median (IQR): 1.7 (0.7–3.3) years), 54% patients discontinued therapy (87% for treatment failure, 10% for adverse events). Two-year treatment persistence was 59%. In multivariable regression analysis, predictors of longer Abatacept survival were younger baseline HAQ [HR (95% CI) for unit increase ≥0.29 (1.5–3.48), p < 0.001], longer disease duration [HR (95% CI) for >8 vs ≤8 years=0.51 (0.30–0.88), p=0.016], Abatacept as 2nd vs 1st or ≥3rd bDMARD [HR=0.50 (0.30–0.81), p=0.022] and a more recent year of therapy start [HR=0.39 (0.16–0.95), p=0.035].

DAS28-3.2 and remission at 6 (12) months were achieved by 12% (18%) and 5% (7%) of patients respectively. DAS28 difference at 12 months was greater in patients who received Abatacept as the ≥2nd than those on ≥3rd bDMARD (p=0.009). A total of 312 adverse events were registered, of which 65 were serious (SAE). Incidence of total (serious) adverse events was 61 (13)/100 patients/year. SAE included 5 cases of cancer, 10 cardiovascular events and 24 infections, mainly of the respiratory tract.

Conclusions: In the present study, Abatacept survival at 2 years was 59%. The majority of patients discontinued therapy due to inadequate response. Use as a 2nd line biologic agent and lower baseline HAQ predicted better survival. Improvement in DAS was higher when Abatacept was used as the ≥2nd bDMARD. Rates of remission or low disease activity in clinical practice are rather low, while the safety profile was excellent.

RETENTION OF TOCILIZUMAB AS MONOTHERAPY VERSUS TNF INHIBITORS WITH CONVENTIONAL SYNTHETIC DMARDS IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO TNF INHIBITORS: A STUDY FROM THE TOCERRA COLLABORATION

K. Lauper1, 2, D.C. Nordström3, K. Pavelka1, V. Hernandez4, M.J. Santos6, Z. Rotar5, F. Iannone2, C. Codreanu2, G. Lukina2, L.L. Gale5, K. Sarsour1, A. Petheos-Schramm1, D.S. Couvoisier1, C. Gabay1, 2, Univ Hosp of Geneva, Geneva; 2SCOM Registry, Zurich, Switzerland; 3ROB-FIN Helsinki Univ Central Hosp, Helsinki, Finland; 4Charles Univ, Prague, Czech Republic; 5Rheumatology Department, Hospital Clinic Barcelona, Barcelona, Spain; 6Rheumatology Unit, Hospital Garcia de Orta, Almada, Portugal; 7BioRx.si, Univ Med Center, Ljubljana, Slovenia; 8GISEA Univ Hosp of Bari, Bari, Italy; 9Univ of Medicine and Pharmacy, Bucharest, Romania; 10ARBITER, Inst of Rheumatology, Moscow, Russian Federation; 11Genentech, South San Francisco, CA, United States; 12F. Hoffmann-La Roche, Basel, Switzerland

Background: Tocilizumab (TCZ) as monotherapy has been shown to be more efficacious than the TNF inhibitor (TNFi) adalimumab as monotherapy in patients with rheumatoid arthritis (RA). However, effectiveness data comparing TCZ as monotherapy versus TNFi in combination with csDMARDs is limited.

Objectives: To examine retention of TCZ administered alone (TCZ mono) versus TNFi in combination with csDMARDs (TNFi-combo) in patients with RA who had an inadequate response to ≥1 TNFi (TNFi-IR).

Methods: Patients with RA who were TNFi-IR and treated with TCZ mono or TNFi combo with baseline (BL) data, not immediately lost to follow-up and started treatment after TCZ was available across 9 European registries in TOCERRA from 2009 to 2016 were included. The hazard for TCZ discontinuation was modeled using a country-stratified Cox proportional hazards model, adjusting for

patients were as follows: female gender 86%, mean age 52±13 years, median disease duration 10 (IQR 11) years, Rheumatoid Factor positive 94%, Anti-Cyclic Citrullinated Peptide Antibodies 89%, and erosive phenotype 35%. At baseline, mean DAS28 and RAPID3 were 5.4±1.3 and 16.6±6.8, respectively. SC abatacept monotherapy was reported in 27%. Demographics and disease characteristics were similar in all groups, except for baseline DAS28 and RAPID3 in switch group (p=0.0001). According to the Mantel-Haenszel test (Fig.1), there were no significant differences between survival curves (p=0.158). Forty-three patients (33%) discontinued treatment. The most frequent reasons for drug suspension were loss of efficacy in 25%, insurance-related problems (i.e., access to medication/specialist) and adverse drug reactions in 16%. Other causes include lack of efficacy, surgeries (i.e., arthritic replacement), patient preference, and pregnancy.

Conclusions: Our results disclose a similar drug survival of SC abatacept regardless of treatment background. Patients switching from IV to SC formulation of abatacept had lower activity and functional impairment at baseline, and survival tends to be higher through follow-up. The insurance-related limitations is a reality in Latin American countries, and could have a negative impact on survival time of several drugs.

RETENTION OF TOCILIZUMAB AS MONOTHERAPY VERSUS TNF INHIBITORS WITH CONVENTIONAL SYNTHETIC DMARDS IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO TNF INHIBITORS: A STUDY FROM THE TOCERRA COLLABORATION

K. Lauper1, 2, D.C. Nordström3, K. Pavelka4, V. Hernandez5, M.J. Santos6, Z. Rotar2, F. Iannone1, C. Codreanu2, G. Lukina2, L.L. Gale5, K. Sarsour1, A. Petheos-Schramm1, D.S. Couvoisier1, C. Gabay1, 2, Univ Hosp of Geneva, Geneva; 2SCOM Registry, Zurich, Switzerland; 3ROB-FIN Helsinki Univ Central Hosp, Helsinki, Finland; 4Charles Univ, Prague, Czech Republic; 5Rheumatology Department, Hospital Clinic Barcelona, Barcelona, Spain; 6Rheumatology Unit, Hospital Garcia de Orta, Almada, Portugal; 7BioRx.si, Univ Med Center, Ljubljana, Slovenia; 8GISEA Univ Hosp of Bari, Bari, Italy; 9Univ of Medicine and Pharmacy, Bucharest, Romania; 10ARBITER, Inst of Rheumatology, Moscow, Russian Federation; 11Genentech, South San Francisco, CA, United States; 12F. Hoffmann-La Roche, Basel, Switzerland

Background: Tocilizumab (TCZ) as monotherapy has been shown to be more efficacious than the TNF inhibitor (TNFi) adalimumab as monotherapy in patients with rheumatoid arthritis (RA). However, effectiveness data comparing TCZ as monotherapy versus TNFi in combination with csDMARDs is limited.

Objectives: To examine retention of TCZ administered alone (TCZ mono) versus TNFi in combination with csDMARDs (TNFi-combo) in patients with RA who had an inadequate response to ≥1 TNFi (TNFi-IR).

Methods: Patients with RA who were TNFi-IR and treated with TCZ mono or TNFi combo with baseline (BL) data, not immediately lost to follow-up and started treatment after TCZ was available across 9 European registries in TOCERRA from 2009 to 2016 were included. The hazard for TCZ discontinuation was modeled using a country-stratified Cox proportional hazards model, adjusting for
age, gender, disease duration, seropositivity, HAQ and CDAI at BL, number of previous csDMARD and biological DMARD (bDMARD), glucocorticoid and calendar year of treatment initiation. Missing data on covariates were imputed using multiple imputation with chained equations. Results: A total of 4748 patients were eligible, including 585 who received TCZ mono and 4163 who received TNFi combo. Patients who received TCZ mono were older with a longer disease duration, more previous bDMARDS and less glucocorticoids at baseline (Table 1) compared with patients who received TNFi combo. The crude median retention for TCZ mono was 1.82 years (95% CI: 1.59–2.09) and 1.54 years (95% CI: 1.43–1.64) for TNFi combo. (P<0.65). Causes of discontinuation differed between TCZ mono and TNFi combo (P<0.001): TCZ mono stopped more frequently for ineffectiveness (25.7% vs. 13.8%) and TNFi combo stopped more frequently for safety issues (18.3% vs. 12.8%). In a country-stratified, covariate-adjusted analysis, we found that hazards of discontinuation were significantly lower among those who received TCZ mono vs. TNFi combo (HR: 0.71, P<0.001). More previous treatment with bDMARDS and a greater HAQ and CDAI at BL were significantly associated with greater risk of discontinuation.

Acknowledgements: This study is the first to assess the effects of biological RA therapies as compared to synthetic DMARD ones. It highlights the protective effect of both biological and non-biological DMARD on bone loss during the first two years of treatment with no significant difference between them. Our results suggest that the effects of RA treatments depend on the inflammatory and disease activity which must be monitored clearly. Tocilizumab seems to be more effective than the other biological therapies, but further studies are necessary to confirm or infirm this tendency.

Disclosure of Interest: None declared.

SAT0208 CYCLING VERSUS SWAPPING IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH AN INADEQUATE RESPONSE TO AT LEAST ONE TUMOR NECROSIS FACTOR ALPHA INHIBITOR: A SYSTEMATIC REVIEW AND META-ANALYSIS OF OBSERVATIONAL STUDIES

M.A. Lopez-Olivo1, A. Matusevich2, M.E. Suarez-Almazor1,1, General Internal Medicine, The University of Texas, MD Anderson Cancer Center; 1School of Public Health, The University of Texas, Health Science Center at Houston, Houston, United States

Background: In patients with rheumatoid arthritis (RA) who do not respond or lose response, opinions are divided on whether it is better to try an alternative TNFi (cycling) or switch to a therapy with a different mode of action (swapping).

Objectives: To compare the efficacy and safety of the cycling versus the swapping strategies.

Methods: We searched 4 electronic databases, sources of gray literature, and bibliographic references of relevant articles for observational studies evaluating the efficacy and safety of targeted therapies in adult RA patients who failed to respond to at least one TNFi. Studies were excluded if they were single-arm or had insufficient data to evaluate the outcomes of interest. Two independent reviewers selected studies, extracted data and evaluated study quality using the Newcastle-Ottawa Scale (NOS). Our primary outcome measure was change in Disease Activity Score 28 joints (DAS28). We also evaluated the modified American College of Rheumatology 20%, 50% and 70% response criteria (mACR20, mACR50, mACR70) with the majority response criteria (mACR which excludes acute phase reactants) and total serious adverse events. All analyses were based on the random-effects model.

Results: Of 33,716 citations, 24 observational studies (n=10,074 patients) representing 14 countries, met the inclusion criteria. Eight were conference abstracts. Most publications (13 of 24) were based on registries. Most studies had a NOS score equal to or greater than 7 (out of 9) with comparability being the weakest domain. The mean age of patients was 48.7–62.8 years, the majority were females (78%) with a disease duration of 6–17.3 years and a baseline disability score 0–2.0. Sixteen studies compared TNFi swapping directly with TNFi cycling while 13 were suitable for analysis. Most compared TNFi to rituximab (10 of 13) with two studies investigating tocilizumab or abatacept and one comparing non-TNFi as a group. Other comparisons reported were: (i) cycling vs. switching for well disease modifying anti-rheumatic drugs (cDMARDs) vs. cDMARDs, (ii) cycling vs. another cycling alternative, (iii) swapping vs. another swapping alternative, (iv) swapping monotherapy vs. swapping combined with cDMARDs, and (v) combination of TNFi and non-TNFi vs. TNFi alone. At 12 and 24 weeks, DAS28 score improved significantly in those swapping compared to those cycling (mean difference (MD) 0.89, 95% confidence interval (CI) 0.03 to 1.74 and MD 0.34 95% CI: 0.2, 0.48; respectively). Similar results were observed for the mACR50 favoring the swapping strategy at 24 weeks (OR =1.45 95% CI: 1.06, 1.98). At 52 weeks no difference was observed. No statistically significant differences were observed across groups in the odds of achieving DAS28 remission, mACR20 or mACR70, or experiencing a serious adverse event.

Conclusions: Current evidence from observational studies shows greater improvements with the swapping strategy compared with the cycling strategy in terms of efficacy for RA patients failing their first TNFi. No differences were observed when those failing their second TNFi were compared. Clinical trials were not available for anakinra, certolizumab pegol, golimumab, or tocilizumab.

**SAT0209** OBSERVATIONAL STUDY ON THE EFFECTS OF IL-6 INHIBITOR THERAPY ON MYOSTATIN IN PATIENTS WITH RHEUMATOID ARTHRITIS

M.J. Chapman, 1 R.P. Narayanan, 2 A. Cross, 3 R. Moots, 3 J. Widing, 2 N. Goodson 3 1Department of Obesity and Endocrinology; 2Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, United Kingdom

**Background:** Rheumatoid cachexia (RC), a phenotype of increased adiposity, reduced lean mass and insulin resistance can occur in rheumatoid arthritis (RA). It is most prevalent in those with high disease activity and is associated with increased cardiovascular morbidity and mortality. Tocilizumab (TCZ), a monoclonal anti-IL-6 antibody, successfully reduces disease activity in RA. It has also been associated with improved insulin sensitivity, increased lean mass and hyperlipidaemia. The serum concentration of myostatin, a myokine released by skeletal muscle, is increased in most disease states associated with cachexia. Moreover, its knockdown and inhibition increase lean mass. However, its role in RA has not been fully elucidated.

**Objectives:** To investigate the effect of tocilizumab treatment on serum myostatin in patients with RA.

**Methods:** 19 patients with RA (16 female, 3 male) mean age 49.6yrs, mean DAS28 6.1, median disease duration 10yrs (range 0 to 30), mean BMI 27.4, received 13 IV infusions of TCZ 8mg/kg every four weeks as part of a 52 week, single-centre, open-label study (ACT-NEUT [1]). 8 had previously been exposed to a biological agent, 4 were on regular steroids, and all patients received concurrent methotrexate. Serum myostatin was measured at 0, 1, 3 and 6months of treatment using ELISA, BMI, serum lipid profile, CRP, ESR and DAS28 were measured at each visit (0, 1, 3 and 6months). Data were analysed using STATA 14. Change between 0, 3 and 6months was analysed using Wilcoxon signed rank test. Statistical significance was confirmed using mixed model analysis adjusting for BMI, age and gender.

**Results:** DAS28, CRP and ESR all significantly decreased with TCZ treatment. A significant increase in BMI (25.5 (IQR 21.6–31.7) vs 26.0 (IQR 21.4–32.5) p=0.028) was seen with TCZ. Baseline serum myostatin concentrations were negatively correlated with baseline DAS28 (r2=0.39 p=0.038). Treatment with tocilizumab was seen with TCZ. Baseline serum myostatin concentrations were negatively correlated with baseline BMI, age and gender. Linear regression with adjustment for age, BMI and gender assessed correlation at baseline.

**Conclusions:** There was a global improvement of DAS28 in a cohort of RA patients receiving biological therapy followed and treated under recommendations of T2T approach demonstrating that with the strategies mentioned above it is possible to obtain a good control of the activity of the disease.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.5579

**SAT0210** IMPROVEMENT OF DISEASE ACTIVITY IN A 5-YEAR COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED UNDER TREAT TO TARGET RECOMMENDATIONS RECEIVING BIOLOGICAL THERAPY

P. Santos-Moreno 1, D. Gomez 1, E. Castillo 1, R. Giraldo 1, G. Ballesteros 1, L. Villarreal 1, J. Bello 1, D. Buitrago-Garcia 1, 1Rheumatology; 2Psychology and processes; 3Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia

**Background:** Treat to Target (T2T) strategy becomes from the need to develop therapeutic targets and tools to achieve defined outcomes in rheumatoid arthritis (RA), this strategy has become recognized as a standard of good practice embodying the principle that rapid attainment of remission, or low disease activity, can halt joint damage and maintain good quality of life. However, there is no direct comparison between biologicals in cohorts of patients with long-standing RA using T2T approach in real-life settings, which could have implications in treatment decisions and health economics.

**Objectives:** The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) using T2T strategy for a 5 year period in patients with biological therapy in a large cohort of patients from a Colombian specialized in RA center with multidisciplinary approach.

**Methods:** A descriptive dynamic cohort study was performed. Records of patients using biological DMARD treatment (Anti-TNF and others) from specialized in RA centre were reviewed; those patients were followed-up under T2T strategy. Clinical follow-up was according to DAS28 as follows: every 3–5 weeks (DAS28 ≥ 3.1), every 7–9 weeks (DAS28 ≥ 3.1 and ≤ 5.1), and every 11–13 weeks (DAS28 ≤ 3.1). Therapy had to be adjusted with DAS28 ≥ 3.2 unless patient’s conditions don’t permit it. We divided patients in three groups: low disease activity (LDA), moderate disease activity (MDA) and severe disease activity (SDA) patients. Descriptive epidemiology was done, percentages and averages were calculated; the median of each variable was analyzed using t-Student assuming normality for DAS28 distribution and the level activity disease was analyzed using Pearson’s statistics.

**Results:** During 60 month period we included 695 patients with biological therapy, 85% were female and 15% male. Mean age was 58 years ± 11. At beginning mean DAS28 was 4.1±1.1 and 20% of patients were in SDA, and 55% in MDA. At the end of 5 year period mean DAS28 was 3.2±0.89 and only 7% of patients were in SDA and 33% in MDA. The median was analyzed using t-Student assuming normality for DAS28 distribution. It showed statistical significant improvement (p<0.00).

**Conclusions:** We have demonstrated a significant correlation between myostatin and DAS28 and a significant change in myostatin with tocilizumab treatment. It is possible that IL-6 blockade results in a rise in myostatin. This might attenuate any improvement in muscle wasting. Future studies should measure body composition and muscle function to help understand the changes we have observed.

**SAT0211** REAL WORLD DATA OF RITUXIMAB EFFECTIVENESS IN RHEUMATOID ARTHRITIS: DIFFERENCES BETWEEN BIOLOGIC-NAIVE PATIENTS AND PREVIOUSLY EXPOSED TO BIOLOGICS

**Background:** Rituximab is only approved for rheumatoid arthritis (RA) treatment in patients with an incomplete response or intolerance to others DMARDs, including TNF alfa inhibitors. It represents a significant advance in RA biologics arsenal due to its safety and efficacy profiles.

**Objectives:** To evaluate the effectiveness of rituximab in RA patients and to compare the response between first-line rituximab patients and those previously exposed to other biologics.

**Methods:** An observational retrospective study was conducted, including all the consecutive patients with diagnosis of RA under rituximab, followed at our Rheumatology department until December 2016. Demographic and clinical data were obtained by consulting the national database (Reuma.pt). DAS28 variations and EULAR response were measured at 6, 12 and 18 months. Parametric and non parametric tests were used for statistics (SPSS 20.0).

**Results:** We included 63 RA patients (81% of women), with a mean (SD) age of 61 (10) years and a mean disease duration of 19 (10) years; 86% rheumatoid factor positive and 87% anti- citrullinated peptide antibody (ACPA) positive. Bone erosions and extra-articular manifestations were present in 85,7% and 58,7% of the patients, respectively. At baseline, the mean DAS28 was 5.79 (65% and 29% of patients with severe and moderate disease activity, respectively, and 6% in clinical remission). Thirty patients were treated with rituximab as first-line therapy and 33 patients were previously exposed to other biologics. Combination therapy
with methotrexate (MTX) was observed in 48% and with other classic DMARDs in 30%, while 22.3% received rituximab monotherapy. First-line rituximab option was justified by lung involvement in 21%, past malignancy in 13%, recurrent infections in 5%, congestive cardiac failure in 3%, vascular involvement in 3% and untreated latent tuberculosis in 3%. In the group previously exposed to biologics, 13% switched therapy due to ineffectiveness and 87% due to adverse events. No significant differences were found among the 2 groups in terms of age, gender, comorbid use of MTX and baseline DAS28. The group previously exposed to biologics had a longer disease duration (mean 23 vs 15 years, p<0.001) and fewer patients with ACPA seropositivity (79% vs 97%, p=0.035). There was a significant reduction of DAS28 at 6, 12 and 18 months (p<0.001 for all). Fifty six percent of the patients achieved a EULAR response at 6 months, 46% at 12 months and 59% at 18 months. DAS28 variation at 6 months differed significantly between groups, with a better clinical response in naive biological patients comparing to their previously exposed to biologics (mean ± SD 1.17 ± 0.67 vs 3.47 ± 0.20, p=0.038). There were no differences in terms of DAS28 variation at 12 and 18 months (p=0.642 and p=0.135, respectively) and in EULAR responses at 6, 12 and 18 months between the groups (p=0.289, p=0.523 and p=1.000, respectively).

Conclusions: Our study confirms the effectiveness of rituximab in RA patients and suggests a higher magnitude of response in naive biological patients at 6 months of RTX therapy. These findings put in perspective an extension of rituximab as a first-line biologic for RA treatment.

CHARACTERISTICS OF PATIENTS WITH ANKYLOSING Spondylitis, RHEUMATOID and PSORIATIC ARTHRITIS IN TREATMENT WITH BIOLOGIC AGENTS IN VERONA’S COHORT: RESULTS FROM VENETO’S REGION BIOLOGICS REGISTRY

S. Troplini, O. Viapiana, E. Fracassi, A. Carletto, L. Idolazzli, G. Orsolini, A. Giolo, M. Rossini. Rheumatology Unit, University of Verona, Verona, Italy

Background: Since 2013, in Verona’s Region, data registration is mandatory for all patients affected by Rheumatoid arthritis (RA), Psoriatic Arthritis (PsA), Ankylosing Spondylitis (AS) in treatment with biologic agents. The biologic DMARDs currently marketed in Italy are: anti-TNF (originator and biosimilar infliximab, etanercept, adalimumab, certolizumab and golimumab), anti-IL6 (tocilizumab), anti-CD20 (rituximab), CTLA4-4 like (abatacept) and anti-IL12/23 (ustekinumab).

Objectives: The aim of this study was first to describe the characteristics of patients treated with RA, PA, AS under biologics and then, to extract and analyze real-life data regarding rheumatic treatments in Verona’s cohort.

Methods: The study has been carried out on behalf of Regione del Veneto, Giunta regionale -Ricerca Sanitaria Finalizzata-Venezia-Italy. Data used for analysis were recorded in the Veneto Region Biologics Registry (VRBR). VRBR provides the core variables such as onset and type of disease, anthropometric characteristics (age, sex, body weight, height) are registered at the beginning. Furthermore, prior and concomitant rheumatic treatment (conventional and biologic DMARDs, corticosteroids, NSAIDs), disease activity indicators (DAS 28-PCR, ASDAS-PCR, pain-NRS), prognostic factors (positivity for rheumatoid factor and/or anti-citrulline antibodies in AR, presence of radiological erosions) were assembled at baseline, every 6 months and at the time of biologic’s switch or swap.

Results: A total of 983 patients under biologics were examined; 543 (55.2%) with RA, 272 (27.2%) with PsA, 108 (11.0%) with AS, and 58 (5.9%) with AS between these. 27%), 27.2% of patients were naïve to biologics, 128 with AR, 84 with AP, 50 with SA. Mean duration of disease was of 15.3, 10.7 and 12.6 years respectively for RA, PA and AS. Radiological erosions were present in 73% of RA-patients and the percentage was higher in those with positivity for rheumatoid factor and/ or anti-CCP antibodies (84.4% versus 56.2%). More than half of the patients in this cohort were treated at least with one biologic agent; anti-TNFs were the main biologic used (RA:54.8%, PA:92.7%, AS: 100%) followed by Abatacept (25.4%), tocilizumab (12.3%) and rituximab (5.9%) in patients with RA. Methotrexate (MTX) was the prevalent associated c-DMARDs (41.8% in RA and 34.2% in PA) with mean dose of 11.9 mg/week in RA and 12.1 mg/week in PA. The optimal dose of methotrexate was not achieved prevalently because of drug intolerance.

Conclusions: In our database, 70% of RA patients received ABA were biologic naive. Remission or low disease activity was achieved approximately 50% of patients in first follow-up visit with an average of 4.5 months after beginning of the treatment. Functional improvement was observed in two thirds of patients.
EARLY PATIENT-REPORTED OUTCOMES AND CLINICAL OUTCOMES WITH ABT-494 IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS WHO ARE INADEQUATE RESPONDERS TO METHOTREXATE OR TUMOR NECROSIS FACTOR INHIBITORS: POST-HOC ANALYSIS OF PHASE 2 RANDOMIZED CONTROLLED TRIALS

V. Strand1, N. Tundia2, I.H. Song2, S. Meerwein2, J. Lin2, N. Chen2, A. Friedman2, *1Stanford University, Palo Alto; AbbVie Inc., North Chicago, United States

Background: Janus kinase (JAK) inhibitors are being evaluated for treatment of active rheumatoid arthritis (RA). Understanding their onset of action on patient reported outcomes (PROs) and clinical endpoints in RA patients (pts) is limited.

Objectives: To assess onset of benefit with ABT-494, a selective JAK1 inhibitor vs placebo (PBO) in RA pts with active disease ≥3 months in 2 randomized controlled trials (RCTs) evaluating safety and efficacy of ABT-494. MTX-IR and MTX-NAI (NCT01960855) to tumor necrosis factor inhibitors (TNF-IR).

Methods: Data were pooled separately for each RCT in pts who received 6mg or 12mg bid ABT-494 or PBO. Analyses included cumulative assessment of PROs such as patient global assessment of disease activity (PIGA), pain Visual Analogue Scale (VAS) and Health Assessment Questionnaire Disability Index (HAQ-DI) in terms of Routine Assessment of Patient Index Data 3 (RAPID3) scores, and clinical outcomes such as DAS28 (CRP) and CDAI. To assess onset and maintenance of effect, the number of pts whose improvements met or exceeded minimal important differences (MID) RAPID3: reduction ≥3.6; DAS28: reduction ≥1.2; CDAI: reduction ≥11.0 and were calculated at weeks 2 and 12.

Results: In M13–537 (N=150 pts) and M13–550 (N=166 pts) RCTs, significantly more pts in ABT-494 12mg groups reported improvements ≥MID in RAPID3 vs PBO at Wk 2: 68% vs 30% and 73% vs 38%, respectively (Table). In M13–537, significantly more pts receiving ABT-494 6mg bid vs PBO (54% vs 30%) had improvements ≥MID in RAPID3. These responses were sustained throughout both trials in pts receiving 12mg ABT-494 (M13–537: 80%; M13–550: 71%). Significantly higher MID and maintained changes ≥MID in DAS28 were seen both in RCTs and in CDAI in M13–550. Based on KM analyses, in M13–537, estimated mean time to achievement of RAPID3 MID was shorter for both ABT-494 doses vs PBO (12mg: 3.9±0.5 weeks; 6mg: 3.9±0.4 weeks; PBO 6.0±0.6 weeks). Similarly, estimated mean time to these responses was shorter with both ABT-494 doses vs PBO (12mg: 3.6±0.4 weeks; 6mg: 4.9±0.6 weeks; PBO 6.0±0.6 weeks) in M13–550, although it was underestimated due to censoring.

Table. Number of patients reporting clinically meaningful improvements over study period.

SAT0218 EFFECT OF TOCILIZUMAB IN DMARD-NAÏVE EARLY RHEUMATOID ARTHRITIS PATIENTS ON HEALTH-RELATED QUALITY OF LIFE: RESULTS OF THE U-ACT-EARLY TRIAL

X.M. Teitgema1, J.W. Jacobs2, P.M. Welsing2, A. Pethö-Schramm3, M.E. Born4, J.M. van Laar1, F.P. Laeberle1, J.W. Bijlsma1, J.H. Song1,2, I.H. Song1,2, J. Lin2, S. Meerwein2, J. van Dijk5, F. Hoffmann-La Roche, Basel, Switzerland; 2Roche Nederland B.V., Woerden, Netherlands

Background: Tocilizumab (TCZ), a humanized interleukin-6 receptor inhibitor, has been shown effective in suppressing symptoms of rheumatoid arthritis (RA). In U-Act-Early, a significantly greater proportion of patients with early RA who initiated TCZ (84%) or TCZ plus MTX therapy (86%) achieved sustained remission (Disease Activity Score assessing 28 joints (DAS28) <2.6 with <2 swollen joints for ≥24 weeks), when compared to those initiating MTX (44%)[1].

Objectives: To determine the effect of treat-to-target TCZ therapy, with or without MTX, on health-related quality of life (HRQoL) in disease modifying anti-rheumatic drugs (DMARD)-naive patients with early RA.

Methods: Patients (n=317) were randomized to initiate TCZ, TCZ+MTX or MTX therapy and treated according to a step-up strategy. TCZ was given (8 mg/kg) every 4 weeks and MTX (oral) was started at 10 mg/week and increased with steps of 5 mg steps 4 weekly up to 30 mg/week (or maximum tolerable dose) until remission. If after 20 weeks remission was not achieved, hydroxychloroquine was added and discontinued 12 weeks thereafter if the target still was not achieved. Patients who originally initiated monotherapy then switched to TCZ+MTX therapy and those already on this combination therapy switched to a tumour necrosis factor inhibitor. To evaluate the effect of TCZ on HRQoL, we used the 36-item Short-Form (SF-36), which can be summarized into a physical (PCS) and mental (MCS) component score. HRQoL was measured at baseline and after 12, 24, 52, and 104 weeks. A linear mixed effect model with a random intercept was used to evaluate differences between treatment strategies over time with visit (time), strategy, baseline SF-36 score, baseline DAS28 level (i.e., DAS28 <5.1 or ≥5.1) and centre as fixed effects. The proportions of patients exceeding the minimum clinically important differences (MCID, ≥2.5-point increase from baseline) were tested for significance using the two-sided Pearson’s chi-squared test.

Results: In the SF-36 PCS in patients initiating treatment with TCZ (TCZ vs MTX: p=0.041, TCZ+MTX vs MTX; p<0.011, Fig. 1). For the SF-36 MCS, no significant differences over time were noted between the treatment arms (p=0.11). A significantly higher proportion of patients initiating treatment with TCZ (76%; p=0.016, 89%; p=0.009) or TCZ-MTX (73%; p=0.049, 89%; p=0.027) achieved MCID in the SF-36 PCS at week 12 and week 52, when compared to those initiating treatment with MTX (59% and 73%, respectively). Although the proportions of patients achieving MCID in the SF-36 MCS were numerically higher in the TCZ arms, no significant differences were found (p=0.06).

Conclusions: Initiation of TCZ, with or without MTX, at start of therapy resulted in statistically significant and clinically relevant improvements in the SF-36 PCS when compared to initiation of MTX alone and may be considered as a valuable treatment strategy in DMARD-naive patients with early RA.

SAT0219  Efficacy and Safety of Atacicept in Patients with High Disease Activity in a 24-Week, Randomized, Placebo-Controlled, Phase IIb Study (ADDRESS II)

J.T. Merrill1, D.J. Wallace2, A. Kao3, C. Vazquez Mateo4, P.A. Fraser1, P. Chang1, D. Isenberg4, O. Oklahoma Medical Research Foundation, Oklahoma City; 2Cedars-Sinai Medical Center, University of California Los Angeles, Los Angeles; 3EMD Serono Research & Development Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany), Billerica, United States; 4University College London, London, United Kingdom

Background: Atacicept targets B-cell stimulating factors BlyS and APRIL, and has shown evidence of clinical response in SLE.

Objectives: Exploration of atacicept efficacy and safety in a pre-defined subpopulation of SLE patients with high disease activity (HDA, SLEDAI-2K ≥10 at Screening) in the phase IIb ADDRESS II study (NCT01972588).

Methods: Autoantibody positive patients on standard of care therapy were randomized 1:1:1 to double-blind weekly SC injections of atacicept 75 or 150 mg or placebo (PBO) for 24 weeks. Analyses of the HDA subpopulation are now reported.

Results: 52% of the ITT population had HDA (n=158: 52 PBO; 55 atacicept 75 mg; 51 atacicept 150 mg). 92% were female, 67% were white, and baseline characteristics were balanced between groups. At week 24 (Table 1; Figure 1), the proportion of SLE Responder Index (SRI)-4 (p<0.05) and SRI-6 (p<0.005) responses was greater with atacicept 150 mg vs PBO. BICLA response rate was higher with both doses (p<0.05). More patients achieved SLEDAI-2K ≤2 with atacicept 150 mg vs PBO (p<0.01). Time to severe/flare was significantly reduced at both atacicept doses vs PBO (p<0.05). Patients in the quartile with the largest decline in serum IgG had the highest SRI-6 response rates (Table 2). Treatment-emergent adverse event (TEAE) rates were similar between groups (PBO 71.2%; 75 mg 78.2%; 150 mg 74.5%). Serious/severe infections were not increased with atacicept 150 mg (PBO 9.6%; 75 mg 10.9%; 150 mg 0%). There were no patient deaths.

Conclusions: In SLE patients with HDA, Atacicept 150 mg demonstrated significant clinical responses in a pre-defined subset of patients with acceptable safety.

SIX-MONTH PROTEINURIA MEASUREMENT PREDICTS RENAL RESPONSE AT 18 MONTHS IN LUPUS NEPHRITIS: ANALYSIS OF TWO PHASE III RANDOMIZED CLINICAL TRIALS

M.D. Cascino 1, 2, T. Schindler 3, L.M. Gomez Mendez 2, P. Brunetta 1, L. Dragoni 1, M. Dall’Era 4, J. Garg 1, 5, Genentech, Inc., South San Francisco; 2University of California – San Francisco, San Francisco, United States; 3F. Hofmann-La Roche, Basel, Switzerland

Background: Early identification of patients with lupus nephritis (LN) likely to achieve complete renal response (CRR) may expedite the evaluation of new therapies and guide clinical care. Prior analyses have shown that early improvement in proteinuria is associated with subsequent renal response. Several ongoing LN trials including NOBILITY, an assessment of the efficacy of the anti-CD20 monoclonal antibody obinutuzumab in combination with standard of care immunosuppression, will evaluate proteinuric response at 6 months as a key secondary endpoint. Whether short-term response accurately predicts future CRR, however, is uncertain.

Objectives: To assess the predictive value of early measurements of the level of proteinuria and to identify proteinuria cutoffs that best identify patients who will achieve CRR at 18 months.

Methods: LUNAR and BIIB059 were multicenter, double-blinded studies that in total randomized 522 patients with ISN/RPS class III or class IV LN to blinded investigational infusions or placebo in combination with standard of care immunosuppression. 4, 5 CRR was assessed at 18 months and defined for this analysis as achievement of urine protein to creatinine ratio (UPCR) <0.5 with normal serum creatinine that was not increased from baseline by >25%. Bootstrapping was used to generate nonparametric receiver operating characteristic (ROC) curves and estimate area under the curve (AUC). The Youden index was used to identify UPCR cutoff values that best identify patients who will achieve CRR at 18 months.

Results: ROC curves were constructed for proteinuric measurements at baseline and 3, 6, 9, and 12 months after randomization (Figure 1). AUC increased from baseline to month 3 (0.64 vs. 0.80, P <0.001) and from month 3 to month 6 (0.80 vs. 0.84, P =0.01) but did not increase beyond month 6 (P >0.05 for each pairwise comparison). Achievement of 6-month UPCR <1 was 83.8% sensitive and 71.0% specific for CRR at 18 months and had PPV and NPV of 64.9% and 87.2%, respectively. Evaluation of lower 6-month UPCR cutoff values yielded improvements in specificity and PPV but marked decreases in sensitivity and NPV. In multivariate analysis, the addition of 6-month serum creatinine and percent change in UPCR from baseline did not result in meaningful increases in AUC compared with 6-month proteinuria measurement alone.

Figure: Receiver operating characteristic curves for CRR at 18 months

Conclusions: Level of proteinuria at 6 months alone was predictive of CRR at 18 months in aggregated data from two phase III LN clinical trials. After 6 months of treatment, UPCR <1 had high sensitivity and NPV for CRR at 18 months. This cutoff might be used to prospectively identify patients who are unlikely to achieve complete response within 18 months on the initial therapy for LN. The impact of these findings on guiding treatment decisions outside the setting of randomized clinical trials requires further investigation.

SAT0222

BIIB059, A MONOClonAL ANTIBODY TARGETING BDCA2, SHOWS EVIDENCE OF BIOLOGICAL ACTIVITY AND EARLY CLINICAL PROOF OF CONCEPT IN SUBJECTS WITH ACTIVE CUTANEOUS LE

R. Furie 1, W.P. Werth 2, J.F. Merola 3, T.L. Reynolds 4, L. Stevenson 4, W. Wang 4, K. Smirnakis 4, C. Barbey 5, C. Musselli 5, 6, B. Werneburg 5, D. Rabah 5, N. Franchimont 4, 1Northwell Health, Great Neck; 2Hospital of the University of Pennsylvania and the Veteran’s Administration Medical Center, Philadelphia; 3Brigham and Women’s Hospital, Harvard Medical School, Boston; 4Biogen, Cambridge, United States; 5Biogen, Zug, Switzerland

Background: Type I interferons (IFN-I) are central to the pathogenesis of systemic lupus erythematosus (SLE). BDCA2 is a plasmacytoid dendritic cell (pDC)-specific receptor that, upon engagement, inhibits the production of IFN-I and other inflammatory mediators. Targeting BDCA2, therefore, represents an attractive therapeutic strategy for inhibiting pDC-driven inflammation that is such a key feature of SLE pathogenesis. BIIB059, an investigational anti-BDCA2 humanized monoclonal antibody has been shown to engage BDCA2, and this interaction leads to BDCA2 internalization and the consequent in vitro inhibition of TLR-induced IFN-I production by pDCs (Pellerin 2015).

Objectives: This first-in-patient study aimed to assess safety, tolerability, pharmacokinetic (PK) and pharmacodynamic (PD) effects and clinical activity of BIIB059 in adult SLE patients with active cutaneous lupus (CLE) following administration of a single BIIB059 dose.

Methods: A Phase 1b randomized, double-blinded, placebo controlled, multicenter clinical trial was conducted in 12 adult SLE subjects (meeting 1997 ACR criteria) with active cutaneous manifestations (including acnè sub-acute and/or chronic cutaneous forms of cutaneous lupus erythematosus (CLE)). Subjects received a single IV administration of either BIIB059 20mg/kg (n=8) or placebo (n=4). A panel of IFN-responsive genes (IRG) was assessed from whole blood by qPCR at baseline and several post-dose time points. Skin biopsies from active lesions were obtained and evaluated at baseline and week 4 for IFN-regulated proteins, including MxA and IFITM3 using quantitative immunohistochemistry.CLE disease activity was assessed using the Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI), and safety data, including adverse events (AEs) and laboratory tests, were also evaluated. The incidence of AEs was similar between BIIB059- and placebo-treated SLE subjects, and most AEs were mild or moderate in severity.

Conclusions: A single dose of BIIB059 resulted in inhibition of the IRG in peripheral blood and MxA and IFITM3 expression in lesional skin of SLE subjects, consistent with BIIB059’s proposed mechanism of action. The clinical and biomarker data together confirm the role of human pDCs in the pathogenesis of SLE, and support further development of BIIB059 in SLE.

patients with active, autoimmunocomplex-positive systemic lupus erythematosus (SLE) who are receiving standard SLE therapy has been demonstrated. To date, no direct comparison of intravenous (IV) BEL vs subcutaneous (SC) BEL has been performed, hence the importance of an indirect treatment comparison (ITC).

**Objectives:** To indirectly compare the clinical effectiveness of BEL IV and SC formulations in patients with SLE high disease activity (HDA) via an ITC.

**Methods:**
Three BEL IV Phase III randomised controlled trials (RCTs; HDA/BLISS-52, 327/577; HDA/BLISS-76, 265/548; HDA/North East Asia study [BEL113750], 427/677) and one BEL SC RCT (HDA/BEL112341; 356/836) were compared via a Bayesian ITC (BEL207255). We evaluated the relative efficacy of the formulations in patients meeting three measures of HDA at baseline: 1; BLISS-52 and BLISS-76, CR < 0.9 g/L or C4 < 0.16 g/L; BEL112341 and BEL113750, C3 <0.9 g/L or C4 < 0.10 g/L; and 2; anti-dsDNA positive [≥30 IU/ml] or 3; Safety of Estrogen in Lupus Erythematosus National Assessment-SLE Disease Activity Index [SELENA-SLEDAI] scores ≥10). Analyses were conducted in patients meeting Criteria 1; low C3/C4 and anti-dsDNA; and Criteria 2; low C3/C4 and high anti-dsDNA or SELENA-SLEDAI ≥10 or low C3/C4. The primary endpoint was SLE Responder Index (SRI) response (≥4-point reduction in SELENA-SLEDAI, no worsening in Physician’s Global Assessment, no new 1A/2B British Isles Lupus Assessment Group domain scores) at Week 52. Secondary endpoints included ≥4-point reduction in SELENA-SLEDAI and SLE Flare Index rate. Safety endpoints were not assessed.

**Results:** Baseline characteristics were relatively similar between RCTs and a fixed effects model binomial distribution with logit link was used for all efficacy endpoints (Table). In this indirect comparison, no differences were identified between BEL IV and BEL SC for the efficacy endpoints.

**Conclusions:** In this indirect comparison, BEL IV and BEL SC were similar for SRI response; ≥4-point reduction in SELENA-SLEDAI, or rate of severe flare at Week 52 in patients with SLE. Outcomes were consistent irrespective of the criteria applied.

**SAT0224**

THE ROLE OF INTENSIVE IMMUNOSUPPRESSIVE THERAPY IN THE MANAGEMENT OF SLE-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION: A SINGLE-CENTER COHORT STUDY

Q. Wang, J. Zhao, J. Qian, Z. Tian, M. Li, X. Zeng.1 Rheumatology; 2Internal Medicine; 3Cardiology, Peking Union Medical College Hospital, Beijing, China

**Background:** Autoimmune and inflammatory mechanisms could play a significant role in the pathogenesis of pulmonary arterial hypertension (PAH), especially in patients with systemic lupus erythematosus (SLE). The effect of immunosuppressive therapy in the treatment of SLE-associated PAH (SLE-PAH) has not been fully investigated in a large cohort previously.

**Objectives:** We aimed to review the clinical outcomes in patients with SLE-PAH cohort treated with intensive immunosuppressive therapy with or without PAH-targeted therapy.

**Methods:** In this single-center cohort study, 126 patients with SLE-PAH were consecutively enrolled between May 2006 through December 2015. All patients were performed right heart catheterization to confirm the diagnosis of PAH, and all received intensive immunosuppressive therapy including combination of high-dose glucocorticosteroids and immunosuppressants, such as cyclophosphamide, mycophenolate and calcineurin inhibitors. Baseline demographics, clinical features, laboratory findings, hemodynamic measurements and treatment were analyzed.

- Kaplan-Meier curves and Cox proportional hazards regression analysis were performed, hence the importance of an indirect treatment comparison (ITC).
- **Patients** included**: Patients with SLE-PAH cohort treated with intensive immunosuppressive therapy with or without PAH-targeted therapy.

**Conclusions:** Intensive immunosuppressive therapy markedly improved the long-term outcomes of SLE patients with PAH, especially in the early stage of PAH.

CEREBLON MODULATOR CC-220 DECREASES NAÏVE AND MEMORY B CELLS AND PLASMACYTOID DENDRITIC CELLS IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS: EXPOSURE-RESPONSE RESULTS FROM A PHASE 2A PROOF OF CONCEPT STUDY

A. Gaudy1, Y. Ye1, S. Korish1, D. Hough1, M. Weiswasser1, S. Choi1, R. Furie2, V. Werth3, P. Schater1,1 Celgene Corporation, Summit, NJ; 2Northwell Health, Great Neck, NY; 3University of Pennsylvania and the VA Medical Center, Philadelphia, United States

**Background:** CC-220 is a cereblon E3 ligase modulatory compound currently in development for the treatment of Systemic Lupus Erythematosus as well as other autoimmune conditions and multiple myeloma. As a high affinity ligand for cereblon, CC-220 administration results in significant reductions in ikaros (IKZF1) and aixol (IKZF3), transcription factors which are genetically linked to SLE risk, are over expressed in the peripheral blood of SLE patients compared to healthy controls.

**Objectives:** To describe the pharmacokinetics (PK), pharmacodynamics (PD), and the PK-PD relationship of CC-220 in subjects with SLE.

**Methods:** CC-220-SLE-001 is a randomized, double-blind, placebo-controlled,

SAT0226 | A FIRST-IN-HUMAN STUDY OF BMS-986165, A SELECTIVE, POTENT, ALLOSTERIC SMALL MOLECULE INHIBITOR OF TYROSINE KINASE 2

Innovative Clinical Development; 2Clinical Pharmacology; 3Global Biometric Sciences, Bristol-Myers Squibb, Princeton, United States

Background: Tyrosine kinase 2 (Tyk2) is a member of the JAK family that phosphorylates STAT proteins downstream of the IL-12, IL-23 and the Type I interferon pathways and thus is a highly promising therapeutic target for SLE. CC-220 in patients with SLE. Forty-two (42) adult SLE subjects fulfilling SLE ACR phase 2a dose escalation study to investigate the safety, PK, PD, and efficacy of BMS-986165, a novel inhibitor of Tyk2.

Methods: We report the first evidence of safety, pharmacokinetics (PK), target engagement (TE), and pharmacodynamic activity (PD) of BMS-986165, a novel inhibitor of Tyk2.

Results: BMS-986165 was safe and overall well-tolerated. There were no serious adverse events and the frequency of non-serious adverse events were similar between cohorts, with moderate accumulation in the non-alternating dose cohort. CC-220 significantly reduced total CD20+ B cells by as much as 91.2%, switched memory B cells by as much as 81.4%, BAFFR+ B cells by as much as 67.5%, and plasmacytoid dendritic cells (pDCs) by as much as 86.5% (Day 85 median percent change from baseline). Whereas reductions in B cells were observed, CD4+ as well as CD8+ T cells increased, and the rise in T cells paralleled the drop in plasma. In plasma, we preferentially observed decreased B cells, pDCs and neutrophils with increased exposure to CC-220.

Conclusions: It was determined that 0.3 mg QD to 0.6/0.3 mg alternating QD reduced concentrations of B cells and pDCs while avoiding neutropenia. These findings, in combination with the PK, safety, and exploratory efficacy data, support continued development of CC-220 in SLE.

larger when derived from commercial claims ($21,600–55,400) than from public
payers (Medicare and Medicaid, $16,000–23,000).
Conclusions: Our ﬁndings suggest that patients with SLE, especially those with
moderate or severe disease, use considerably more health care services and
incur greater direct and indirect costs relative to those with mild disease. Thus,
SLE remains a signiﬁcant driver of health care resource utilization and costs.

SAT0228

APOPTOTIC EFFECT OF BLYS ON ENDOTHELIAL CELLS AND
ENDOTHELIAL PROGENITOR CELLS IS MEDIATED BY BLYS
RECEPTROS AND IS REVERTED BY BELIMUMAB

F.R. Spinelli, C. Barbati, F. Ceccarelli, T. Colasanti, F. Morello, L. Massaro,
V. Oreﬁce, C. Alessandri, F. Conti, G. Valesini. Dipartimento di Medicina Interna e
Specialità Mediche - Reumatologia, Sapienza Università di Roma, Rome, Italy
Background: Circulating endothelial progenitor cells (EPCs) are surrogate
markers of endothelial function. Several studies demonstrated a reduction and
functional impairment of EPCs in patients with Systemic Lupus Erythematosus
(SLE), partially accounting for endothelial dysfunction. In murine models of
atherosclerosis, treatment with a B Lymphocyte Stimulator (BLyS) inhibitor slowed
the progression and reduced the size of atherosclerotic plaque. Belimumab (BLM)
is a human anti-BLyS monoclonal antibody approved for the treatment of SLE.
Objectives: We aimed at evaluating the effect of BLyS inhibition on EPCs and
endothelial cells both ex vivo – in SLE patients receiving BLM– and in vitro.
Moreover we investigated the expression of receptors for BLyS on EPC and
mature endothelial cell surface.
Methods: We enrolled consecutive patients with SLE who were due to start BLM,
without known cardiovascular disease and age and sex-matched healthy subjects.
Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll densitygradient centrifugation. Cells were incubated with anti-CD34 and anti-VEGFR2/KDR monoclonal antibodies; acquisition was performed by ﬂow cytometry:
EPCs were deﬁned as CD34/KDR double-positive cells. Recovered EPC isolated
from healthy donors’ PBMC were plated on dishes coated with human ﬁbronectin.
Apoptosis was investigated after 6, 12 and 24 hours of incubation with BLyS
at different concentrations – 5, 20 and 100 ng/ml – and re-evaluated after 6
hours of co-incubation with BLM at 173 and 300 μg/ml. The same experiments
were repeated with the human endothelial cell line EA.hy926. Finally, EPCs and
EA.hy926 were incubated with monoclonal antibodies anti-B Activating FactorReceptor (BAFF-R), B-cell maturation antigen (BCMA) and transmembrane
activator and calcium modulator and cyclophilin ligand (CAML) interactor (TACI)
and analysed by ﬂow cytometry; the results were expressed as mean ﬂuorescence
intensity (MFI).
Results: We treated with BLM 10 female patients (mean age 45.6±10.2 yrs,
mean disease duration 17.8±10.8 yrs) with active disease (mean baseline SLEDAI
8.4±2.6). Number of EPCs was signiﬁcantly lower in SLE patients than in NHS
(p=0.005). After 4 weeks of BLM, mean EPC number increased from 0.013±0.016
to 0.021±0.016 (p=0.012 vs baseline; p=n.s. vs NHS). At week 12, EPC number
did not signiﬁcantly differ compared to week 4 nor to baseline.
In vitro studies demonstrated that 20 ng/ml of BLyS induced apoptosis of EPC
after 6 hours of incubation; this effect was reverted by the addiction of BLM.
Similarly, after 6 hours of incubation with 20 ng/ml of BLyS we detected an
increase in EA.hy926 apoptosis that was reverted by co-incubation BLM. Both
EPCs and EA.hy926 expressed on their surface BAFF-R (MFI =3.8 and 1.5,
respectively) and BCMA (MFI =1.25 and 1.15, respectively); EPCs also expressed
TACI (MFI =1.4).
Conclusions: The results of this study demonstrated that the reduction of EPCs
number detected in SLE patients was restored by BLM. In vitro results support
a direct pro-apoptotic effect of BLyS that was reverted by the addition of BLM
both in EPCs and EA.hy926 culture. The apoptotic effect of BLyS seems to be
mediated by the three receptors (BAFF-R, BCMA and TACI) that are expressed
on EPCs and mature endothelial cells surface.

SAT0229

THE USE OF ANTIMALARIAL DRUGS DURING PREGNANCY
CAN PREVENT THE DEVELOPMENT OF PREECLAMPSIA IN
WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M.A. Saavedra 1 , D. Miranda-Hernández 1 , A. Lara-Mejía 1 , A. Sánchez 1 ,
C.V. Cruz-Reyes 1 , U. Angeles 2 , L.J. Jara 3 . 1 Rheumatology; 2 Epidemiology
Direction; 3 Education and Research Direction, Hospital de Especialidades, Cmn
la Raza, IMSS, México, Mexico
Background: The antimalarial drugs decrease the risk of lupus activity during
gestation, but the beneﬁcial effect on other maternal-fetal complications is
controversial.
Objectives: To analyze the beneﬁcial effect of antimalarial drugs on maternal-fetal
complications in pregnant women with systemic lupus erythematosus (SLE).

Methods: A prospective cohort of pregnant women with SLE (ACR 1997) from
January 2009 to June 2015 was studied. The patients were assessed every
4 to 6 weeks and postpartum both, by a rheumatologist and a gynecologist.
Clinical, biochemical, and immunological characteristics, along with maternal and
fetal complications were registered. For analysis, the patients were allocated to
one of two groups: pregnancies exposed to antimalarial drugs in comparison
to those not exposed. A logistic regression analysis including variables such as
smoking, obesity, infections, ﬁrst pregnancy, age, SLE ﬂare, drugs (prednisone,
antimalarials, aspirin, and azathioprine), anti-DNA antibodies, anticardiolipin
antibodies, and antiphospholipid syndrome was performed.
Results: We studied 197 lupus pregnancies, 154 expose to antimalarial drugs
and 47 unexposed. We found no differences between groups in age, years of
evolution of SLE, ﬁrst pregnancy, childhood-onset SLE, lupus nephritis, and use
of prednisone, aspirin and azathioprine. The rate of most maternal and fetal
complications was also similar in both groups (Table). A lower incidence of
preeclampsia was observed in patients exposed to antimalarial drugs compared
to those not exposed (9% vs 23%, p=0.01). Additionally, 2 maternal deaths
in patients not exposed to antimalarial drugs. The logistic regression analysis
showed that the use of antimalarial drugs during pregnancy is a protective factor
for the development of preeclampsia (RR 0.1, 95% CI 0.05–0.58, p=0.004); on
the other hand, active SLE before pregnancy (RR 4.8, 95% CI 1.3–17.8, p=0.01)
and lupus nephritis (RR 2.9, 95% CI 0.9–8.8, p=0.05) were associated factors
with the development of preeclampsia.

NEW ORAL ANICOAGULANTS IN PATIENTS WITH
ANTIPHOSPHOLIPID SYNDROME

M.A. Satybaldyeva, N. Seredavkina, L. Kashnikova, E. Nasonov, T. Reshetnyak.
Nasonova Research Institute of Rheumatology, MOSCOW, RUSSIA, Moscow,
Russian Federation
Background: Antiphospholipid syndrome (APS) is an acquired thrombophilia
characterized by reccurent venous and arterial thrombosis, obstetric pathology
(fetal loss), and synthesis of antiphospholipid antibodies. Warfarin is a “golden”
standard of APS therapy. However it has number of disadvantages. Dabigatran
etexilate is a direct thrombin inhibitor and its main differences from warfarin are
ﬁxed dose, no need of regular INR monitoring,less elimination half-life.
Objectives: To evaluate efﬁcacy and safety of dabigatran etexilate in patients
with APS.
Methods: 38 patients (pts) (F:26, M:12) with primary and secondary APS,
37,2±9,9 years old. 24 pts with primary APS, 14 pts with secondary APS: 13 had
systemic lupus erythematosus (SLE) + APS, 1 rheumathoid arthritis (RA) + APS.
The diagnosis of APS was established due to international APS criteria (Sydney),
SLE – SLICC 2012, RA - ACR/EULAR 2010. The majority number of pts (n=28)
received warfarin, others – sulodexide (n=1), low molecular heparin (n=1), had no
anticoagulant therapy (n=3), 5 pts received dabigatran etexilate before inclusion
to trial. The control of coagulogram was done 3 times: before inclusion to trial,
in 24 weeks and in 48 weeks after inclusion. Trial assays were performed in
the laboratory in V.A. Nasonova Research Institute of Rheumatology, Moscow,
Russian Federation. APPT and thrombin time tests were done with the automated
coagulometer Coalysys Plus C (Behnk Electronic, Germany); thrombin time test
was done with STA-thrombin reagent (Diagnostica Stago, France), APPT with
STA-Cephascreen reagent (Diagnostica Stago, France). Lupus anticoagulant was
assessed by the dilute Russell’s viper venom time, using Siemens Healthcare
(Germany) LA1 (screening) and LA2 (conﬁrmation). IgG or IgM antibodies
against cardiolipin and β2 glycoprotein I (β2GPI) were measured with automated
enzyme-immunoassay analyzer Alegria with Anti-Cardiolipin IgG/IgM and Antibeta-2-Glycoprotein I IgG/IgM reagents (Orgentec Diagnostika GmbH, Germany).


Triple positivity was defined as positive antibodies against cardiolipin and j2GPI and a positive test for lupus anticoagulant.

Results: 32 pts had high or medium level of aPL (cardiolipin antibodies IgG,IgM, anti-j2GPI antibodies IgG,IgM). 6 had low or normal level of aPL. 12 pts were triple positive. APPT and thrombin time before inclusion to trial were 30.2 [28.5;33.5] and 16.1 [14.9;17.0], on 24 week after dabigatran etexilate start 51.0 [40.6;57.0] and 163.5 [108;240.0] and on 48 week 58.7 [45.6;63.2] and 194.1 [152;265.5] respectively. 1 patient was excluded due to non-compliance. During follow-up period from 1.5 to 12 (10.6;3.2) months 7 pts (22.6%, 20.7 per 100 patient-years) experienced recurrent thrombosis including superficial vein thrombosis (n=3, 6.5, 5.9 per 100 patient-years), thrombosis of paraneoplastic veins (n=1, 3.2%, 2.9 per 100 patient-years), acute cerebrovascular disorders (n=4; 12.9%, 11.8 per 100 patient-years). All pts with recurrent thrombosis had high or medium level of aPL; 2/7 were triple positive, both had acute cerebrovascular disorders. 5 pts (16.1%, 14.8 per 100 patient-years) experienced bleeding; 2 hemorrhoidal bleedings, 1 uterine bleeding, 2 nasal bleedings. There was no case of severe bleeding.

Conclusions: Dabigitran etexilate could be used in patients with APS in the case of warfarin non-effectiveness. These findings need to be confirmed in larger studies.

SAT0232 B-CELL SUBPOPULATION DYNAMICS IN SLE PATIENTS FOLLOWING RITUXIMAB THERAPY

Research Institute of Rheumatology, Moscow, Russian Federation

Objectives: To study B-cell subpopulation dynamics in SLE patients following Rituximab (RTX) therapy.

Methods: The study included 31 SLE pts (3m/28f) with high (SLEDAI≥20–28 pts.) and moderate (SLEDAI<20–10–3 pts.) disease activity; out of them 12 pts with SLE nephritis, 5 pts with neuropsychiatric and 8 with vasculitis. RTX was administered to pts who failed to respond to glucocorticoids (GCs) and cytostatics (CTs). B-cells subpopulations were assessed before RTX administration (Mo0), and at Mo3 and Mo6 of RTX therapy, RTX was administered at 500 to 2000 mg doses depending on disease activity. The absolute counts of CD19+ B-cells, the total population of memory B-cells (CD19+CD27+), “preswitch” (CD19+IgD-CD27+) and “postswitch” (CD19+IgD-CD27+) memory B-cells, “naïve” (CD19+IgD-CD27-), plasma cells (CD19+CD38+) and double negative B-cells (CD19+CD27-IgD-) were measured. 3 cell subsets were analyzed with multicolor flow cytometry using a panel of monoclonal antibodies to B-lymphocytes’ surface membrane markers.

Results: Following initiation of RTX SLE clinical and lab activity indices decreased in all 31 pts by Mo3 and Mo6 of follow up (SLEDAI-2K Mo0–Mo3 12.18; Mo3–Mo6 6.4; Mo6–Mo24 2.4, as well as absolute count CD19+ B-cell population (Mo0–Mo6 0.1,19x10^9 [0.05;0.26], Mo3–Mo6 0.1x10^9 [0.003;0.005], Mo6–Mo24 0.004x10^9 [0.002;0.005]). B-cell repopulation by Mo6 in 15 out of 31 pts without signs of relapse and 4 pts with earlier relapse SLE was dependent on “naïve” B-cells (Mo 0.005x10^9 [0.0026;0.005] vs Mo 0.003x10^9 [0.0023;0.003]), double negative (Mo 0.001x10^9 [0.0002;0.002] vs Me 0.0035x10^9 [0.0018;0.005]), “postswitch” memory B-cells (Me 0.0006x10^9 [0.00007;0.0001] vs Me 0.0023x10^9 [0.0005;0.003]).

Conclusions: Decrease in clinical and lab SLE activity was documented in all 31 pts by Mo3 after one course of RTX therapy. In 4 pts with earlier relapse SLE at Mo3 B-cell was found repopulation and significant increase “naïve” B-cells, double negative, “postswitch” and “preswitch” memory B-cells compared with the group without relapse.

DOI: 10.1136/annrheumdis-2017-eular.8174
immune complexes (IC), and autoantibodies are supposed to participate in IC formation. Thus, the fraction of autoantibodies participating in IC formation merits a diagnosis as a diagnostic and/or prognostic marker. We have developed a technique to quantify autoantibody content in IC (Sohrabian et al. Ann Rheum Dis 2015;74(Suppl 1):A74).

Objectives: To elaborate on the quantification of autoantibodies in IC as a measure of disease activity and prognosis for response in belimumab-treated SLE patients.

Methods: Fifty-five SLE cases classified according to the ACR criteria were treated with belimumab and followed for one year. High disease activity was defined as SLE Disease Activity Index 2000 (SLEDAI-2K) ≥10, or as low levels of complements C3 and/or C4. Treatment regimens were recorded using the SLE Responder Index (SRI), or as a value of modified SLEDAI-2K with suppression of autoantibody and complement data (clinical remission). Low disease activity was also recorded as Lupus Low Disease Activity State (LLDAS).

Results: Data were recorded at 3, 6, and 12 months. IC were purified from sera by binding to C1q-coated beads, and thereafter eluted. Autoantibody levels were determined in unmodified serum and in solubilised IC with addressable laser bead immunoassay (FIDIS Connective, TheraDiag, Paris) for autoantibodies against dsDNA, histones, ribosomal P antigen, proliferating cell nuclear antigen (PCNA), SSA/Ro60, SSA/Ro66, SSB, Sm, U1RNP, and the Sm/RNP complex.

Autoantibody levels in serum and in IC were compared with Mann-Whitney’s U test between patients with high and low disease activity at baseline and between patients with and without treatment response during the follow-up period.

Results: Antibodies against dsDNA, SSA/Ro60 and Sm/RNP were found in 65%, 54% and 43%, other antibodies with lower percentages. Low complement levels were associated with high serum anti-dsDNA (p=0.003) and anti-ribosomal P antibody (p=0.008) levels, whereas high SLEDAI-2K associated with high anti-dsDNA (p=0.02) and anti-SM/RNP (p=0.047) levels. Serum levels of antibodies against SSA/Ro60, SSA/Ro66, SSB and SSA/Ro66 were lower in patients attaining LLDAS after 6 months (p=0.02, 0.051 [trend] and 0.04, respectively); these associations were stronger for corresponding IC fractions (p=0.01, 0.005, and 0.02, respectively). Baseline levels of anti-dsDNA and anti-histones in IC associated with clinical remission ever during the follow-up period (p=0.003 and p=0.05). Low levels of anti-Sm and anti-Sm/RNP in serum but not in IC associated with clinical remission at month 6 (p=0.02 and 0.04 respectively), and for Sm/RNP also at month 3 (p=0.04).

Serum levels of all antibodies except SSA/Ro52 declined during the first 6 months, most prominently for dsDNA, histones ribosomal P, PCNA and Sm/RNP (p<0.0001 for all). Levels of antibodies in IC declined only for dsDNA (p=0.048).

Conclusions: Autoantibodies in serum and in IC show different associations to disease activity and to treatment response. High baseline anti-dsDNA levels in IC were most strongly associated with clinical remission, and decreased during belimumab treatment. Belimumab effect might primarily relate to autoantibodies in IC.

SAT0235  BII059, A MONOCLONAL ANTIBODY TARGETING BDCA2 SHOWS SAFETY, TOLERABILITY, PHARMACOKINETICS, PHARMACODYNAMICS IN HEALTHY VOLUNTEER SUBJECTS

D. Martin¹, L. Stevenson¹, P. Prasad¹, K. Smirnakis¹, A. Kao¹, D. Rabah¹, W. Wang¹, C. Barbery², C. Russelle³, N. Franchimont¹, ²Biogen, Cambridge, United States; ³Biogen, Zug, Switzerland

Background: Type I interferons (IFN-I) are central to the pathogenesis of systemic lupus erythematosus (SLE). BDCA2 is a plasmacytoid dendritic cell (pDC)-specific receptor that, upon engagement, inhibits the production of IFN-I and other inflammatory cytokines. Targeting BDCA2 therefore represents an attractive therapeutic strategy for inhibiting pDC-derived IFN-I and may be an effective therapy for the treatment of SLE. BII059, an investigational anti-BDCA2 humanized monoclonal antibody, has been shown to engage BDCA2, and this interaction leads to BDCA2 internalization and the consequent in vitro inhibition of TLR-induced IFN-I by pDCs (Pellerin 2015).

Objectives: This study is a first-in-human study that aimed to assess safety, tolerability, PK and PD of BII059 in HV subjects following administration of single ascending doses of BII059.

Methods: A randomized, double-blind, placebo controlled, single ascending dose-escalation was conducted in adult HV. Subjects received a single administration of either BII059 or placebo. BII059 was administered IV at 0.05, 0.3, 1, 3, 10 or 20mg/kg or SC at 50mg at ratio of 2:1:3. Blood samples were obtained before and after dose administration up to week 16. Target modulation of BDCA2 and serum BDCA2 concentration were measured using flow cytometry, and an enzyme-linked immunosorbent assay (ELISA), respectively, and anti-drug antibodies (ADA) were measured using a bridging ELISA.

Results: 54 HV (38 BII059; 16 placebo) were assigned to cohort 1–7. BII059 demonstrated non-linear PK consistent with target mediated drug disposition. Bioavailability of SC administration was ~50%. Treatment with BII059 led to rapid and complete down-modulation of BDCA2 on the surface of pDCs at all doses levels. Time to reappearance of BDCA2 on pDC surface correlated with circulating levels of BII059, establishing an in vivo pharmacokinetic/pharmacodynamics (PK/PD) relationship. Single dose administration of BII059 was well tolerated across all dose levels. All AEs were mild to moderate in severity with no serious AEs. There were no clinically significant changes in laboratory assessments, physical examinations, or electrocardiogram (ECG) values. Anti-drug antibodies were detected at low levels in a small number of BII059-treated subjects. Responses were largely transient and demonstrated no impact on BII059 exposure or association with any safety event.

Conclusions: The first-in-human study in HV demonstrated acceptable safety/tolerability and PK profile in healthy subjects and supports further multiple-dose studies with BII059. BII059 treatment showed dose dependent target engagement and internalization of BDCA2 establishing a PK/PD correlation in vivo on circulating pDCs. These data support further evaluation of clinical efficacy and safety of BII059 as a potential novel therapy in SLE patients.

SAT0234  PROSPECTIVE SINGLE CENTRE STUDY OF EFFECTIVENESS OF UPFRONT RITUXIMAB AND MYCOPHENOLENATE WITH MINIMUM STEROID IN SLE

B.G. Dharmarajand, Rheumatology, Sakra World Hospital, Sy No.52/2 & 52/3, Devarabeesanahalli, Oppsite Intel, Varthur Hobli, Bengaluru 560103, Bangalore, India

Background: Treatment options for SLE have significant morbidity and mortality. Side effects from corticosteroid usage limit patient adherence and treatment efficacy. B cell depletion appears to target a critical pathophysiological pathway in SLE. Trials with rituximab have shown mixed results. Rituximab study demonstrated efficacy and steroid sparing action of rituximab and mycophenolate (1).

Objectives: We aim to analyse our experience of using rituximab and mycophenolate upfront on presentation with minimum oral steroids.

Methods: 19 patients with SLE, seen between Jan 2015 to march 2016, were included in the study. All patients completed 6 months of follow-up. Patients were treated with 2 doses of rituximab (1 g) and mycophenolate (500 mg) on days 1 and 15, and maintenance treatment of mycophenolate mofetil (2000mg) and low dose prednisolone (<7.5 mg) which was tapered off.

Results: 10 were females and 2 males. Mean age of the patients was 24.5. 9 had lupus nephritis, 1 mesentric vasculitis, 1 CNS vasculitis and 1 severe cutaneous vasculitis with pancytopenia. Average SLEDAI improved from 14 to 4. 6/9 LN attained complete renal remission and 2 partial remission, one patient died due to infection and renal disease 15 days after infusion. 2 vasculitis and one NPSLE patient improved completely. Two patients had infection requiring hospitalization with in 6 weeks of infusion and one patient had severe bradycardia during the infusion and received only one rituximab. Steroid was stopped by 6 months in 6 patients and in the dose was below 5 mg in rest.

Conclusions: Early Rituximab and mycophenolate is an effective option for treating severe lupus and has steroid sparing property.

DOI: 10.1136/annrheumdis-2017-eular.3665

Methods: Atacicept was given as weekly subcutaneous injection to completers of ADDRESS II on average for an additional ≥ 24 weeks (i.e. ≥ 48 weeks total from Day 1 of ADDRESS II). Patients already receiving atacicept continued on the same dose (75 mg or 150 mg); those receiving placebo (PBO) switched to atacicept 150 mg (PBO/150 mg).

Conclusions: This extension study of ADDRESS II evaluated safety and disease activity in patients with SLE given continued atacicept treatment to week 48 (NCT01972568).

BONE MARROW AS A TARGET ORGAN OF SYSTEMIC LUPUS ERYTHEMATOSUS: ANALYSIS OF CASES WITH AUTOIMMUNE MYELOFIBROSIS

D. Üsküdar Canu, H. Üsküdar Tekë, S. İskıyög, C. Korkmaz, E. Eskışer Osmangazi University, School of Medicine, Rheumatology; E. Eskışer Osmangazi University, School of Medicine, Hematology; E. Eskışer Osmangazi University, School of Medicine, Pathology, Eskışer, Turkey

Background: Cytopenia in the course of systemic lupus erythematosus (SLE) may be due to multiple factors. One of these factors can be SLE-associated autoimmune myelofibrosis (AIMF). However, the frequency of SLE-associated AIMF is unknown as well as the role of clinical and laboratory parameters in the development of AIMF is not clear.

Objectives: Our aim was to identify the frequency of SLE-associated AIMF and compared SLE-associated AIMF group with non-AIMF group in terms of clinical findings and morphological properties of the bone marrow (BM) in cytopenic SLE patients.

Methods: We retrospectively analyzed 224 SLE patients’ files who met 1997 revised Classification criteria for SLE. BM aspirates and trephine biopsies were re-examined. Patients were divided into two groups according to whether they had cytophoblastic crisis or not. In the BM aspirate, the presence of dysplasia, and lymphoid infiltration were recorded.

Results: 45 (20%) of 224 SLE patients were found to experience BM biopsy due to cytopenia. Four patients were excluded from analyses (2 drug-induced cytopenia, 1 lymphoma, 1 insufficient BM biopsy samples). While AIMF was detected in 29 (70.7%) of the 41 patients, 12 patients did not have AIMF. All patients with AIMF had reticulin fibrosis, 2 patients (6.9%) had also collagen fibrosis. Between the AIMF and non-AIMF groups, Concor differences were identified in terms of erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), SLEDAI, BM cellularity, or BM dysplastic changes (p<0.989, p=0.387, p=0.788, p=0.672, and p=0.494, respectively). In the AIMF group, 27 patients responded to immunosuppressive therapy and corticosteroids, but 2 patients were unresponsive. The response time was longer for the AIMF group compared to the non-AIMF group (3.3±3.1 months vs 1.7±1.2 months, p=0.091). Correlation analysis revealed that higher the grade of BM fibrosis, longer the response time (r=0.471, p=0.002).

Conclusions: AIMF may be underestimated in SLE patients. AIMF as an additional factor for cytopenia in SLE patients may lead to delayed response to appropriate therapy, which was dependent on the presence of high grade fibrosis.

GLUCOCORTICOID WITHDRAWAL IN AN INCEPTION COHORT OF LUPUS NEPHRITIS PATIENTS

S. Wautier, F. Tamirou, S. Nieuwland-Husson, E. Housiaux, Rheumatology Department, Cliniques Universitaires Saint-Luc, Bruxelles, Belgium

Background: Few studies have addressed glucocorticoid (GC) withdrawal in lupus nephritis (LN). Yet, this remains a pivotal issue due to GC-induced side effects on the one hand, and to the risk of relapse on the other hand.

Objectives: We reviewed the data of the Louvain Lupus Nephritis Inception Cohort (LOULLINIC) i.e. to determine the percentage of patients able to permanently or transiently stop GC; ii): to compare their baseline and follow-up characteristics to patients who never stopped; and iii): to assess the consequences of GC withdrawal.

Methods: Ninety patients with new-onset biopsy-proven LN were included. All were under the care of the same senior physician (FAH) during follow-up. Clinical, pathological and biological data were extracted from our data base. The SLICC/ACR-DI was assessed at last visit. Unpaired t-tests, Mann-Whitney tests and ANOVA were used, as appropriate.

Results: Out of 90 patients with incident LN, 43 (48%) ever stopped GC (group P), of which 32 permanently (group DP). Median time to stop GC was 37 months. 47 patients (52%) never stopped GC (group N). At baseline, serum creatinine, uP/C ratio, ISN/RPS classes, activity and chronicity indices did not differ between groups, nor did the mean initial dose of methylprednisolone (MP) (N: 28 mg/d; E: 32 mg/d; P: 31 mg/d), the use of IV MP pulses (82
and 77% in N and E groups, respectively) and of IV cyclophosphamide (61 and 77%, respectively).

During the first year, mean (SD) u/pC decreased statistically more in group E compared to group N (p=0.028 by ANOVA), with striking differences at month 3 (N: 1.73±1.87; E: 0.96±1.34; p<0.038 by unpaired t-test). This difference at month 3 was also observed in P patients (0.85±0.76; p=0.02 by unpaired t-test).

Interestingly, the median MP dose at month 3 was statistically higher in group E (19.8±3) compared to group N (15±3) (p=0.005 by unpaired t-test).

At last follow-up, serum creatinine was statistically lower in E and P patients compared to N patients. Eight of the 11 patients from the T group suffered from a renal relapse (100% of the rest of patients, after a median time of 30 months). Importantly, SLICC/ACR-DI was significantly lower in E and P patients, compared to N patients (p=0.0068 and 0.0027, respectively).

Conclusions: In half of LN patients, complete GC withdrawal is achievable and in one-third it can be maintained long-term. As expected, patients able to stop GC display less damage at last follow-up. Patients who were able to stop GC decreased their proteinuria much more promptly during the first year of treatment.

SAT0239  | LATE-ONSET NEUTROPENIA FOLLOWING RITUXIMAB TREATMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS – A ROLE OF THE BAFF/APRIL PATHWAY

I. Paradis, S. Föder, F. Faustini, F. Wermeling, R.F. van Vollenhoven, E. Svenningsson, I. Gunnarsson. Department of Medicine, Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden

Background: Rituximab-mediated late-onset neutropenia (LON) has been studied in various diseases, but data from systemic lupus erythematosus (SLE) are limited.

Objectives: To study the prevalence and contributing factors for LON following treatment with rituximab in patients with SLE, including B cell related cytokines and growth factors of the myeloid lineage.

Methods: Patients from the Karolinska SLE cohort treated with rituximab (n=107) were enrolled in this observational study. Rituximab was given according to the lymphoma course (weekly for four weeks), the arthritis course (at week 0 and 2), or as a single infusion, with or without concomitant pulses of cyclophosphamide. LON was defined as an absolute neutrophil count <1500 cells/μL, occurring four weeks to two years after initiation of rituximab treatment, provided that other apparent causes were excluded. Neutropenia occurring later than two years after treatment initiation but during sustained B cell depletion were also considered LON.

Blisibimod was well-tolerated. The most common adverse events were upper respiratory tract infection (10.6% vs 14.3% on placebo), urinary tract infection (6.9% vs 10.7%), injection site erythema (7.8% vs 2.0%), injection site reaction (7.3% vs 2.6%), and diarrhea (7.3% vs 2.6%).

SAT0240  | PHASE 3 TRIAL RESULTS WITH BLISIBIMOD, A SELECTIVE INHIBITOR OF B-CELL ACTIVATING FACTOR, IN SUBJECTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

J. Merrill1, R.S. Martin2, W.R. Shanahan3, M. Scheinberg4, K. Kalunian4, D. Wofsy4, OMRF Oklahoma; 4ANTHERA, Hayward, United States; 2Hospital Abreu Sodré, São Paulo, Brazil; 1UCSD, San Diego; 3UCSF, San Francisco, United States

Background: Targeted, biologic inhibitors of B-cell Activating Factor (BAFF) have been evaluated in Phase 3 trials in over 5000 patients with SLE. Post hoc analyses of these studies identify lower placebo response and greater treatment effect using more stringent endpoints in patients entering with higher disease activity, greater corticosteroid doses, and/or anti-double-stranded DNA (dsDNA) and low complement C3 or C4.

Objectives: The Phase 3 CHABILIS-SCL-01 trial evaluated blisibimod, an inhibitor of B-cell activating factor (BAFF), in a "responder population" identified from prior studies with this drug class.

Methods: 442 SLE patients with anti-nuclear antibodies or anti-dsDNA, SELENA-SLEDAI score ≤10 on standard of care medications were randomized to receive weekly subcutaneous blisibimod (200 mg) or placebo. Corticosteroid taper was encouraged from Week 8 with the goal to reach <7.5 mg prednisone/day.

Conclusions: With a deliberate focus on a "responder population" for whom lower placebo responses were observed in previous trials, much higher placebo response rates were observed in the CHABILIS-SCL-01 trial. Modest benefits of blisibimod were observed on serological effects and corticosteroid tapering.

SAT0241  | EARLY RESPONSE TO BELIMUMAB IN SLE-RELATED JOINT INVOLVEMENT EVALUATED BY ULTRASOUND GRADIENT ASSESSMENT

L. Massaro, F. Ceccharelli, F.R. Spinelli, F. Morello, C. Perricone, F. Miranda, S. Truglia, V. Orfece, I.M. Rutigliano, C. Alessandri, G. Valesini, F. Conti. Medicina Interna e Specialità Mediche, Reumatologia, Sapienza Università di Roma, Roma, Italy

Background: Belimumab (BLM), a fully human monoclonal antibody directed against B lymphocyte stimulator (BllyS), is currently the only biological drug...
approved for the treatment of active Systemic Lupus erythematosus (SLE) patients not responding to standard of care. Data from RCTs and observational studies have demonstrated its efficacy, especially in patients with joint involvement. Focusing on this specific manifestation, the response has been also demonstrated by using Disease Activity Score on 28 joints (DAS28) (1). No data are available about the response to BLM in terms of synovitis, assessed by ultrasound (US).

Objectives: In the present 6-months longitudinal study, we evaluated the response to BLM in SLE patients treated for joint involvement, by using clinimetric indices and US assessment.

Methods: SLE patients starting BLM in the period between August 2013 and December 2016 were prospectively examined. The present analysis was restricted to patients requiring BLM for joint involvement. A complete physical examination and US assessment were performed at baseline (T0) and after 3 (T3) and 6 months (T6). At each time, we assessed the global disease activity by Systemic Lupus Erythematosus Disease Activity Index-2000 (SLEDAI-2K) and the joint involvement activity by DAS28. US evaluation of 12 joints (I-V metacarpophalangeal, I-V proximal interphalangeal, wrist and knee bilateral) was performed to identify inflammatory features (synovial effusion and hypertrophy, power Doppler) according to the OMERAQI definitions. These elementary lesions were scored according to a semi-quantitative scale (0=absent, 1=mild, 2=moderate and 3=severe) and a total score, corresponding to the patient’s inflammatory status (0–216) was obtained by their sum.

Results: Moving from 35 SLE patients starting BLM, 14 (14 female; mean age±SD 48.6±18.6 years; mean disease duration±SD 255.4±124.2 months) were treated for prevalent joint involvement. At baseline, the mean DAS28±SD was 4.5±1.1 and the mean SLEDAI-2K±SD was 6.1±1.5 and the mean daily prednisone±SD was 7.8±3.5 mg. After 3 months of treatment we observed a significant reduction in mean DAS28 (3.1±0.6 vs 4.5±1.1, P=0.007) and in mean SLEDAI-2K (3.5±2.1 vs 6.1±1.5, P=0.003) compared to baseline. The mean daily prednisone significantly decreased at T6 (4.7±1.4 vs 7.8±3.5 mg, P=0.03) while the rest of the therapy remained stable for 6 months. Of note, the mean total US score significantly decreased at T3 compared to T0 (13.7±24.4 vs 22.2±22.6, P=0.001). This result was maintained in 12 patients (85.7%) after 6 months with a statistically significant difference compared to T0 (7.9±6.6 vs 22.2±22.6, P=0.003) (Figure 1).

Conclusions: The results of the present study demonstrated the efficacy of BLM in SLE-related joint involvement, evaluated by SLEDAI-2K and DAS28, confirming previous data reported in the scientific literature. For the first time, we demonstrated an improvement to BLM as proved by the reduction of the total US synovitis score after 3 months, reflecting the improvement of the joint inflammatory status.

DOI: 10.1136/annrheumdis-2017-eular.4238
result may be limited by small sample size. In type I IFNGS test—high pts, a log-linear logistic model was used to describe the treatment effect of aniflurab. PT dropouts were more likely in nonresponders. Clinical simulations demonstrated dosages <300 mg would result in inadequate PK exposure and suboptimal efficacy in some pts with SLE. In contrast, simulations indicated minimal efficacy improvement for dosages >300 mg, consistent with the Phase IIb MUSE study outcomes.

Conclusions: Based on E—R analyses and overall risk assessment, a 300 mg Q4W, intravenous dosage regimen is recommended for pivotal aniflurab studies in pts with SLE.

SAT0244 | A LONG-TERM FOLLOW-UP STUDY OF ALLOGENIC MESENCHYAL STEM CELLS TRANSPLANTATION IN PATIENTS WITH DRUG-RESISTANT SYSTEMIC LUPUS ERYTHEMATOSUS
D. Wang, L. Sun, 1Department of Rheumatology and Immunology; 2Department of Rheumatology: The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: Allogenic mesenchymal stem cells (MSC) transplantation showed therapeutic effect in active and refractory systemic lupus erythematosus (SLE).

Objectives: To determine the long-term safety and efficacy of allogenic MSC transplantation (allo-MSC) in severe SLE patients refractory to previous therapies.

Methods: All consecutive SLE patients who received at least one allo-MSCST were analyzed. SLEDAI score of more than or equal to 8 or with at least one BILAG grade A or at least two BILAG grade B manifestations. All the patients were refractory to corticosteroid and/or immunosuppressive drugs treatment. Allogenic bone marrow and/or umbilical cord derived MSCs were infused intravenously, with one million cells per kilogram of bodyweight for each infusion. The primary end point was 5-year overall survival. Secondary end points included complete clinical remission, partial clinical remission and relapse.

Results: Eighty-one patients were enrolled and underwent allo-MSCST. Thirteen patients died within 5 years post-MSCST and the 5-year overall survival rate was 84% (68/81). At 5-year follow-up, 22 patients (22/68, 32%) were in complete clinical remission and another 6 patients (6/68, 9%) were in partial clinical remission, and the 5-year disease remission rate was 41% (28/68). In total, 37 patients had achieved clinical remission (27 in complete remission and 10 in partial remission) at the 5 years visit and then 9 patients subsequently relapsed. The 5-year overall rate of relapse was 24% (9/37). SLEDAI scores, levels of serum albumin and complement C3, peripheral white blood cell and platelet numbers, as well as proteinuria levels continued to improve during the follow-up.

Conclusions: Allogenic MSCST is safe and resulted in long-term clinical remission in severe and drug-resistant SLE patients.

SAT0246 | EXPLORE STUDY: RITUXIMAB USE IN SYSTEMIC LUPUS ERYTHEMATOSUS, A NEW LOOK ON OLD DATA
M. Scherlinger, C. Carcaud, M.E. Truchetet, P. Dufau, L. Couzy, J. Seneschal, T. Barretche, E. Lazaro, G. Dechez, Fhu Acronym, Chau de Bordeaux, Bordeaux, France

Background: Even if randomized trials EXPLORER and LUNAR failed to prove the superiority of rituximab versus placebo in patients with systemic lupus erythematosus, several encouraging indications as refractory lupus nephritis and new clinical trials renewed interest for this molecule.

We hypothesized that SLE response criteria used in EXPLORER were not sensible enough to show rituximab efficacy and that new response criteria could show a significant difference.

Objectives: Our objective was to reanalyze EXPLORER trial’s raw data using the newly described SLE response criteria.

Methods: We proceeded to a pre-specified re-analyze of EXPLORER trial’s raw data. The patients included in EXPLORER study had active SLE disease defined by a British Isles Lupus Assessment Group (BILAG) score A or 2 BILAG B despite immunosuppressive regimen. Renal and neurological SLE were excluded.

Patients were randomized through a 2/1 ratio to receive either two 1gr rituximab infusions (day 0 and 15) repeated at month 6 or a placebo. Standard SLE treatment and other immunosuppressant were continued. Patients received in a stratified manner prednisone ranging from 0.5 to 1.0 mg/kg depending on disease severity at inclusion. The original efficacy criterion was a composite clinical score using BILAG at week 52.

In our new analysis, rituximab efficacy was assessed at week 52 using 4 criteria: SRI-4 (Systemic lupus erythematosus Responder Index) with and without a concomitant oral prednisone (OP) tapering objective of -10mg at month 6 (SRI-4 with and without OP tapering), Lupus Low Disease Activity Score (LLDAS) and BILAG-based Combined Lupus Assessment (BICLA).

Results: Data from all 257 patients were available. There was 234 women (91%) with a mean age of 40.3 years among which 177 (69%) received hydroxychloroquine.

At week 52, SRI-4 response rate was 27.2% in the rituximab group vs 22.7% in the placebo group (p=0.43); SRI-4 with OP tapering was 16% in the rituximab group vs 13.6% in the placebo group (p=0.62); LLDAS was 16% in the rituximab group vs 12.5% in the placebo group (p=0.46) and BICLA was 15.4% in the rituximab group vs 15.9% in the placebo group (p=0.91).

Subgroup analyses demonstrated a trend for better efficacy of rituximab compared to placebo in the subgroup of patients co-treated with methotrexate: SRI-4 of 30.6% in the rituximab group vs 12% in the placebo group (p=0.08). This trend was not found in the subgroup co-treated with azathioprine: SRI-4 of 26.7% in the rituximab group vs 30.6% in the placebo group (p=0.68), nor in the subgroup co-treated with mycophenolic acid: SRI-4 of 23.1% in the rituximab group vs 21.6% in the placebo group (p=0.86). In the subgroup of patients with a BILAG A/B in hematological system or vasculitis at baseline, there was a significantly higher SRI-4 response rate with rituximab: 28.6% vs 5.3% in the hematological group (n=61, p=0.047) and 39.3% vs 0% in the vasculitis group (n=38, p=0.037).

Cumulative dose of steroids at week 52 were not statistically different: 423mg in the rituximab group vs 4390mg in the placebo group (p=0.65).

Conclusions: Our study confirms the results from the original EXPLORER study. These results might be partly related to the study’s design, notably the high daily oral prednisone used. Our work suggests efficacy in subgroups with vasculitis and hematological involvement.

SAT0245 | SERUM IFN GAMA MAY PREDICT THERAPEUTIC EFFECT OF MESENCHYAL STEM CELLS TRANSPLANTATION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS
D. Wang, L. Sun, Department of Rheumatology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: Umbilical cord (UC) derived mesenchymal stem cells (MSCs) show immunoregulatory properties on various immune cells and display clinical effect on lots of autoimmune disease like systemic lupus erythematosus (SLE).

Objectives: The aim of this study is to investigate the effect of SLE environment on UC MSCs and to observe the possible serum biomarker to predict the therapeutic effect.

Methods: UC MSCs were co-cultured with peripheral blood mononuclear cells (PBMC) from active lupus patients at a ratio of 1:4. The proliferation, apoptosis and surface markers of UC MSCs were observed. UC MSCs functional molecules were assessed by real-time PCR and the signaling pathways were analyzed by western blot. Different recombinant cytokines were used to stimulate UC MSCs and the functional factors were determined by real-time PCR. In the last, twenty-six patients with SLE, refractory to conventional therapies, were given UC MSCs transplantation. The clinical effect was followed-up for one year to classify responder and non-responder groups, and baseline serum cytokines were analyzed by ELISA.

Results: The co-culture of lupus patients PBMC had no effect on UC MSCs surface markers and apoptosis, but promoted MSCs proliferation. Lupus PBMC were more prone to stimulate UC MSCs to secret VEGF as well as CXCL-12, compared to PBMC from normal controls. Furthermore, lupus PBMC activated Akt, ikB and Stat5 signaling pathways in UC MSCs but did not affect Erk1/2 and Smad3 pathways. When stimulated by different cytokines, we found that interferon-γ (IFN-γ) was still the most important cytokine to induce IDO1 as well as IDO2 productions in UC MSCs: both had dose-dependent manners. Moreover, our clinical study showed that baseline higher levels IFN-γ might predict a good response to MSCs transplantation in active lupus patients.

Conclusions: Baseline IFN-γ levels may predict clinical response to MSCs therapy for active lupus patients, which will help us to choose appropriate patient for clinical transplantation.

**SAT0247 Efficacy and Safety of Modified-Release Prednisone in Managing Moderate Activity Systemic Lupus Erythematosus During Pregnancy: An Implemented Case-Control Study**

M. Meroni1,2, V. Ramoni2, M. Limonta2, M. Cutolo1,1, Research Laboratory and Academic Division of Clinical Rheumatology, Internal Medicine Dept., University of Genova, Genova; 2Rheumatology Unit, ASST Papa Giovanni XXIII, Bergamo; 3Division of Rheumatology, IRCCS San Matteo Hospital Foundation, University of Pavia, Pavia, Italy

**Background:** Systemic lupus erythematosus (SLE) primarily affects women of childbearing age. Despite the overall favorable outcome, pregnancy represents a challenge for both patients and clinicians. Since the complications rate is linked to the baseline disease activity, the achievement of remission is recommended before pregnancy. Prednisone represents a cornerstone in SLE management and is safely used, at low doses (< 7.5 mg daily), during pregnancy. Modified-release prednisone (MRP) optimize corticosteroid treatment strategy in rheumatic diseases, thanks to its capability of respect the physiological cortisol circadian secretion. MRP has been approved from FDA in SLE treatment, but no data are available regarding its administration during pregnancy.

**Objectives:** We aimed to investigate whether this drug is safe and effective as the immediate release prednisone (IRP) in SLE pregnant patients.

**Methods:** We retrospectively evaluated 9 female patients, fulfilling the ACR criteria for SLE, consulting our Centers in a 4-years observational range. All of them, thanks to a stable disease (not requiring treatment regimen modifications during 12 months), experienced a successful pregnancy during the observation. All the cases were taking low-dose MRP (5 to 7.5 mg/daily) as a baseline treatment, from at least 6 months. They were matched to 9 controls, defined as SLE patients with the same age and duration of disease, taking the same prednisone dose from at least 6 months, in the IR formulation. Overall pregnancy outcome features: SLE disease activity (calculated at least once during pregnancy, SLEPDAI) and at baseline/post-partum (SLEDAI) score; patient’s global assessment (VAS) at baseline, during pregnancy and in postpartum (mm); need of treatment changes at baseline/post-partum (SLEDAI) score; patient’s global assessment (VAS) at baseline, during pregnancy and in postpartum (mm); need of treatment changes (add-on strategy), the observed rates involved 1/9 (MRP) and 5/9 (IR) (p<0.05). Patients VAS (MRP vs. IR) was 0.001). Results

**Results:** Mean MRP age group was 26±7; disease duration, 4±8 years; IR one, respectively, 28±6 and 3±9 (both, p=ns). SLEDAI at baseline was 1±0.1 among MRP and 1±0.3 among IR women; SLEPDAI, 1±0.9 and 2±0.2 (both, p=ns). No major perinatal complications were detected. Preterm births, cesarean section rates, newborns weight and APGAR scores did not differ between the two subpopulations (all, p=ns). SLEDAI assessed at postpartum was 2±0.6 in MRP subjects and 3±0.4 in IR (p=0.05). Patients VAS (MRP vs IR) was 3±0.4 and 2±09 at baseline (p=ns); 2±0.6 and 4±0.7 during pregnancy (p<0.05) and 3±0.3 and 4±0.9 at postpartum (p<0.05). Regarding treatment regimen changes (add-on strategy), the observed rates involved 1/9 (MRP) and 5/9 (IR) women during the observational gap (pregnancy+postpartum) (p=0.001). Results

**Conclusion:** Activity (SLEDAI) score was significantly higher at postpartum and treatment had to be increased in IR patients, in comparison to the MRP, to manage SLE. VAS, conversely, was significantly higher among IR, both during pregnancy and postpartum. No major perinatal side effects were observed during the study; minor and expected complications rates did not differ between the two subpopulations. Despite the limited number of subjects, MRP treatment seems to be as safe, but more effective, in comparison to the standard IR one, during pregnancy of SLE-affected women.

**SAT0248 Baseline Clas-Damage Is a Major Predictor of Skin Response to Belimumab in a Multicentric Cohort of SLE Patients**

M. Gatto1, L. Iacarino1, L. Andreoli2, F. Conti1, R. De Angelis4, S. De Vita5, L. Emmi6, R. Gerli7, M. Govoni8, M. Mosca9, C. Salvadori10, A. Tincani2, A. Doria1,1 Unit of Rheumatology, University of Padova, Padova; 2Rheumatology and Clinical Immunology Unit, Spedali Civili and University of Brescia, Brescia; 3University LA Sapienza, Rome; 4Rheumatology Unit, University of Marche, Iesi; 5University of Udine, Udine; 6AOU Careggi, Florence; 7Rheumatology Unit, University of Perugia, Perugia; 8Unit of Rheumatology, University of Ferrara, Ferrara; 9Unit of Rheumatology, University of Pisa, Pisa; 10Rheumatology Unit, Arcispedale S Maria Nuova - IRCCS, Reggio Emilia, Italy

**Background:** Belimumab is used to treat several systemic lupus erythematosus (SLE) manifestations and predictors of response are advisable in clinical practice.

**Objectives:** To explore the effects of belimumab treatment on skin involvement in SLE patients in a real-life setting.

**Methods:** SLE patients treated with belimumab (10 mg/kg day 0, 14, 28 and then every 28 days), as add-on therapy in 11 Italian cohorts were prospectively followed-up for 24 months. Skin involvement was measured by the CLASIa score (Cutaneous Cutaneous LE Disease Area and Severity Index Activity) at baseline and every six months until month 24. Damage was measured by CLASI-Damage (CLASId); Response was defined as CLASId <2 at measured timepoints.

**Results:** The following variables were tested to determine baseline predictors of response at 12, 18 and 24 months: age, disease duration, cumulative prednisone dose; SLE activity index 2000 (SLEDAI-2K); prednisone dose >7.5 mg/day, baseline CLASId and CLASId, concomitant immunosuppressants (yes/no) and number of previous immunosuppressants. Statistical analysis was performed with SPSS 22.0 software.

**Results:** 188 patients were studied, among whom 48 (25.5%) had skin involvement as the leading feature for belimumab therapy. Mean follow-up period was 17.5±10.96 months. Thirty-eight patients completed a 6-month follow-up; 27 completed a 12-month follow-up; 19 completed a 18-month follow-up and 15 completed a 24-month follow-up. None of the patients discontinued due to adverse events (7/14, 50%), lack of efficacy (4/14, 28.5%) or other causes (3/14, 21.4%). CLASId, daily prednisone dosage and SLEDAI-2K significantly decreased during the follow-up (p<0.001). CLASId was achieved by 25 (38%) patients (65.7%) at 6 months, 19/27 (70%) at 12 months, 11/19 (58%) at 18 months and 10/15 (67%) at 24 months. A lower baseline CLASId was associated with CLASIa response at 18 and 24 months (responders vs. non-responders: 3.4±2.4 vs. 9.5±5.6; 3.5±2.5 vs. 11.2±6.5; p<0.005 for both), while a lower baseline CLASId was associated with CLASIa response at each timepoint (responders vs. non-responders: at 12 months 0.3±0.9 vs. 2.4±2.6; at 18 months 0.3±0.8 vs. 2.5±2.9; at 24 months 0.6±0.8 vs. 3.25±2.7; p=0.01 for all). Multivariate analysis was only performed at 12 months due to low patient number at 24 months. CLASId was the only independent negative predictor of response (OR 0.52, p=0.05). Notably, CLASId remained stable during the follow-up.

**Conclusions:** Belimumab use in cutaneous involvement is associated with reduced activity in skin lesions and hindrance of skin damage. Early use of belimumab before damage is established is likely to be associated with a better outcome.

**SAT0249 Safety, Pharmacokinetics, Pharmacodynamics and Inhibition of T-Cell Dependent Antibody Response (TDAR) With MEDI4920, a Novel Engineered CD40 Ligand (CD40L) Antagonist: Results of a First-Time-in-Human Study**

M.G. Albulescu1, M. Gunson2, J. Li3, J. Bush4, A. Godwood1, R. Midday2, E. Grant5, D. Howe1, R. Faggioni3, L. Roskos2, 1MedImmune, Cambridge, United Kingdom; 2MedImmune, Gaithersburg; 3MedImmune, Mountain View, United States; 4Covance Clinical Research Unit Ltd, Leeds, United Kingdom; 5Gilead Sciences Inc, Foster City, United States

**Background:** The CD40/CD40L pathway is involved in the T-cell-dependent activation of B cells, which subsequently produce autoantibodies and inflammatory mediators that contribute to autoimmune disease pathology. MEDI4920 is an engineered fusion protein and antagonist of CD40L that lacks the fragment crystallisable (Fc) domain thought to be involved in thromboembolic events (TEs) and neutralizes the FcγR-dependent co-stimulatory activity of Fc fusion products. MEDI4920 has demonstrated a favorable tolerability profile in healthy volunteers. We report the results of a first-time-in-human study evaluating the safety, tolerability, pharmacokinetics (PK), and antibody responses to MEDI4920 in healthy adult male subjects.

**Objectives:** The primary objective of this Phase I, randomised, double-blind, placebo-controlled, single-ascending dose study was to evaluate the safety and tolerability of MEDI4920 in healthy subjects. Secondary objectives were to characterize T-cell dependent antibody response (TDAR) to keyhole limpet hemocyanin (KLH) neoantigen, pharmacokinetics (PK), and anti-drug antibodies (ADAs) to MEDI4920.

**Methods:** Fifty-six healthy adult male subjects, aged 19–49 years, received a single intravenous dose of either MEDI4920 (3, 10, 30, 100, 300, 1000 or 3000 mg) or placebo. TDAR inhibition was analysed by measuring serum concentrations of ADAs to MEDI4920.
IgG and IgM antibodies to KLH over time. A dose—response model was generated for TDAR inhibition. Blood samples were collected to evaluate PK, total soluble CD40L (sCD40L) and ADA concentrations.

Results: No deaths, TEs, severe or serious hypersensitivity reactions or infections or infusion-related reactions were observed in the study. One serious adverse event (fractured tibia) was reported in the placebo arm. MEDI4920 showed inhibition of the TDAR IgG response after the second administration of KLH on Day 15 at higher doses (≥300 mg; Figure 1A). An E\textsubscript{max} model adequately characterised the TDAR dose—response at Day 43 (p<0.001; ED\textsubscript{50}=491 mg), with the 3000 mg dose showing 86% inhibition of the TDAR (95% CI: 68–94%; Figure 1B). MEDI4920 exhibited linear PK. MEDI4920 produced a dose-dependent increase in total sCD40L concentrations. A high ADA incidence (90%) was observed in dose cohorts <100 mg; however, ADA incidence (29%) and ADA titres decreased with ≥300 mg doses of MEDI4920. ADA-high subjects had reduced MEDI4920 and total sCD40L concentrations compared with ADA-negative subjects or those with low ADA titres. ADA incidence did not correlate with any clinical events.

Conclusions: MEDI4920 demonstrated an acceptable safety and tolerability profile, and dose-dependent inhibition of TDAR. The dose-dependent increase in total sCD40L concentrations indicates binding of MEDI4920 to sCD40L and target engagement. The decreases in ADA incidence and ADA titres correlate with increasing MEDI4920 dose, consistent with the immunosuppressive mechanism of action of this molecule. These results support further exploration of MEDI4920 administration in subjects with autoimmune diseases where the CD40/CD40L pathway is activated.

SAT0250 BODY MASS INDEX IS INVERSELY ASSOCIATED WITH RESPONSE TO RITUXIMAB IN LUPUS NEPHRITIS: ANALYSIS OF THE LUNAR TRIAL

M.D. Cascino 1,2, L.M. Gomez Mendez 1, J. Garg 2, L. Dragone 2, M. Dall’Era 1, P. Brunetta 2, 3, University of California – San Francisco, San Francisco; 4Genentech, Inc., South San Francisco, United States

Background: Increased body mass index (BMI) has been associated with poor functional capacity and systemic inflammation in lupus, 1 alterations in rituximab (RTX) pharmacokinetics, 2 and failure to achieve trial endpoints among patients treated with RTX for ANCA-associated vasculitis. 3 Although RTX is not approved for the treatment of lupus nephritis (LN), current EULAR/ERA-EDTA guidelines include RTX for use in refractory cases. 4 The effect of BMI on outcomes of patients treated with RTX for LN is unknown.

Objectives: To assess the association between pre-treatment BMI and renal response using data from the LUNAR trial.

Methods: LUNAR randomized 144 patients with ISN/RPS class III or IV LN to RTX (2 doses of 1000 mg at baseline and month 6) or placebo in combination with mycophenolate and a steroid taper. 5 BMI was measured at the screening visit. Complete renal response (CRR) was defined as achievement of UPCR <0.5, normal serum creatinine not increased from baseline by >15%, and inactive urinary sediment at week 52. Alternative definitions of response and achievement of CRR at week 78 were also considered. Logistic regression was used to model interactions and to calculate odds ratios (OR) and 95% CI. Peripheral CD19+ B cell measurements were examined.

Results: We identified qualitative interactions between BMI and treatment for CRR and alternative response measures. In unadjusted analysis, each 5 kg/m\textsuperscript{2} increase in pre-treatment BMI was associated with OR =0.47 (95% CI 0.24–0.92) in the RTX group and OR =1.44 (95% CI 0.93–2.23) in the placebo group for achievement of CRR (P value for interaction =0.006). The results of analysis adjusted for baseline UPCR and serum creatinine are presented in the Table. A sensitivity analysis identified consistent associations between BMI and response in the RTX group only. Among patients in the RTX group, increased BMI was associated with increased time to peripheral CD19+ B cell measurements observed differences in response are mediated by differences in the timing and/or degree of B cell depletion. These findings warrant additional analyses to better understand the relationships between patient characteristics, pharmacokinetics, B cell depletion, and treatment response in the LN population.

SAT0251 | PREDICTING AND MANAGING PRIMARY AND SECONDARY NON-RESPONSE TO RITUXIMAB USING B-CELL BIOMARKERS IN SYSTEMIC LUPUS ERYTHEMATOSUS

M.Y. Md Yusof1,2, D. Shaw1, Y.M. El-Sherbiny1,2, A.C. Rawstron3, P. Emery1,2, E.M. Vital3,4,5,6,7, E. Miossec3,7,8,9,10,11, M. Dall’Era:

Background: Rituximab (RTX) is the most commonly used biologic for the treatment of SLE. However, there is no currently acceptable predictors of response, which is of particular importance in this heterogeneous disease with other biologics being restricted to certain subgroups.

Objectives: To assess factors associated with primary and secondary non-response to RTX in SLE in order to develop more targeted and effective B-cell therapy.

Methods: A prospective observational study was conducted in 125 SLE patients treated with RTX in Leeds for over 12 years. A major clinical response was defined as improvement of all active BILAG-2004 domains to grade C/better and no A/B flare. Partial responders were defined by 1 persistent BILAG B. B-cell subsets were measured using highly sensitive flow cytometry. Predictors of response were analysed using logistic regression analysis.

Results: 117 patients had evaluable data. In cycle 1 (C1), 96/117 (82%) achieved BILAG response [major=50%-partial=32%]. In MVA, younger age & B-cell depletion at 6 weeks increased the odds of major response (Table 1). Complete depletion was predicted by normal complement & lower pre-RTX plasmablasts. 77 (with data on 72) C1 responders were retreated on clinical relapse. Of these, 61/72 (85%) responded in C2. Of 11 C2 non-responders, 9 met secondary non-depletion non response (2NDNR) criteria, as defined by infusion reaction & defective depletion (incidence=12%) and tested positive for anti-RTX antibodies. Lack of concomitant immunosuppressant & higher pre-RTX plasmablasts predicted 2NDNR.

Conclusions: B-cell subsets should be monitored in the routine care of SLE patients receiving RTX and should aim to achieve complete depletion. About 1 in 8 SLE patients lose depletion on repeat cycles and this is associated with anti-RTX antibodies. Intensive RTX treatment regimens in those predicted not to completely deplete, or alternatively use of humanised anti-CD20mAbs are likely to increase clinical response rates to B-cell depleting agents.

SAT0252 | THE NUMBER OF TREG CELLS IN PERIPHERAL BLOOD IN PSS PATIENTS IS DECREASED AND LOW DOSE IL-2 CAN PROMOTE ITS PROLIFERATION

M. Miao1, Z. Hao1, Y. Guo1, X. Zhang2, S. Zhang1, X. Wu2, D. Xu2, C. Gao3, X. Li1,2,3,7,8,9,10 The Second Hospital of Shanxi Medical University, 2Department of Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; 3Department of Pathology, Joint Program in Transfusion Medicine, Brigham and Women’s Hospital/Children’s Hospital Boston, Boston, United States

Background: PSS is a kind of autoimmune disease without clear pathogenesis. Treg cell plays an important role in autoimmune disease. However, opinions about change of amount of Treg cells in peripheral blood in autoimmune disease are various. Besides, the researches mainly focus on RA and SLE but not PSS.

Objectives: To explore the change of the number of Th17 and Treg (CD4+CD25+Fopx3+T cells) cells in peripheral blood in PSS and the effects of low dose IL-2 therapy on the balance of Treg and Th17 cells.

Methods: One hundred and ninety two PSS patients in our department, and 30 healthy controls were put in the research. The amount of Th17 cells and Treg cells were calculated by flow cytometry. Eighty eight in 192 were given low-dose IL-2 (50 WIU/day for 5 days) by hypodermic injection combined with standard therapy which includes glucocorticoid, immune-suppressants, biological agents or combination of them, while others (12 in 69) were given standard therapy only. The amount of these cells were calculated again after therapy.

Results: There was significant decrease in the absolute number of Treg cells and significant increase of the ratio of Th17/Treg in PSS patients when compared with healthy controls. There was no significant difference in absolute number of Th17 cells between PSS patients and healthy controls. Further, the number of Treg cells were negatively relative to ESSDAI. Traditional DMARDs had no obvious impact on Treg and Th17 cells. The amount of Treg cells significantly increased after the treatment of IL-2 by 1 week. But there was no significant improvement in clinical manifestations in the short time when comparing combinational treatment of IL-2 and classical drugs with classical therapy. No obvious adverse reactions were observed.

Table 1. Absolute number and percentage of CD4+T subsets in peripheral blood in PSS patients and Healthy controls.

</table>

Conclusions: The number of CD4+CD25+Fopx3+T cells in peripheral blood was decreased obviously and was inversely related to ESSDAI. While there was no significant difference of Th17 cells between PSS patients and healthy controls. And there was no correlation between the number of Th17 cells and ESSDAI. So the imbalance of Th17/Treg is due to the decrease of Treg cells not increase of Th17 cell which indicates that the pathogenesis of PSS maybe mainly because of shortage of autoimmune tolerance. Low dose IL-2 therapy can effectively promote proliferation of Treg cells by which low dose IL-2 may induce and restore autoimmune tolerance to benefit disease control.

SAT0253  Efficacy and Safety of Leflunomide Therapy in Lupus Nephritis: A Meta-Analysis

Q. Ren1, H. Zeng2, 1Department of Pediatric Allergy, Immunology and Rheumatology; 2Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children’s Medical Center, Guangzhou, China

Objectives: To evaluate the efficacy and safety of leflunomide in treating lupus nephritis (LN).

Methods: According to the requirements of meta-analysis, a literature search about efficacy and safety of leflunomide therapy in LN was performed among Cochrane clinical controlled trials database, PubMed, BMJ-Clinical Evidence, CNKI, VIP and Wanfang data from the establishment of the database till December 2010. All included RCTs were graded in term of randomization, allocation concealment and blinding and non-RCTs were graded in term of grouping method, blinding, withdrawal and loss of follow-up, baseline comparability, diagnostic criteria and bias control. RevMan 5.0 software was used for meta-analysis.

Results: A total of 682 literatures were included. Five RCTs and 2 non-RCTs were enrolled for meta-analysis. Leflunomide group was treated with leflunomide and glucocorticoid, while control group was given cyclophosphamide and glucocorticoid or placebo. The 24 h urine protein, SCR and SLEDAI scores of leflunomide group were significantly lower than that of cyclophosphamide group. There was no significant difference in C3, positive rate of anti-ds DNA between leflunomide group and cyclophosphamide group. There was no significant difference in infection, herpes zoster, interstitial lung disease, hypertension or cardiovascular disease between the two groups.

Conclusions: Based on the current evidence, the efficacy and safety of leflunomide for treatment of LN are close to cyclophosphamide. Further evidence from RCT studies is needed to elucidate the efficacy and safety of leflunomide for LN.

SAT0254  Safety, Tolerability, and Pharmacokinetics of Subcutaneous and Intravenous Anifrolumab in Healthy Volunteers

R. Tummala1, T. Rouse2, A. Berglind2, L. Santiago3, 1AstraZeneca, Gaithersburg, MD, United States; 2AstraZeneca, Gothenburg, Sweden; 3MedImmune, Mountain View, CA, United States

Background: Anifrolumab is a fully human anti–interferon-α receptor monoclonal antibody in Phase III development for systemic lupus erythematosus (SLE). In Phase IIb trials, intravenous (IV) anifrolumab (300 mg every 4 weeks) significantly decreased SLE disease activity with safety and tolerability comparable to placebo.

Objectives: The primary objective of this Phase I, double-blind, randomized, controlled study (NCT02601625) was to characterize the pharmacokinetics (PK), safety, and tolerability of anifrolumab administered subcutaneously (SC) and intravenously to healthy volunteers.

Methods: Thirty male and female adults were assigned to three sequential treatment cohorts of equal size (anifrolumab 300 mg SC injection; anifrolumab 300 mg IV; anifrolumab 600 mg SC by infusion). Individuals were randomized within each cohort to receive a single dose of either anifrolumab (n=6/cohort) or placebo (PBO) (n=4/cohort). Serial blood samples were collected up to Day 85. Serum anifrolumab concentrations were analyzed with a validated assay. PK parameters were estimated by noncompartmental analysis. Immunogenicity of anifrolumab was assessed by measuring serum anti-drug antibodies (ADAs).

Results: Anifrolumab serum concentration-time profiles and primary PK parameters in healthy volunteers are presented in the figure and table, respectively. Anifrolumab serum concentrations were below the limit of detection in all individuals by 85 days post dose. Maximum serum concentrations in the SC cohorts occurred after 4 to 7 days. Exposure to SC anifrolumab increased approximately dose proportionally from 300 mg to 600 mg based on AUC. At the 300 mg dose, anifrolumab SC administration reached approximately 86% of the IV administration exposure. SC administration of anifrolumab 300 mg and PBO elicited minimal injection-site reactions. Transient injection-site induration followed by 12 weeks of observational follow-up and/or long-term extension. Stable doses of corticosteroids (<10 mg prednisone or equivalent daily), non-steroidal anti-inflammatory drugs, and antimalarials were permitted. Safety assessments included clinical evaluation of adverse events (AEs), laboratory parameters, electrocardiograms, physical examinations, and overall tolerability. Exploratory efficacy assessments included hSS, Cutaneous Lupus Area and Severity Index (CLASI) skin scores, Physician Global Assessment (PGA), swollen joint counts (SJC), and tender joint counts (TJC).

Conclusions: Exposure of anifrolumab 300 mg SC was approximately 86% of IV administration, with single SC administrations of anifrolumab being generally well-tolerated in healthy volunteers.

SAT0255  A Randomized, Placebo-Controlled, Double-Blind, Ascending-Dose, Safety Study of CC-220 in Subjects with Systemic Lupus Erythematosus

V.P. Werth1, R. Furie2, S. Korish3, M. Weiswasser4, A. Azaryan5, PH. Schafer6, N. Dilev7, S. Choi2, D. Hough8, 1University of Pennsylvania School of Medicine, Philadelphia; 2Northwell Health, Great Neck; 3Celgene Corporation, Summit, United States

Background: CC-220 is a CUL4CRBN E3 ubiquitin ligase modulator that binds to cereblon and leads to potent and deep reduction of the transcription factors Ikaros (IKZF1) and Aiolos (IKZF3), which are overexpressed in the peripheral blood of Systemic Lupus Erythematosus (SLE) subjects. This study evaluated the safety, and tolerability of CC-220 in subjects in SLE. Exploratory efficacy assessments were included.

Methods: Subjects with history of SLE ≥6 months and a baseline of hybrid SLENA-SLEDAI (hSS) score ≥4 were randomized to 1 of 4 escalating doses of CC-220 or matching placebo (PBO). The 4 active treatments were CC-220 0.3 mg QOD, 0.3 mg QD, 0.3 mg alternating with 0.6 mg QD, and 0.6 mg QD; subjects were randomized 4:1 active to PBO in each group for 12 weeks of treatment, followed by 12 weeks of observational follow-up and/or long-term extension. Stable doses of corticosteroids (<10 mg prednisone or equivalent daily), non-steroidal anti-inflammatory drugs, and antimalarials were permitted. Safety assessments included clinical evaluation of adverse events (AEs), laboratory parameters, electrocardiograms, physical examinations, and overall tolerability. Exploratory efficacy assessments included hSS, Cutaneous Lupus Area and Severity Index (CLASI) skin scores, Physician Global Assessment (PGA), swollen joint counts (SJC), and tender joint counts (TJC).

Results: A total of 42 adult subjects were randomized; 39 subjects were female (93%); Mean age was 47.2 years; 64% were White and 31% were Black or African-American. Mean SLE duration was 9.4 years, with a mean baseline hSS score of 6.6, CLASI activity score of 9.8, and PGA score of 1.3. Seventy-nine percent of subjects completed the study; 9 of 42 subjects discontinued, of which 6 subjects discontinued due to an adverse event (AE): 1 in the placebo group and 5 in the 2 highest CC-220 groups combined. No discontinuations were due to lack of efficacy. Four subjects had serious AEs (highest CC-220 doses: n=2 [pneumonia]; PBO: n=2). Three subjects had neutropenia (grade 3: n=2; grade 1: n=1); 2 subjects in the highest CC-220 dose group had dermatitis, and 1 subject in the 0.3 mg QD and 1 in the 0.6 mg QD dose groups had urticaria. Mean reductions in the CLASI activity score at day 85 ranged from 4.3 to 7.8 in the CC-220 treatment groups compared to an increase of 0.4 in the placebo group.

Conclusions: CC-220 was generally well tolerated in this SLE population over 12 weeks of treatment, with neutropenia and dermatitis observed at the highest doses studied. Treatment with CC-220 resulted in a trend toward greater improvement in five of six individuals in the anifrolumab 600-mg group and two of four in the PBO group. Transient, mild to moderate injection-site induration and pruritus occurred simultaneously in two of six individuals in the anifrolumab 600-mg group, but not those in the PBO group. Adverse events were reported by 50% (n=9) of anifrolumab-treated and 33% (n=4) of PBO-treated individuals. No serious adverse events were observed. ADAs were detected in only one individual in the anifrolumab 300-mg IV group at the Day-85 assessment.

Anifrolumab Serum Concentration-Time Profiles

Conclusions: Exposure of anifrolumab 300 mg SC was approximately 86% of IV administration, with single SC administrations of anifrolumab being generally well-tolerated in healthy volunteers.

Conclusions: Exposure of anifrolumab 300 mg SC was approximately 86% of IV administration, with single SC administrations of anifrolumab being generally well-tolerated in healthy volunteers.

**SAT0256**

**MULTI-TARGET THERAPY WITH MIZORIBINE, TACROLIMUS, AND PREDNISOLONE IN LUPUS NEPHRITIS: ANALYSIS OF 47 CASES**

R. Kawato, R. Rokutanda, M. Kishimoto, M. Okada.

**Immune-rheumatology center, St.luke hospital, Tokyo, Japan**

**Background:** Mizoribine (MIZB), an inosine monophosphate dehydrogenase inhibitor, is an effective glucocorticoid-sparing agent for gromerulonephritis and variety of rheumatic diseases. However, its clinical usefulness as multi-target therapy in patients of lupus nephritis has been unclear.

**Objectives:** To evaluate efficacy of multi-target therapy with MIZB, tacrolimus (TAC) and prednisolone (PSL) for lupus nephritis.

**Methods:** We extracted all the cases with lupus nephritis treated with PSL, MIZB and TAC during period from 2008/1 to 2016/10. A retrospective medical chart review was performed to collect following data: baseline patient characteristics, dose of PSL, serum creatinine, urine protein, compliment, anti-DNA ab, remission rates, and safety profiles. We define complete remission as urine protein <0.5 g/gCr and normal serum creatinine, partial remission as urine protein decreasing more than 50% of baseline, and -3g/day of proteinuria and creatinine not increasing within 15%. Patients' records were followed from the beginning of multi-target treatment to 12 months after.

**Results:** 43 cases (female: n=37; male: n=6; mean age: 37.4 years old) were included for analysis. Of 30 cases who underwent renal biopsy, 10 cases were classified as class IV nephritis, and 7 cases were classified as class III nephritis. Mean urine protein (g/gCr) at baseline, at 3 months, and at 6 months were 1.9, 0.4, and 0, respectively. Mean dose of steroid was 32.8 mg/day at baseline, 9.8 mg/day at 3 months, and 8.7 mg/day at 6 month. 79.1% of the patients achieved complete remission at 3 months, and the remission rate was more than 80% at 6 months and later. As for adverse events, 14 cases had some infection, 3 out of 14 needed antibiotics treatment. Four cases had renal impairment after starting TAC, all of them recovered after stopping or decreasing dose of TAC.

**Conclusions:** Multi-target therapy with MIZB, TAC and PSL showed good remission rate, and few severe adverse events. We need the further evaluation of long-term efficacy of the therapy.

**SAT0258**

**SYNERGIC B-CELL IMMUNOMODULATION WITH RITUXIMAB AND BELIMUMAB IS CLINICALLY EFFECTIVE IN SEVERE AND REFRACTORY SYSTEMIC LUPUS ERYTHEMATOSUS – THE SYNOBIOE PROOF-OF-CONCEPT STUDY**

K. Krajii1, S. W. Kamerling1, E. de Rooij1, P. L. van Dalea2, I. Bajema3, O. W. van Tongt1, T. J. Dijkhuizen1, C. W. van Kooij1, Y. K. Teng1, V. Nephrology, LUMC, Leiden; 2Immunology, Erasmus MC, Rotterdam; 3Pathology, Rheumatology, LUMC, Leiden, Netherlands

**Background:** The pathogenesis of systemic lupus erythematosus (SLE) is characterized by B-cell hyperactivity leading to autoreactive plasma cells (PCs) that produce pathogenic autoantibodies and contribute to onset and maintenance of SLE. Therefore, novel treatment strategies in SLE are aimed at targeting autoreactive PCs. Rituximab (RTX) is used as off-label treatment in SLE and depletes CD20+ B-cells effectively, but is unable to deplete CD20- PCs. Belimumab (BLM), an anti-BAFF (B-cell activating factor) antibody, demonstrated efficacy in SLE as add-on therapy and resulted in reduction of B-cells and PCs.

**Objectives:** Because RTX+BLM has potential to target autoreactive PCs, we designed an open-label, proof-of-concept study to assess the clinical efficacy and safety of RTX+BLM in severe, refractory SLE patients.

**Methods:** A phase 2 proof-of-concept study, the SynBioSe study, was set up to treat severe, serologically active and refractory SLE patients with RTX following BLM treatment. The following endpoints were assessed at 24 weeks: a) clinical efficacy by SLEDAI; b) immunological effects on B-cells and PCs by high sensitivity flow cytometry, immunoglobulins and autoantibody levels, and c) safety parameters.

**Results:** The study included 11 severe, refractory SLE patients of which 10 had lupus nephritis and 1 patient had neuropsychiatric lupus with a median SLEDAI of 18 (range 8–29). Treatment with RTX+BLM led to clinically significant improvement to a median SLEDAI score of 2 [0–13] (p=0.002). Low disease activity (SLEDAI <4) was achieved in 80%. Clinical response was achieved while tapering steroids from a median dose of 60 [60–70] mg to 7.5 mg [0–12.5] and concomitant mycophenolate (MMF) was tapered to zero in all patients. With respect to safety, 23 adverse events (AEs) were reported of which none were serious AEs, 8 mild infections and 2 hypogammaglobulinemia. Complement usage was restored in all patients with a median increase in C3 of 33% [range 0–100%] at 12 weeks. At 12 weeks, RTX+BLM led to reduction of anti-dsDNA antibodies, from median 120 IU/ml [18–505] to 35 IU/ml [10–374] (p=0.012). CD19+ B-cells were depleted throughout the complete follow up from median 206106 cells/L [range 210105–511105] at screening to 5x104 [0–24x104] at 24 weeks, p=0.004, including transitional B-cells (from median 1.3x104 cells/L [1.1–3x104] at screening to 9.85 [0–3.4x104] at 24 weeks, p<NS). Importantly, total immunoglobulin levels only declined temporarily. The latter was further corroborated by transient reductions in CD3-CD38brCD27brCD20- PCs from median 1.6x105 cells/L [5.6x105–1.1x106] to 1.5x105 cells/L [5.3x105–3.1x105] at 12 weeks (p=NS). At 24 weeks, these PCs were restored to baseline levels (1.4x105 cells/L [9.2x104–3x105]).

**Conclusions:** This is the first study to demonstrate that RTX+BLM effectively reduced disease activity in severe, refractory SLE without raising major safety issues, while reducing other immunosuppressant drugs. Autoreactive PCs were specifically targeted by RTX+BLM. Therefore, combination therapy of RTX+BLM is a promising strategy in severe SLE.

HIGH PLASMA CONCENTRATION OF MYCOPHENOLATE ACID IN EARLY PHASE OF INDUCTION THERAPY PREDICTS GOODrenal function in LN class III-IV

T. Kiyokawa, H. Hanaoka, H. Ida, K. Ishimori, Y. Takakawa, T. Okazaki, S. Ozaki. Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Mycophenolate mofetil (MMF) is recommended as initial induction treatment for most cases of lupus nephritis (LN) class III-IV. Although the association between area under the concentration-versus-time curve (AUC) of mycophenolic acid (MPA) and therapeutic efficacy has been well shown in renal transplantation, it has been poorly investigated in LN. Furthermore, MMF interacts with multiple factors and its concentration may be decreased by high renal transplantation, it has been poorly investigated in LN. Furthermore, MMF treatment for most cases of lupus nephritis (LN) class III-IV. Although the background of LN class III-IV.

Methods: We prospectively enrolled patients with biopsy proven LN class III or IV who hospitalized from Apr to Oct 2016. As induction therapy, PSL was started at dose of 1mg/kg/day and tapered to 10mg/day by 12 weeks. Fixed dose of MMF at 2mg/kg/day was continuously introduced. We evaluated the association between AUC of MPA at different phases of induction treatment, early and middle, and prospectively investigated which concentration predicted future renal response in LN class III-IV.

Objectives: To investigate the relationship between the plasma concentration of MPA in early or middle phase of induction therapy and future renal response.

Methods: We prospectively enrolled patients with biopsy proven LN class III or IV who hospitalized from Apr to Oct 2016. As induction therapy, PSL was started at dose of 1mg/kg/day and tapered to 10mg/day by 12 weeks. Fixed dose of MMF at 2mg/kg/day was continuously introduced. We evaluated the association between AUC of MPA at different phases of induction treatment, early and middle, and prospectively investigated which concentration predicted future renal response in LN class III-IV.

Results: We enrolled 35 patients. AUC of MPA in early phase was correlated (R²=0.54, P<0.001) with CRI at week 12. The AUC of MPA in middle phase was not correlated (R²=0.17, P=0.7), but that of the early phase tended to correlate with CRI at week 12 (R²=0.43, P=0.02).

Conclusions: High AUC of MPA at the early phase of induction therapy might predict renal response.

SAT0260 OROVAN FUNCTION PRESERVATION WITH GONADOTROPIN-RELEASING HORMONE ANALOGUES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH CYCLOPHOSPHAMIDE

V.A. Pacucci1, F. Ceccarelli1, G. Perrone2, I. Zannini2, M. Candelieri2, I. Leccese1, C. Perricone1, F. Miranda1, S. Truglia1, F. R. Spinelli1, I. Zannini 2, M. Candelieri 2, C. Perricone1, F. Miranda1, S. Truglia1, F. R. Spinelli1

1Lupus Clinic, Rheumatology, Division of Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China; 2Department of Rheumatology, Polyclinic Umberto I Sapienza University of Rome, rome, italy

Background: The fertility in childbearing Systemic Lupus Erythematosus (SLE) patients can be impaired due to several conditions. In particular, treatment with alkylating agents, as cyclophosphamide (CYC), could determine menstrual irregularities and premature ovarian failure (POF). Gonadotropin-releasing hormone analogues (GnRH-a) is one of the preventive strategy suggested by the recently published EULAR recommendations (1). They are characterized by good safety profile and effectiveness in reducing POF rate in patients with malignancies and autoimmune diseases. So far, only few studies have been published focusing on the use of GnRH-a to prevent POF in SLE patients receiving CYC treatment.

Objectives: In the present case-control study, we aimed at evaluating the efficacy of GnRH-a on the ovarian function preservation in SLE patients treated with CYC.

Methods: We enrolled consecutive SLE patients, fulfilled the 1997 ACR revised criteria treated with CYC in the period between 2005 and 2012, receiving GnRH-a (GnRH-a-). As control, SLE patients treated with CYC not receiving GnRH-a (GnRH-a-) were assessed. Clinical and laboratory data were collected in a standardized, computerized and electronically filled form. Ovarian function was assessed by the evaluation of FSH and estradiol level (E2). GnRH-a (triptorelin 3.75 mg/monthly intramuscularly) was prescribed. SLE patients treated with CYC were followed after the treatment every six months during the first year and then annually.

Results: Thirty-three SLE patients treated by CYC were evaluated in the present analysis. 75.7% of patients were treated for lupus nephritis. Among [FC1] those, 18 (52.9%) were LN (class III-IV) for more than 6 years, mean age of 36.2±12.4 years; and 15 GnRH-a- (mean±SD age 31±0.10±5.6 years) and 15 GnRH-a+ (mean±SD age 31±0.10±5.6 years; mean±SD disease duration 6.3±7.7 years). The mean±SD SLEDAI-2K score in GnRH-a- patients was 10.1±3.7, in GnRH-a+ patients 8.3±3.3 (P=NS). Moreover, no differences were identified concerning the duration of CYC treatment (GnRH-a+: 6.1±2.6 months versus GnRH-a+: 6.1±2.6 months, P=NS) and follow-up (GnRH-a+: 8.1±1.2 years versus GnRH-a+: 9.3±7.2 years, P=NS). The prevalence of POF was significantly higher in GnRH-a- (5 patients, 33.3%) in comparison with GnRH-a+ (2 patients, 11.1%, P=0.0002). A significantly higher mean age at the time of CYC treatment was observed in GnRH-a+ (27.5±8 months, P=0.0002) than in GnRH-a- (21.7±5 months, P=0.0002). The prevalence of POF was significantly higher in GnRH-a- (5 patients, 33.3%) in comparison with GnRH-a+ (2 patients, 11.1%, P=0.0002). A significantly higher mean age at the time of CYC treatment was observed in GnRH-a+ (27.5±8 months, P=0.0002) than in GnRH-a- (21.7±5 months, P=0.0002). The prevalence of POF was significantly higher in GnRH-a- (5 patients, 33.3%) in comparison with GnRH-a+ (2 patients, 11.1%, P=0.0002). A significantly higher mean age at the time of CYC treatment was observed in GnRH-a+ (27.5±8 months, P=0.0002) than in GnRH-a- (21.7±5 months, P=0.0002). The prevalence of POF was significantly higher in GnRH-a- (5 patients, 33.3%) in comparison with GnRH-a+ (2 patients, 11.1%, P=0.0002). A significantly higher mean age at the time of CYC treatment was observed in GnRH-a+ (27.5±8 months, P=0.0002) than in GnRH-a- (21.7±5 months, P=0.0002).

Conclusions: The results of the present study showed the protective role of GnRH-a for the preservation of ovarian function in SLE patients treated by CYC. Furthermore, the age resulted the only risk factor associated with POF development.

BCL2-ASSOCIATED ATHANOGENE 3 PROTEIN IS ASSOCIATED WITH B-CELL HYPERACTIVITY INCLUDING LYMPHOMA IN PRIMARY SJÖGREN’S SYNDROME

A. Alunno1, F. Carubbi2,3, A. Falco4, O. Bistoni1, V. Valentini1, G. Cafaro1, I. Rua-Figueroa2, M.A. Martín-Martínez3, F. Alonso4, R. Giacomelli2, M. Pascale4, R. Gerli1.

1Department of Medicine, Rheumatology Unit, University of Perugia, Perugia; 2Department of Biotechnological and Applied Clinical Sciences, University of L’Aquila; 3Department of Medicine, ASL 1 Avezzano-L’Aquila-Sulmona, L’Aquila; 4Department of Pharmacy, University of Salerno, Salerno, Italy

Background: Bcl2-associated athanogene 3 (BAG-3) is a co-chaperone protein that interacts with the ATPase domain on heat-shock protein 70. BAG-3 is involved in several biologic processes including apoptosis, cytoskeleton organization and autophagy and, therefore, it has been extensively investigated in the field of tumorigenesis (1). In particular, BAG-3 expression is constitutive in human primary tumors including leukemias and lymphomas and it is induced in different normal cell types, including leukocytes, by a variety of stimuli. BAG-3 is able to induce and maintain cell proliferation, resistance to therapy and cell motility, namely metastatization. On this basis, a role of BAG-3 in chronic inflammatory diseases may be postulated, but data on this topic are not available.

Objectives: The purpose of our study was to investigate the expression of BAG-3 in primary Sjögren’s syndrome (pSS) and the relationship with clinical and serological features.

Methods: BAG-3 concentration was assessed in the serum of 103 patients with pSS according to the 2002 American-European classification criteria and in 40 sex and age matched healthy donors (HD). Clinical and serological records were collected and statistical analysis was performed with SPSS 21.0.

Results: Twenty-six pSS patients were positive for BAG-3 (BAG-3+), with serum levels ranging from 32.1 to 950 pg/ml. When setting the cut off value according to the highest value found in HD (300 pg/ml), we identified 13 pSS patients displaying a peculiar clinical serological phenotype. In detail, in this subgroup of pSS patients the prevalence of purpura, low C4, both anti-RO and anti-La autoantibodies, rheumatoid factor and lymphoma was higher, when compared to pSS patients with BAG-3 levels <300 pg/ml or BAG-3- (all p<0.05). Furthermore, they displayed less frequently sicca symptoms such as xerostomia and xerophtalmia (both p<0.05). Binary logistic regression analysis revealed that pSS patients with BAG-3 levels >300 pg/ml had on odds ratio (OR) of 12 (95% CI 1.9–86, p=0.009) for lymphoma and this association was independent of the presence of purpura, a well known marker of lymphoma in pSS. When including low complement, another feature associated with lymphoma, in the multivariable analysis, both low C4 and BAG-3 levels >300 pg/ml resulted independently associated to lymphoma (OR=24 and 12.4 respectively).

Conclusions: Our study assessed for the first time serum BAG-3 levels in a large cohort of pSS patients. The results showed that the highest levels of BAG-3 identify a peculiar clinical and serological pSS phenotype, as consequence of a B-cell hyperactivity. Since it is known that BAG-3 is an anti-apoptotic protein involved in B-cell proliferation and activity, as well as in oligoclonal and monoclonal expansion in pSS.

NEOPLASIA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN SPAIN: RELESSER REGISTRY DATA

1Rheumatology, Can Misses Hospital, Ibiza; 2Rheumatology, Hospital Universitari Son Espases, Palma; 3Rheumatology, Germans Trias and Pujol hospital, Madrid; 4Rheumatology, Hospital Universitario de Canarias, Santa Cruz de Tenerife; 5Rheumatology, Hospital de la Princesa, Madrid; 6Rheumatology, Hospital Universitario Miguel Servet, Zaragoza; 7Rheumatology, Hospital del Mar, Barcelona; 8Rheumatology, Hospital Universitario Miguel Servet, Zaragoza; 9Pharmacology, University of Zaragoza; 10Pharmacology, School of Medicine, University of Alcalá

Background: There is limited evidence on the risk of neoplasia in autoimmune diseases such as systemic lupus erythematosus.

Objectives: The objective of this study is to analyze the incidence of cancer in the Spanish population with SLE and the factors associated in its development: RelesSER Registry Data.

Methods: We calculated the incidence density of malignant neoplasms, the standardized incidence ratio and the average time to develop the first neoplasm after diagnosis of SLE in patients of the SLE registry of the Spanish Rheumatology Society (RelesSER) fulfilling ACF97 criteria. We carried out a bivariate analysis of the associated factors to neoplasms and multivariate by logistic regression.

Results: A total of 3607 patients (90.4% female) were included. We registered 140 neoplasms in women (4.3%) and 14 in men (4%) (p<0.821). Incidence density 7.3/1000 patient-years (95% CI:4.85–10.98) (7.39 in patient-years women and 6.93 in men) without significant differences. After stratification by gender and age, cancer appeared in 3.2% of the women aged under 45 versus 3.8% of the men; 4.1% of women aged 45–65 years versus 5.9% of men and a 5.3% of women 65 and older versus 2.5% of men the same age. The standardized incidence ratio (SIR) was 2.16; 1.51 in men and 2.38 in women, highest for women under 65 years old. The SIR for >65 years was 0.96; 0.59 in men and 1.55 in women.

The average time until de development of the first malignant neoplasm was 10 years (RI:5.75–17.00), being lower in women (9.5 [RI: 5.00–17.00]) than in men [12.5 (8.75–17.5)] and in patients under 45 years versus over 45 years [8.0 (RI: 5.00–16.00)].

Malignant neoplasms were the cause of death in 10% of the patients (15/154), predominantly hematological and breast cancers, both at 19% followed by lung cancer in 14.3%.

Factors associated to malignant neoplasms in the bivariate analysis are shown in (table 1). No immunosuppressive therapy was associated with the development of neoplasms. In the multivariable model, adjusted for age and time of disease duration, age was the only significant variable (OR:1.030; 95% CI: 1.003–1.059; p<0.029) with a trend for ACE inhibitors use (OR:1.866; 95% CI: 0.808–4.306; p=0.144), SLEDAI (last visit) (OR: 0.904; 95% CI: 0.806–1.015; p=0.089), SLICC/ACR DI (without neoplasias) (OR: 1.160; 95% CI: 0.961–1.401; p=0.123), and duration of the disease in months (OR: 1.003; 95% CI: 1.000–1.006; p=0.068).

Conclusions: The incidence of neoplasia in Spanish women with SLE is higher than expected for age and gender. Malignant neoplasms were the cause of death in 10% of the patients, predominating hematological and breast cancers followed by lung cancer.

Acknowledgments: The RelesSER registry has been supported by the FIS (ISCIII) - European Regional Development Fund (FEDER), fellowship P11/02857. It has also been partially funded by: GSK, UCB, Roche and Novartis.

VALVULOPATHY AND PULMONARY HYPERTENSION IN A SERIES OF PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

1Rheumatology, Hospital Universitario la Paz, Madrid, Spain

Objectives: To evaluate the prevalence of cardiac valvular involvement and the risk of pulmonary arterial hypertension (PAH) associated with antiphospholipid syndrome (APS) in a series of patients fulfilling ACR1997 criteria.
pulmonary arterial hypertension (PAH) and predictive risk factors in a cohort of patients with antiphospholipid antibodies.

Methods: We included 232 patients from our cohort who underwent an echocardiogram. A total of 84 (36%) patients with primary antiphospholipid syndrome (PFS), 47 (20%) with APS secondary to systemic lupus erythematosus (SLE), 47 (20%) patients with antiphospholipid antibodies 23%) with SLE without AAF. The determinations of AAF and lupus anticoagulant were performed according to the indications of the international thrombosis society. Statistical analysis was performed with SPSS 18; using the Chi square test and the Fisher exact test.

Results: In patients with AAF, the echocardiogram was pathological in 88 patients (52%) (p=0.023). Valvular affection was evidenced in 64 (38%) (p=0.005) and PAH in 16 (p ns). Seventeen patients (35%), SAF (48), SAFS (26), AIF (14) and 9 patients in the non-AAF group (12%) presented with valvular affection (p=0.002). PAH presented 19 patients, 9 with SAFP (47%), 6 in the SAFS group (32%), 1 in the silent AAF group (5%) and 3 in the non-AAF group (16%) (p=). Both PAH and valvular involvement were asymptomatic in most cases, although two patients required valvular replacement. The most frequently affected valve in all groups was mitral valve (84%), except in patients with PAH where the most prevalent valvular pathology was tricuspid insufficiency. Patients with valvulopathy and APS had a higher prevalence of total thrombosis than SLE without valvulopathy (p=0.05). Patients with valvulopathy also significantly increased stroke and thrombocytopenia (p=0.04).

Conclusions: Subclinical valvular involvement is very common in patients with AAF. Every patient with AAA should be given an echocardiogram in the initial protocol of their study in order to rule out both significant valvulopathy and PAH that can modify the patient's condition.

SAT0265 | CLINICAL CHARACTERISTICS OF SYSTEMIC LUPUS ERYTHEMATOSUS IN AN EGYPTIAN POPULATION: A RETROSPECTIVE COHORT

B. Medhat 1, T. El Hadidi 2, K. El Hadidi 2, A. Youssi 1, D. Hassan 1, F. Talaat 1, L. Maged 1, M. Shabaan 3, M. Eissa 1, N. Hamdy El Gobashy 1, N. Sobhy 1, N. Abd El Baki 1, R. El Refai 1, S. Ghoneim 1, W. Abd Rahman 2, 1Rheumatology and Rehabilitation, Faculty of Medicine-Cairo University; 2Rheumatology and Rehabilitation, Armed forced hospital; 3Rheumatology and Rehabilitation, Helwan hospital, Cairo, Egypt

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with a myriad of manifestations, that could vary among different ethnic and racial groups.

Objectives: To study the prevalence of various manifestations of SLE in an Egyptian population.

Methods: Information in this study was derived from the medical records of SLE patients who followed up in a private clinic in Cairo from January 1980 to June 2015.

Results: This descriptive retrospective case series included 1109 juvenile (19.4%) and adult (80.6%) patients, of which 114 (10.3%) were males and 995 were females (89.7%). Age of onset showed a mean of 26±11.19 years, and the mean of disease duration was 48.78±58.46 months (median: 26 years). The most common manifestations were synovitis (76.7%), malar rash (48.5%), leukopenia (45.7%), and photosensitivity (45.6%). At least one of the antiphospholipid antibodies was present in 41.8% of the patients tested for APL (636 patients). However thrombocytopenic manifestations and/or recurrent fetal loss occurred in 11.5% of the patients. Neuropsychiatric manifestations were evident only in 6.4% of the patients, with seizures as the most common neuropsychiatric manifestation, present in 4% of the patients. 33.1% of the patients had nephritis, which followed the onset of the disease by a mean duration of 20±21.3 months (median=12 months). There were gender differences in the disease characteristics. Cutaneous vasculitis, nephritis, retinopathy, and pleuritis (ISEDAI) were statistically higher in males (p=0.04), p=0.001, and p=0.041 respectively). Whereas, synovitis, and alopecia were statistically higher in females (p=0.012 and p=0.006 respectively). Patients with juvenile onset had a statistically higher frequency of nephritis (p=0.01), seizures (p=0.012) haemolytic anemia (p=0.001), and hypocomplementinemia (p=0.02).

Conclusions: Synovitis and malar rash were the most common manifestations in our study. Secondary antiphospholipid was present in 11.5% of the patients. Male patients and juvenile patients showed a tendency towards a more severe disease.

SAT0266 | EFFECT OF THE METABOLIC SYNDROME ON ORGAN DAMAGE AND MORTALITY IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL ANALYSIS

C.C. Moh 1, S.M. Tse, L.Y. Ho. Medicine, Tuen Mun Hospital, HK, Hong Kong; 1Medicine, Tuen Mun Hospital, HK, Hong Kong; 2Laboratory Medicine and Pathology, Mayo Clinic, Rochester, United States

Objectives: To study the relationship between serum 25-hydroxyvitamin D3 levels and flares of systemic lupus erythematosus (SLE) in a longitudinal cohort of Chinese patients.

Methods: Patients who fulfilled ≥4 of the ACR criteria for SLE were recruited from our rheumatology out-patient clinics in November 2011. Blood was taken at 10 AM and was assayed for the serum levels of 25-hydroxyvitamin D3 by liquid chromatography tandem mass spectrometry (LC-MS/MS) in our laboratory, using an assay with a coefficient of variation < 5%. Patients were followed longitudinally every 2–4 months for serial assessment of disease activity by SELENA-SLEDAI and the occurrence of mild/moderate or severe SLE flares (by SELENA flare instrument). Comparison was made among these groups in the baseline and mean sumrated SLEDAI over time (area under the curve), and the annual incidence of mild/moderate and severe flares by the one-way ANOVA test.

Results: 276 SLE patients were studied (94% women; age 41.0±13.8 years; SLE duration 9.3±7.2 years). The mean follow-up time of the patients since accrual at their last clinic visits (0.7±0.7 vs 0.26±0.6; p=0.001). The annual incidence of mild/moderate and severe flares by the one-way ANOVA test. Comparison was made among these groups in the baseline and mean sumrated SLEDAI over time (area under the curve), and the annual incidence of mild/moderate and severe flares by the one-way ANOVA test.

Conclusions: In this 5-year longitudinal study, the MetS was significantly associated with need for organ damage, vascular events and mortality in patients with SLE.

Disclosure of Interest: None declared

SAT0267 | SERUM 25-HYDROXYVITAMIN D3 LEVELS AND FLARES OF SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL COHORT ANALYSIS

C.C. Moh 1, R. Singh 2, L.Y. Ho 1, P. Jannetto 2, 1Medicine, Tuen Mun Hospital, HK, Hong Kong; 2Laboratory Medicine and Pathology, Mayo Clinic, Rochester, United States

Objectives: To study the relationship between serum 25-hydroxyvitamin D3 levels and flares of systemic lupus erythematosus (SLE) in a longitudinal cohort of Chinese patients.

Methods: Patients who fulfilled ≥4 of the ACR criteria for SLE were recruited from our rheumatology out-patient clinics in November 2011. Blood was taken at 10 AM and was assayed for the serum levels of 25-hydroxyvitamin D3 by liquid chromatography tandem mass spectrometry (LC-MS/MS) in our laboratory, using an assay with a coefficient of variation < 5%. Patients were followed longitudinally every 2–4 months for serial assessment of disease activity by SELENA-SLEDAI and the occurrence of mild/moderate or severe SLE flares (by SELENA flare instrument). Comparison was made among these groups in the baseline and mean sumrated SLEDAI over time (area under the curve), and the annual incidence of mild/moderate and severe flares by the one-way ANOVA test.

Results: 276 SLE patients were studied (94% women; age 41.0±13.8 years; SLE duration 9.3±7.2 years). The mean follow-up time of the patients since accrual at their last clinic visits (0.7±0.7 vs 0.26±0.6; p=0.001). The annual incidence of mild/moderate and severe flares by the one-way ANOVA test. Comparison was made among these groups in the baseline and mean sumrated SLEDAI over time (area under the curve), and the annual incidence of mild/moderate and severe flares by the one-way ANOVA test.

Conclusions: In this 5-year longitudinal study, the MetS was significantly associated with need for organ damage, vascular events and mortality in patients with SLE.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.2548
but non-significant trend of higher annual rates of mild/moderate and severe flares over time was also observed in patients with vitamin D deficiency. At the last visit, 27 (10%) patients had new damage scores; 5 patients had new vascular events; and 4 patients had new onset diabetes mellitus. There were no significant differences among the three groups of patients with regard to the incidence of new damage or vascular events over time.

Conclusions: Vitamin D insufficiency and deficiency were frequent in our cohort of SLE patients. Patients with vitamin D deficiency were associated with higher baseline and mean disease activity scores, as well as a trend of more severe lupus flares over time.

SAT0268 CLINICAL PRESENTATION OF NASAL INVOLVEMENT IN PRIMARY SJÖGREN’S SYNDROME: A MULTIDISCIPLINARY TEAM APPROACH TO A NEGLECTED AND DISABLING CONDITION

C. Baldo1 V. Secchia2 E. Elefante1 M. Scarcano2 L. Cristofani2 F. Ferro1 N. Luciano1 M. Mosca1
1Clinical and Experimental Medicine, Rheumatology Unit, University of Pisa; 2Otorhinolaryngology Unit, University of Pisa, Italy

Background: Dry nose is reported quite frequently by patients affected by primary Sjögren’s syndrome (pSS) in daily practice. However, a clear definition of nasal involvement in pSS is not available.

Objectives: a) to explore clinical presentation of nasal involvement in pSS analyzing key symptoms, objective findings at the inspection of the external and inner nose and nasal cytology b) to investigate any associations/correlation between nasal involvement and other clinical-serological disease manifestations c) to assess the overall impact of nasal involvement on patients reported outcomes (PROs).

Methods: Consecutive pSS patients (AECG 2002) were seen by a team of ENT specialists and through patient interview. SGUS of the parotid and submandibular glands were performed. Nasal symptoms were recorded using a self-reported questionnaire and through patient interview. Additional clinical information was obtained from the medical records review.

Results: Forty-six pSS patients were included in the study [M:F =45:1; median age 55 (33–79) years]. Nasal symptoms were more frequently present in patients with RS and AR. The SNOT22 scores were more frequently positive in patients with RS and AR. Nasal cytology evaluation, all the patients underwent a complete ENT evaluation. Nasal symptoms were recorded using a self-reported questionnaire and through patient interview. Additional clinical information was obtained from the medical records review.

Conclusions: Dry nose is reported quite frequently by patients affected by primary Sjögren’s syndrome (pSS) in daily practice. However, a clear definition of nasal involvement in pSS is not available.

Background: Juvenile Sjögren’s syndrome (JS) is a rare, poorly defined and possibly underdiagnosed condition. There is little information on the use of major salivary gland ultrasonography (SGUS) in this patient-group.

Objectives: To characterize symptoms and clinical findings of JS and to investigate SGUS as a diagnostic tool.

Methods: Sixty-four patients were recruited from Brazil (n=40), Norway (n=11), the Netherlands (n=8) and Spain (n=5). All patients had disease onset at the age of 18 or younger. Clinical examination and sialometry was performed in 60/64 patients. Additional clinical information was obtained from the medical records and through patient interview. SGUS of the parotid and submandibular glands was performed in all patients using linear high-frequency transducers (6–15 MHz), by an expert in SGUS. Glanderal homogeneity and presence of hypoechogenic areas were evaluated and glands characterized as normal or SS-like.

Results: The female:male ratio was 6:1. Mean age at diagnosis was 12.1 years (range 4–18), with first symptoms occurring at 10.3 years (range 1–17). Time from onset of symptoms until diagnosis was 1.6 years (range 2–8 years). Subjective oral and ocular symptoms were reported in 70% and 64% patients, respectively. Reduced secretion of tears was detected in 41% patients, and hyposalivation was recorded in 31% patients. Minor salivary gland lip biopsy had been performed and focus score determined in 34 patients; 28 biopsies (82%) had focus score ≥ 1. Serologically, 92% were positive for ANA, 73% were anti-Ro/SSA+, 38% were anti-La/SSB+, and 41% were RF+. Salivary gland enlargement had been experienced by 53% of the patients; one patient had also experienced lacrimal gland enlargement. Systemic manifestations at some time-point, was registered in 66% of the patients. Systemic treatment at inclusion was registered in 67% of the patients; previous systemic treatment was registered in 83%. Diagnostic criteria for primary Sjögren’s syndrome (pSS) was fulfilled by 54/64 patients (53%) and 39/64 patients (61%),

RDW LEVELS ARE ASSOCIATED WITH DAMAGE ACCRUAL IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

1Clinical and Experimental Medicine, Rheumatology Unit, University of Pisa; 2Otorhinolaryngology Unit, University of Pisa, Italy

Background: Systemic Lupus Erythematosus (SLE) patients show higher Red blood cells Distribution Width (RDW) regardless of anaemia status. RDW has been proposed to provide evidence of subclinical iron deficiency. Increased RDW is associated with increased damage accrual.

Objectives: To determine whether RDW levels in SLE patients are associated with damage accrual.

Methods: This cross-sectional study was conducted in 276 SLE patients, 257 females and 19 males. Evaluations included interview, medical records review, physical examination and laboratory tests. Disease activity was measured with the SLEDAI. Damage accrual was ascertained with the SLICC/ACR damage index (SDI). Univariable and multivariable Poison regression models were performed to determine associations of RDW levels with damage accrual. RDW levels were stratified by tertiles of RDW. The multivariable model was adjusted for variables known to be associated with this outcome (age at diagnosis, gender, socioeconomic status, ethnicity, tobacco use, disease duration, SLEDAI, anemia, antimalarials and immunosuppressive drugs use, average daily dose and time of exposure to prednisone (PNDI)).

Results: The patients mean (SD) age at diagnosis was 34.38 (13.33) years; nearly all patients were mestizo. Disease duration was 7.04 (6.16) years. The SLEDAI was 5.24 (4.67) and the SDI 0.92 (1.28). The average daily dose of PNDI was 6.39 (6.07) mg/d and the time of exposure to PNDI was 85.89 (59.59) years. RDW levels were 14.57 (1.52)% Hemoglobin levels were 12.4 (1.7) g/dl. We divided the RDW levels into tertiles with cut points in 13.8 and 14.0; the highest tertiles were associated with disease damage; with a Rate Ratio (RR) 1.57 (1.07–2.28; p: 0.020 for the highest tertile, and 1.67 (1.52–4.02; p: 0.007) for the medium tertile.

Conclusions: Higher RDW levels are associated with damage accrual in SLE patients independent of other well-known risk factors for such occurrence.

References:
AECG criteria and ACR/EULAR criteria, respectively. SGUS revealed SS-like changes in 37/64 patients (59%); interestingly, SS-like findings were observed in 22/23 patients in the European cohort, compared to 15/40 patients in the Brazilian cohort.

Conclusions: Common symptoms and findings in SS include dry mouth, systemic manifestations and salivary gland enlargement, followed by reduced tear secretion and hyposalivation.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.5804

SAT0271 | IS THERE A NEED TO INCLUDE SEROLOGICAL PATTERN TO PREDICT DAMAGE IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME: DIAPS APPLICATION

D. Mazilu, L. Potarchie, I. Saulescu, A. Borangiu, L. Groseau, C. Constantinescu, V. Vlad, D. Opris, A. Balanescu, D. Predeleanu, R. Ionescu. 1, 2, 3, 4 "Stanta Maria" Clinical Hospital, "Carol Davila" University of Medicine, 1, 2, 3, 4 "Stanta Maria" Clinical Hospital, "Carol Davila" University of Medicine, Bucharest, Romania

Background: Antiphospholipid syndrome (APS) is an autoimmune disease defined as the presence of antiphospholipid antibodies (aPL), at least a clinical thrombotic event and is associated with an important risk of organ damage. The new index proposed, Damage Index in patients with Thrombotic Antiphospholipid Syndrome (DIAPS) may be an useful tool to estimate cumulative damage in patients with primary and secondary APS. It includes 38 clinical items expanded in order to show the complexity of clinical manifestations in APS patients.

Objectives: The aim of this study is to analyze the serological pattern as potential predictive factor for an increased DIAPS.

Methods: All consecutive patients known with APS according to the Sapporo and/or Sydney classification criteria were included in our monocentric cohort. Data on medical history, clinical manifestations, aPL profile and medication were collected. DIAPS score was used to measure damage in each patient. The relation between DIAPS and positive aPL and DIAPS score was analysed.

Results: Seventy six patients with APS were included: 11 patients with primary APS, 65 patients with secondary APS. Their mean disease duration was 9.59±3.39years. The most frequent clinical manifestation from DIAPS was the peripheral vascular (deep vein thrombosis, intermittent claudication, tissue loss, venous varus insufficiency) found in 61.8% of patients, followed by hypertension; fasting glucose >5.6mmol/L or treatment for hyperglycaemia. 289 patients included were 87% female; 51% Caucasian, 29% Asian, and 12% African American; median follow-up was 10.0 (4.6 -15.0) years. Time-adjusted-mean SLEDAI (AMS) over the study period was 3.67. 81% (211) patients received GC (time-adjusted mean 4.25mg prednisolone) and AMS was significantly higher in GC-exposed patients (4.19 ± 1.97 [EMI], p<0.01). MetS criteria were met by 49 (17%) of patients (Table I). Hyperglycemia and hypertension were significantly more frequent in GC-treated patients, but the prevalence of obesity and other MetS domains, or MetS overall, were not. There were significantly more patients with MetS score ≥0 in the GC-exposed subset (43/78 vs 76/211, p<0.01).

The prevalence of obesity of 17% is lower than in the general population. There was no significant change in BMI across the period of observation and surprisingly, no association between GC exposure and change in BMI.

Conclusions: The prevalence of MetS in SLE was lower than previously reported in other, smaller, lupus cohorts. This study suggests GC exposure was associated with hyperglycemia and hypertension in SLE. Potential negative effects of active disease on MetS domains require further investigation.

SAT0273 | FACTORS RELATED TO ALEXITHYMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS

D.P. Marigotia, F. Basta, M. Vadacca, G. Dolcini, M. Lo Vullo, A. Rigon, A. Afflit, Unit of Allergy, Immunology and Rheumatology, Università Campus Bio-Medico di Roma, Rome, Italy, Rome, Italy

Background: Several evidences described a considerable prevalence of alexithymia among patients with chronic diseases, such as systemic autoimmune diseases. In patients affected by Systemic Lupus Erythematosus (SLE), alexithymia seems to be related to mood disorders and personality traits. The association between alexithymia and quality of life was also found.

Objectives: In this study we evaluated alexithymia in relation to HR-Qol (Health related Quality of Life) and to factor associated to HR-Qol, such as mood disorders, fatigue, work activity and physical activity.

Methods: We consecutively enrolled SLE patients and healthy controls in a cross sectional study with a retrospective design. We used the Toronto Alexithymia Scale 20 (TAS-20). AHF-Qol was expressed by MOS-SF-36. Mood disorders was assessed by BDI and HAM-H. Fatigue was assessed by Work Productivity and Activity Impairment (WPAI). Cognitive impairment was defined according to MOCA screening test.

Results: Fifty-two SLE patients and 50 age-matched healthy subjects were enrolled in the study. Mean TAS-20 score was significantly higher in SLE compared to controls (p<0.01). Alexithymic patients presented increased values of BDI score and HAM-H score (p<0.05) and reduced Facit-Fatigue score (p<0.05). We found increased values of Work missed due to health reasons (p<0.05) and activity impairment score (p<0.05) in patients with SLE compared to controls. No differences were found between SLE and controls in mood disorders, fatigue, physical activity and sleep quality.

Conclusion: This study indicated that alexithymia is strongly associated with HR-Qol, such as mood disorders, fatigue, work ability, sleep quality and physical activity.
predictors of TAS-20 values were to be fibromyalgic and to have mild-to-severe depression according to BDI. In multiple logistic regression, alexithymia was significantly associated to BDI score (OR 1.2, 95% CI 1.0–1.4) and inversely associated to cognitive impairment (OR 0.91, 95% CI 0.02–0.8).

Conclusions: SLE patients frequently present alexithymic tract. Alexithymia status seems correlated to be disease stage, to disease course (activity and damage) and to SLE therapy, nor to HR-QoL expressed by SF-36. Nevertheless, alexithymia could be tightly related to QoL-associated factors as depression and fibromyalgia.

SAT0274 UNRINARY VITAMIN D-BINDING PROTEIN AS A BIOMARKER FOR LUPUS NEPHRITIS

D.J. Go1,2, J.Y. Lee1, M.J. Kang1, I.A. Choi1, E.Y. Lee1, E.B. Lee1, E.Y.2, Y.W. Song1,2
1Department of Internal Medicine, Seoul National University Hospital; 2Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, and College of Medicine, Medical Research Institute, Seoul National University, Seoul.

Background: Lupus nephritis (LN) is a major complication of systemic lupus erythematosus (SLE). However, conventional biomarkers for assessing renal disease activity are imperfect in predicting clinical outcomes associated with LN.

Objectives: The aim of this study is to identify urinary protein biomarkers that reliably reflect the disease activity or predict clinical outcomes.

Methods: A quantitative proteomic analysis using liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS), was performed to identify protein biomarker candidates that can differentiate between SLE patients with and without LN. Selected biomarker candidates were further verified using urine samples from a larger cohort of SLE patients (n=121) by enzyme-linked immunosorbent assay (ELISA) to investigate their predictive values for LN activity measure. Furthermore, association between urinary level of selected panel of potential biomarkers and prognosis of LN was assessed with a 4-year follow-up study of renal outcomes.

Results: From proteomic assay, vitamin D binding protein (VDBP), transthyretin (TH), retinol binding protein 4 (RBP4) and progestin D synthase (PTGDS) were selected as candidates for quantification. These proteins were significantly elevated in SLE patients with LN, especially in patients with active LN (n=21). Among them, VDBP well correlated with severity of proteinuria (rho =0.661, P<0.001) and renal SLE disease activity index (renal SLEDAI) (rho =0.520, P<0.001). In the 4-year follow-up, VDBP was a significant risk factor (hazard ratio 9.627, 95% CI 1.698 to 54.571, P=0.011) for the development of proteinic flare (random urine protein/creatinine ratio >1.0) in SLE patients without proteinuria (random urine protein/creatinine ratio <0.5) (n=100) after adjustments of multiple flares.

Conclusions: Urinary VDBP correlated with proteinuria and renal SLEDAI, and predicted the development of proteinuria.

SAT0275 COMPARISON OF CLINICAL AND SEROLOGICAL DIFFERENCES ACCORDING TO THE AUTOANTIBODY CLUSTER IN WOMEN WITH SYSTEMIC LUPUS ERTHEMATOSUS: RESULTS FROM THE KOREAN LUPUS NETWORK (KORNET) REGISTRY

D.-J. Park, J.-H. Kang, J.-E. Kim, K.-E. Lee, S.-S. Lee. Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic Of

Objectives: Individual autoantibodies are associated with the clinical features in patients with systemic lupus erythematosus (SLE). However, few studies have investigated differences in disease presentation based on autoantibody profiles in Korean SLE patients. This study evaluated autoantibody clusters and investigated differences in disease presentation based on autoantibody profiles in Korean SLE patients.

Methods: A quantitative proteomic analysis using liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS), was performed to identify protein biomarker candidates that can differentiate between SLE patients with and without LN. Selected biomarker candidates were further verified using urine samples from a larger cohort of SLE patients (n=121) by enzyme-linked immunosorbent assay (ELISA) to investigate their predictive values for LN activity measure. Furthermore, association between urinary level of selected panel of potential biomarkers and prognosis of LN was assessed with a 4-year follow-up study of renal outcomes.

Results: From proteomic assay, vitamin D binding protein (VDBP), transthyretin (TH), retinol binding protein 4 (RBPA) and progestin D synthase (PTGDS) were selected as candidates for quantification. These proteins were significantly elevated in SLE patients with LN, especially in patients with active LN (n=21). Among them, VDBP well correlated with severity of proteinuria (rho =0.661, P<0.001) and renal SLE disease activity index (renal SLEDAI) (rho =0.520, P<0.001). In the 4-year follow-up, VDBP was a significant risk factor (hazard ratio 9.627, 95% CI 1.698 to 54.571, P=0.011) for the development of proteinic flare (random urine protein/creatinine ratio >1.0) in SLE patients without proteinuria (random urine protein/creatinine ratio <0.5) (n=100) after adjustments of multiple flares.

Conclusions: Urinary VDBP correlated with proteinuria and renal SLEDAI, and predicted the development of proteinuria.

SAT0277 EYE TOXICITY IN PATIENTS WITH SYSTEMIC LUPUS ERTHEMATOSUS TREATED WITH ANTIMALARIALS IN DOMINICAN REPUBLIC

E. Rodriguez-Bautista 1, Y. Cruz-Rojas 1, I. Mercedes-Nuñez 2, E. Tejada-Reyes 1, N. Abreu-Arbaje 1, M. Arbeja-Khoury 2, V. Rosario 3, R. Munoz-Louis 1, R. Peña-Blanco 3, T. Valdez-Lorie 2, R. Alba-Fériz 2, P. Rheumatology, Hospital Docente Padre Billini; 2Ophthalmology, Centro de Oftalmología y Glaucóma; 3Rheumatology, Hospital Docente Universitario Francisco Moscoso Puerto, Santo Domingo, Dominican Republic

Background: Antimalarials are derivatives of quinine indicated in the treatment of autoimmune inflammatory diseases. The mechanism of antimalarial toxicity is unclear. It is hypothesized that toxicity is a result of drug binding to retinal pigments, damaging photoreceptors resulting in vision loss. Early retinal toxicity is asymptomatic with subtle alterations in foveal pigmentation generally not evident at routine ophthalmologic examination, progressively producing classic “bull’s-eye” maculopathy, manifested as a decrease in central, color and night vision, and central scotoma. To prevent the sequelae of antimalarial use, sensitive tools are used to detect toxic maculopathy such as: campimetry, optical coherence tomography (OCT) and eye fundus.

Objectives: To evaluate ocular toxicity in patients with systemic lupus erythematosus treated with antimalarials.

Methods: Multicenter cross-sectional study, two rheumatology departments clinical records were analyzed from January 2016 to January 2017, with diagnosis of systemic lupus erythematosus according to ACR 1997 criteria, with >4 years using antimalarial drugs. 298 patients were identified, 93 of them fulfilled inclusion criteria, and were evaluated by two retinologists performing OCT on each patient. Accumulated antimalarial doses were calculated and all variables were analyzed with SPSS software V.22.

Results: 97.8% were females, the mean age was 37±13 years, 78.5% of the patients used 4mg/kg of chloroquine (CQ) versus 21.5% took 6mg/kg of hydroxychloroquine (HCQ), the mean use duration was 5.1±2 years, 19.4% of patients had retinal pigment epithelium (RPE) changes suggesting maculopathy, of which, 15% used CQ versus 4.35% with HCQ, 54.50% using CQ had a cumulative dose of 365 grams, 10.50% with HCQ had cumulative doses of 292 grams, and the mean for the cumulative dose of both antimalarials was 485 grams.

Conclusions: Previous studies have shown that the antimalarial toxicity rate are between 7.5% - 13.1%, in our population we observed that our patients had a higher toxicity rate associated with the use of CQ compared to HCQ, and no association was found relevant with other variables. We understand that both, patients and physicians who manage this drug, should be educated about the need to maintain an adequate ophthalmologic control, due to the progressive toxic damage from 1 to 3 years of drug use, and the discontinuation of treatment is necessary to carry out prospective studies with a greater number of patients.

SAT0278 COGNITIVE DYSFUNCTION IN PATIENTS WITH SYSTEMIC LUPUS ERTHEMATOSUS IN DOMINICAN REPUBLIC

E. Tejada-Reyes 1, I. Mercedes-Nuñez 2, Y. Cruz-Rojas 1, E. Rodríguez-Bautista 1, K. Polanco-Soriano 2, M. Perdomo-Ramirez 2, V. Rosario 3, R. Muñoz-Louis 1, R. Peña-Blanco 3, T. Valdez-Lorie 2, R. Alba-Fériz 2, P. Rheumatology, Hospital Docente Padre Billini; 2Rheumatology, Hospital Docente Universitario Dr. Francisco E. Moscoso Puerto, Santo Domingo, Dominic Republic

Background: Cognitive dysfunction (CD) is a deficit of cognitive faculties including attention, memory, language, executive function and visuospatial processing. CD is the most frequent neuropsychiatric manifestation of SLE (55–80%) 1 and this is 3 times higher in patients with Systemic Lupus Erythematosus (SLE) than in healthy subjects. 2 This is not routinely evaluated because it requires a lot of time. Brief and simple questionnaires are needed to identify CD. A study carried out by D’Amico et al. evaluated 21 SLE patients and all of them had CD.3 Pedraza et al. analyzed the MMSE score and Montreal Cognitiv
Assessment (MOCA) and concluded that MOCA performs much better than MMSE for cognitive impairment correct diagnosis.

**Objectives:** To determine the prevalence of CD in SLE patients and compare MMSE and MOCA diagnostic effectiveness.

**Methods:** All patients with at least 18 years old that met ACR/EULAR 2012 SLE classification criteria were included. Patients with associated comorbidity; not SLE related, that could alter cognitive functions, were excluded. 55 patients that fulfilled the inclusion criteria were admitted to Hospital Doctorc Padre Billini’s rheumatology department from March to April 2016. After obtaining written consent, the psychology department applied both tests, MMSE and MOCA. A standardized form registered demographic variables. Data was analyzed using Microsoft Excel 2013.

**Results:** 94.5% of the patients were women, 53% were between 31–45 years old, 52.7% were mulatto ethnic, 34.5% had at least a high school degree, 27.2% were diagnosed 1 year before enrollment, 60% had a low activity score using SLEDAI (≤4). hypertension was the most common comorbidity with a 38.1%, 90.9% were taking corticoids, 80% were on antimalarial drugs (6 abandoned treatment, 2 by eye involvement, 1 allergic reaction, 2 were diagnosed with SLE the interview day), the most frequent neuropsychiatric symptom ever presented was convulsion (7.2%). Using MMSE 25.4% of the patients showed CD, however after adjusting the results according to the educational level, the percentage increased to 41.8%. MOCA classified that 67.2% of the patients had CD, of which 13 patients were MMSS positive, and finally, 22 classified after the score adjustment.

**Conclusions:** MOCA is more effective than MMSE to detect CD. Nonetheless the MMSE SE should be considered as an option for patients with low levels of education.

**INCREASED FREQUENCY OF NAILFOLD VIDEOCAPILLAROSCOPY ABNORMALITIES IN PRIMARY ANTIPHOSPHOLIPID (PAPS) PATIENTS**

E. Martín-Naress, G. Hernández-Molina, P. Bermúdez-Bermejo, V. Zamora-Legoff, T.S. Rodríguez-Reyna. Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico

**Background:** Primary antiphospholipid syndrome (PAPS) is characterized by venous and arterial thrombosis, obstetric morbidity and the presence of antiphospholipid antibodies. Nailfold videocapillaroscopy is considered a tool of choice in the identification of cutaneous microangiopathy, a specific feature of this disease.

**Objectives:** To evaluate findings on nailfold videocapillaroscopy in patients with PAPS and their association with clinical and serological features.

**Methods:** We prospectively included 26 PAPS patients according to the modified SLEDAI 2012 criteria and the Alarcón-Segovia criteria for haemato logic antiphospholipid syndrome, who regularly attend a tertiary referral center in Mexico City, and who fulfilled the ACR/EULAR 2012 SLE classification criteria. A complete clinical, demographic, and serological investigation was performed. Nailfold videocapillaroscopy was performed using the Optilia 200x (Optilia Ltd, Berlin, Germany) at the baseline. Capillary morphology was evaluated by a rheumatologist certified by the EULAR Working Group on Optical Imaging and identified five categories of abnormalities: dilated capillaries, capillary haemorrhages, capillary rarefactions, microaneurysms and abnormal patterns, according to the 2015 Cutolo technique.

**Results:** Data were analyzed using statistical software. The proportions of abnormalities in the capillaries of PAPS patients were significantly higher compared to controls group (p<0.05) with a higher frequency of dilated capillaries (23% vs 7%), capillary haemorrhages (11% vs 5%), capillary rarefactions (27% vs 12%) and abnormal patterns (27% vs 7%). A sub-analysis of patients with high titers of anti-Ro52KDa antibodies showed a frequency of abnormalities similar to the group overall.

**Conclusions:** These findings suggest that scalaring and microvascular involvement is more frequent in PAPS patients. The coexistence of hypertension or other comorbidities may contribute to the development of capillary abnormalities in PAPS patients.

**ANTI-RO52 KDA AND ANTI-RO60 KDA ANALYSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS TO DETECT ANTI-RO FALSE-NEGATIVES**

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by immune system disruption with autoantibodies production. One of theeregulated autoantibodies is the specific to the Ro antigen, a ribonucleoprotein associated to a small RNA, constituted by the 52KDa and 60 KDa polypeptides, whose epitopes are mainly conformational. The routine detection method for anti-Ro is an enzyme immunoassay, however, is possible to obtain false-negatives for anti-Ro and this could be avoided by analyzing both subunits. These cases with high levels of anti-Ro52KDa and anti-Ro60KDa levels have been measured by colorimetric methods. Biostatistical analysis was performed with R 3.3.2.

**Objectives:** To identify false-negatives for anti-Ro by analyzing both 52KDa and 60 KDa subunits separately, as well as to characterize if there are clinical or molecular differences in this subgroup of patients compared to anti-Ro negative cases.

**Methods:** A cross-sectional, observational study of patients diagnosed of SLE according to SLICC 2012 criteria was performed. In these patients a complete blood-test was made, and clinical data by personal interview was collected. INFA. Anti-Ro, Anti-Ro52KDa and anti-Ro60KDa levels were measured by colorimetric methods. Biostatistical analysis was performed with R 3.3.2.

**Results:** We selected 69 SLE patients with negative results for anti-Ro (2.34±4.17 U/mL) out of 142 total SLE patients. A total of 51 patients were negative for both anti-Ro subunits and 18 cases presented positive results (up to 20 pg/mL) for at least one of them. The subgroup of patients that exhibit simultaneously high levels of anti-Ro52KDa and anti-Ro60KDa have higher clinical activity compared to negative anti-Ro cases (75% of active patients against 41.2% in anti-Ro negative patients). However, no differences in the accumulated damage evaluated by SLICC score between negative anti-Ro cases and patients with at least one positive subunit were observed. We analyzed serum levels of INF1A cytokine in the four groups of patients, and anti-Ro and subunits negative cases showed significant lower INF1A levels than the other patients (8.26±14.87 pg/mL and 26.62±40.71 pg/mL respectively; P=0.04). In addition, patients with high levels of anti-Ro52KDa subunit are those with the highest INF1A levels (anti-Ro S2+/anti-Ro06- 23.5±47.6pg/mL of INF1A; Anti-Ro S2+/anti-Ro60+ 36.4±37.9pg/mL of INF1A).

**Conclusions:** In our anti-Ro seronegative patients, a 26% of false-negative cases were detected. These cases with high levels of almost one anti-Ro subunit showed significantly higher levels of INF1A in contrast to negative cases, supporting the fact that they are indeed a different group from the negative cases. Moreover, the high INF1A levels could be the reason of the observed differences in the clinical activity measured by SLEDAI score in both groups.

**A TEN-YEAR SURVIVAL ANALYSIS OF FILIPINO PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AT THE NATIONAL KIDNEY AND TRANSPLANT INSTITUTE (PHILIPPINES)**

E.M.L. Yap, C.C. Bermudez. Internal Medicine, National Kidney and Transplant Institute, Quezon City, Philippines.

**Background:** Systemic lupus erythematosus (SLE) is increasingly being diagnosed in our country. Despite the increasing number of patients, there are no studies describing their clinical profile at the time of diagnosis at the National Kidney and Transplant Institute (NKTI). This study aims to describe patients’ initial clinical presentations, outcomes, and their survival rate within ten years.

**Objectives:** To determine survival rate and presenting characteristics of Filipino patients first diagnosed with SLE at the National Kidney and Transplant Institute (NKTI)

**Methods:** This is a retrospective cohort study using chart review of patients first diagnosed with SLE in 2004 followed up in the next ten years.
Results: Eighty-five patients were first diagnosed with SLE wherein their average age was 28.10 years old ± 12.03, 34.12% had hypertension, and 74.12% with renal involvement. The patients’ cumulative 10-year survival was 75% with average survival time of 9.84 years. Moreover, biopsy- proven lupus nephritis had significantly longer survival time (mean=10.57 years, p=0.006) while those with joint and cardopulmonary manifestion had shorter survival (mean=0.71 years, p=0.030) as well as those on hemodialysis (mean=8.82 years, p=0.040). Lastly, eleven patients (12.94%) expired during the study period with active diseases and infections as the common causes of mortality.

Conclusions: Although renal involvement was the most common initial manifestation, it did not correlated with disease activity indices, such as DAS28.

SAT0281 JOINT ACTIVITY INDICES CORRELATES WITH ULTRASONOGRAPHIC SCORE IN SLE PATIENTS WITH MUSCULO-SKELETAL INVOLVEMENT

E. Cipriano, F. Ceccarelli, C. Perricone, L. Massaro, G. Capalbo, F. Natalucci, F.R. Spinelli, F. Miranda, S. Truglia, C. Alessandri, G. Valesini, F. Conti. Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Roma, Italy

Background: Joint involvement represents one of the most frequent manifestations in Systemic Lupus Erythematosus (SLE) patients (incidence 69–95%), with different degrees of severity. Currently, there are no validated indices to evaluate joint involvement in SLE. Musculo-skeletal ultrasonography (US) has been widely applied in patients affected by different arthropathies. US-detected synovitis reflects the inflammatory state at the joint level, as demonstrated by the correlation with histological modifications. Furthermore, US-synovitis significantly correlates with disease activity indices, such as DAS28.

Objectives: In the present study, we aimed assessing a correlation between the composite indices DAS28 (Disease Activity Score 28), CDAI (Clinical Disease Activity Index), SDAI (Simplified Disease Activity Index), STR (Swollen to Tender Ratio) and the US-detected synovitis in a cohort of SLE patients with joint involvement.

Methods: One hundred seven patients (M/F 7/100, mean age ±SD 48.4±13.6 years, mean disease duration ±SD 156.0±129.6 months) with at least one tender joint were enrolled. We registred the number of swollen and tender joint count (0–28) and the patient’s/physician’s disease activity on visual analogue scale (0–100). DAS28-ESR, CDAI, SDAI and STR were calculated. The US evaluation of 12 joints (I-V metacarpophalangeal, I-V proximal interphalangeal, wrist and knee bilateral) was performed to identify inflammatory features (synovial effusion, synovial hypertrophy and power Doppler) according with OMERACT definitions. These elementary lesions were scored according to a semi-quantitative scale (0 = absent, 1 = mild, 2 = moderate and 3 = severe). The sum of the semi-quantitative scores allows obtaining a total score of the patient’s inflammatory state (0–216).

Results: As reported in Figure 1, by using the Spearman analysis, a positive correlation between US-score and SDAI (r=0.33, P=0.02), CDAI (r=0.29, P=0.03) and STR (r=0.42, P=0.0005) was identified. In particular, SLE patients with high disease activity according with STR value (≥1) showed a higher US score (16.3±19.3) in comparison with moderate (7.7±4.5, P=NS) or low disease activity (7.1±7.9, P=0.02). Moreover, US score resulted significantly lower in patients with DAS28 remission compared to those with an active disease (4.5±4.4 versus 7.05±5.1, P=0.03; Mann-Whitney test).

Conclusions: We analyzed a large SLE cohort with articular involvement identifying a significant correlation between US scoreand the composite indices CDAI, SDAI and STR. Furthermore, US-score may be able to discriminate DAS28-remission patients. Taken together, these results suggest the ability of composite indices in detecting the joint activity in SLE patients and the possibility to use them in clinical practice to assess this frequent and potentially disabling manifestation.

SAT0282 AUTOIMMUNITY AND PREGNANCY: EVIDENCE FROM AN OBSERVATIONAL STUDY

F. Del Porto 1, S. Ferreiro 2, M. Prioletta 3, N. Cifani 2, M. Catoni 1, F.M. Ubaldi 2, L. Rienzi 2, L. Ferri 1, R. Di Rosa 3, F. Natalucci 1, S. Ferrero 2, M. Proietta 3, N. Cifani 3, M. Catoni 1, F. M. Ubaldi 2.

1Sapienza University, Rome, Italy; 2Generale Valle Giulia, Roma; 3Sapienza University, Rome, Italy

Background: Obstetrical APS is defined by positive aPLs and a history of one or more unexplained deaths of morphologically normal fetus at or beyond the 10th week of gestation (WG) or one or more consecutive spontaneous abortions before the 10th WG. Also one or more premature birth before 34 WG because of eclampsia, severe pre-eclampsia, or recognized features of placental insufficiency represent one of the diagnostic criteria (1). Infertility is defined as the inability of a couple practicing frequent intercourse and not using contraception to conceive a child after 12 months. Autoimmune diseases are not included among major causes of infertility, despite defective embryonic implantation could be considered an aspect of recurrent fetal losses in patients with positive antiphospholipid antibodies, due to their capabilities to reduce trophoblast proliferation and growth (2).

Objectives: The aim of our study was to evaluate the prevalence of aPLs and pregnancy outcome in a population of women undergoing in vitro fertilization.

Methods: from December 2012 to December 2016, we selected 75 consecutive patients undergoing in vitro fertilization and evidence positive autoantibodies. Each of them was evaluated for genetic, anatomic, hormonal and infective causes of infertility. Moreover antinuclear antibodies (ANA), anticardiolipin antibodies (aCL), anti-β2-glycoprotein I (β2GPI), lupus anticoagulant (LA) and extractable nuclear antigens (ENA) profile were assessed.

Results: patients mean age was 41.38±4.87 years, ranging from 31 to 53 years. Prevalence of aPLs in our population was 68%. All women showed at least twice positive aPLs. aCL IgM and LA were the main antibody populations observed. ANA were positive in 50% of women, whereas SSA or SSB were positive in 4.17%. In 22.9% of patients a systemic autoimmune disease was newly diagnosed, mainly systemic lupus erythematosus. All patients with history of recurrent miscarriages and positive aPLs were treated with subcutaneous low weight heparin plus daily oral acetylsalicylic acid (ASA 100 mg) (3). Full term pregnancy was obtained in 45.8% of patients.

Conclusions: Prevalence of aPLs in the general population is 1–5%, whereas in our selected series positive aPLs were detected in 68% of the patients, suggesting that prevalence of aPLs may be increased in infertile patients (4). Moreover, a systemic autoimmune disease was newly diagnosed in 22.9% of patients suggesting that paucisymptomatic disease can be underestimated. Finally we would suggest that treating autoimmune co-morbidities ameliorates implantation rates in women undergoing in vitro fertilization (5).

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.6425
OBJECTIVES: Aim of the study was to assess the prevalence of anti-carbamylated vimentin in a cohort of SLE patients and to evaluate the possible associations with clinical and histological features of the disease.

Methods: Patients with SLE classified according to 1987 ACR criteria were enrolled. Clinical, serological and histological data were collected. Sera obtained from each patient were tested for anti-carbamylated vimentin by a home-made enzyme-linked immunosorbent assay. Data were analyzed using the mean ± standard deviation or median (interquartile range) when appropriate. To investigate difference in anti-carbamylated vimentin prevalence and anti-carbamylated vimentin serum levels Mann-Whitney and Chi square test were applied. P value <0.05 was considered statistically significant.

Results: We enrolled 109 SLE patients (102F:7M, mean age 39.4±12.6 years, mean disease duration 10.5±9.5 years, mean SLEDAI 2K 5±5.5).

Overall, 30 out of 109 patients (27.5%) were positive for anti-carbamylated vimentin. According to the clinical features, the prevalence of anti-carbamylated vimentin was significantly higher in patients with lupus nephritis (18/44) compared to those without renal involvement (12/66) (41.8% vs 18.2%, p=0.006; moreover, anti-carbamylated vimentin serum levels were significantly higher in patients with lupus nephritis (2561 (1783) OD) compared to those without [1970 (1123) OD; p=0.0178].

We didn’t find any difference in prevalence or titre of anti-carbamylated vimentin according to sex, age, disease duration, cumulative damage or the presence of anti-double-stranded DNA antibodies.

Conclusions: Higher prevalence and serum levels of anti-carbamylated vimentin in patients with lupus nephritis compared to those without renal involvement may suggest a role of the immune response in patients with glomerulonephritis and suggest their possible role as a biomarker of kidney involvement in SLE patients.

SAT0284 ASSOCIATION OF PATHOGENIC AND REGULATORY B-CELL SUBSETS WITH CLINICAL AND HISTOLOGICAL FEATURES IN PRIMARY SJÖGREN’S SYNDROME

F. Carubbi1,2, A. Alunno3, P. Cipriani1, A. Di Benedetto1, V. Liakoul1, P. Rusconi1, O. Berardicurti1, S. Di Bartolomeo1, R. Gerli2, R. Giacomelli1, 1Department of Biotechnological and Applied Clinical Science, Rheumatology Unit, School of Medicine, University of L’Aquila; 2Department of Medicine, ASL Avezzano-Sulmona-L’Aquila, L’Aquila; 3Department of Medicine, Rheumatology Unit, University of Perugia, Perugia, Italy

Background: Several data pointed out that B-cells play a central role in the development, maintenance and progression of primary Sjögren’s syndrome (pSS). B-lymphocyte hyperactivity, salivary gland (SG) infiltration, and the development of B-cell follicles containing germinal center (GC)-like structures, represent hallmark of the disease. On this basis, B-cell depletion therapy with anti-CD20 monoclonal antibodies is widely accepted; however, the percentage of IL-10-producing B-cells was higher in patients with GC (p=0.02) compared to those without GC. Although we observed a reduction of all B-cell subsets in pSS patients with ESSDAI≥5 compared to patients with ESSDAI<5 (p=0.02), we didn’t find any difference in prevalence or titre of anti-carbamylated vimentin antibodies in patients with rheumatoid arthritis.

Carbamylation is a non-enzymatic post-translational modification consisting in the addition of a cyanate group on lysine and arginine residues; since carbamylation has not been yet evaluated.

We demonstrated for the first time that a subset of circulating mature B-cells, Bm2’, also called GC founders, is strongly associated with higher disease activity and with the presence of SG-GC. Moreover, a higher ESSDAI in a subset of patients with higher IL-10-producing B-cells is associated with systemic lupus erythematosus (SLE). Pathogenic B-cell hyperactivity is a hallmark of pSS, however B-cells are also a source of inhibitory cytokines such as IL-10 and TGF-beta and the increase of IL-10 producing B cells that we observed in active pSS patients may suggest an ongoing compensatory mechanism to counteract chronic inflammation. Therefore, the design of novel B cell targeted therapies should ensure that only pathogenic B cells are depleted and regulatory B cell subsets are not hampered while, ideally, potentiated.

SAT0285 THE PHYSICAL PERFORMANCE OF SYMBIOTIC LUPUS ERYTHEMATOSUS PATIENTS WITH LOW DISEASE ACTIVITY: COULD THE CARDIOPULMONARY EXERCISE TESTING REFINE ITS ASSESSMENT?

G. Gusset1, A. Mociran2, C. Pamitli3, L. Damian2, D. Pop, D. Zdrengh, S. Rednic2, 1Cardiology, University of Medicine and Pharmacy; 2Rheumatology, County Emergency Hospital; 3Rheumatology, University of Medicine and Pharmacy Cluj-Napoca, Romania

Background: Even during remission, the systemic lupus erythematosus (SLE) patients have reduced exercise performance and this contributes to impairment of their quality of life. Several causes as depression and deconditioning, arthrosis, anemia, cardiovascular and respiratory involvement are widely accepted; however the weight of each factor is less known in particular individuals.

Objectives: Our study aimed to assess through cardiopulmonary exercise testing (CPX) the exercise performance of a SLE cohort and to establish its main determinants.

Methods: Thirty-one SLE patients with low disease activity underwent a CPX cycle ergometer; the main metabolic parameters and standard 12-leads ECG were recorded; before exercise testing, a cardiac Doppler ultrasound was performed. The patient’s characteristics, cumulative organ damage and laboratory data were retrieved by medical chart review. The control group consisted of 25 age and sex-matched healthy, non-trained individuals.

Results: Within the study group, 28 (90.3%) were female, the mean age was 42.7±10.6 years and disease median duration 7.9 years. The aerobic performance was decreased by 16.2% (17.6 vs 21.36 ml/kg/min, p=0.022), the main disease characteristics which correlated with maximum oxygen uptake (VO2max) were anemia (p=0.035), renal involvement (p=0.05) and antiphospholipid syndrome (APS) (p=0.042) but not disease duration, cumulative organ damage and laboratory tests. The immunological tests (hypocomplementemia, anti-Ro, anti-Smith, anti-dsDNA, AAN or APL antibodies).

One quarter of patients did not reach the ventilatory anaerobic threshold (VAT, exercise intensity that is associated with VO2max). Moreover, due to musculoskeletal pain (5 patients), dyspnea (2 patients with history of pulmonary embolism) and sudden rise in blood pressure (1 patient). Among the rest of them (23 patients, 74%), the VAT was at the lower limit of normal range (41.03% vs 54.0% for controls, p=0.014) corresponding to a “training reserve” of 31%. Of particular importance from this point of view were the criteria for test termination: dyspnea in 4 patients (1 with anemia, 1 with pulmonary fibrosis and 2 by hyperventilation proved by mean VE/VO2 = 4.15, fatigue (9 patients) and arthrosis (7 patients). Notably, among patients with established diagnosis of mild pulmonary fibrosis, COPD, ischemic or valvular heart disease, not dyspnea but arthrosis or fatigue was the reason for test termination, even if the VO2max was lower than recorded in the rest of the group (15.8 vs 19.2 ml/kg/min, p=0.037).

Conclusions: The exercise aerobic capacity of SLE patients is diminished and correlates with anemia, renal involvement and with history of pulmonary embolism. Surprisingly, even in patients with mild cardiovascular or respiratory involvement, the decreasing of exercise performance is limited mainly from musculoskeletal symptoms and from deconditioning.

scientific abstracts

SAT0286 | INCIDENCE AND MORTALITY OF PRIMARY SJÖGREN’S SYNDROME: TIME TRENDS OVER A 40-YEAR PERIOD IN A POPULATION-BASED COHORT IN THE UNITED STATES

G. Maciel 1,2, C. Crowson3, E. Matteson3, D. Conr4, 5. Rheumatology, Mayo Clinic, Rochester Minnesota, United States; 3Hospital Maciel, Montevideo, Uruguay; 4Division of Biomedical Statistics and Informatics, Department of Health Sciences Research; 5Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester Minnesota, United States; 6Rheumatology, CHRU Brest, Brest, France

Background: Few studies have reported the incidence of primary Sjögren’s syndrome (pSS) in well-defined populations worldwide, and none of them covered a period of time long-enough to analyze potential time trends in incidence rates. Whether pSS is associated with a higher mortality rate compared to the general population is also unclear from previously published studies.

Objectives: To estimate the incidence and mortality rates of pSS among residents of Olmsted County, Minnesota, and their evolution over time.

Methods: All medical records of patients with a diagnosis or suspicion of SS in Olmsted County, MN, from January 1, 2006 to December 31, 2015 were reviewed to identify incident cases of pSS (defined according to physician diagnosis). All patients with doubtful cases and all patients with an associated systemic autoimmune disease were excluded. These cases were combined with a previous 1976–2005 incident cohort from the same population (reference). Incidence rates were age and sex adjusted to the US white 2010 population. Survival rates were compared with the expected rates in the general population of Minnesota.

Results: With 61 incident cases of pSS diagnosed in Olmsted County in 2006–2015, the total cohort included 172 patients with incident pSS in 1976–2015. Of the 172 patients, 151 (88%) were women and 161 (94%) were white, with a mean (SD) age at diagnosis of 58.3 (16.7) years. The average age- and sex-adjusted annual incidence for 2006–2015 was 5.9 per 100,000 population (95% CI 4.4–7.4), and overall incidence for the entire period was 5.8 (95% CI 4.9–6.6) per 100,000. Incidence was 2 to 7 times higher in females compared to males in the different age classes (5.9 times higher on average), and increased progressively with age, culminating at 19.6 per 100,000 in females aged 65–74 years, with a slight decline thereafter to 15.9 per 100,000 among females aged 75 years and older. The incidence increased with calendar time over the 40-year period (p=0.005, figure). There was no apparent seasonality in the incidence of pSS, with similar number of cases diagnosed during all four seasons. There was no difference in mortality in the pSS cohort compared to expected (standardized mortality ratio 1.15, 95% CI 0.86–1.50).

Conclusions: The average annual incidence of pSS in this population based-cohort was 5.8/100,000, with a progressive increase over the 40 years of the study. Overall survival of pSS patients was not different from the general population.

SAT0287 | TH1, TH2 AND TH17 LYMPHOCYTE SUBPOPULATIONS IN PRIMARY ANTIPHOSPHOLIPID SYNDROME

G. Voicu 1, L. Groseanu 1, M. Abobul 2, V. Vlad 1, F. Bergheta 1, D. Predeteanu 1, V. Bojnicu 1, A. Saulescu 2, A. Bozianu 2, S. Dajla 2, D. Mazilu 2, A. Balanescu 2, C. Constantinescu 3, O. Opris 4, R. Ionescu 5, 1Rheumatology; 2Internal Medicine; 3Rheumatology; 4Pathology; 5 Pathology, Sfanta Maria Clinic Hospital, Bucharest, Romania

Background: Antiphospholipid antibody syndrome (APS) is characterized by thrombosis at different levels and maternal fetal complications in the presence of antiphospholipid antibodies (aPL). Lymphoid subpopulations and cellular immune responses have not been fully studied.

Objectives: To analyze the lymphoid subpopulations, Th1, Th2 and Th17 immune response in patients with APS and long term evolution.

Methods: Patients with APS, > 18 years of age, of both sexes and a group of healthy blood donors matched for age and sex were included. All patients were receiving oral anticoagulants (Coumadin type). No patient had a recent episode of thrombosis or other manifestation of APS at the time of the study. Peripheral blood was obtained and lymphoid subpopulations were determined by flow cytometry in order to identify cells expressing CD4+CD25+Foxp3+ and CD8+CD25+Foxp3+. The dendriticritic cells analyzed were: Type 1: Lin-1–HLA-DR+CD11c+; Type 2: Lin-HLA-DR+CD123+; B lymphocytes with antiCD19-APC; Monocytes with anti-CD14-PE; NK: CD3-/CD16+56+ and NKT: CD3+CD16+56+. Th1 cells were identified by IFN-g positivity; Th2: positivity for IL-4+; Th17: positivity for IL-17+. Parametric statistics and Mann-Whitney U-test were used.

Results: A total of 39 patients with APS were included, age: 51±9.12±8.9, evolution time: 12.8±5.9 years and 35 healthy controls. In patients with APS there was a decrease in the total CD6 count (p<0.05) in NK (p<0.005), DC1 (p<0.005) and DC2 (p<0.0005) compared to the control group (Table 1). We found a significant decrease in Th1, Th2 and Th17 cytokines basal and after activation compared to healthy controls.

Conclusions: This study shows profound alterations in innate and adaptive immunity in patients with long-term APS, characterized by a decrease in certain lymphocyte subpopulations, with consequent functional alteration. These abnormalities can become new therapeutic targets in order to restore immune imbalance. Our findings may explain in part, the development of thrombosis and other complications, despite treatment with oral anticoagulants in APS patients with long term disease evolution.

SAT0288 | QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

G. Voicu 1, L. Groseanu 1, M. Abobul 2, V. Vlad 1, F. Bergheta 1, D. Predeteanu 1, V. Bojnicu 1, A. Saulescu 2, A. Bozianu 2, S. Dajla 2, D. Mazilu 2, A. Balanescu 2, C. Constantinescu 3, O. Opris 4, R. Ionescu 5, 1Rheumatology; 2Internal Medicine; 3Rheumatology; 4Pathology; 5 Pathology, Sfanta Maria Clinic Hospital, Bucharest, Romania

Background: The quality of life (QoL) in patients with SLE is deeply affected by multiple factors including psychological and physical factors, the functional status and the general perception over health.

Objectives: Evaluation of Quality of life and the perceptions over the disease in patients with SLE functional status and the general perception over health.

Methods: This is a 10 month prospective, cross-sectional study performed on 52 patients hospitalized diagnosed with SLE according to SLICC 2012 criteria. There were evaluated demographic data, organs manifestations, disease activity scores (SLEDAI, SLICC) and treatment. To evaluate the QoL several questionnaires were performed: Health Assessment Questionnaire (HAQ), EuroQol five dimensions questionnaire (EQ5d), Illness Perception Questionnaire and SF-36.

Results: All patients were women with the mean age 49 years with a mean duration of illness 136 months (14). The mean SLEDAI – 5.52 (5.37) and SLICC – 2.25 (1.71). The mean HAQ value was 0.83 (0.81). The HAQ score doesn’t correlate with SLLC (p<0.461) with SLEDAI (p=0.172), but it was correlated with the neuropsychiatric manifestations. So the psychiatric affection influences performing the usually daily activities (p<0.005).

When assessing Illness Perception Questionnaire, patients considered their life seriously affected by pain, mean value 6,3 (2,6), 72% consider the illness will be worse in the future, 58% would avoid the same situation, 72% consider the illness will be more extensive.

The mean HAQ value was 0.83 (0.81). The HAQ score doesn’t correlate with SLLC (p<0.461) with SLEDAI (p=0.172), but it was correlated with the neuropsychiatric manifestations. So the psychiatric affection influences performing the usually daily activities (p<0.005).

When assessing Illness Perception Questionnaire, patients considered their life seriously affected by pain, mean value 6,3 (2,6), 72% consider the illness will be worse in the future, 58% would avoid the same situation, 72% consider the illness will be more extensive.
present for the rest of their lives, 90% appreciate that treatment is improving the QoL mean 9.3 (1.3), 68% consider to have many severe symptoms, more than 80% patients consider themselves preoccupied for their illness, more than 70% are emotionally affected by their illness and 48% consider stress being the main determinant factor of their illness. Our patients required preoccupation to stay in bed due to the disease, 8.33% can not wash or dress themselves, 12.5% are unable to perform usual daily activities, 62% experience pain or a moderate uncomfortable state and 65% are worried and or depressed. Cardio-vascular manifestations are correlated with diminished mobility (p<0.002), leading to deficiency in self care (p<0.002)also correlated with renal (p=0.001) and psychiatric (p<0.002) manifestations. Psychiatric manifestations also affect usual daily activities (p=0.05). Age is correlated with pain and uncomfortable state (p<0.004) but the responses to this item of EQ5D are not correlated with organ affection, biological modification or disease activity scores. The presence of cutaneous manifestations is correlated with anxiety and depression (p<0.002).

Based on SF36 when calculating the mean value on each category was observed all the 8 categories affected - smallest values at physical role (37,32) and general health (34,21), less influenced part being the social function (51,32).None of this items of SF36 is correlated with SLICC or SLEDAI.

SAT0289 | CARDIOVASCULAR RISK STATUS MODIFICATION IN SLE PATIENTS: MEANS OF CAROTID ULTRASOUND EXAMINATION

H. Sánchez-Pérez, B. Tejera-Segura, I. Ferraz-Amaro, Rheumatology, Hospital Universitario de Canarias, la Laguna, Spain

Background: Systemic lupus erythematosus (SLE) is associated with a higher cardiovascular risk (CVR), at least doubled when compared with the general population, as well as an increased prevalence of atherosclerosis,which occurs prematurely and independently of traditional CVR factors. The presence of atheromatous plaques documented with carotid ultrasound (US) examination implies a change in the patient’s CVR category to “very high risk”, according to the European Guidelines on cardiovascular disease prevention in clinical practice, 2016”. General guidelines do not take into account the specific increase in CVR risk that it’s present in patients with autoimmune diseases.

Objectives: To examine if the use of carotid US leads to a more accurate CVR classification in SLE patients, and in that way to a better CVR management.

Methods: Cross-sectional study that encompassed 102 SLE patients currently being followed in our Rheumatology Department. Demographic variables, the presence of CVR factors and previous/current CV events, disease duration and dose of prednisolone were analyzed and profile was assessed using blood tests, as well as carotid intima media thickness and the presence of carotid plaques using US scan. The current CVR status was calculated using the SCORE classification (low risk <1%, moderate risk <5%, high risk <10% and very high risk >10%).

Results: 95% of our patients were women, mean age was 51.6±11.0 years, median disease duration was 16 years (IQR 9–28). 35.29% of patients presented with at least one CVR factor before the SLE diagnosis,and 61.76% at the time of the research (19.60% current smokers, 39.21% high blood pressure (HBP), 33.33% dyslipidemia, 7.84% type II diabetes. A CV event was diagnosed in 11.76% of our patients throughout their SLE disease. According to the SCORE classification, 55% of them had a low CVR (53.92%), 26 moderate CVR (25.49%), 6 high CVR (5.88%) and 15 of them very highCVR (14.70%). Carotid plaques were found in 28 patients (27.45%): 23 of them had never had a CV event (22.54%), 21.42% of them were former smokers, 4.28% had HBP, 5.77% dyslipidemia and 17.86% type II diabetes. After adjustment of the SCORE classification with the presence of carotid plaques,16.36% of patients from the “low CVR” category would be re-classified as having “very high CVR”, as well as 30.76% from the “moderate CVR” category and 50% from the “high CVR” category. Of note,8 patients within the “very high CVR” category also presented carotid plaques. Out of this patients with atheroma plaque,13 were not using statins,and in 2 of them it would have been mandatory in order to achieve the LDL <70mg/dl target. In 2 of the 15 patients that were indeed under statins this target was not achieved. In 60.71% of the patients under hypothyroidism use and 17.64% of them used steroids as a regular basis (33.33% of them within the medium range dose).

Conclusions: More than half of our SLE patients presented with at least 1 CVR factor. Around 15% of patients were categorized as ‘very high CVR” according to the SCORE classification. The presence of carotid plaque was found in 27.45% of our patients and 82% of them hadn’t suffered any CV event. The use of carotid US examination allowed us to re-classify 20 patients (19.60% in the “very high risk” category according to the SCORE classification. The need for a change in CVR management (i.e., change in statin regime)was demonstrated in 4 of this 20 “re-classified” patients.

SAT0290 | OSTEONECROSIS IS THE MOST COMMON ORGAN DAMAGE AND IS ASSOCIATED WITH CUMULATIVE STEROID DOSAGE AS WELL AS LUPUS NEPHRITIS ETHIS ITSELF IN PATIENTS WITH SLE

H.H. Kwon1, S. Won2, Y.B. Joo3, M.J. Kim1, H.Y. Kim1, G.Y. Ahn1, S.-C. Bae1. 1Hanyang University Hospital for Rheumatic Diseases; 2Clinical Research Center for Rheumatoid Arthritis (CRORA), Seoul; 3St Vincent’s Hospital, Suwon, Korea, Republic Of

Background: In patients with SLE, musculoskeletal system is common organ system affected cumulative dosages of corticosteroids. Osteonecrosis (ON) is common in musculoskeletal damage accrual and often disabling. Steroid use has been a risk factor in the development of ON, but SLE itself has also been suggested to have a role. It is important to understand factors related to the development of ON.

Objectives: We investigated the overall profile of organ damage accrual, particularly musculoskeletal damage and focused on factors associated with ON in a single Asian cohort.

Methods: Patients with SLE who met American College of Rheumatology (ACR) criteria were enrolled and followed from 1998 to 2014 in the Hanyang BAE Lupus cohort. Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) was measured annually. ON was confirmed by X-ray, bone scan or MRI. Patients with ON was compared to controls without ON from the same cohort for clinical, laboratory, and therapeutic factors. Univariate logistic regression followed by multivariate logistic regression were used to determine risk factors for ON.

Results: We recruited 1,219 SLE patients. The most common type of organ damage was musculoskeletal damage (205 patients, 16.8%). ON was the most common subtype (133 patients, 10.9%) of the musculoskeletal damage. The mean time from diagnosis of SLE to development of ON was 4.97±4.15 (0.17–20.25) years. One hundred twenty-nine patients were eligible for identifying distribution of ON. Overall, 291 joints were affected by ON and mean number of ON joint per patients with ON was 2.3±1.23 (1–9). The percentage of >2 joint involvement was 24.6%. The hip (femoral head) was the most frequently involved joint (65.6%), followed by the knee (distal femur, proximal tibia, proximal fibula, patella) (23.6%), shoulder (humeral head: 5.2%) and ankle (distal tibia, distal fibula, talus: 5.2%). In univariate analysis, age at diagnosis, follow up duration, accumulative number of ACR criteria, serositis, renal disorder & neurologic disorder (based on ACR criteria), cyclophosphamide & mycophenolate use, and cumulative steroid dosages were significantly associated with ON. In multivariate analysis, renal disorder (p=0.019), and cumulative steroid usage (p=0.0131) were significantly associated with ON.

To evaluate the effect of cumulative steroid usage on ON, age, sex and disease duration matched ON cases and controls (1:4, a total of 665 patients) were selected from the same cohort. Total cumulative steroid dosage was divided into 4 groups by grams (>0 & ≤5g, >5g & ≤10g, >10g & ≤20g, >20g). More than 10g group of cumulative steroid use was significantly associated with ON. And then we stratified 530 patients according to biopsy proven lupus nephritis (class III to V) and cumulative steroid dose (10g cut-off), and tested Chi-square test and logistic regression. ON was significantly higher in the group with lupus nephritis within >10g group of total cumulative steroid.

Conclusions: ON was the most frequent damage in lupus patients. We confirmed again cumulative steroid dosage as a risk factor for the development of ON. In addition, lupus nephritis itself was suggested as an independent risk factor for ON.

SAT0291  NON-REPORTING OF SYSTEMIC LUPUS ERYTHEMATOSUS IN DEATH CERTIFICATES OF LUPUS PATIENTS: ITS EXTENT AND PREDICTORS
I. Padenj 2, M. Erceg 4, M. Cerovec 1,2, M. Mayer 1,2, R. Stevanović 3, B. Anić 1,2.
1 Department of Internal Medicine, Division of Clinical Immunology and Rheumatology, University Hospital Centre Zagreb; 2University of Zagreb, School of Medicine; 3Croatian Institute of Public Health, Zagreb, Croatia

Background: Systemic lupus erythematosus (SLE) is frequently not reported in death certificates of lupus patients, despite its known role as an underlying and/or immediate cause of death. Possible reasons may be insufficient access to patients’ medical records at time of death (including details on their medical history) and/or physicians’ unawareness of the contribution of SLE to death.

Objectives: We aimed to analyze the extent and predictors of non-reporting of SLE in death certificates of 90 deceased SLE patients regularly followed-up in a routine academic setting at our Department.

Methods: We retrospectively observed 90 SLE patients (68 females) deceased within the 2002-2011 period. All patients were ≥18 years of age and Croatian residents at the time of death, fulfilling >4 classification criteria of the American College of Rheumatology (ACR). We identified patients with SLE listed as a cause of death in the death certificate. An extensive set of variables was compared between patients with and without SLE reported in the certificate: demographics, ACR criteria at time of death and damage according to the Systemic Lupus Erythematosus International Collaborating Clinics (SLICC)/ACR index and its components at the time of death. We also compared the proportion of in-hospital deaths and autopsies performed. Frequencies were compared using the χ² and Fisher’s exact test, and continuous variables using the t-test and Mann-Whitney U test.

Results: SLE was reported in death certificates of 41/90 (46%) patients. Patients with SLE not reported in their death certificates were older at death (62±14 vs. 53±15 years) and diagnosed (53±14 vs 42±18 years) and had a lower proportion of renal disorder (20/49 vs. 29/41), cardiovascular and pulmonary damage (18/49 vs. 28/41 and 7/49 vs. 13/41, respectively), and died less frequently in hospital (28/49 vs. 35/41) and due to infections (4/49 vs. 26/41) (p<0.05). Conversely, these patients had a higher frequency of malignancy as a feature of damage (17/49 vs. 6/41) and a cause of death (14/49 vs. 1/41) (p<0.05). Only patients without SLE listed in their death certificate accrued gastrointestinal damage (7/49 vs. 0/41, p=0.015), hence this type of damage could not be included in the multivariate logistic regression model. In the multivariate model, the presence of infection as a cause of death was the single variable related to (non-)reporting of SLE (OR 0.053; 95% CI 0.012-0.237) (Table 1).

Conclusions: Non-reporting of SLE in death certificates of lupus patients may be an obstacle towards assessing the true extent of SLE-related mortality, calling into question the reliability of vital statistics data extracted only from death certificates. Infections as causes of death and gastrointestinal damage may influence reporting of SLE in death certificates.

SAT0292  LONG-TERM PROGNOSIS AND PREDICTING FACTORS OF CHINESE PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME
J. Zhao, Y. Sun, P. Zhang, Q. Wang, M. Li, X. Zeng. Peking Union Medical College Hospital, Beijing, China

Background: Antiphospholipid syndrome (APS) is an acquired autoimmune prothrombotic condition characterized by persistent circulating antiphospholipid antibodies (APL). The pathogenic mechanisms that lead to clinical manifestations associated with APL are only partially understood. And to date, long-term anticoagulation has been the only treatment shown to reduce vascular complications. Objectives: The aims of the present study were to assess and identify the predictive factors of long-term outcomes and mortality of antiphospholipid syndrome (APS) in Chinese patients.

Methods: Records of 160 patients with APS admitted to Peking Union Medical College Hospital in Beijing between 2005 and 2015 were investigated. Demographic characteristics, cumulative clinical and laboratory features, autoantibody profiles were retrieved from the database. Survival rates were studied by Kaplan-Meier method, and COX proportional hazard model was adopted to perform the analysis of predicting factors for mortality.

Results: The entire cohort consisted of 110 (68.8%) female and 50 (31.3%) male patients. Mean (SD) age at study entry was 36.5±14.9 years. The most prevalent thrombotic risk factors were hypertension, dyslipidemia, and smoking, present in 5-15% of the total cohort. In total, 50.6% of the patients had primary APS, 45.9% had APS associated with SLE, 2.0% APS associated with other connective tissue diseases. The most prevalent immunological features at baseline were LA (71.3%), aCL (55.0%), and j2GPI (49.4%). No significant statistical differences were found in the clinical presentation of the APS according to absence or presence of any of these antibodies. During the 10-year period, 16 (10.0%) patients (8 female and 8 male) died. The overall 1, 3, and 5-year survival rate was 92.6%, 89.1% and 87.1%, respectively. The most common causes of death were severe thrombotic events, including pulmonary embolism, strokes, and myocardial infarction (43.8% of total deaths), infections (18.8%). COX proportional hazard model show thrombocytopenia is the independent prognostic factor of mortality (HR 8.228, 95% CI 1.866-36.282).

SAT0293  PNEUMOCOCCAL INFECTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS
J. Schurder, T. Goulenok, R. Jouenne, A. Dossier, D. van Gysel, T. Papo, K. Sacre, Paris-7 University, APHP, Bichat Hospital, Paris, France

Background: A 5-fold increase in the risk of death is due to infection in systemic lupus erythematosus (SLE) patients when compared to age- and sex-matched controls Pneumococcal infection (PI) has been reported to be more frequent and severe in SLE

Objectives: Our study aimed to analyze the risk factors associated with the occurrence and severity of PI in SLE patients.

Methods: Medical records of all SLE patients and all patients admitted with PI in the Department of Internal Medicine (Bichat Hospital, Paris, France) from January 2005 to December 2014 were retrospectively reviewed. Clinical characteristics and APS associated with PI occurrence and severity were analyzed, both in SLE and non-SLE patients.

Results: One hundred and ninety SLE patients (42.2±14.9 years; 87.4% females) were hospitalized over a 10-year period. PI was the reason for admission in 6 (3.2%) patients, including 5 cases of invasive infection. With a follow-up of 2112.8
years for the total cohort, incidence of invasive PI in SLE was of 236/100,000 patient-years. As compared to the incidence in general French population, invasive PI was 26 times more frequent in SLE patients. PI occurred at a younger age (43.5 ± 14.9 versus 65.3 ± 18.7 years, p < 0.009) and was more severe, with a higher frequency of invasive infection (p < 0.001) and higher need for ICU admission (p < 0.05) in SLE as compared to non-SLE patients. Of note, unlike PI sites, including pneumococcal endocarditis (n=1), arthritis (n=1) and peritonitis (n=1) were observed in SLE patients only. Risk factors associated with PI in SLE patients were a serum gammaglobulin level ≤5g/L (p=0.003) and a past history of lupus nephritis (p=0.047), only. Steroids (p < 0.001) and immunosuppressive drugs (p=0.027) were associated with infection severity.

Conclusions: Pneumococcal infections occur at a younger age, are more frequent and severe in SLE patients. Hypogammaglobulinemia and lupus nephritis increased the risk for PI, whereas steroids and immunosuppressive drugs were associated with infection severity only. Our study shows that SLE patients have an increased risk for invasive PI and points to the need for vaccination against streptococcus pneumoniae in SLE.

SAT0294 | COMPARISON OF CLINICAL CARE BETWEEN CHINESE AND AMERICAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J. Dong1, H. Ma1, W.N. Roberts2, L. Wang1, F. Khan3, K.A. Lyn Shue3, L. Zhao1, L. Pan1.

Background: In addition to gender and ethnicity, modifiable variables like geography, socioeconomic status, health system structure, education, and physician expertise may influence outcomes in systemic lupus erythematosus (SLE).

Objectives: To compare characteristics of and treatment options for subsets of Chinese and American patients with SLE to elucidate factors that contribute to disease activity and damage.

Methods: Chart review of 77 Chinese (Qingdao) and 48 Midwestern American (Louisville, Kentucky) patients meeting American College of Rheumatology (ACR) criteria for a diagnosis of SLE followed up for four years were analyzed retrospectively. Organ damage was assessed using the Systemic Lupus International Collaborating Clinics (SLICC)/ACR Damage Index (SDI), and disease activity was assessed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). Statistics were parametric exploratory tests of significance and multiple regression analyses in this hypothesis-generating effort.

Results: The interval between the time of onset and diagnosis was 44 months shorter in the Chinese arm (p < 0.001), and Chinese patients followed up at six times greater frequency than American patients (p < 0.001). Despite the lack of formal matching, the two cohorts featured similar disease activity according to the SLEDAI. Based on the SDI, rates of organ damage were higher in the American group. Chinese patients received more steroids, cyclophosphamide, hydroxychloroquine, intravenous immune globulin, and cyclosporine than the Louisville group, while the Louisville patients received more myophenolate mofetil and azathioprine (p < 0.001).

Conclusions: Our results strengthen the hypothesis that a specific autoantibody-mediated LQTS occur in SLE patients positive to anti-Ro antibodies. This interference in the ventricular repolarization appears to be associated with increased levels of antibodies against Ro52/TRIM21 antibodies, and supports the realization of an electrocardiogram as part of the routine evaluation in SLE patient with circulating anti-Ro antibodies.

SAT0296 | RELATIONSHIP BETWEEN DISEASE ACTIVITY INDEX SCORES AND SUBJECTIVE ASSESSMENTS IN EARLY SYSTEMIC LUPUS ERYTHEMATOSUS

M. Garabu1, V. Sadovoi-Bebelea1, L. Mazur-Nicorici1, M. Cebaru1, V. Salaru2, M. Mazur1, 1Rheumatology; 2Family Medicine, State University of Medicine and Pharmacy "Nicolae Testemițanu", Chisinau, Moldova, Republic of Moldova

Objectives: To evaluate the disease activity in patients with early systemic lupus erythematosus (early SLE) and to compare it to patient’s and physician’s global assessment.

Methods: Cross-sectional study including 41 early SLE patients that fulfilled the classification criteria. The early disease was defined one with the duration 2 years from the diagnosis. The disease activity was assessed by SLEDAI-2K and SLAM. Global indices were anticipated by patient and physician global assessments (PGA and MDGA), rated by 0–100 numeric score. We correlated disease activity indices with global assessments by Pearson coefficient.

SAT0295 | ANTI-RO52/TRIM21 ANTIBODIES ARE ASSOCIATED WITH QT INTERVAL PROLONGATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

L.F. Perez, L.H. Silveira, L. Amezgua, O. Estevez, M. Moreno. Reumatologia, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico

Background: Long QT syndrome (LQTS) is characterized by an abnormal QT corrected (QTC) interval prolongation that is associated with increased risk of sudden death. Studies have associated LQTS with several rheumatic diseases, and evidence points towards a link between the degree of systemic inflammation and the duration of QTC interval. Moreover, recent evidence suggests that anti-Ro antibodies may play a role in the QTC prolongation by mechanisms not fully understood, thus constituting a novel autoimmune-mediated LQTS.

Objectives: This study aimed to assess whether QTC interval prolongation is associated with the presence of anti-Ro antibodies in SLE, particularly with reactivities against Ro52/TRIM21 antigens.

Methods: Consecutive patients fulfilling the 1997 ACR criteria for SLE were included. Patients with history of ischemic heart disease, with implantable pacemakers, and those taking drugs that potentially could affect QT interval (except for antimalarials) were excluded. Patients underwent a resting 12-lead electrocardiogram to measure QTC interval corrected by Bazett’s formula. A QTC interval duration greater than 480 msec in women and 440 msec in men was set to be abnormal. Serum anti-Ro and anti-Ro52/TRIM21 antibody levels were measured by ELISA. Data were expressed as frequencies and means ± standard deviation, and differences were tested by Yates’O continuity corrected chi square or Mann-Whitney tests, while linear regressions were performed to assess linearity between autoantibody levels and QTC duration. The GraphPad Prism 4.02 software was used for calculations.

Results: Sixty-six patients with mean age of 39±13 years (57 female gender) were included. A QTC prolongation was found in 10 patients (15%), with mean QTC interval of 470±18 msec as compared to 414±23 sec in those with no LQTS. Main clinical and demographic characteristics were similar for both groups, except for a lesser use of antimalarials and higher serum creatinine levels in patients with LQTS. Disease activity was similar between groups. Anti-Ro antibody levels were significantly higher in patients with prolonged QTC interval (75±66 U/mL vs. 29±44 U/mL; P<0.005); similarly, anti-Ro52/TRIM21 levels were higher in those with LQTS (50±55 U/mL vs. 14±30 U/mL; P=0.01). Notably, a linear association (see the Figure) between the QTC intervals and levels of anti-Ro antibodies (r2=0.073; P=0.02) and anti-Ro52/TRIM21 antibodies (r2=0.078; P=0.02) was observed.

Conclusions: Our results strengthen the hypothesis that a specific autoantibody-mediated LQTS occur in SLE patients positive to anti-Ro antibodies. This interference in the ventricular repolarization appears to be associated with increased levels of antibodies against Ro52/TRIM21 antigens, and supports the realization of an electrocardiogram as part of the routine evaluation in SLE patient with circulating anti-Ro antibodies.

DOI: 10.1136/annrheumdis-2017-eular.5561

884 Saturday, 17 June 2017 Scientific Abstracts
Results: There were 41 SLE patients integrated in the study, female: male ratio 9.25:1, mean age (SD) 39 (12.35) years (range 20–67 years), disease duration (SD) was 9.92 (9.18) month (range 1–24). The mean disease activity by SLEDAI was 11.2±7.84 (range 2–34) and SLAM – 8.83±4.41 (range 3–22) points, both indices denoted high disease activity level. Mean PGA values were 48.93 (19.13) (range 1–80), and mean MDGA values 45 (19.04) (range 1–80). Also, PGA and MDGA didn’t correlate with SLEDAI (r=0.25, p=0.05; r=0.27, p=0.05), while a statistically significant correlation was determined with SLAM index (r=0.85, p<0.001; r=0.46, p=0.002). A subclass analysis of SLAM components showed that cortical dysfunction (depression, psychosis) and the presence of headache correlated with PGA (r=0.36, p=0.05; r=0.4, p=0.05), so we can establish that the difference in correlation between SLAM and SLEDAI with PGA and MDGA is explained by a more accurate disease assessment by SLAM, including also subjective complaints that influences the global patient’s status.

Conclusions: The use of SLAM for disease activity assessment in early SLE patients is more sensible than SLEDAI and its results correlates with PGA and MDGA.

SAT0297 SLE PATIENTS WITH SECONDARY SJÖGREN’S SYNDROME ARE CHARACTERIZED BY TYPICAL AUTOANTIBODIES AND A PRO-INFLAMMATORY STATE

1Dep. of Medicine, Unit of Experimental Rheumatology, Karolinska Institutet, Karolinska University Hospital, Stockholm; 2Centre for Clinical Research Sörmland, Uppsala University; 3Dep. of Medicine, Unit of Rheumatology, Karolinska Institutet, Karolinska University Hospital, Stockholm; 4Department of Immunology, Genetics and Pathology, Uppsala University; 5Unit of Clinical Genetics and Pathology, Department of Clinical Immunology and Transfusion Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

Background: Sjögren’s syndrome occurs in isolation (primary Sjögren’s syndrome, pSS), but it is also often secondary (sSS) to, and sometimes difficult to delineate from, other rheumatic diseases, in particular from systemic lupus erythematosus (SLE). Consequently there is a need to investigate similarities and differences between SLE patients with (SLE-sSS) and without sSS (SLE-noSS).

Objectives: To investigate the occurrence of sSS in a large cohort of SLE patients and to explore clinical and laboratory characteristics associated with SLE-sSS as compared to SLE-noSS and controls.

Methods: We included 504 consecutive SLE patients and 322 population controls, individually matched for age and gender to the first patients. All patients fulfilled the 1982 revised ACR criteria for SLE. SLE-sSS was defined according to the American-European consensus criteria (AECC). Accordingly, subjective and objective quantifications of sicca symptoms were recorded on all subjects. All underwent a thorough clinical investigation. SLE-associated autoantibodies, (ANA screening by BioPlex 2200 system, Bio-Rad) and Rheumatoid factor (RF, Phadia Immunocap 250) were determined with standardized methods for all subjects, Routine laboratory workup and a panel of cytokines (MSD 30-plex cytokine assays, performed on samples from 433 consecutive SLE patients and 319 controls) were measured on fasting blood samples.

Results: SLE-sSS, as defined by AECC, occurred in 23% of the SLE patients. Compared to SLE-noSS the SLE-sSS group was older, both at inclusion (55 vs 43yrs, p<0.0001) and at disease onset (40 vs. 32 yrs p<0.0001), and with a greater number of females (96 vs. 83%, p=0.0007), higher occurrence of leucopenia (57 vs. 45%, p=0.02) and peripheral neuropathy (15 vs 7%, p=0.01). Nephritis was less common in SLE-sSS (32 vs 43%, p=0.03). Higher levels of total IgG, positivity for anti-SSA/Ro52, anti-SSA/Ro60, anti-SSB antibodies, RF, and ANA further confirmed the SLE-sSS group. 20/30 investigated cytokines were detectable, of these 19/20 were higher in SLE than in controls. 6/20 cytokines (TNF-a, IL-6, MCP-4, MIP-1j, IL12/IL-23p40 and IP-10) were upregulated in SLE-sSS vs. SLE-noSS (see table for figures).

Conclusions: Through strictly applying the AECC criteria we report that the frequency of SLE-sSS increases with age and affects roughly 1/4 of SLE patients. Nephritis was less common while leucopenia and peripheral neuropathy were more common among SLE-sSS patients. In addition to excess of well-known SS-associated autoantibodies we report higher levels of six pro-inflammatory cytokines in SLE-sSS as compared to SLE-noSS. These findings demonstrate that, though often regarded as a milder version of SLE, patients with SLE-sSS are characterized by a state of chronic systemic inflammation.

SAT0298 INFLUENCE OF AGE ONSET IN CLINICAL AND BIOLOGICAL SPECTRUM OF SYSTEMIC LUPUS ERYTHEMATOSUS

M. Kechida1, N. Lorenzo2, I. Ben Chaabene3, R. Kili3, S. Hammami1, I. Khochtali1.

1Internal Medicine and Endocrinology Department, Fattouma Bourguiba Hospital, Monastir, Tunisia; 2Internal Medicine and oncology Department, Saint-Cyr Hospital, France

Background: Systemic lupus erythematosus (SLE) is a multi systemic autoimmune disease which can affect patients at any age. Objectives: We aimed to study influence of age onset in clinical and biological spectrum of SLE. Methods: medical records of 89 patients diagnosed as SLE according to the ACR criteria of 1997, between January 2004 and December 2016, were retrospectively analyzed. Patients were divided into 3 groups according to the age of onset: Juvenile onset patients (group 1) (G1) (<16 years), Adult onset patients (group 2) (G2) (>16 and <50 years). Late onset patients (group 3) (G3) (>50 years). Clinical and biological comparative study was conducted between the 3 groups. Data were analyzed by chi-square test and potentially associated factors were tested by binary logistic regression.

Results: among the patients 11.2% are in G1, 75.3% in G2 and 13.5% in G3. Prevalence of SLE was higher in female than male (F/M=9/1) but predominance of women was lower in G1 than in G2 (F/M=10/1) compared to G2 (F/M=10/1) and G3 (F/M=11/1). Patients in G3 had more hypertenion (41.7%) compared to G2 (6%) (p=0.05) and G1 (0%) (p=0.04). Vespertilio erythema was less frequently found in G3 (33.3%) compared to G2 (64.2%) (p=0.045) and G1 (80%) (p=0.04). Anti Sm antibodies were more frequent in G1 (87.5%) compared to G2 (38.5%) (p=0.009) and G3 (18.2%) (p=0.003). Multivariate analysis showed that hypertension is significantly associated to late onset lupus (OR=29, 95% IC=[2.77 – 320], p=0.05) and anti Sm antibody is more frequent in juvenile onset patients (OR=12, 95% CI=[1.4 – 117], p=0.024).

Conclusions: according to our study, prevalence of lupus is higher in female regardless of age onset. Late onset lupus is associated to a high frequency of co morbidity while anti Sm antibody seems to be a hallmark of juvenile onset.

SAT0299 ATYPICAL ANTIbODIES IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

1Rheumatology, Hospital Infanta Sofía; 2Rheumatology, Hospital Puerta de Hierro Majadahonda; 3Research unit, Spanish Society of Rheumatology, Madrid; 4Rheumatology, Hospital Marqués de Valdecilla, Santander; 5Rheumatology, Hospital German Trias i Pujol, Barcelona; 6Rheumatology, Hospital Hospital Marina Baixa, Alicante, Spain

Background: One of the main features of primary Sjögren’s syndrome (pSS) is...
the polyclonal activation of B cells, leading to the synthesis of a large variety of autoantibodies.

**Objectives:** The aim of this study is to describe the prevalence of atypical autoantibodies in patients with pSS from the JpSgrenSER registry.

**Methods:** JpSgrenSER is a multicenter transversal study of pSS patients fulfilling the 2010 European/American consensus criteria. Patients were included by randomization from thirty-three Rheumatology Spanish departments. Data were collected by reviewing clinical records and interviewing the patients. Informed consent was obtained and local ethics committees approved the study. Variables were analysed by descriptive statistical methods, using means, medians, and rates. Chi-square was used to establish the statistical associations, being considered as p < 0.05 as significant.

**Results:** Four hundred and thirty-seven patients were included. Ninety-five percent of them were women. The median age of the cohort was 58 years. Thirty-six percent of patients AntiSSA+ and 21% of patients AntiScl-70+ were significantly related to the presence of antiRo, antiDNA antibodies (p = 0.001). Regarding AntiDNA+ patients, there were minimal non-significant differences in age at diagnosis and age at onset of symptoms compared to AntiDNA- patients (47 ± 0.5 years and 43.5 ± 4.6 years, respectively). The association with some systemic manifestation was only observed with joint involvement, which was significantly more frequent in AntiDNA+ patients (56.5% vs 34.2%, p < 0.003).

Regarding AntiSm+ patients, a significant negative association with AntiDNA antibodies was observed, being 70% of patients AntiDNA-; we also found a significant positive association with AntiRo and AntiLa, being 100% and 68% of patients AntiRo+ and AntiLa+ respectively. A significant negative association with lymphopenia was observed (no AntiSm+ patient had lymphopenia). AntiRNP+ patients showed a significant negative association with AntiDNA antibodies, being 80% of patients AntiDNA-, and a significant positive association with AntiRo (96% AntiRo+). A significant positive association was also observed with decreased C4 compared to AntiRNP- patients (28% vs 13.38%, p < 0.025).

Regarding patients with antiphospholipid antibodies, a significant negative association was observed with antiDNA antibodies, being 93% of patients AntiDNA-. A significant positive association with some systemic manifestation was only observed with the presence of anaemia (44% vs 17.7%). A significant positive association with decreased C3 and C4 was also observed, compared with the AntiRNP- patients (C3 20% vs 13.67% and C4 33% vs 12.67%).

**Conclusions:** More than 5% of pSS patients had antibodies characteristic of other autoimmune diseases. These atypical autoantibodies were significantly related to some pSS characteristic: antiSm, antiRNP and antiLa+, respectively. A significant negative association with lymphopenia was observed (no AntiSm+ patient had lymphopenia). AntiRNP+ patients showed a significant negative association with AntiDNA antibodies, being 80% of patients AntiDNA-, and a significant positive association with AntiRo (96% AntiRo+). A significant positive association was also observed with decreased C4 compared to AntiRNP- patients (28% vs 13.38%, p < 0.025).

Sacco Univ, Milan, Italy; 72German Hosp, Buenos Aires, Argentina

Objectives: Baseline characterization of European patients diagnosed with primary Sjögren syndrome (SS) according to the 2002 AE criteria. Methods: The Big Data SS Project was founded in 2014 to take a “high-definition” picture of the main features of primary SS by merging international SS databases. International experts of the EULAR-SS Task Force were invited to participate. By January 2017, the database included 9302 consecutive patients recruited from 21 counties of the 5 continents.

Results: A total of 6866 (71%) patients were included from European countries. In comparison with non-European countries, European patients had a higher mean age (54 ± 51 yrs, p < 0.001), higher frequency of men (7% vs 5%, p=0.001), dry eyes (94% vs 88%, p < 0.001), dry mouth (94% vs 91%, p < 0.001), and lower frequency of abnormal ocular (84 vs 86%, p=0.049) and oral (75 vs 81%, p < 0.001) tests. Immunologically, European patients had a lower frequency of anti-Ro/La antibodies (69 vs 78%, p < 0.001) and a higher frequency of RF (50 vs 47%, p=0.01), low C4 (14 vs 9%, p < 0.001) and cryoglobulins (8% vs 3%, p < 0.001). Logistic regression identified as independent variables older age (OR 1.02, male gender (OR 2.62), abnormal oral tests (OR 2.26), anti-Ro/La antibodies (OR 0.69), RF (OR 1.76), low C4 (OR 1.97) and cryoglobulins (OR 3.85).

Conclusions: European patients are diagnosed at older age, are more frequently men, and presented a lower frequency of anti-Ro/La antibodies and a higher frequency of immunological markers related to mixed cryoglobulinemia.

SAT0303 CLINICAL DIFFERENCES BETWEEN DEFINITE AND PROBABLE ANTIPHOSPHOLIPID (APS) PATIENTS: SHOULD THEY BE TREATED THE SAME?
F. Signorelli, G. Balbi, R.A. Levv, Rheumatology, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil

Background: The management of patients with recurrent thromboses/pregnancy morbidity and transient detection of antiphospholipids antibodies (aPL) can be a medical challenge. Although these patients are commonly seen in practice, there are no specific guidelines for the treatment in this situations.

Objectives: To investigate the clinical differences between definite and probable APS patients.

Methods: We performed a cross-sectional study in a group of 90 outpatients seen in our department. Seventy-seven of them met the Sydney classification criteria for definite APS, and thirteen had thrombosis or gestational morbidity, but no definite serological criteria for the diagnosis of APS. Clinical and serological features were collected during visits and by chart review, and the two groups were compared. Transient aPL was defined as only one detection of aPL (lupus anticoagulant, anticardiolipin IgM/IgG and/or anti-beta-2-glycoprotein 1 IgM/IgG) after 2 or more assays, at least 12 weeks apart.

Results: Demographic and clinical characteristics are shown in Table 1. In a bivariate analysis, there was no difference between groups regarding the criteria and non-criteria manifestations of APS, except for the presence of livedo (<p=0.033). In a multivariate regression analysis, the model was adjusted to age, sex, and variables with p  0.10 in the bivariate analysis (age, sex, race, livedo, Raynaud’s phenomenon). No difference between groups was found after the analysis.

Conclusions: This study suggests patients with transient detection of aPL have the same clinical characteristics of patients with definite APS, including thrombotic features, pregnancy morbidity, and non-criteria manifestations. In this context, our data suggests that both groups should be treated according to the current treatment guidelines for APS.

SAT0304 STIMULATORY AND INHIBITORY KILLER IMMUNOGLOBULIN-LIKE RECEPTORS ON NATURAL KILLER T (NKT) CELLS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): RELATION TO DISEASE ACTIVITY
S.I. Nasef1, A.M. Askar1, Y.H. Omar2, H.M. Hassoba3. 1Physical Medicine, Rheumatology and Rehabilitation; 2Clinical Pathology, Faculty of Medicine, Suez Canal University, Ismailia, Egypt

Background: Natural killer T (NKT) cells are a unique subgroup of T cells that represents a bridge between innate and adaptive immunity. The functions of NKT-cells are regulated by the balance between activating and inhibitory Killer cell immunoglobulin-like receptors (KIRs). Systemic lupus erythematosus (SLE) patients showed aberrant expression of KIRs on NKT-cells. Whether the expression pattern of KIRs on NKT-cells is associated with disease activity in SLE is still unknown.

Objectives: Assessment of expression of stimulatory and inhibitory KIRs on NKT-cells in SLE patients and its relation to disease activity.

Methods: We recruited 40 SLE patients and 20 age and gender matched healthy controls. According to SLE disease activity index (SLEDAI), patients were divided into two groups; active SLE (n=20) and inactive SLE (n=20). SLE was active when SLEDAI was ≥4. Immuno-phenotyping by flow cytometry was done using markers for NKT-cells (CD3 and CD56), stimulatory KIRs (KIR2DL4, CD158D) and inhibitory KIRs (KIR3DL1, CD158E1). Absolute counts and percentage of NKT-cells expressing CD158D and CD158E1 together with their mean fluorescence intensity (MFI) were measured. The histogram of CD158 expression was used to assess KIRs on NKT-cells.

Flow cytometry charts of lymphocytes and NKT-cells in SLE patients (active and inactive) and controls are shown in (Figure 1).

Laboratory work included ANA, anti-dsDNA, Anti-smith, C3, C4, CRP and ESR.

Results: Mean age of patients was 29.9±10.8 years. Females constituted 95% (n=38) of patients. Mean disease duration was 4.4±4.5 years. Mean SLEDAI was 11.7±7.43.

NKT-cells absolute number (cell/mm³) was significantly decreased in SLE patients (89±135) compared to controls (287±133), (P<0.001). Likewise, the absolute number of NKT-cells (cell/mm³) was significantly lower in active SLE patients (65.2±57.8) compared to inactive ones (114.5±181.1), (P<0.001).

NP=64; ††=12; †††=9, †††=9. Mo = months. CVD = cardiovascular disease. Values showed as N (%) for categorical variables, mean ± SD for normal distribution and Median (interquartile range) for asymmetric distribution.
The expression of inhibitory KIRs was significantly lower in SLE patients (2.8±2.8%) compared to controls (5.5±2.01%) (P<0.001). While, stimulatory KIRs were significantly higher in SLE patients (3.2±3.7%) than controls (1.0±0.5%) (P<0.001). Active SLE patients showed significantly increased expression of stimulatory KIRs (5.29±4.29%) than inactive patients (1.13±0.89%) (P<0.004). However, inhibitory KIRs were significantly decreased in active (1.28±1.32%) than inactive SLE patients (4.38±3.05%) (P<0.003). Expression of stimulatory KIRs correlated positively with ESR (r=0.3, P=0.04) and negatively with C4 (r=0.4, P=0.01). In contrast, inhibitory KIRs negatively correlated with ESR (r=-0.5, P=0.03) and positively with C4 (r=0.4, P=0.02). Using Receiver operating characteristic (ROC) curve analysis, expression of inhibitory KIRs on NKT-cells predicted disease activity at a cut-off value of ≤1.7% with 80% sensitivity and 80% specificity (P=0.001). While, expression of stimulatory KIRs on NKT-cells predicted active disease at a cut-off value of ≥1.4% with 80% sensitivity (P=0.001) and specificity (80%) (P=0.003).

Conclusions: SLE activity is associated with an increased expression of stimulatory KIRs as well as a decreased expression of inhibitory KIRs on NKT cells. This may play a role in the pathogenesis of flares and acceleration of disease activity in SLE and could be a therapeutic target for SLE patients.

SAT0306

ASSOCIATION BETWEEN QUALITY OF SLEEP, QUALITY OF LIFE AND DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Monov1, D. Monova2, M. Ivanova3, 1Department of Rheumatology, Medical University - Sofia; 2Department of Internal Diseases, Medical University - Sofia, Medical Institute; 3Department of Internal Diseases, Medical Institute, Sofia, Bulgaria

Background: Systemic Lupus Erythematosus (SLE) patients are known to have sleep disturbances. Quality of sleep may affect quality of life, but this association has not been systematically evaluated.

Objectives: The aim of this study was to examine the association of quality of sleep, quality of life and SLE disease activity in patients diagnosed with SLE.

Methods: 132 SLE patients with a confirmed diagnosis of SLE according to the ACR classification criteria (GCS) by hematoin eosin (HE) and/or IHC staining for follicular dendritic cells (FDC) detection is mandatory, representa-
ing a risk factor for lymphoma development. Focus score (FS) is one of the main instrument to quantify MSG impairment, nonetheless quality information regarding the type of infiltrate such as the entity, structure and localization, are lacking.

Objectives: Aim of this study is to find any association of specific histological features of MSG from patients with pSS with the principal clinical and laboratory features. Moreover, to investigate the utility of histological parameters, other than FDC or GCS, in characterizing patients.

Methods: Patients with pSS were enrolled in our SS clinic, and clinical/laboratory data (table) referring to the time of MSG biopsy, gathered on a dedicated database. MSG, removed for diagnostic purposes, were preserved as paraffin embedded tissue, then cut and sequentially stained by H&E and IHC [polyclonal rabbit anti-CD21 (FDC)]. Images were collected by Zeiss Axioscan and analysed (ZEN software) as follows: FS calculation, mean foci area, percentage of infiltration, presence of segregated foci (SF) (specifically, clear evidence of T and B cells area by CD3-CD20 double staining), GCS and lymphoepithelial lesions (LELs) detection.

Results: 53 MSG from patients with pSS were collected and analysed. Patients clinical and laboratory data are reported in table. FS positively correlated with the percentage of infiltration (p<0.001) as well as with the presence of SF (p<0.005), GCS (p<0.02) and LELs (p<0.005). Mean foci area and percentage of infiltration correlated with SF (p=0.0002 and p<0.001, respectively), GCS (p=0.0004 and p<0.001, respectively) and LELs (both p<0.001). SF correlated with GCS and LEL (p<0.001). Anti nuclear antibodies (ANA) were associated with the presence of SF (p=0.029, OR=5.7 CI=1.1–28.8) while gland swelling was associated with the presence of GCS (p=0.043, OR=1.1–15).

Conclusions: The FS was associated with the presence of GCS and LELs, as well as with more organized infiltrates characterized by segregation in T and B areas (SF), thus representing an useful tool which mirrors the risk of lymphoma. From our study, the qualitative characteristics of the biopsy, including SF, percentage of infiltration or the mean foci area, appear to be strictly linked.

Moreover, their association with the presence of GCS and LELs supports the importance to consider also these features during histological examination. The lack of correlation between histological features and specific SS phenotypes except for the relationship between glandular swelling and GCS which confirms how this clinical aspect should be considered as a risk factor for lymphoma development.

SAT0307

RECURRENT RATE OF THROMBOSIS FOR PATIENTS WITH ANTI-PHOSPHOLIPID ANTIBODIES INITIALLY AND DISAPPEARED LATER AFTER THROMBOLYSIS

S.M. Kim1, J. Kim2, Y. Kim3, S.W. Kang2, S.-C. Shin1, S.-J. Yoo1, J. J. Kim4, K. Kim5, K. Jung2, H.J. Kim2, S. Han2, S.H. Lee2, S.-J. Hwang2. 1Internal Medicine, Chungbuk National University Hospital, Cheongju; 2 Internal Medicine, School of Medicine Chungnam National University; 3 Internal Medicine, Chungnam National University Hospital, Daejeon, Korea, Republic Of

Background: In case of anti-phospholipid syndrome, anticoagulants are recommended. However, there were no data about recurrence rate for thrombosis in patients with anti phospholipid antibodies (APS) initially which disappeared later.

Objectives: We compared recurrence rate of thrombosis between negative conversion group and control group.

Methods: We reviewed the medical records of patients diagnosed with thrombosis such as cerebral infarct, myocardial infarct, deep vein thrombosis, or thrombosis of other vessels at a tertiary medical center from January 2013 to March 2016. Of these, 14 patients whose APA status was converted from positive to negative after more than 12 weeks were enrolled as negative conversion group. Forty-six patients without APA were matched with the ratio of 1:3 according to age, sex, sex, thrombosis type (arterial or venous) and therapeutic agents as control group.

Results: There was no difference between negative conversion group and control group in smoking status, presence of diabetes or hypertension, duration from the thrombosis to last visits or to recurrence, the proportion of patients taking glucocorticoids. There was no difference in the overall recurrence of thrombosis between two groups (negative conversion group, 3/14 (21%) vs. control group,
Background: Sjögren syndrome (SS) is a chronic autoimmune disease characterized by a sicca syndrome and a wide spectrum of extra-glandular manifestations.

Objectives: The aim of this study was to describe clinical, biological and immunological characteristics of patients with SS and to compare them in primary and associated SS.

Methods: We conducted a monocentric, retrospective study over a period of 15 years. Patients who fulfilled the American European Consensus Group criteria for SS were included. The sex-ratio female/male was 9/1. The mean age at disease onset was 45 years (range 15–74 years) and at diagnosis was 47 years (range 20–94 years). Sjögren syndrome was diagnosed in 270 patients. The sex-ratio female/male was 27/3. The mean age at disease onset was 47 years (range 15–76 years) with a mean delay of 3 years (range 0–25 years). The aim of this study was to describe clinical, biological and immunological characteristics of patients with SS and to compare them in primary and associated SS.

Results: SS was diagnosed in 270 patients. The sex-ratio female/male was 9/1. The mean age at disease onset was 45 years (range 15–74 years) and at diagnosis was 47 years (range 20–94 years). Sjögren syndrome was diagnosed in 270 patients. The sex-ratio female/male was 27/3. The mean age at disease onset was 47 years (range 15–76 years) with a mean delay of 3 years (range 0–25 years). Sjögren syndrome was diagnosed in 270 patients. The sex-ratio female/male was 27/3. The mean age at disease onset was 47 years (range 15–76 years) with a mean delay of 3 years (range 0–25 years).

Conclusions: The cumulative incidence of thrombotic events was not significantly different between SS and the control group.

SAT0309 | CAN WE FORESEE SLE IN ITP PATIENTS? TO DISTINGUISH ITP PATIENTS WITH HIGH RISK OF SLE BY A NATIONWIDE COHORT STUDY-BASED DECISION TREE

T.-H. Li¹, Y.-S. Chang², C.-Y. Tsai³. ¹Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Chiayi Branch, Taichung Veteran General Hospital, Chiayi City; ²Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei Hospital, Ministry of Health and Welfare, New Taipei City; ³Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei Veteran General Hospital, Taipei City, Taiwan, Province of China

Background: Immune thrombocytopenic purpura (ITP) is an autoimmune- mediated disease, which is occasionally the initial presentation of systemic lupus erythematosus (SLE), and thus periodical follow up has been suggested. Whereas long-term surveillance on all ITP patients would be time and cost-consuming, and thus to distinguish those with high probability of SLE development among ITP patients should be more practical.

Objectives: To distinguish ITP patients with high risk of SLE development by a decision tree model.

Methods: We enrolled ITP patients without previous SLE diagnosis from the National Health Insurance research database between 1997 and 2012 and identified those certificated with catastrophic illness of SLE during follow up, by which the diagnosis was reconfirmed by another rheumatologists. We also analyzed the symptoms and comorbidities as well as the dose of average oral steroid to derive the decision trees, which classified the ITP patients with different probability of development of SLE.

Results: A total of 10,265 ITP patients were enrolled, among whom 80 patients developed SLE while following up. The whole ITP patients were allocated to training group (7,186 patients including 57 with SLE) and testing group (3,079 patients including 23 with SLE); the former was used for derivation of the decision-tree based model and the latter for validation of the previously mentioned model, and provided high sensitivity (78.2%), specificity (99.2%) and negative prediction value (99.8%, Fig.). To reduce the complexity, we also pruned our decision tree to propose less-complicated models.

Conclusions: We derived classification decision tree suitable for various clinical scenarios of ITP patients, among whom those with high probability of development of SLE would be distinguished.

SAT0310 | ULTRASONOGRAPHIC SCORING OF THE MAJOR SALIVARY GLANDS IN SJÖGREN’S SYNDROME: A COMPARATIVE STUDY WITH DISEASE ACTIVITY INDEXES

N. İnan¹, Y. Volqunayka¹, G. Mumcu², Z. Ertürk¹, A.U. Unal¹, P. Atagündüz¹, H. Direkseven¹. ¹Department of Internal Medicine, Division of Rheumatology, Marmara University, School of Medicine, ²Marmara University, Faculty of Dentistry, Istanbul, Turkey

Background: Sjögren’s syndrome (SS) is characterised by chronic autoimmune inflammation primarily affects the salivary and lacrimal glands. Recently, ultrasonography (USG) of major salivary glands (SG-USG) has been used to evaluate salivary glands in primary and secondary SS.

Objectives: We aimed to investigate the association between the ultrasonographic scores of major salivary glands and disease activity indexes in patients with primary SS.

Methods: Forty-two primary SS patients fulfilling ACR-EULAR classification criteria (2002) were included. Disease activity indexes (Sjögren’s Syndrome Patients Reported Index (ESSPRI), Visual Analogue Scale (VAS), EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI)) were recorded. Major salivary glands (bilateral parotids and submandibular glands) were scored according to two different scoring system [Hocevar A. (0–48) ve Milic VD. (0–12)].

Results: Demographics, clinical characteristics, disease activity indexes and SG-USG scores were summarised in table 1 and table 2.
Table 1. Demographics and Clinical Characteristics of SjS patients (n=42)

| Age (year) | 54±11 |
| Duration of follow-up (month) | 55±51 |
| Skin symptoms | SjS complicated |
| Arthritis | R/C |
| Parotitis | 9 (21%)
| Raynaud’s Phenomenon | 5 (12%)
| Leucocyte cholestasis | 5 (12%)
| Peripheral neuropathy | 1 (2%)
| Intestinal anastomosis | 2 (5%)
| Lymphadenopathy | 1 (2%)
| SjS disease severity | ANA 34 (81%)
| Anti-Ro/La | 19 (45%)

Twenty-four (57%) and 25 (60%) patients had the cut-off-values of >17 (Hocevar) and ≥6 (Mic USG). The patients with the scores of >17 (Hocevar) were found to have higher scores of ESSPR total (18±5 vs 14±5; P=0.01) and higher lymph nodes and USG scores were shown to be higher in anti-Ro(+) SjS patients (25±10 vs 14±5; P<0.01) USG scores were not found to be associated with the scores of ESSDI, VAS, and ESSPR items.

**Conclusions:** The scoring system of major salivary glands was found to be related to patient reported activity in SjS. USG scores were associated with anti-Ro positivity. Evaluation of SG-USG might promote the diagnosis and follow-up of the SjS patients.

**SAT0311 PROLONGED EXPOSURE TO ANTIPHOSPHOLIPID ANTIBODIES IS ASSOCIATED WITH ENDOTHELIAL DYSFUNCTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

**Y. J. Park, I.-W. Baek, K.-J. Kim, W.-U. Kim, C.-S. Cho**

1 Division of Rheumatology, St. Vincent Hospital, The Catholic University of Korea, Suwon; 2 Division of Rheumatology, Yeouido St. Mary’s Hospital, The Catholic University of Korea; 3 Division of Rheumatology, Seoul St. Mary’s Hospital, The Catholic University of Korea, Seoul, Republic Of

**Background:** Antiphospholipid syndrome has been shown to be associated with increased cardiovascular mortality, but the role of antiphospholipid antibodies (aPL) on endothelial dysfunction remains elusive.

**Objectives:** We investigated the association between endothelial dysfunction and aPL in systemic lupus erythematosus (SLE) patients.

**Methods:** 188 SLE patients and 62 controls were enrolled. Endothelial function was measured by flow-mediated dilatation (FMD). Cardiovascular risk factors were assessed and quarter measurement of anti-cardiolipin (aCL) and anti-β2-glycoprotein I Ab were used to calculate time-integrated values throughout disease duration. Circulating endothelial progenitor cell (EPC), defined by CD34+KDR+ mononuclear cells, was quantified by flow cytometry.

**Results:** Median FMD was significantly lower in SLE patient than in controls (6.9 versus 9.3%, P<0.001). In univariate analysis, older age, hypertension, thrombocytopenia, and persistent positive lupus anticoagulant (LAC) were associated with decreased FMD in SLE patients (P<0.021, P<0.001, P<0.004, and P=0.028). Time-integrated aCL value (TI-aCL), but not a single value, was correlated with decreased FMD (P<0.001). Multivariate analysis showed that hypertension and Ti-aCL were independent factors for decreased FMD (P=0.027, P=0.008). Addition of positive LAC increased the adjusted probability of decreased FMD (P=0.023). FMD was correlated with EPC number (γ=0.342, P=0.005) and Ti-aCL was also an independent factor of reduced EPC after multiple adjustment (P=0.019). The predicted probability of endothelial dysfunction at median EPC level was higher in group with high Ti-aCL than in group with low Ti-aCL (P=0.004).

**Conclusions:** Cumulative burden of sPLA2 is closely associated with endothelial dysfunction in SLE patients, which was mediated in part by reduction of EPC.

**Disclosure of Interest:** None declared

**SAT0312 MICRONRNA-125B AS A POTENTIAL FIBROTIC AND APOTOTIC REGULATOR IN SYSTEMIC SCLEROSIS**

A. Kozlova, E. Pacher, F. Renoux, M. Rudnik, B. Maurer, A. Jüngel, J.H. Distler, G. Kania, O. Distler

1 Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; 2 Department of Internal Medicine 3, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen-Nuremberg, Germany

**Background:** MicroRNAs (miRs) are a class of small, noncoding RNAs that regulate many biological processes. Some microRNAs are involved in skin fibrosis.

**Objectives:** To analyze the differential expression, regulation and the pathophysiological role of miR-125b in systemic sclerosis (SSc).

**Methods:** For screening a low density array was run on pooled RNA from fibroblasts derived from 3 SSc patients vs. 3 healthy controls (HC). For further validation we performed qPCR on RNA derived from cultured fibroblasts, whole skin biopsies as well as on paraffin fixed dermis and epidermis. Next, fibroblasts were stimulated with pro-inflammatory and/or pro-fibrotic cytokines such as TGFBβ, IL-1β, -13, -17A, TNFa and PDDG. In order to identify downstream effects of miR-125b, knockdown with anti-miR-125b (or scrambled controls) in HC fibroblasts was performed. RNA was isolated from healthy fibroblasts (n=4) after knockdown and was proceeded to deep sequencing (Illumina HiSeq2000). Sequencing data were validated using qPCR on HC as well as SSc fibroblasts. Apoptosis was assessed by Caspase-Glo 3/7 assay and immunofluorescence of cleaved caspase 3 on cultured fibroblasts.

**Results:** Screening identified miR-125b as one of the candidate miRs differentially expressed in SSc. MiR-125b was confirmed by qPCR in primary dermal fibroblasts (SSc =11, HC =8), where it was downregulated by 47% (median expression 53%, Q1,3 33%, 70%; P<0.001). MiR-125b expression appeared to be independent from main cytokines operative in SSc. Additionally, the expression of miR-125b was assessed in skin biopsies of both SSc patients (n=4) and HC (n=5). In SSc, miR-125b was downregulated by 35% (median expression 65%, Q1,3 61%, 78%; P<0.05). To localize its expression in the skin, we separately analyzed miR-125b expression in dermis and epidermis of paraffin fixed skin. In both cases, expression of miR-125b was downregulated RNA sequencing identified >3500 differentially expressed genes with P<0.05. More than half of the differently expressed genes with at least 15% change were predicted targets of miR-125b by TargetScan and MirWalk, indicating successful functional inhibition of miR-125b. Gene ontology revealed extracellular matrix organization and apoptosis regulation as the two main clusters of differentially expressed genes. Among them, BAK1, BMF and BBC3 are participants of the BCL2 apoptosis pathway and predicted targets of miR-125b. Consistent with the sequencing results, qPCR showed that knockdown of miR-125b upregulates their target gene BCL2L1 (4x±1, 48 and 72 hours after transfection (P<0.05 for each). That was confirmed also on protein level by Western blot. Accordingly, miR-125b knockdown resulted in a higher rate of apoptosis (mean±SD: 60% ± 29%, P=0.01) compared to scrambled controls, measured by Caspase-Glo 3/7 assay. Moreover, miR-125b knockdown reduced TGFB-induced γSMA expression both on RNA and protein levels, suggesting that miR-125b might play an additional role in the cytoksete reorganization of fibroblasts during fibrosis.

**Conclusions:** MiR-125b is differentially expressed in SSc skin and primary dermal fibroblasts. MiR-125b downregulation increases apoptosis, inhibits cytoksete reorganization and therefore might become a potential anti-fibrotic therapeutic strategy.

Scleroderma, myositis and related syndromes - etiology, pathogenesis and animal models
ROLE OF CD248 MOLECULE AS POTENTIAL REGULATOR OF TRANS-DIFFERENTIATION TOWARD MYOFIBROBLASTS OF PERIVASCULAR STROMAL CELLS IN SYSTEMIC SCLEROSIS PATIENTS

Department of Applied Clinical Sciences and Biotechnology, Rheumatology Unit, School of Medicine; Department of Applied Clinical Sciences and Biotechnology, University of Laquila, L’Aquila, Italy

Background: The microvascular damage is a pivotal event in the pathogenesis of Systemic Sclerosis (SSc) and, after injury, both endothelial cells (ECs) and pericytes might trans-differentiate toward myofibroblast, responsible of fibrosis. Platelet-derived growth factor B (PDGF-B) and transforming growth factor-β (TGF-β) play a key role in myofibrogenesis. PDGF-B is a potent mitogen for myofibroblastic cells, while TGF-β stimulates myofibroblast activation, including alpha smooth muscle actin (αSMA) expression. A key regulator of PDGF-B and TGF-β signaling may be the CD248, a trans-membrane receptor required for proliferation and migration of pericytes and fibroblasts. It has been showed that, in an animal model of kidney fibrosis, the genetic deletion of CD248 modulates the response of renal pericytes to injury, by reducing the differentiation of myofibroblasts. The expression of CD248 is required for TGF-β-induced αSMA expression in pericytes and CD248 enhances the PDGF pathway, mediating the proliferation and migration of pericytes and fibroblasts.

Objectives: The aim of this work was to evaluate the expression of CD248, in SSc skin biopsies and its possible role in perivascular stromal cells proliferation, responsible to myofibroblast trans-differentiation, during SSc.

Methods: After ethical approval, skin biopsies and bone marrow mesenchymal stem cells (MSCs) were collected from 20 diffuse SSc patients and 10 healthy controls (HC). CD248 expression was investigated in the skin, and in isolated MSCs treated with TGF-β or PDGF-B, by immunofluorescence, qRT-PCR and western. Furthermore, we silenced CD248 in SSc-MSCs, to confirm the role of this molecule in TGF-β- or PDGF-signaling modulation.

Results: CD248 expression in SSc skin was significantly higher when compared with HC skin. In particular, an increased expression of CD248 was found in ECs, stromal fibroblast and perivascular like stromal cells, co-expressing CD90, a marker of un-differentiated MSCs. Furthermore, in both, HC- and SSc-MSCs, TGF-β treatment induced a significant reduction of CD248 mRNA expression in parallel with a significant increase of αSMA and a decrease of proliferation (ki67), when compared with untreated-(UT-) cells. Interestingly, the ability of TGF-β to inhibit CD248 expression in HC-MSCs was significantly higher than SSc-MSCs, suggesting that local environment in SSc patients affect TGF-β ability to suppress CD248 expression in SSc-MSCs. After treatment with PDGF-B in both SSc- and HC-MSCs, CD248 expression was not affected, while significant reduction of αSMA and an increased expression of ki67 was observed compared with UT-cells. After silencing of CD248 in SSc-MSCs, both TGF-β and PDGFB signaling were inhibited.

Conclusions: CD248 over-expression may play an important role in tissue fibrosis by modulating the pericytes to myofibroblast trans-differentiation, via regulation of both PDGFB and TGF-β signaling, during SSc.

IN VITRO AMELIORATE EXPERIMENTAL LUNG FIBROSIS INDUCED BY BLEOMYCIN

IRCCS polyclinico San Matteo Foundation, Pavia; University of Milan - Bicocca, Milan; University of Verona, Verona, Italy; Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany

Background: Systemic Sclerosis (SSc) is an autoimmune disorder frequently affected by interstitial lung disease (ILD) that significantly deteriorates long term outcomes. In previous experiments we proved that specifically engineered gold-nanoparticles (GNP) loaded with imatinib and targeted with an anti CD44 Ab (GNP-HCim) significantly inhibited proliferation and induced apoptosis of fibroblast-like cells derived from I LD-SSC patients [1]. In vitro, GNP-HCim showed higher efficacy compared to the drug alone.

Objectives: To demonstrate in vivo the efficacy of GNP-HCim in ameliorating bleomycin-induced lung fibrosis.

Methods: Eight-week-old C57BL6 male mice (n=8/group) were assigned to either: (1) controls receiving intratracheal aerosolization of saline solution and unloaded functionalised GNP (GNP-HC); (2) mice treated with intratracheal instillation of bleomycin (50 μL) on day 0 and GNP-HC; (3) mice treated with bleomycin on day 0 plus GNP-HCim; (4) mice treated with bleomycin plus intraperitoneal (i.p.) imatinib (50 mg/kg, once daily). GNP-HC or GNP-HCim were administered by intratracheal instillation on day 10–15–20–25 and 3 h before culling. All mice were sacrificed on day 28. Lung specimens were analysed by electron microscopy, immunohistochemistry and immunofluorescence (IF). Data were evaluated by 2 blind observers and analysed with GraphPrism software for statistics.

Results: The administration of imatinib i.p. or via GNP-HCim reduced pathologic changes of the lungs as evaluated by the Lung Injury score and the Ashcroft score (p<0.05 for both). Collagen quantification by Picro Sirius Red revealed a significantly reduced staining only in the GNP-HCim group (p=0.0135 vs controls). IF revealed a significant reduction in the number of CD45+ lymphocyte and myofibroblast counts when mice were implanted with GNP-HCim (14.5±2.9/50 μm² of lung), while mice injected with GNP-HC (7.6±1.7/50 μm²) were comparable to the controls (24.0±3.5/50 μm², p=0.003 and p=0.0013 respectively). IF also showed significantly reduced counts of CD45+ (15.21±1.67/50 μm² vs 29±2.247/50 μm² in controls, p=0.0006) and CD44+ cells in groups treated with GNP-HCim (18.6±1.49/sq mm) or imatinib (13.57±0.864) versus controls (28.56±2.854, p=0.0111 and p=0.0004 respectively). In imatinib i.p. and GNP-HCim-treated groups there was a significant reduction of phosphorylated c-Abl and PDGF-R, two downstream targets of imatinib, to levels comparable to group 1 controls with respect to the bleomycin group (p<0.05 for both). Finally, electron microscopy revealed accumulation of GNP-HCim and GNP in alveolar macrophages.

Conclusions: In the experimental model of bleomycin-induced lung fibrosis imatinib delivered to lungs through inhalation of anti CD44 targeted GNP was as effective as imatinib administered by i.p. route. These data favour the use of GNP-HCim as a new therapeutic approach to SSC-ILD, which might be associated to a lower toxicity and side effects of systemic treatment.

PSGL-1-deficient female mice. Aged PSGL-1-/- females showed reduced flow TPV/ET ratio in the pulmonary artery and RV remodeling, indicating PAH. Moreover, pulmonary artery rings from aged PSGL-1-/- females presented increased vasoconstriction response to KCl and reduced vasodilation response to acetylcholine. Importantly, NO production by lung EC was reduced in aged PSGL-1-/- females. Expression of AT2R was reduced in lungs of PSGL-1-/- females from a young age. With ageing, the levels of angiotensin II and the percentages of IFN-γ were increased in PSGL-1-/- females.

Conclusions: Together, these studies implicate leukocyte-endothelium interactions for the maintenance of vascular homeostasis and protection against PAH in PSGL-1-deficient female mice.

**SAT0320** SSc-IGG EFFECTS ARE MEDIATED THROUGH DISTINCT PATHWAYS IN THP-1 CELLS

G. Eleftheriadis 1, M. Wannick 1, C. Sadik 1, G. Riemenkasten 2, 1Institute of Experimental Dermatology; 2Department of Rheumatology, University of Lübeck, Lübeck, Germany

**Background:** Peripheral blood mononuclear cells (PBMCs) are thought to play a key role in the pathogenesis and progress of systemic scleroderma (SSc) with patients displaying distinct changes in cell counts, receptor expression profile and cytokine secretion patterns. SSc-IgG with elevated anti-AT,R (angiotensin II type 1 receptor)/ET,R (endothelin-1 type 1 A receptor) - AAb (autoantibody) titers have been correlated to disease severity and progression 1. It remains poorly understood through which pathways SSc-IgG mediates its effects.

**Objectives:** In this study we sought to analyze the expression patterns of THP-1 cells (a monocytic cell line) after SSc-IgG application and their reversibility through application of numerous pharmacological inhibitors.

**Methods:** Transcription of IL-8 and CCL-18 in THP-1 cells after SSc-IgG and normal IgG stimulation was quantified by qPCR. Simulations of THP-1 cells with total IgG of phenotypically different groups of SSc patients as well as ET-1 and AT-2 were carried out. In addition, stimulation with pharmacological inhibitors was conducted in a dose-dependent manner. The results were quantified by IL-8- and CCL18-ELISA of the supernatants.

**Results:** Expression of IL-8 and CCL-18 is induced by SSc-IgG treatment in comparison to normal IgG which does not follow this trend. IL-8 secretion of THP-1 cells upon SSc-IgG stimulation is mediated through specific autoantibody effects and transduced through NF-κB, ERK-, and AP-1 pathways. CCL-18 secretion of THP-1 cells upon SSc-IgG stimulation is not mediated through aforementioned pathways.

**Conclusions:** A stable cell culture system able to reproduce previous PBMC data on IL-8 and CCL-18 induction upon SSc-IgG-treatment could be established and insight was gained regarding key pathways which are involved in the transduction leading to IL-8 secretion. The effects of specific surface receptor expression profiles on transcription remain to be elucidated.

**SAT0319** MULTIPARAMETRIC DETECTION OF AUTOANTIBODIES TO INVESTIGATE RELATIONSHIPS BETWEEN SEROLOGICAL AND CLINICAL SUBSETS OF SYSTEMIC SCLEROSIS PATIENTS

P. Budde 1, H.-D. Zucht 1, D.S. Wirtz 2, K. Marquart 1, M. Schneider 2, P. Schulz-Knappe 1, N. Hunzelmann 1, 1Protagen Ag, Dortmund; 2Rheumatology & Health Research Center, Heinrich-Heine-University, Düsseldorf; 3Dermatology, University of Cologne, Cologne, Germany

**Background:** Systemic sclerosis (SSc) is a largely heterogeneous autoimmune disease, with patients exhibiting an extensive range of clinical presentations and various disease course. The most widely used classification divides SSc into two major subsets diffuse cutaneous (dcSSc) and limited (lcSSc) SSc by the extent and severity of skin fibrosis. However, not all patients fit into these subsets. This has created great interest to examine disease heterogeneity at the molecular level to uncover unrecognized SSc subtypes that may differ with regard to clinical and severity of skin fibrosis. However, not all patients fit into these subsets. This has created great interest to examine disease heterogeneity at the molecular level to uncover unrecognized SSc subtypes that may differ with regard to clinical manifestations, prognosis or therapy response.

**Objectives:** In large-scale "omics"-type autoantibody (AAB) profiling studies we have recently identified novel SSc-associated autoantigens. Here, we describe the development of a 50 marker multiplexed AAB assay to facilitate the discovery and validation of AAB-based patient subgroups.

**Methods:** A Luminex bead-based AAB assay was designed by combining 8 connective tissue disease (anti-centromere, anti-Scl70, U1-snRNP, SSA, SSc, Ro52, RNP, dsDNA) and anti-functional AAB (P) antigens with 12 novel antigens (including BC022, JMJD3/KDM6B, and PPP1R12). Novel AAB targets were previously detected in SSc patients with a p-value <0.05 (Mann-Whitney-U-test) and frequency>15%. AAB reactivity was analysed in 92 SSc patients (dcSSc: n=32; lcSSc: n=50, SSc overlap: n=9). The mean modified Rodnan skin score (MRRSS), mean disease duration (month), and mean age (years) of the SSc cohort was 10.51, 162.5 and 56.94, respectively. To analyze the individual-level patient similarity of AAB reactivity, the total number of AAB reactive in each patient was calculated and referenced to the number of all available antigens in percent. Patient’s demographic and clinical data were dichotomized into patients with higher or lower than the mean value. Hierarchical cluster analysis was performed to investigate the relationship between AAB patient signatures and clinical and demographic features.

**Results:** Based on their AAB reactivity pattern, the Scs sample cohort can be decomposed into four prominent clusters and additional fine-level clusters. lcSSc patients were spread over three clusters, each with clearly distinct AAB profile. Compared to dcSSc patients, lcSSc patients were more heterogeneous in their AAB profile. The percentage of lcSSc patients in clusters 1-3 was 70%, 90% and 50%, respectively. Patients in cluster 2 had an extended AAB repertoire that is anti-centromere, KDM6B, SSA, BC022 and PPP1R12. 63% of all patients in cluster 4 were dcSSc and anti-Scl70 positive, who were most afflicted of the disease. AAB signatures of patients were mapped against dichotomized demographic and clinical features. Moving from cluster 1 to 4 the number of patients with shorter disease duration, lower age, higher mRSS and higher frequency of lung involvement increased.

**Conclusions:** The multiplexed analysis of AABs in SSc enables defining an AAB reactivity score and patient clusters. This might support to subclassify SSc beyond lcSSc and dcSSc.

**SAT0321** MKP-1 AS A PROTECTIVE FACTOR AND NOVEL DRUG TARGET IN SCLERODERMA: MKP-1 DEFICIENT MICE DEVELOP MORE SEVERE DERMAL FIBROSIS IN A WIDELY USED EXPERIMENTAL MODEL OF SCLERODERMA

M. Scotece, M. Hämäläinen, T. Leppänen, E. Mollanen. The Immunopharmacology Research Group, Faculty of Medicine and Life Sciences, University of Tampere and Tampere University Hospital, Tampere, Finland

**Background:** Scleroderma is a chronic connective tissue disease of unknown etiology. In early stages, vascular injury and inflammation lead to fibrosis, resulting in irreversible damage in various organs. Inflammation is believed to be necessary in order to activate fibroblasts to over-produce extracellular matrix components. At the present, there is no effective standard treatment to reverse or slow down the progression of scleroderma but one of the feasible approaches is to target key inflammatory pathways that are involved in the pathogenesis of the disease.

MKP-1 (Mitogen-Activated Protein Kinase Phosphatase-1) is a nuclear phosphatase present in most cell types and tissues. Studies with MKP-1 deficient mice have undoubtedly shown that MKP-1 is an important regulator of innate and adaptive immune responses to limit and suppress inflammation (1) but its role in fibrosing diseases has not been studied.

**Objectives:** In the present study, we aimed to investigate the potential protective role of MKP-1 in the pathogenesis of scleroderma by using MKP-1 deficient mice and a widely studied experimental model of scleroderma.

**Methods:** We used bleomycin-induced dermal fibrosis in the mouse as an experimental model of scleroderma (2). Wild type (WT) and MKP-1 deficient mice were injected subcutaneously with bleomycin every other day for 28 days. Dermal mortality. Epigenetic changes might play important roles in mediating chronic fibroblast activation. Trimethylation of H3 at lysine residue K27 (H3K27me3) is a repressive epigenetic mark that was recently identified as an important negative regulator of fibroblast activation [1]. Jumonji domain containing protein 3 (JMJD3) mediates H3K27me3-demethylation. JMJD3 inhibitors are being tested as a therapeutic approach in the treatment of the fibrogenic disease.
thickness and collagen accumulation were determined by histological analyses. The expression of several inflammatory and pro-fibrotic mediators were measured by quantitative RT-PCR.

Results: We found that bleomycin-induced dermal thickness and lipodystrophy were increased in MKP-1 deficient mice. Collagen accumulation in the dermis and expression of MMPs and TIMPs in the epidermis were enhanced in the skin from MKP-1 deficient mice as compared to the skin from WT animals. Affected skin from MKP-1 deficient mice presented increased expression of factors related to inflammation and fibrosis, namely IL-6, TGF-β1, fibronectin-1 and YKL-40 as well as chemokines MCP-1, MIP-1α and MIP-2.

Conclusions: This study demonstrates, for the first time, that MKP-1 deficient mice develop more severe bleomycin-induced dermal fibrosis than their WT counterparts, indicating that MKP-1 regulates the inflammatory and fibrotic processes typical for experimentally-induced scleroderma. These findings suggest that compounds which enhance expression/activity of MKP-1 have potential as novel drugs for the stage-specific modulation of the pathogenesis of scleroderma.

SAT0323 ADAM-17 IS EXPRESSED IN THE INFLAMMATORY MYOPATHY, AND IS INVOLVED WITH INTERRUSSIONAL LUNG DISEASE (ILD)
A. Nishimi, T. Isozaki, S. Nishimi, S. Ichii, T. Tokunaga, H. Furuya, K. Wakabayashi, T. Kawai. Division of Rheumatology, Department of Pathology, School of Medicine, University of Tokyo, Japan.

Background: A disintegrin and metalloprotease (ADAM) family is protease that is thought to have an important role in tissue destruction and inflammatory reaction. ADAMs are also involved in the amputation from the cell surface of inflammatory cytokines. ADAM-17 is one of the ADAM family, and is first described as the protease responsible for tumor necrosis factor (TNF)-α shedding. The implication of ADAM-17 substrates in immunoregulation has made this enzyme an efficient therapeutic target in the treatment of a number of pathological conditions including airway inflammation and arthritis.

Objectives: The function of ADAM-17 in myositis is unclear. Therefore, we clarify the expression of ADAM-17 in inflammatory myopathy and the role of inflammation in interstitial lung diseases (ILD).

Methods: The serum were collected from the patients who were diagnosed with inflammatory myopathy in Showa University Hospital from 2003 to 2015. Twenty-six patients were diagnosed with dermatomyositis (DM), and 10 patients were diagnosed clinically amyopathic dermatomyositis (CADM). Clinical manifestations and clinical data were also collected. The levels of ADAM-17 in the serum samples were measured using enzyme-linked immunosorbent assay (ELISA). ADAM-17 expression was determined in MVEC cocultures from DM using immunohistological staining. To determine that the role of lung fibrosis in inflammatory myopathy with ILD, we used human lung fibroblasts (HLF). ADAM-17 expression on HLF was also demonstrated by immunohistological staining. ADAM-17 expression in interleukine (IL)-6 and IL-6 receptor (IL-6R) stimulated HLF was performed by ELISA.

Results: ADAM-17 in inflammatory myopathy was significantly higher than in healthy control (n=19) (1048±312 pg/ml and 36±18 pg/ml, respectively, p<0.05). ADAM-17 in corticosteroid and/or immunosuppressant treatment patient serum was also significantly decreased compared with in pre-treatment patient serum (1465±562 pg/ml and 1069±503 pg/ml, respectively, p<0.01). In addition, ADAM-17 in inflammatory myopathy with ILD patients (n=46) was significantly higher than in non-ILD patients (n=24) (1379±454 pg/ml and 413±526 pg/ml, respectively, p<0.05), while ADAM-15 did not have the differences between ILD and non-ILD group. Finally, we found the expression of ADAM-17 in muscle biopsy tissue. Hence, ADAM-17 on HLF was expressed by immunohistochemistry. ADAM-17 in IL-6 and IL-6R stimulated HLF was significantly higher compared with non-stimulated HLF (485±6 pg/ml and 0±0 pg/ml, respectively, p<0.05).

Conclusions: ADAM-17 is expressed in inflammatory myopathies especially with ILD and expressed on HLF, suggesting that ADAM-17 may play the role in lung fibrosis. ADAM-17 may be a potential target in inflammatory myopathies with ILD.

SAT0324 INCREASED FREQUENCIES OF CIRCULATING CXCL10-, CXCL8- AND CCL4-PRODUCING MONOCYTES AND SIGLEC-3-EXPRESSION MYELOID DENDRITIC CELLS IN SYSTEMIC SCLEROSIS PATIENTS
T. Carvalheiro,1,2,3, S. Horta,4,5, J.A. van Roon2,6, M. Santiago 6, M.J. Salvador,5, T.R. Radvatak,6, H. Trindade,1,4, J.A. da Silva 6,5, A. Paiva 7,1,7,1,7, Blood and Transplantation Center of Coimbra, Portuguese Institute of Blood and Transplantation, Coimbra, Portugal; 2Department of Rheumatology, Clinical Immunology; 3Laboratory of Translational Immunology, University Medical Center Utrecht, Utrecht, Netherlands; 4Department of Chemistry, University of Averio, Averio; 5Department of Rheumatology, Coimbra University Hospital Center; 6Faculty of Medicine, University of Coimbra; 7Flow Cytometry Unit, Clinical Pathology Service, Coimbra University Hospital Center, Coimbra, Portugal.

Background: Systemic sclerosis (SSc) is an inflammatory and fibrotic disease characterized by vascular dysfunction, excessive extracellular matrix deposition and immune dysregulation. Recent observations suggest that monocytes and dendritic cells (DCs) might be involved in SSc; including cell recruitment, trafficking, activation and an enhanced pro-fibrotic phenotype. Hence these cells might be important contributors to the disease pathogenesis. However, detailed analysis of circulating monocytes and DCs in SSc in relationship to disease activity has not been performed so far.

Objectives: To investigate the ex vivo pro-inflammatory properties of classical and non-classical monocytes as well as myeloid dendritic cells (mDCs) in SSc patients in relationship to disease activity.

Methods: This study enrolled 43 SSc patients, 30 classified as limited cutaneous SSc (lcSSc) and 13 as diffuse cutaneous (dcSSc). The healthy control group (HC) included 20 age- and gender- matched individuals. The Spontaneous production of CXCL10, CCL4, CXCL4 and IL-6 was intracellularly evaluated in classical and non-classical monocyte-665b. SIGLEC-3-expressing mDCs from peripheral blood using flow cytometry. In addition, the production of these cytokines was determined upon toll like receptor 4 (TLR4) plus Interferon-γ (IFN-γ) in vitro stimulation.

Results: The frequency of non-classical monocytes spontaneously producing CXCL10 was increased in both lcSSc and dcSSc subsets of SSc patients (p<0.05) and CCL4 was augmented in the dcSSc patient subset (p<0.05). The proportion of CCL4 producing- mDCs were also elevated in dcSSc patients (p<0.01) compared to HC, but p<0.01 compared to dcSSc. Upon in vitro stimulation the frequency of non-classical monocytes expressing CXCL8 was significantly lower compared to untreated conditions (p=0.016) in both lcSSc and dcSSc patients. In nonclassical mDCs, the proportion of CCL4 producing mDCs was significantly increased in dcSSc compared to lcSSc (p<0.01). The percentage of CCL4 producing mDCs was significantly greater in the dcSSc group compared to both lcSSc and HC (p<0.01). In both SSc subsets and HC, the percentage of mDCs producing CXCL10 was significantly greater in the dcSSc group compared to both lcSSc and HC (p<0.01) and the percentage of mDCs producing CXCL8 was significantly lower in the dcSSc group compared to both lcSSc and HC (p<0.01). In SSc subsets and HC, the percentage of mDCs producing CXCL8 was significantly lower compared to untreated conditions (p<0.01). The proportion of mDCs producing CXCL10 was also significantly greater in the dcSSc group compared to untreated conditions (p<0.01).

Conclusions: The frequency of non-classical monocytes spontaneously producing CXCL10 was increased in both lcSSc and dcSSc subsets of SSc patients (p<0.05) and CCL4 was augmented in the dcSSc patient subset (p<0.05). The proportion of CCL4 producing- mDCs were also elevated in dcSSc patients (p<0.01) compared to HC, but p<0.01 compared to dcSSc. Upon in vitro stimulation the frequency of non-classical monocytes expressing CXCL8 was significantly lower compared to untreated conditions (p=0.016) in both lcSSc and dcSSc patients. In nonclassical mDCs, the proportion of CCL4 producing mDCs was significantly increased in dcSSc compared to lcSSc (p<0.01). The percentage of CCL4 producing mDCs was significantly greater in the dcSSc group compared to both lcSSc and HC (p<0.01). In both SSc subsets and HC, the percentage of mDCs producing CXCL10 was significantly greater in the dcSSc group compared to both lcSSc and HC (p<0.01) and the percentage of mDCs producing CXCL8 was significantly lower in the dcSSc group compared to both lcSSc and HC (p<0.01). In SSc subsets and HC, the percentage of mDCs producing CXCL8 was significantly lower compared to untreated conditions (p<0.01). The proportion of mDCs producing CXCL10 was also significantly greater in the dcSSc group compared to untreated conditions (p<0.01).

DOI: 10.1136/annrheumdis-2017-eular.5173
increased in both patient groups (p<0.01) and mDCs expressing CXCL8 only in lcSSc (p<0.01). SSC patients characterized by the presence or history of lung fibrosis, displayed a higher frequency of non-classical monocytes expressing CCL4 and CXCL10 in dSSc patients as compared to those without this clinical manifestation (p<0.01 and p<0.05 respectively). Strikingly, the percentage of classical monocytes producing CXCL8 was augmented upon in vitro stimulation in lcSSc patients with lung fibrosis as compared to those without (p<0.01). No differences were found in the percentage of IL-6 producing cells.

Conclusions: These data point towards a role of activated non-classical monocytes and mDCs producing enhanced levels of proinflammatory cytokines in SSC patients with lung fibrosis.

Scleroderma, myositis and related syndromes

A. Corrado

THE ASSOCIATION OF SERUM TYPE 1 INTERFERON ACTIVITY AND AUTOANTIBODIES IN INFAMMATORY MYOSITIS

A. Maruyama, N. Ono, M. Sakai, Y. Sadanaga, S. Koarada, Y. Tada. Rheumatology, Saga university, Saga, Japan

Background: Recent reports had shown that most of clinically amyopathic dermatomyositis (CADM), which showed poor prognosis, was positive for anti-Melanoma differentiation-associated gene 5 (MDA5) antibody (Ab). It had been shown that patients not only with lupus but with dermatomyositis (DM) also showed increased type 1 interferon (IFN) signature. MIK acts as a cytosolic RNA sensor, which drives type 1 IFN production. These facts suggested that type 1 IFN might have some roles in anti-MDA5 Ab positive patients.

Objectives: We evaluated the association of serum type 1 IFN signature and autoantibodies in patients with inflammatory myositis, in particular anti-MDA5 Ab positive patients and anti-aminocytic/IFN syntheses (ARS) Ab positive patients.

Methods: Sera from 33 inflammatory myositis patients (13 DM, 10 PM and 10 CADM) were studied for type 1 IFN activity, using a functional reporter cell assay. Briefly WISH cells were incubated with serum containing media for 6 hours. Serum IFN signature scores of the incubated cells were evaluated by the summ of gene expressions of Mx1, IFIT3, IFI44L and IFI44 by real time PCR (Reference).

Anti-MDA5 Ab and Anti-ARS Ab were measured by ELISA. We divided these patients into three groups, anti-MDAS Ab positive group (MDA5 group), anti-ARS Ab positive group (ARS group) and double negative group (DN group). We included double positive patients into MDA5 group. The presence of interstitial lung disease (ILD) and the prognosis were also investigated.

Results: MDA5 group had 12 patients (8 CADM and 4 DM), ARS group had 8 patients (4 DM, 1 CADM and 3 PM), and DN group had 13 patients (5 DM, 1 CADM and 7 PM). 9 of MDA5 group, 5 of ARS group, and 1 of DN group were complicated with ILD. Serum IFN signature scores of MDA5 group were significant higher than those of ARS group and DN group (12.43 1.406, 2.407, p=0.0005).

Conclusions: We characterized two major groups in inflammatory myositis patients. ARS group was characterized by low IFN signature with the susceptibility to DM and ILD. MDA5 group was characterized by high serum IFN signature with the high susceptibility to CADM. Our results suggest that these two entities may have different onset mechanisms, leading to different outcomes.

SAT0326 | NUTRITIONAL STATUS IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Wołczek 1, M. Ziętlikiewicz 1, S. Małgorzaczek 2, Z. Zdrojewski 1, 1 Department of Clinical Nutrition, Medical University of Gdańsk, Gdańsk, Poland

Background: Systemic sclerosis (SSc) is a chronic connective tissue disease characterized by involvement of multiple organs. Many clinical aspects, such as gastrointestinal involvement, mood disturbances, functional status, and inflammation, may lead to disease-related malnutrition [1]. The connection between inadequate nutritional status and systemic sclerosis is still not well established. It is important to identify the symptoms of malnutrition, because it is known as a predictor of poor clinical outcome [2].

Objectives: To assess nutritional status in patients with systemic sclerosis.

Methods: The study involved fifty-two patients with SSc (44 women and 8 men, mean age 54.3±11.7 year) who were diagnosed according to ACR/EULAR criteria. Inadequate nutritional status and systemic sclerosis is still not well established. It was assessed by simplified nutritional appetite questionnaire (SNAQ). In all patients hand grip strength and triceps skinfold were established. The C-reactive protein (CRP), lipid profile, and level of haemoglobin/lymphocytes were measured in serum.

Results: Inadequate nutritional status was diagnosed in 14 patients (26.9%) with SSc. According to SGA 11 (21.15%) patients had signs of mild malnutrition, while 41 (78,85%) were well-nourished. Considering BMI, 1 patient (1,92%) was underweight, 24 (46,15%) were eutrophic, 21 (40,38%) overweight and 6 (11,54%) obese. Significantly lower BMI had patients with inadequate nutritional status (23,17±4,77 vs. 25,98±3,34; p=0,009).

Conclusions: Malnutrition in systemic sclerosis is still underestimated clinical issue. This study provides useful data about nutritional status of patients with systemic sclerosis.
systemic sclerosis. Altered level of albumin and decreased appetite may lead to worsening in nutritional status. Assessment of nutritional status in this group of patients should be performed regularly, because it can be potentially modified.

SAT0328 AN OPEN-LABEL STUDY OF AMBRISENTAN WITH ANTI-FIBROTIc AGENT COMBINATION THERAPY IN THE TREATMENT OF DIFFUSE SYSTEMIC SCLEROSIS
Division of Rheumatology, Hospital of the University of Pennsylvania;1Division of Rheumatology, Thomas Jefferson University Hospital, Philadelphia, United States

Background: Systemic sclerosis (SSc) is marked by immune dysregulation, inappropriate fibrosis and a vasculopathy for which there is currently no universally accepted disease modifying regimen. Ambisentan, a selective type A endothelin receptor antagonist (ERA) has known benefits in the treatment of the vasculopathy and pulmonary arterial hypertension and has been postulated to have anti-fibrotic effects. The additive effect of an ERA in combination with an anti-fibrotic agent has not previously been studied in SSc.

Objectives: To determine the safety and efficacy of ambisentan in combination with an anti-fibrotic agent in diffuse systemic sclerosis (dSSc) patients.

Methods: Patients already on anti-fibrotic therapy for early dSSc with onset of skin sclerosis less than 48 months before study entry were placed on ambisentan 5mg daily for 12 months in an open-label study. Laboratory and clinical parameters to assess safety, as well as severity and progression of SSc were obtained at study entry and at 3, 6, 9, and 12 months. The primary end point of this study was the median skin score. No statistically significant change was observed in PFTs and HRCT findings. The total amount of ambisentan was maintained throughout the study.

Results: Of 15 patients who were recruited, 10 patients were on anti-fibrotic therapy at study entry. Among this group, 4 patients (30.8%) developed renal crisis (CI 95% 16.1–45.8) (December 2015). The Incidence rate was 72 patients (88% women, mean±SD age at diagnosis 48.5±16.7 years [range 15–87]) were identified, corresponding to a crude point prevalence of 13.8/10 5 (CI 95% 11–17/10 5) (December 2015). The Incidence rate was also observed to be 268 cases per 100,000/y (95% CI 250–287) (December 2015). Mortality in SSc patients remains 3.5 times higher than the general population3. We sought to generate updated data on the epidemiology and burden of SSc in the Greek population.

Objectives: To study the prevalence and incidence of SSc, describe the clinical characteristics and assess mortality and main causes of death in Crete (Greece) over a 5-year period (2010–2015).

Methods: We conducted a cohort Study in defined geographic area (6.5% of Greek population). We reviewed demographics, clinical features, autoantibodies status and the causes of death from the Scleroderma cohort followed at the Rheumatology clinic of the University Hospital, Heraklion. The cause of death was categorized as related or not to scleroderma. Incidence and prevalence were estimated including patients living permanently in Crete who fulfilled SSc 2013 criteria and HRCT findings improved in PM/DM patients with ILD without any adverse events or drug toxicity was observed.

Conclusions: After IVCYC according to the Euro-Lupus nephritis protocol PFT and HRCT findings improved in PM/DM patients with ILD without any adverse events or drug toxicity was observed. Longitudinal controlled studies are needed to confirm the safety and the efficacy of this treatment protocol.

SAT0330 LOWER PREVALENCE BUT COMPARABLE CLINICAL CHARACTERISTICS AND PROGNOSIS OF SYSTEMIC SCLEROSIS IN CRETE-GREECE AS COMPARED TO OTHER EUROPEAN COUNTRIES: A SINGLE CENTER EXPERIENCE

Background: Systemic Sclerosis (SSc) is a rare, multisystemic connective tissue disease with significant morbidity. Prevalence and incidence of SSc varies worldwide (0.7–265 cases per 100,000/y1,2 and 0.06–12.2 cases per 100,000/y3,4 respectively). Mortality in SSc patients remains 3.5 times higher than the general population. We sought to generate updated data on the epidemiology and burden of SSc in the Greek population.

Objectives: To study the prevalence and incidence of SSc, describe the clinical characteristics and assess mortality and main causes of death in Crete (Greece) over a 5-year period (2010–2015).

Methods: We conducted a cohort Study in defined geographic area (6.5% of Greek population). We reviewed demographics, clinical features, autoantibodies status and the causes of death from the Scleroderma cohort followed at the Rheumatology clinic of the University Hospital, Heraklion. The cause of death was categorized as related or not to scleroderma. Incidence and prevalence were estimated including patients living permanently in Crete who fulfilled SSc 2013 ACR/EULAR Classification Criteria for Scleroderma.

Results: 72 patients (88% women, mean±SD age at diagnosis 48.5±16.7 years [range 15–87]) were identified, corresponding to a crude point prevalence of 13.8/10 5 (CI 95% 11–17/10 5) (December 2015). The Incidence rate was estimated at 0.05/10 5 per year (period 2010–2015). Diffuse SSc (dSSc) was present in 77% (CI 95% 72.2–81.8). Mortality in dSSc occurred in 19.4% (9.7% with systemic lupus erythematosus). Frequencies of anti-Scl70 and anti-centromere antibodies were 59.7% and 9.7%, respectively. Arthritis was present in 69.5%, lung involvement in 61% (9.7% pulmonary arterial hypertension [PAH]), whereas only a single patient developed renal crisis. 8.3% developed cancer. Case fatality rate during 2010–2015 was 9.7% (CI 95% 7.4–11.9) with an average (±SD) age of death at 65.2 (± 17.6) years. Mortality cases were related to SSc in 30.7%. The main cause of death was sepsis (30.8%) followed by PAH and cardiac arrest (15.4%) each. Male gender (p=0.001) and presence of PAH (p=0.001) were related to mortality. Mean disease duration until death was 5.3 years.
AMINAPHTONE INCREASES SKIN BLOOD PERFUSION AND IMPROVES CLINICAL SYMPTOMS IN PATIENTS’ WITH BOTH PRIMARY AND SECONDARY RAYNAUD’S PHENOMENON: AN OPEN SIX MONTH PILOT STUDY

Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS AOI San Martino, Genoa, Italy

Background: Aminaphtone (1,4-Dihydroxy-3-methyl-2-naphthyl-4-aminobenzoate) is a vasoactive drug that was recently demonstrated to improve the symptoms of Raynaud’s phenomenon (RP) and to down-regulate endothelin-1 production by endothelial cells (1–3).

Objectives: To evaluate skin blood perfusion and clinical symptom changes during aminaphtone treatment in patients with both primary and secondary RP, during a six-month follow-up.

Methods: Forty-six patients with active RP were enrolled during routine clinical assessment in November 2015 (11 primary RP, mean age 49±19SD years, mean RP duration 6±3 years; 35 secondary RP to systemic sclerosis, mean age 61±17 years, mean RP duration 11±9 years), after informed consent. Aminaphtone was administered 75 mg twice daily (off label) in addition to current treatments (the patients were on a stable drug regimen for at least two months before, which remained unmodified during the follow-up). Blood perfusion was measured by Laser Speckle Contrast Analysis (LASCA) and values recorded as perfusion units (PU) (4), at the level of fingertips, periungual areas, dorsum and palm of hands, and face, at baseline (T0), after one (T1), four (T4), twelve (T12) and twenty-four weeks (T24) of treatment. Raynaud’s condition score (RCS) and both frequency and duration of Raynaud’s attacks were assessed at the same time. Forty-six patients with RP (9 primary RP and 37 secondary RP to systemic sclerosis) not treated with aminaphtone were also enrolled as a control group and evaluated at T0 and T24.

Results: A progressive statistically significant increase of blood perfusion was observed from T0 to T12 in all skin areas analyzed (median PU at T0, T1, T4, T12, T24 respectively: fingertips 55, 88, 101, 107, 98 periungual areas 44, 88, 91, 92; dorsum of hands 38, 61, 71, 75; palm of hands 56, 85, 94, 82, whole face 127, 138, 144, 159; p<0.001 for all areas). From T12 to T24 was not observed any further increase of blood perfusion. A progressive statistically significant decrease of RCS (median at T0, T1, T4, T12, T24: 7, 6, 4, 4, 4, p<0.0001) and Raynaud duration (median: 20, 20, 10, 4, 4 minutes; p<0.0001) was also recorded from T0 to T12. The results were similar in both primary and secondary RP patients (p=0.40). Aminaphtone administration had to be stopped in 2 patients due to headache, and one patient was lost during follow-up. Any statistically significant variation of blood perfusion was not observed in the control group (median PU at T0 and T24 respectively: fingertips 70, 71; periungual areas 68, 70; dorsum of hands 57, 57; palm of hands 59, 59; whole face 132, 130; p=n.s. for all areas).

Conclusions: This study demonstrates that aminaphtone treatment seems able to increase skin blood perfusion and to improve RP symptoms, even in patients affected by systemic sclerosis. These preliminary results should be further confirmed by a randomized clinical trial, also to assess the role that aminaphtone plays in the treatment/prevention of disease clinical complications.

ARA+SSc had a significantly higher ratio compared to ARA- and ACA+ pts (mean 61.24±41.40 [45.78 – 76.70] vs. 39.62±17.99 [29.66 – 49.58] and 37.77±10.20 [32.12 – 43.42] μmol/mmol respectively, p<0.05). Kyn/Tp ratio was significantly correlated with SRC (p<0.05). We found a direct correlation with mRSS (r=0.269, p<0.05), peak mRSS (r=0.276), urate level (r=0.376), CRP (r=0.285) and ESR (r=0.301) respectively. Conversely, Neo levels, although considered significantly higher in SSc compared to HC (mean 12.63±9.30 [10.21 – 15.06] vs. 7.11±3.31 [4.74 – 9.48] mmol/L, respectively, p<0.05), were not significantly different in diffuse compared to limited SSc, but were higher in ARA+ compared to ARA- and ATA+ patients (mean 19.33±7.52 [16.43 – 22.23] vs 10.54 – 19.31 vs 10.81±4.95 [8.07 – 13.56] vs 10.02±6.63 [6.24 – 13.80] respectively, p<0.05). Neo levels significantly correlated with PAH. A direct correlation (p=0.05) was found with CRP (r=0.471) and ESR (r=0.430).

Conclusions: These data suggest that Kyn/Tp ratio and Neo levels may reflect auto-pathogenic mechanisms in SSc and be elevated in the subgroup of dCSSc that are ARA+, or those manifesting SSc manifestations highly associated with ARA+. A specific IFN-gamma signature could be thought to be responsible for the higher levels found in patients although larger studies are required.

SAT0336 MALNUTRITION AND SARCOPENIA IN A LARGE COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS

C. Caimmi¹, P. Caramaschi¹, A. Venturini¹, E. Bertoldo¹, M. Ferrari², M. Rossini¹, ¹Rheumatology Unit; ²Internal Medicine, University of Verona, Verona, Italy

Background: Systemic sclerosis (SSc) is an autoimmune disease that may affect gastrointestinal tract, leading to malabsorption and malnutrition. Previous studies defined this complication with no widely accepted criteria. No thorough evaluations of sarcopenia are available.

Methods: 141 SSc consecutive outpatients have been enrolled. A thorough history, blood samples and body composition by densitometry were collected. Malnutrition was defined accordingly to recently published and widely accepted ESPEN criteria (1); sarcopenia was diagnosed in patients with a reduced skeletal muscle mass index (2).

Results: The table summarizes cohort's characteristics. Malnutrition was diagnosed in 9.2% (CI95%: 4.4–14.0%). Malnourished patients were more often treated with steroids (p=0.039), had worse gastrointestinal symptoms accordingly to UCLA questionnaire (p=0.007), lower physical activity accordingly to International physical activity questionnaire (p=0.029), longer disease duration (p=0.019), worse predicted DLSO/VA and FVC (p=0.006 and 0.009 respectively, p=0.013), confirmed to be worse in malnourished patients, and were associated with more frequent visceral manifestation (73% vs. 63%). Sarcopenia was diagnosed in 20.7% (CI95% 14.0–27.4%); 11/29 sarcopenic patients were also malnourished and 6/29 were cachectic (i.e. sarcopenia + systemic inflammation).

¹Expressed as media (IQ); ²Expressed as absolute value (%).

Conclusions: Malnutrition defined with widely accepted diagnostic criteria was found to be lower than previously reported (3–7) using screening tool or non-validated criteria. Sarcopenia was found to be somewhat common, although no previous study on comparable cohorts are available. Lung involvement and dysfunction was shown to be significantly linked with nutritional status and may not be explained only by muscle weakness given the absence of correlation between muscle weakness and FVC but only with DLSO/VA.

SAT0337 IMPACT OF ORGAN INVOLVEMENT ON PATIENT-REPORTED OUTCOMES IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

D. Huscher¹, K. Albrecht¹, J. Richter², J. Hennes³, T. Alexander⁴, A. Zink⁴, ¹Epidemiology, German Rheumatism Research Centre, Berlin; ²Policlinic & Hiller Research Unit for Rheumatology, Medical Faculty, Heinrich-Heine-University Duesseldorf, University Clinic, Duesseldorf; ³Department of Rheumatology and Clinical Immunology, Eberhard Karls-University of Tuebingen, Tuebingen; ⁴Department of Rheumatology and Clinical Immunology, Charité University Hospital, Berlin, Germany

Background: Idiopathic inflammatory myopathies (IIM) are associated with considerable morbidity, primarily related to severe muscle weakness and visceral involvement, resulting in decreased mobility and impaired quality of life. Results from the OMERACT Myositis Special Interest Group indicate that there is insufficient knowledge on patient-reported outcomes (PROs) in IIM².

Objectives: To analyse the association between organ involvement and PROs in IIM patients, taking the presence of autoantibodies into account.

Methods: Data of IIM patients, recorded in the National Database of the German collaborative arthritis centres between 2007 and 2014, were analysed. Physician-reported data on myositis disease phenotypes, organ involvement and antibody status were linked with PROs on functional status (FFBH, range 0–100, 100 indicating full capability), and numerical rating scales (0–10) for pain, fatigue, general health, physical and emotional well-being and coping. Multivariable linear regression analysis was used to investigate the impact of phenotype, organ involvement and autoantibodies on PROs, adjusted for sex, age and disease duration.

Results: A total of 142 IIM patients - 60 polymyositis (PM), 46 dermatomyositis (DM), 15 antisyntethase syndrome (ASS), 12 overlap (OL), 9 others - with mean disease duration of 7.4 years were included. 85% showed muscular, 36% skin involvement, 22% arthritis, 28% interstitial lung disease, 17% dysphagia and 9% cardiomyopathy. Visceral (lung, cardiac or gastrointestinal) manifestation was present in 46% (PM), 54% (DM), 100% (ASS), and 80% (overlap). While moderate to severe (4–10) fatigue was predominately reported in overlap (64%) and ASS (70%), pain was more frequent in overlap (55%) and emotional discomfort was reported most frequently in ASS (57%). For all PROs, worse outcomes were documented in patients with visceral manifestation. Myositis-specific autoantibodies, predominantly Anti-Jo1, were present in 63% of the patients, and were associated with more frequent visceral manifestation (73% vs. 46%), especially interstitial lung disease (50% vs. 15%), and arthritis (32% vs. 13%), but less skin involvement (49% vs. 67%), DM and PM subtypes showed almost identical coefficients for fatigue, physical well-being, general health and coping, while PM was associated with higher emotional strain. Pulmonary hypertension had a severe impact on pain, functional status and daily activities. Cardiomyopathy was associated with impaired general health, arthritis with poorer scores for coping, physical and emotional well-being.

Conclusions: IIM patients with distinct subtypes differ considerably regarding the frequency of organ involvement and self-reported dimensions of disease burden. Anti-Jo1 positivity is associated with higher visceral organ involvement and arthritic manifestations and may therefore also indicate a higher patient-reported disease burden.

SAT0338 SURVIVAL IN A TURKISH INFLAMMATORY MYOSITIS COHORT: A SINGLE-CENTRE STUDY

E. Er Gülbezer, F. Yargıcı Zihni, G. Karabulut, G. Keser, Y. Kabasakal. Rheumatology, Ege University Medical Faculty Internal Medicine, Izmir, Turkey

Background: Inflammatory myositis is an uncommon group of diseases that
can be associated with significant morbidity and mortality related to systemic involvement or treatment-related complications.  

**Objectives:** This study aimed to describe the clinical features and survival of patients with inflammatory myositis in our centre.  

**Methods:** We performed a single-centre, retrospective study on patients with inflammatory myositis (polymyositis [PM], dermatomyositis [DM], or Anti-Jo1 syndrome) seen from 2000 to 2014, noting their demographic data, clinical features and outcome until December 2016. The primary outcome assessed was all-cause mortality. Cumulative mortality rates were estimated using the Kaplan-Meier test; the Log Rank (Mantle-Cox) test was used to compare subgroup differences in survival.  

**Results:** Seventy-four patients (19 PM, 28 DM, 27 Anti-Jo1 syndrome) were available for the study. Median age at diagnosis was 47 years (min 17, max 75) and median follow-up time was 93 months (min 4, max 311). Sixty-one patients (82.4%) were female and 13 (17.6%) were male. Malignancy was found in 4 patients (2 invasive ductal adenocarcinoma of breast, 1 over cancer and 1 non-small cell lung cancer) and they were all female DM patients. Nineteen patients (25.7%) died at the end of the follow-up. The 19 patients with PM consisted of 15 female and 6 male, with a median age at diagnosis of 45 years (min 22, max 74) and median follow-up time of 88 months (min 5, max 204). The 28 patients with DM consisted of 24 female and 4 male, with a median age at diagnosis of 52 years (min 17, max 75) and median follow-up time of 80 months (min 4, max 288). The 27 patients with Anti-Jo1 syndrome consisted of 22 female and 5 male, with a median age at diagnosis of 50 years (min 22, max 63) and median follow-up time of 117 months (min 5, max 311).  

Overall survival rates of the whole group were 91%, 83%, and 76% for 1, 5, and 10 years, respectively. The survival rates at 1, 5 and 10 years from the diagnosis were respectively 88%, 82%, and 82% for PM, 89%, 80%, and 80% for DM, and 96%, 88%, 74.5% for Anti-Jo1 syndrome. But there was no significant difference between the survival rates of the diagnose groups (p=0.734). Also there wasn’t a significant difference between the survival rates of sex and age groups (p=0.503, p=0.112). But the survival rates were significantly lower in patients with the time from diagnose less than 8 years (p=0.000).

**Conclusions:** Our study involved 74 patients followed up for a median of 7.7 years and is one of the largest cohorts of patients with inflammatory myositis in Turkey. Survival was quite similar with the literature. Usually mortality has been expected in the first years after the diagnosis.

**SAT0339**  
**LUNG TRANSPLANTATION IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH ANTISynthetase AND ANTI-MDA5 SYNDROMES. EXPERIENCE FROM A REFERENCE SPANISH HOSPITAL**  
E. Trallero-Araguás 1, C. Berastegui 2, M. López-Corbeto 1, I. Bello 3, A. Román 2, A. Selva-O’Callaghan 1, 1Rheumatology Unit; 2Pneumology Department; 3Thoracic Surgery Department; 4Internal Medicine Department, Hospital Vall d’Hebron, Barcelona, Spain

**Background:** Interstitial lung disease (ILD) is the most characteristic feature and prognosis determinant of patients with antisynthetase (AS) and anti-MDA5 syndromes. Despite immunosuppressive treatment, ILD sometimes progresses to an end-stage lung disease, for which lung transplantation (LT) is the only therapeutic option. There is scarce data about post-LT outcome in this group of patients.  

**Objectives:** To describe clinical characteristics and post-LT outcome of patients with ILD associated to AS and anti-MDA5 syndromes included in the LT program of the Vall d’Hebron Hospital of Barcelona.  

**Methods:** We performed a review of patient records listed in the LT program.  

**Results:** From 1990 to 2016 ten patients (6 women) with ILD related to AS or anti-MDA5 syndromes were included in the LT program (3% of patients with ILD accepted for LT). Nine patients (2 anti-MDA5, 4 anti-Jo1, 2 anti-PL12 and 1 anti-PL7) received LT while 1 patient (anti-Jo1) was still in list at the end of this study. Median age (range) of disease diagnosis was 39 years (25–55). Six patients had clinical myopathy [2 dermatomyositis (DM) and 4 polymyositis] whereas 1 patient was diagnosed with amyopathic DM.  

Four patients had associated pulmonary hypertension. Time between disease diagnosis and patient inclusion in LT list was higher in anti-Jo1 patients [median (range) 8.8 years (8.3–17.6)] than in the rest of the cohort [anti-MDA5 –1 year; anti-PL12 0.7 and 3.9 years; anti-PL1 7.1 years] (p<0.05). Four patients underwent bilateral LT and one patient received a single LT. Three patients received an urgent LT (2 anti-MDA5 and 1 anti-Jo1). Six patients presented an anatomico mediated rejection 8 and 10 months from LT respectively; 4 patients suffered chronic lung allograft dysfunction (CLAD), 2 of whom are still alive; Infection was diagnosed in 6 patients. One patient developed Aqueous skin disease and his myositis disease was observed after LT in any case. Four patients (44%) died; 2 of an acute respiratory failure in the immediate postoperative period (1 caused by suture dehiscence and 1 by refractory ACR); 1 of an invasive aspergillosis, 17 months after LT; and 1 of CLAD after 54 months. Median follow-up (range) of the rest of the cohort was 35 months (8–70). All patients who survived more than 45 days recovered an optimal functional capacity for daily activities with no request for long-term oxygen therapy.  

**Conclusions:** LT should be considered a valid option to treat patients with end-stage or severe and rapidly progressive ILD associated to AS and anti-MDA5 syndromes. An early remission to LT referral centers for evaluation should be considered especially in non-Jo1 patients. No relapse of myositis or ILD was observed after LT. Mortality could not be attributed to the primary disease.

**SUBCLINICAL CARDIOVASCULAR DISEASE IN SCLERODERMA: A STUDY WITH CARDIOVASCULAR RISK CHARTS, CT CORONARY CALCIUM SCORE AND CAROTID ULTRASONOGRAPHY**  
I. Sanz Pérez 1, F. Martínez Valle 1, A. Guillén del Castillo 1, N. Pizzi 2, A. Roque Pérez 2, H. Cuéllar Calabria 3, A. Fernández Codina 1, E. Callejas Moragas 1, V. Fonollola Pla 1, C.P. Simeón Aznar 1, 1Internal Medicine; 2Nuclear cardiology; 3Radiology, Hospital Universitari Vall d’Hebron, Barcelona, Spain

**Background:** Recently published population-based cohort studies had shown a high prevalence of cardiovascular (CV) disease in Systemic Sclerosis (SSc) patients.  

**Objectives:** The aim of this study is to compare different methods to measure CV risk in patients with scleroderma.  

**Methods:** We conducted a cross-sectional study in a single center that included 43 SSc patients without CV events. We used both CV risk assessment charts SCORE for populations with low CV risk and REGICOR algorithm adjusted to Spanish subjects. Coronary Computed Tomography (CT) with coronary arterial calcium score (CACscore) was performed considering several cut-off points as predictors of CV risk. Carotid doppler ultrasound was performed to measure the Carotid Intima Media Thickness (CIMT) and for the detection of cholesterol plaques, according to Mannheim consensus criteria.  

**Results:** Risk factors and SSc related features are described in table 1. None of the patients were catalogued as high risk according to SCORE chart (<5%). According to REGICOR chart, 17 patients (39.5%) were catalogued as intermediate risk and none as high risk. Twenty-two patients (51.2%) had carotid plaques (CP) and the CACscore of these patients was 283.4. In patients without CP CACscore was 53.2 (p<0.05). Based on the presence of CP we performed ROC curve with CACscore. The AUC was 0.778. The best cut off point was 28 with a sensibility of 71% and a specificity of 82%. Kappa’s coefficient was 0.54. Twenty patients (46.5%) had CP CACscore was 53,2 (p<0.05).

PILOT STUDY: HOME MANAGEMENT OF ILOPROST IN THE INTERVENTION GROUP

Background: Evaluate the effectiveness of Raynaud’s phenomenon and on digital ulcers, safety and side effects, during intravenous infusion of iloprost therapy in patients with limited subset classification, and limited subset classification.

Methods: 10 patients with the Raynaud's phenomenon, there was a reduction in the daily number of episodes of Raynaud's phenomenon, evaluation of digital ulcers disappeared in 6 patients, they were unchanged in 5 patients, improved although present in 1 patient. In 7 patients capillaroscopic framework remained unchanged, in 5 patients improved capillary density. 10 patients had no pulmonary hypertension, 2 patients had pulmonary hypertension, no change in the two groups at T0 and T12. None of the patients experienced side effects during the infusion.

Conclusions: The cyclical infusion therapy iloprost prevented the onset of ulcers in patients at T0 not presented or the appearance of new ulcers; it has contributed to the reduction in the daily number of Raynaud’s phenomenon and also allowed to reach the same effective dose of a vial of iloprost to dilute in 50 cc of saline solution, allowing the patient to perform at home therapy with greater compliance.

Disclosure of Interest: None declared

SAT0341 PILOT STUDY: HOME MANAGEMENT OF ILOPROST IN THE MICROPUMP/24 HOURS, IN PATIENTS SUFFERING FROM SCLERODERMA, FOLLOWED FOR 12 MONTHS

AZ. OSPARNAS Civic, PALERMO, Italy

Background: Evaluate the effectiveness on Raynaud’s phenomenon and on digital ulcers, safety and side effects, during intravenous infusion of iloprost therapy in patients with limited subset classification, and limited subset classification.

Methods: Enrolled consecutively for a period of 12 months, 12 patients, 9 women and 2 men, 9 suffering from diffuse scleroderma (positive Scl70) and 3 suffering from limited scleroderma (positive anticientromere), middle age 52.91 years, mean age of disease 7.8 years, 11 non-smoking. They were selected based on the infusion of iloprost 1/2 vial diluted in 25 cc of saline solution to 0.6 ml/h, in micropump Infnode for 24 consecutive hours, for 4 days a month for 12 months, 10 patients with peripheral lines and 2 with central venous access.

Results: Of 12 patients with the Raynaud’s phenomenon, there was a reduction in the daily number in 4 patients, unchanged in 8 patients. Digital ulcers disappeared in 6 patients, they were unchanged in 5 patients, improved although present in 1 patient. In 7 patients capillaroscopic framework remained unchanged, in 5 patients improved capillary density. 10 patients had no pulmonary hypertension, 2 patients had pulmonary hypertension, no change in the two groups at T0 and T12. None of the patients experienced side effects during the infusion.

Conclusions: The cyclical infusion therapy iloprost prevented the onset of ulcers in patients at T0 not presented or the appearance of new ulcers; it has contributed to the reduction in the daily number of Raynaud’s phenomenon and also allowed to reach the same effective dose of a vial of iloprost to dilute in 50 cc of saline solution, allowing the patient to perform at home therapy with greater compliance.

SAT0342 TRANSTHORACIC ECHOCARDIOGRAPHY TO QUANTIFY PULMONARY VASCULAR RESISTANCE IN PATIENTS WITH SYSTEMIC SCLEROSIS

S. Billiez1, T. Chetelat1, P. Pichler2, L. Tetu2, G. Prévote2, M. Galinier1, D. Carrié1, O. Lairez1, G. Pugnet1.

1Service de Cardiologie, CHU Rangueil; 2Service de Pneumologie, CHU Larrey; 3Service de Médecine Interne, CHU Toulouse Purpan, Toulouse, France

Background: One of the major causes of systemic sclerosis (SSc)-related death is pulmonary arterial hypertension, which develops in 12–15% of patients with SSc and accounts for 30–40% of deaths. Consequently, monitoring of pulmonary arterial pressures (PAP) is essential in patients with SSc. Abbas formula performed by transthoracic echocardiography (TTE) was reported as a good tool to quantify pulmonary vascular resistances (PVR).

Objectives: Explore the accuracy of TTE and Abbas formula to quantify PVR in patients with SSc.

Methods: All consecutive patients with SSc, diagnosed according to the 2013 ACR/EULAR criteria, or the LeRoy and Medsger criteria for diffuse or limited subsets classification, had within 24H a Doppler echocardiographic examination and right-heart catheterization were performed. The ratio of peak tricuspid regurgitation velocity (TRV, m/s) to the right ventricular outflow tract time–velocity integral (TVI右), cm) obtained by Doppler echocardiography (TRV/TVI右) was then correlated with invasive PVR measurements using regression analysis. An equation was modeled to calculate PVR in Wood units (WU) using echocardiography, and the results were compared with invasive PVR measurements.

Results: Thirty-three consecutive patients were included, 13 (39.4%) were male and the mean age was 64.6±12.1 years. Most were classified as limited cutaneous SSc (cSSc; n=29, 87.9%). All patients tested positive for antinuclear antibodies, 18 (21.2%) for anti-scleroderma-70, 7 (24.5%) for antirecombatere antibodies and 2 (6.1%) for anti-RNA polymerase III antibodies. Mean and systolic PAP were 31±6 and 53±16 mmHg respectively. There was a good correlation between right ventricle to right atrium gradient pressure assessed by TTE and RHC (R=0.620, P<0.001). RVP assessed by Abbas formula (2.6±1.0 wood units) were well correlated with RVP assessed by RHC (R=0.822; R=0.446, P=0.013).

Conclusions: Doppler echocardiography using Abbas formula may provide a reliable, noninvasive method to determine PVR in SSc patients.

SAT0343 SCREENING OF PULMONARY ARTERIAL HYPERTENSION IN PATIENTS WITH SYSTEMIC SCLEROSIS USING DETECT ALGORITHM – VALIDATION IN THE COHORT OF JAPANESE SINGE CENTER

H. Yasuoka1, Y. Shira2, Y. Tamura3, T. Takeuchi1, M. Kuwana2, 1Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; 2Division of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine; 3International University of Health and Welfare Mita Hospital, Tokyo, Japan

Background: Pulmonary arterial hypertension (PAH) complicated with systemic sclerosis (SSc) has the worst prognosis in PAH associated with other connective tissue diseases (1) and is one of leading cause of death in patients with SSc (2). To improve prognosis in SSc patients, earlier detection and diagnosis of PAH by annual screening is recommended even in asymptomatic patients (3). To effectively detect PAH in patients with SSc at earlier phase, DETECT algorithm is reported as a good tool to identify candidates who need right heart catheterization (RHC), with high sensitivity (4). However, its usefulness has not been validated in Japanese cohorts.

Objectives: To validate the effectiveness of DETECT algorithm in the Japanese single center cohort.

Methods: Patients with SSc who visited Keio University Hospital between 2005 and 2016 were included in the study. Patients over 18 years old, disease duration more than 3 years, and DLCO predicted less than 60% were selected and clinical information was retrospectively collected from records. The sensitivity, specificity, and negative and positive predictive values of the algorithm based on the result of RHC evaluation were calculated in a cohort of PAH patients and non-PAH patients, in whom RHC data were available. Validation with patients with data minimally-required for algorithm were also examined.

Results: Three hundred four cases were visited our hospital during from 2005 to 2016. Patients who fulfilled criteria and had data minimally-required for algorithm were 126 cases. Of 126 cases, 50 were examined RHC evaluation and patients diagnosed as pulmonary hypertension were 26 (21%) and 21 (15%) were PAH. When a cohort of PAH patients and non-PAH patients with RHC data was applied to DETECT algorithm, referral rate to RHC evaluation was 78%, missed diagnosis of PAH was 0%, sensitivity/specificity for detecting PAH patients were 100%/42%, and positive/negative predictive values were 60%/100%, respectively. Evaluation of 126 patients with data minimally-required for algorithm was also examined. Referral rate to RHC evaluation was 43%, missed diagnosis of PAH was 0%, and sensitivity/specificity and positive/negative predictive values for detecting PAH patients were 100%/72%, 43%/100%, respectively. However, there was a patient who was initially excluded at Step 1, but developed PAH one year later.

Conclusions: The DETECT algorithm was reassured as a good tool to effectively screening tool for PAH in SSc patients. However, we have to keep in mind that unnecessary of RHC referral judged by this algorithm does not guarantee the patient to be free from future development of PAH.

SAT0344 | DISEASE RELATED MALNUTRITION IN SYSTEMIC SCLEROSIS AND ASSOCIATED FACTORS: A CROSS-SECTIONAL STUDY
I. Türk 1, N. Cuzdan Coskun 2, V. Çifçi 3, D. Arslan Taş 1, M.C. Doğan 4, İ. Unal 5.

Background: The risk of malnutrition increases in patients with systemic sclerosis (SSc) which has a negative prognostic effect. Additionally malnutrition is a significant cause of morbidity and mortality.

Objectives: The aim of this study was to evaluate the associations between malnutrition and clinical features of the disease, depression in SSc patients.

Methods: Concomitant SSc patients followed in our outpatient and inpatient clinics were enrolled in the study. Skin involvement was assessed with modified Rodnan skin score (mRSS), joint/tendon involvement with finger-tip to palm distance (FTP). Intestinal lung disease (ILD) and heart involvement were evaluated with clinical and radiological methods. Patients were questioned for dysphagia and gastrointestinal involvement was diagnosed with endoscopy. Heart involvement was evaluated with electrocardiogram, and heart consumption and diastolic filling were determined with echocardiography. Malnutrition was assessed with Subjective Global Assessment (SGA) method. HAQ-DI, Beck Depression Inventory (BDI), and dietary history were used in the evaluation of malnutrition. Malnutrition risk was higher with patients with bowel involvement, and diarrhea, constipation and bloating as bowel involvement. Interincisal distance measurement was used to assess the maximal mouth opening capacity. Malnutrition risk was assessed by the Malnutrition universal screening tool (MUST). The Beck Depression Inventory (BDI) was used for measuring the severity of depression. The examinations associated between malnutrition risk and clinical features of the disease, depression in SSc patients.

Results: Ninety eight SSc patients with 69 diffuse and 29 limited type of the disease were enrolled in the study. 94.7% of the patients were female and the mean age was 52.67±11.28 years. According to MUST scores 61.2% of patients have low, 15.3% medium and 23.5% high risk for malnutrition. We found no difference between the malnutrition risk among genders (p=0.065). mRSS and FTP were significantly different between malnutrition risk groups (p=0.005, 0.050 respectively). Malnutrition risk was higher with patients with ILD than the patients without ILD (p=0.044). Malnutrition risk was higher with patients with bowel involvement than the patients without bowel involvement (p=0.021). Interincisal distance was significantly different between malnutrition risk groups (p=0.003). 78.7% of SSc patients have BDI scores ≥10, 54.3% of SSc patients have BDI scores ≥17. BDI scores were significantly different between malnutrition risk groups (p<0.001). Factors affecting malnutrition risk were evaluated with logistic regression analysis. Interincisal distance and bowel involvement were found to be the most relevant factors for malnutrition risk. SSc patients with bowel involvement have 2.519-fold increased risk of malnutrition compared to patients without bowel involvement (95% CI 1.039–6.105). Every 1 mm decrement in interincisal distance was associated with 1.101 fold increase in malnutrition risk of SSc patients (95% CI 1.032–1.176).

Conclusions: Malnutrition is common in SSc patients. Malnutrition risk is associated with skin, tendon involvement, bowel involvement, microstomia and depression severity.

SAT0346 | SYSTEMIC SCLEROSIS’S EARLY STAGES AND ITS SIGNIFICANCE IN DAILY PRACTICE

Background: Systemic Sclerosis (ScS) is an autoimmune disease, characterized by skin and internal organs fibrosis. Its clinical manifestations are heterogeneous, hence, the definitive diagnosis of SSc rely on scores, such as American College of Rheumatology (ACR) for SSc. Leroy and Medsger, proposed the potential criteria for the classification of early stages of SSc, due to the insufficient sensitivity previous methods. Lately EUSTAR proposed the concept of Very Early SSc, defined by the presence of 3 red flag – RF, Puffy Fingers and ANA; if ≥2 of these are present, capillaroscopy and specific antibody must be accessed; if one of the last positive, further search for Systemic involvement must be taken in account.

Objectives: We propose to: analyse a group of patients that had been diagnosed with early stages of SSc; study the presence of systemic involvement (at the time of diagnosis and throughout the follow-up), and the possible predictors for progression to definite SSc.

Methods: The patients were selected by consulting the clinical data from patients followed in our hospital with diagnosis of early stages of SSc. Very Early SSc criteria were used to define early stage SSc. The data concerning red flags, capillaroscopy, specific auto-antibodies, systemic involvement (Gastrointestinal, Pulmonary, Cardiac, Kidney, Musculoskeletal).

Results: We obtained a sample of 70 patients, 65 being female subjects (92,9%), with mean age of diagnosis 47.9 years (SD 13.6). 16 patients (22.9%) were classified as Pre-scleroderma at the admission, 16 as Early SSc (22.9%), 15 (21,4%) as Very Early SSc, 16 (22.9%) as possible SSc, 6 (8,6%) as Limited SSc (despite not scoring to ACR criteria) and 1 (1,4%) as Sin Scleroderma SSc. 69 patients (90%) had RP, 15 (21,4%) had puffy fingers, 63 (90%) ANA positivity – 11 patients (15,7%) had 1 red flag, 45 (63,4%) had 2 red flags and 13 (18,6%) had 3 red flags.

Conclusions: Physical components associated to specific SSc autoantibodies; 47 patients (71.2%) had capillaroscopy compatible with SSc in different stages (17.1% Early, 12.9% Active, 4,3% Late and 32.9% compatible). 54 patients (77,1%) scored for Very Early SSc.

At the moment of the diagnosis, 56 patient (81,2%) had systemic involvement. 34 patients (48,6%) scored to the definitive diagnosis by ACR 2013 criteria, after 2,56 years in mean (SD 2,51) of first diagnosis. No correlation was found in what concerns to predictors of progression to SSc or systemic involvement.

Conclusions: This study shed a light on the importance of the recognition of SSc’s early stages, since a significant part of these patients have systemic involvement at the moment of diagnosis, yet not scoring to ACR 2013 criteria. Almost half of the patients scored to definite diagnosis of SSc at the moment of the last appointment. The importance of these findings rely on the possibility to delay systemic involvement and address it in time to prevent/delay further disease progression.

SAT0345 | THE IMPACT OF GASTROINTESTINAL INVOLVEMENT IN HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS
J. Caetano 1, J. Branco 2, S. Oliveira 1, J. Delgado Alves 1, 3. Systemic Autoimmune Diseases Unit, Department of Medicine IV; 2Department of Gastroenterology, Feverdo Fonseca Hospital, Amadora; 3CEDOC, NOVA Medical School, Lisbon, Portugal.

Background: Apart from skin involvement, the gastrointestinal (GI) system is the second most commonly involved organ in systemic sclerosis (SSc), affecting over 80% of the patients. Although rarely being a direct cause of death, it is associated to a high morbidity and to a significant impairment in health-related quality of life (HRQoL) and vascular disease. Considering the influence of GI manifestations in the quality of life of SSc patients.

Objectives: The purpose of this study is to characterize the impact of GI involvement in HRQoL in SSc, and to compare it with that in patients with inflammatory bowel disease (IBD).

Methods: Concomitant SSc patients with GI involvement were selected from a cohort of 44 SSc patients, followed in a single referral centre and classified according to 2013 ACR/EULAR criteria. Comparative analysis was made with 24 consecutive patients with IBD without arthritis (14 Crohn’s disease; 10 - ulcerative colitis). Health Assessment Questionnaire (HAQ-DI) and Short Form 36 (SF36), physical component summary (PCS) and mental component summary (MCS) scales, were used to assess HRQoL in both groups. The UCLA Scleroderma Clinical Trial Consortium Gastrointestinal Tract 2.0 (UCLA SCTG GIT 2.0) was performed in SSc patients to assess the severity of GI involvement. Clinical data were obtained by medical records review. T-Test and Fisher’s exact test were used to compare binary variables. Pearson’s correlation was used for continuous variables.

Results: The most common GI segments involved in SSc patients were the esophagus in 90%, the stomach in 60% and the bowel in 48%, while the anorectum was involved in a smaller percentage (10.3%). The mean UCLA SCTG GIT 2.0 score was 0.64±1.9 (46.8% with a moderate severity, with higher scores obtained for reflux, distention and emotional wellbeing. The mean HAQ-DI score was 1.13±0.57 (0-best health), and the mean PCS and MCS scores were 35.2±9.4 and 35.3±11.4 (100-best health), respectively. These scores were significantly lower than in SSc patients without GI involvement (HAQ-DI: p<0.001; PCS - p<0.04 and MCS - p<0.005). There was a significant correlation between higher UCLA SCTG GIT 2.0 scores and worse quality of life evaluated by HAQ-DI (r=-0.42, p<0.03), but the same correlation was not found for the SF36 components. Comparing with IBD patients, SSc patients with GI involvement had worse life quality, with statistically significantly higher HAQ-DI (p<0.001) and lower PCS (p<0.001) and MCS (p<0.01) scores.

Conclusions: GI involvement in SSc significantly impaired patient’s quality of life. The impact of GI involvement in HRQoL of SSc patients was more severe than in IBD patients. Although physical components were relevant, with esophagus being most frequently involved, multisystemic involvement associated with GI involvement significantly compromised HRQoL in SSc. Therefore, the assessment of SSc patients using clinical severity measure tools, similar to UCLA SCTG GIT 2.0 score, is crucial for a better characterization of the disease and to an optimized clinical approach.

DISEASE MODIFYING EFFECT OF ILOPROST IN PATIENTS WITH SYSTEMIC SCLEROSIS AND POSSIBLE ROLE OF CXCL4 CHEMOKINE

K. Stefanonianti, I. Scialla, M. Vasilei1, R. Palazzo2, L. Frasca3, G. Valesini1, V. Ricietti1, 1Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Universita di Roma; 2National center for research and pre-clinical and clinical evaluation of drugs; 3Immune-mediated diseases UNIT, Istituto Superiore di Sanita (Nat. Inst. of Health), Rome, Italy

Background: Iloprost is a synthetic prostaglandine used for vascular manifestation of Systemic Sclerosis (SSc), in particular it is used for active digital ulcers (DU) and severe Raynaud Phenomenon (RP) (1). It acts on several receptors such as IP and EP receptors and PPRs. Iloprost is also involved in the regulation of gene expression, fibrosis and inflammation (2,3). CXCL4 (CXCL4) is a Platelet Factor 4, a 70Kda CXCL chemokine synthesized in megakaryocytes and plasmacytoid dendritic cells, released after platelet activation. In SSc, it seems to be higher in patients with early diffuse SSC and it correlates with mRSS and presence of PAH (4).

Objectives: To evaluate the effect of iloprost on vascular manifestations, on disease activity and on serum levels of CXCL4 at baseline (T0) and after 1 month (T1), 3 months (T3) and 6 months (T6) of therapy.

Methods: 30 patients (M/F = 1:29; mean age =58.2 ± years; mean disease duration = 12.8± 5 yrs) with established SSc according to ACR criteria, were enrolled. At T0, T1, T3 and T6 treatment with iloprost at standard dosage we used RPMY, a number of DU, European Scleroderma Study Group Activity Index (EScSGAI) and serum levels of CXCL4, measured using commercially available immunoassay kit (human CXCL4/PF4 R&D SYSTEMS®). All patients underwent to a complete clinical, instrumental and laboratory evaluation.

Results: Regarding RP VAS, we found a statistically significant increase (p<0.04) at T3, corresponding to the colder winter period, while it decreased, although not significantly at T1 and at T6, where this reduction was significant compared to T3 values (p=0.0008). Concerning the number of active DU, we highlighted the same trend of the RP VAS. EScSGAI values showed a statistically significant reduction (p<0.03) comparing T3 to T6. Regarding CXCL4, we found significantly higher levels in SSc patients respect to a group of healthy controls (HC) (p<0.047). No significant difference was found in serum levels of CXCL4 at T0, T1,T3 and T6. Evaluating patients with higher levels of CXCL4 at baseline, respect to the average of HC values (CXCL4>25,000 pg/ml) (11/30 patients), we found that 7 subjects had a significant improvement in disease activity at T6 evaluated by EScSGAI (p=0.015). In these patients we also detected a significant reduction in T3 CXCL4 values (p<0.043) persisting and at T6, although not reaching statistical significance. Moreover more basal levels of CXCL4 in patients with disease duration less of 60 months (p=0.05) and in patients with pericardial effusion (p=0.037) were detected. Besides we found significantly lower levels of CXCL4 in patients with DU history (p=0.049) and esophageal involvement (p=0.008).

Conclusions: Our study confirms the efficacy of Iloprost on vascular manifestation of Systemic Sclerosis in particular it is indicated for active digital ulcers (DU) and esophageal involvement (p=0.008). In these patients we also detected a significant reduction in T3 CXCL4 values (p=0.043) persisting and at T6, although not reaching statistical significance. Moreover more basal levels of CXCL4 in patients with disease duration less of 60 months (p=0.05) and in patients with pericardial effusion (p=0.037) were detected. Besides we found significantly lower levels of CXCL4 in patients with DU history (p=0.049) and esophageal involvement (p=0.008).

EVALUATION OF STANDARD SWALLOWING FUNCTION IN ASSESSING ASPIRATION RISK FOR PATIENTS WITH SYSTEMIC SCLEROSIS

L. Yan, P. Yunfeng, Y. Mengru, Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Swallowing dysfunction is a common symptom of systemic sclerosis, which usually induce aspiration pneumonia to aggravate lung progress. It is necessary to screen swallowing disorders effectively at an early stage.

Objectives: To investigate the value of standard swallowing function assessment (SSA) in aspiration screening for inpatients with Systemic sclerosis.

Methods: SSA and Video fluoroscopic swallowing study (VFSS) were performed in 120 inpatients with Systemic sclerosis from March 2014 to September 2016. The sensitivity, specificity, positive predictive value and negative predictive value of SSA in the diagnosis of aspiration in patients were calculated by taking VFSS examination as the gold standard. The incidence of pneumonia in SSA-positive and SSA-negative patients were compared.

Results: The diagnostic sensitivity of SSA was 81.2%, the specificity was 75%, the positive predictive value was 68.6% and the negative predictive value was 90.3%. The incidence of pneumonia in SSA positive patients was higher than that in SSA negative patients (54.1% vs 28.3%) (P<0.01).

Conclusions: SSA is a valuable screening tool for the evaluation of aspiration risk in patients with Systemic sclerosis.

DOES A SYMPTOMATIC SCLEROSIS PATIENTS’ CLINICAL PHENOTYPE DEMONSTRATE HIS AUTOANTIBODY STATUS?

1Rheumatology; 2Clinical Chemistry and Laboratory Medicine; 3Pulmonology; 4Cardiology, LUMC, Leiden, Netherlands

Background: Although antibody status has shown to critical in clinical setting in Systemic Sclerosis (SSc), it is far from perfect. For optimal clinical setting as well as for evaluating the possible pathogenic role of SSc specific antibodies, it is relevant to know to what extent clinical SSc phenotypes are determined by presence of these antibodies.

Objectives: To evaluate 1. if clinical relevant subsets of SSc patients are distinguishable using only clinical data, 2. how SSc specific autoantibodies are distributed among these subsets, and 3. whether adding antibody status to cluster analysis improves recognition of SSc subsets.

Methods: Using data from SSc patients of the Combined Care In Systemic Sclerosis (CCIS) cohort, Leiden University Medical Center, hierarchical clustering based on Ward Method was performed on the first obtained factor of principal compoment analysis of 7 organ systems (skin, lung, heart, kidney, muscle, vascular, gastro-

ASSOCIATION OF VITAMIN D DEFICIENCY WITH REDUCED IL-10-PRODUCING REGULATORY B CELLS IN SYSTEMIC SCLEROSIS

A. Mavropoulos, C. Liaskos, A. Gkoutzourelas, C.G. Katsiari, D.P. Bogdanos, L.I. Sakkas. Rheumatology and Clinical Immunology, University of Thessaly, School of Health Sciences, LARISSA, Greece

Background: IL-10-producing regulatory B cells (Bregs), also known as B10 cells, are decreased and function impaired in patients with systemic sclerosis (SSc), particularly in those with SSc-associated interstitial lung disease (1). As serum 25-OH-vitamin D (vitD) levels are associated with clinical aspects in patients with SSc (2), we investigated whether there is any link between vitD levels and Breg levels.

Objectives: To assess whether or not vitD deficiency in SSc is associated with the percentages of circulating IL-10-producing Breg cells.

Methods: PBMCs and serum samples were isolated from 55 patients with systemic sclerosis. Serum VitD levels were measured using a commercially available sandwich ELISA kit. Phenotypic analysis of CD19, CD24, CD27, CD123 and intracellular expression of cytoklasmic IL-10 following bacterial CpG (ODN2006) and PMA/ionomycin stimulation was examined by flow cytometry using specific fluorochrome-conjugated monoclonal antibodies (BD Biosciences).

Results: Systemic Sclerosis patients were divided into two groups (vitD deficient or not) based on a serum concentration cut of value of 20 ng/ml. The mean vitD levels in the deficient group were 14.1±3.6 ng/ml (n=17) whereas the mean vitD levels in the non-deficient group were 37.5±12.9 ng/ml (n=38). IL-10-producing B cells (B10 cells) were significantly decreased in vitD deficient patients compared to those with medium/high levels (p=0.02). CD19+CD27+ (memory) B cells were also significantly reduced with vitD deficiency (p=0.004). In addition the ratio of naïve/memory B cells was significantly higher in vitD deficient patients (p<0.05). Within the memory B cell fraction, the CD19+CD27+CD24hi cells also known as phenotypic memory Bregs, were mostly decreased (p=0.001). There was no significant association between CD19+CD38hiCD24hi (transitional) Bregs and VitD levels.

Conclusions: Our data suggest that vitamin D deficiency may account for reduced B10 cells in systemic sclerosis.

Scientific Abstracts
Saturday, 17 June 2017 903
intestinal) and time since non-Raynaud phenomenon. Clinical characteristics and prevalence of auto-antibodies within clusters was evaluated. We assessed whether adding autoantibody status as additional factor improved clinical subsetting.

**Results:** Of 407 SSc patients included, 371 patients (91%) fulfilled ACR/EULAR 2013 criteria. Prevalence of anti-centromere (ACA) was 37%, anti-topoisomerase (ATA) 24%, anti-RNAPIII 5%, anti-fibrillarin 4%, anti-Pm/Scl 5%. Cluster analysis identified clinically recognisable clusters of SSc patients based on absence of skin involvement (cluster 1), peripheral vascular involvement (cluster 2), fibrotic complications (cluster 4), and severe vascular complications (pulmonary arterial hypertension [PHT], renal crises; cluster 5). Except for cluster 4, where ATA was diagnostic, in all clusters ACA was the most prevalent auto-antibody. No cluster associated with any of the more rare SSc specific auto-antibodies. Adding of auto-antibodies resulted in increased clinical overlap, with a frequency of PH between 6 – 8% and a frequency of digital ulcers between 24 – 39% in clusters 2, 4 and 5.

Conclusions: Based on clinical data alone, relevant subgroups in SSc can be distinguished. Adding antibody status to cluster analyses increases overlap of clinical features between subgroups. These findings show that solely presence of antibodies does not improve clinical subsetting. Of optimising risk stratification, more complex serological findings as antibody titers might be additive.

**SAT0351** DIFFERENCES AMONG PATIENTS WITH INTERSTITIAL LUNG DISEASE ACCORDING TO THEIR SYSTEMIC SCLEROSIS SUBCLASSIFICATION

1 Reumatología, Hospital Jose Maria Ramos Mejia, Ciudad Autónoma de Buenos Aires, Argentina; 2 Reumatología, Hospital Universitario de la Santa Creu i Sant Pau, Barcelona, Spain

**Background:** Systemic Sclerosis (SSc) has been widely studied from a purely global standpoint, but only a few trials have analysed patients with interstitial lung disease (ILD-SSc) as well.

**Objectives:** 1. Describe the clinical features of a cohort of patients with SSc and ILD-SSc. 2. Determine whether there are disparities among different types of ILD-SSc and their progression according to the SSc-specific autoantibody (AAb).

**Methods:** Retrospective study of a cohort of patients with ILD-SSc controlled during an SSc consultation. The following variables were collected: sex, age, SSc and ILD progress in years, type of SSc and ILD, smoking, digital ulcers (DU), gastrointestinal, digestive disorders, cancer. SSc treatment, corticosteroid doses and lastly, lung function tests upon diagnosis, at treatment onset, and 24 months later. Additionally, a record was kept on the types of AAb present in every SSc. Qualitative and quantitative variables were compared in relation to the clinical and immunological sub-classification. Chi-square and Student’s T Tests were performed. A P-value <0.05 was considered significant.

**Results:** of 266 patients with SSc, data from 47 patients with ILD-SSc were gathered; 89.4% were female, with an age range of 66.09±15.1 years old, and 9.85±10.2 and 4.38±9.24 years of progression of their SSc and ILD respectively. 33 out of 47 sustained ILD-SSc, and both Scl-70/ATA (29.8%) and ACA (26.1%) were the most frequently found AAb. Non-specific interstitial pneumonia (NSIP) was the most common ILD radiological pattern (76.6%). Most patients with SSc underwent treatment (51.1%), 24% with mycophenolate mofetil (MMF); 36.2% of the patients had been concurrently administered corticosteroids with a mean prednisone dose of 15.73±10.3 mg/day. Upon comparing patients with ILD-SSc and dcSSc, prevalence of DU was higher in those with dcSSc (p<0.01), MMF was less frequently used (p<0.02), rituximab was more usually employed (p<0.03), and they presented worse values of FEV1/FVC ratio after 24 months of treatment (p<0.03). No differences were observed as to either type of ILD or progression. However, when variables were analysed regarding AAb in SSc, patients with ACA presented both fewer DU (p<0.02) and NSIP pattern (p<0.02), and more frequent compromise of the small airway (p<0.01), they were younger and thus, they had had shorter progression of the disease. ILD diagnosis was made significantly earlier in those patients with RNA polymerase, and later in those with anti-U1RNP. No AAb was observed associated with neoplasia. Considering the types of ILD, patients with NSIP pattern were younger (p<0.054) and presented worse spirometric values.

**Conclusions:** In terms of ILD-SSc patient stratification, sub-classification by AAb appears to be more specific than the clinical sub-classification. ACA is related to less frequency of NSIP pattern. Unlike what has been described for SSc from a global point of view, in patients with ILD-SSc no association between AAb and neoplasia could be established.

**SAT0352** MORTALITY IN IDIOPATHIC INFLAMMATORY MYOPATHY—RESULTS FROM A SWEDISH NATIONWIDE POPULATION-BASED COHORT STUDY

C. Dob loug 1, J. Svensson 2, I. Lundberg 2, M. Holmqvist 1, 2

1 Osborne University Hospital, Oslo, Norway; 2 Karolinska Institutet, Stockholm, Sweden

**Background:** Little is known about mortality in idiopathic inflammatory myopathies (IIM) compared to the general population, especially the risk development since diagnosis. In a recently published study, the 5- and 10-year mortality was lower for IIM than previously reported, suggesting improved outcomes in recent years.

**Objectives:** To assess the mortality following IIM diagnosis in a nationwide population-based cohort of IIM patients diagnosed 2002–2011 compared to the general population.

**Methods:** We used nationwide fully covering health care registers to identify all individuals who were treated by a rheumatologist, neurologist, or dermatologist for IIM and who had a listing of IIM at ≥two visits within 1–12 months between 2002 and 2011, general population comparators, and death during follow up. We calculated crude and cause-specific mortality rates with 95% confidence intervals (CI) and compared the mortality in IIM to that in the general population using Cox proportional hazards models adjusted for age, sex, year of diagnosis, and residential area.

**Results:** During a median follow up of 4 years, 228 (31%) of the 733 IIM patients and during a median follow up of 6 years, 888 (12%) of the 7,340 general population comparators died. This corresponded to a crude mortality of 61/1,000 person-years in IIM, and 20/1,000 person-years in the comparators. The cumulative mortality at 1 year after diagnosis was 10% in IIM and 1% in the general population, at 5 years it was 24% in IIM and 7% in general population, and at 10 years the proportion was 31% and 12%. The overall hazard ratio (HR) (95% CI) of death comparing the NPR cohort and its comparator, was 3.5 (3.0–4.0). When restricting the outcome to cardiovascular disease-, cancer-, pulmonary disease- specific death we noted increased mortality from all outcomes in IIM compared to the risk in the general population. When we stratified on time since diagnosis we noted an increased absolute and relative risk of death in the first year of diagnosis in particular for pulmonary disease and cancer, whereas cardiovascular mortality was a major cause of death also after 10 years after IIM diagnosis (table).

**Conclusions:** IIM patients are still at increased risk of death. The highest mortality
Small Airways Involvement in Scleroderma Patients: Results of a Case-Control Study

M. Bonifazi, L. M. Rodriguez-Padilla, M. A. Mesa-Navas

Methods:
- Consecutive SSc patients were included in the present study according to eligibility criteria; controls were health volunteers. Both cases and controls underwent IOS measurements; cases also underwent pulmonary function tests and HRCT assessment of SA pathological features and ILD extent were provided for reference to cutaneous subtype a SA dysfunction was more prevalent in the following ILD subtypes: NSIP, BO, UIP, and a direct correlation with pulmonary artery systolic pressure estimated. With reference to cutaneous subtype a SA dysfunction was more prevalent in the limited form compared to the diffuse, respectively in 23% and 12%, Radiologic HRCT assessment of SA pathological features and ILD extent were provided for 77 patients; 19 (24.7%) presented at least one sign of SA disease. An underlying ILD was detected in 40 patients, characterized by NSIP pattern in 37.

Conclusions: A significant involvement of SA was found in a substantial proportion of SSc patients, compared to healthy controls. Moreover, this seemed to be associated with more severe functional obstructive and restrictive impairment, and with higher PAPs values. Therefore, our findings suggest that SA may be a potential, less known, target of disease, and further studies are needed to assess prognostic and therapeutic implications of this pathologic feature.

Neuropathic Pain: Is It an Underestimated Symptom in Systemic Sclerosis?

N. Cuzdan Coskun, I. Turk, T. Sarpe, E. Erken, Z.N. Alparslan

Methods: Diffuse and Limited SSc patients diagnosed by American College of Rheumatology 2013 criteria were included in the study. Pain was evaluated with Visual Analogue Scale (VAS); painful body regions and pain intensity with Brief Pain Inventory (BPI); presence of neuropathic pain with The Leeds Assessment of Neuropathic Symptoms and Signs (LANNS) questionnaire; disease activity with Medsger Disease Severity Scale (MDSS). Mixed-effects regression analysis was used to assess the associations of NPS with sociodemographic and clinical factors.

Results: One hundred twenty patients were included in the study (mean age 53.6 ± 14.4 years, female/male 83.3% ± 16.7%). Total pain frequency was found 69.2% and NPS was 35.9% in the whole patient group. Mean VAS in the study.

Small Airways Involvement in Scleroderma Patients: A Preliminary Observational Study

C.J. Velásquez-Franco, A. Facio-Lince García, A.L. Zapata-Castellanos, L.M. Rodríguez-Padilla, M.A. Mesa-Navas on behalf of Clinical Immunology and Rheumatology Group, Universidad Pontificia Bolivariana. 1Rheumatology, Clinica Universitaria Bolivariana. Universidad Pontificia Bolivariana. 2School of Health Sciences. Universidad Pontificia Bolivariana, Medellin, Colombia

Background: The prevalence of Raynaud’s phenomenon (RP) has been reported between 3–22%. When associated with systemic autoimmune diseases (SAD), especially systemic sclerosis (SSc), it is the sentinel event of irreversible organic damage. NAILfold videocapillaroscopy (NVC) is a non-invasive and safe procedure that allows two observation of the microcirculation. Between 15–20% of SAD cases who have RP with videocapillaroscopic alterations and certain autoantibodies will develop a SAD over two years. In addition, 90% of individuals with SSc and 85% with mixed connective tissue disease (MCTD) had RP as the first symptom.

Objectives: To evaluate the role of NVC in the differential diagnosis of RP, as well as in the early detection of SAD, in a cohort of Colombian patients.

Methods: A prospective, longitudinal, analytical study was conducted in subjects with RP over 18-year-old, not active smokers, without previous connective tissue disease, secondary causes or aggravating factors. OptiNVC with OptiPix software was used (Optilia Instruments, Solentuna, Sweden). Qualitative variables were described by means, as well as absolute and relative frequencies; quantitative variables, according to the distribution of data, were reported by means or median, with standard deviation (SD) and interquartile range (IQR), respectively. We are reporting the baseline characteristics of these individuals.

Results: Fifty-eight individuals were included; 91.4% were female. The mean age was 40.9 years (SD: 14.1). RP was biophasic in 63.6% of the patients, with a median of 30 episodes per month (IQR: 8–30). In 41 subjects (available data), antinuclear antibodies were positive; the most common patterns were: speckled (41.5%) and centromere (26.8%). The median of erythrocytosis rate (ESR) was 9 (IQR 4–13). Ten individuals (19.2%) were diagnosed with SSc in the first NVC: Seven patients with limited SSc, two with MCTD, and one with diffuse SSc. The patterns observed in the individuals with SSc were: early (n = 3), active (n = 3), late (n = 2), and minor and unspecific abnormalities in subjects with MCTD (n = 1 each). The most frequent NVC alterations in subjects with SAD were: megacapillaries (n = 10), microhemorrhages (n = 10), avascular zones (n = 8), neovascularization (n = 6), and capilar disorganization (n = 6). In these subjects, the mean capillary diameter was 76.7 ± 33.9 mm; the median of capillary number per mm was 7 (IQR: 6–8).

Conclusions: The frequency of systemic autoimmune disease was similar to the published reports in the literature. We highlight the following aspects: 1) The normal erythrocytosis rate in subjects with a rheumatologic diagnosis, a particular finding when compared to previous data; 2) The importance of subjects with a specific diagnosis in the first NVC: capillaroscopy; one possible explanation could be a undiagnosed disorder; this fact could be possibly demonstrated by the large capillary diameter found.

group of patients with and without NPS were 5.4±2.0, 3.4±2.1; respectively (P<0.001). Pain was most frequently seen in wrist-hand (50.6%) and ankle-foot (43.4%) regions; albite, NPS rates were highest in face (94.4%), lower leg (87.5%) and gluteal (78.6%) regions. SF-36 scores were lower in patients with NPS than the patients without NPS but the difference has not reached to a statistically significant level (P=0.05). The most associated factors with NPS were Medsger Disease Severity Score for muscle and drug consumption of the patient's quality of life. Extensive studies are necessary to confirm and improve our data into clinical practice.

**Background:** It is estimated that about 28% of Systemic Sclerosis (SSc) patients have moderate to high risk of malnutrition.

**Objectives:** To evaluate differences between SS patients with moderate to high risk of malnutrition and those with low risk.

**Methods:** Cross-sectional, observational, multicentric study. We included patients with SS according to ACR-EULAR 2013 classification criteria. Patients were classified in groups depending on whether they were in low or moderate/high risk of malnutrition, according to the screening method for detection of adult malnutrition (MUST). Were evaluated: disease duration, disease subtype (limited or diffuse), presence of microstomia, xerostomia, active or past digital ulcers, amputations, arthritis, Rodnan Score, gastroesophageal and bowel involvement, anxiety and depression, and hands functionality by Duruöz Index. Continuous variables were described as median (IQR) or mean (SD) and percentages for categorical variables. Mann Whitney or t-test was used for continuous variables, and Fisher exact test or chi-square for categorical variables. A p<0.05 was considered significant. A multivariate analysis was made taking MUST as a dependent variable.

**Results:** 116 patients were included. Thirty percent were at moderate to high risk of malnutrition. These patients experienced significantly higher frequency of diffuse SSc (49% vs 21%, p<0.003), bowel involvement (49% vs 27%, p=0.02), gastroesophageal involvement (74% vs 48%, p=0.009), higher cutaneous involvement (median 12 vs 6, p=0.01, microstomia (40% vs 15%, p=0.003), worst hand functionality (median 11 vs 3, p=0.02), and moderate-severe depression (37% vs 16%, p=0.012). Also, men experienced a higher moderate-high risk of malnutrition (20% vs 6%, p=0.02). In the multivariate analysis, the male sex (OR 4.55, 95% CI 1.11–20, p=0.03), the Rodnan score >9 (OR 3.13, 95% CI, 95% CI, p=0.01), and gastroesophageal involvement (OR 2.87, 95% CI 1.07–7.73, p=0.03), were independently and statistically significant.

**Conclusions:** These results highlight the importance of assessing the nutritional status of our SS patients.

1Department of Rheumatology, 1Medical Faculty, Charles University, Institute of Rheumatology, 2Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

**Background:** Systemic sclerosis (SSc) is characterized by fibrosis of the skin and visceral organs, especially digestive tract, and musculoskeletal involvement, which limit mobility/self-sufficiency of patients, and can have a negative impact on body composition.

**Objectives:** To assess body composition and physical activity of SSc patients and healthy controls (HC).

**Methods:** 59 patients with SSc (50 females, 9 males; mean age 52.1; disease duration 6.7 years; limited cutaneous (lcSSc,36)/diffuse cutaneous (dcSSc,23) and 36 age-/sex-matched HC (30 females, 6 males, mean age 51.4) without rheumatic/tumor diseases or manifest cardiovascular event were included. SSc patients fulfilled EULAR/ACR 2013 criteria. Anthropometric parameters and body composition were assessed (by densitometry-IDXA Lunar, and by bioelectric impedance-BIA-2000-M), and physical activity was evaluated using Human Activity Profile (HAP) questionnaire. Routine biochemistry analysis was performed after 8 hours of fasting. Disease activity was evaluated by EUSTAR SSc activity score. Data are presented as means±SD.

**Results:** Compared to HC, patients with SSc had significantly lower body-mass index (BMI: 26.4±3.3 vs. 22.4±4.3 kg/m², p<0.0001) and body fat % assessed by both IDXA (BF%: 37.2±6.6 vs. 32.6±8.2%, p=0.0014) and BIA (BF%: 31.3±6.4 vs. 34.8±6.8%, p=0.0014). These results highlight the importance of assessing the nutritional status of our SS patients.

THE COURSE OF MOUTH OPENING AND ITS RELATIONSHIP TO DISEASE CHARACTERISTICS, GLOBAL FUNCTIONING, HEALTH-RELATED QUALITY OF LIFE AND MOUTH HANDICAP IN PATIENTS WITH SYSTEMIC SCLEROSIS

Rheumatology; 2Physiotherapy; 3Pulmonology; 4Cardiology, Leiden University Medical Center, Leiden, Netherlands

Background: Systemic sclerosis (SSc) is a fibrotic disease which can lead to reduced maximal mouth opening (MMO). Previous cross-sectional research showed that reduced MMO in SSc correlated with higher disease severity and lower oral quality of life. Interpretation of interventions that possibly influence MMO is difficult, as the natural history of MMO in SSc is not well described.

Objectives: To evaluate in SSc 1) the course of MMO 2) disease characteristics predictive for decreasing MMO and 3) the relationship between the course of MMO and global functioning, health-related quality of life (HRQoL) and mouth handicap.

Methods: SSc patients from the Leiden Combined Care In Systemic Sclerosis (CCIS) cohort, Leiden University Medical Center were included if at least one annual clinical assessment was available. Annual clinical assessment includes MMO measurement, global functioning (HAQ), HRQoL (Short Form-36; SF-36), mouth handicap (Mouth Handicap in Systemic Sclerosis scale; MHISS). We assessed mean MMO, prevalence of microstomia (MMO<30.0 mm) and decreasing MMO (decline >5.00 mm/year) over time. Predictors for decreasing MMO were assessed by a linear mixed model (LMM), including baseline clinical parameters HRQoL, mouth function, quality of life, skin, heart, gastrointestinal, lung, renal, musculoskeletal). Additionally, MMO over time was correlated with baseline HAQ, SF-36 and MHISS in separate LMMs adjusted for gender, Body Mass Index, age and disease characteristics correlated significantly (p<0.05) with the course of MMO.

Results: 382 patients were included with mean age 54±14 years, 83% female and 25% diffuse cutaneous SSc. Mean MMO during 6 years of follow-up ranged from 39.4 to 42.5 mm. The annual mean percentage of patients with microstomia was 9%, range 6 to 12% (Figure 1a). A decrease in MMO between two consecutive annual measurements was observed in 17% of patients, mean 12% (Figure 1b). More extended cutaneous involvement, peripheral vasculopathy, pulmonary and gastrointestinal involvement at baseline were predictive for decreasing MMO over time (Table 1). Baseline HAQ (β=-1.6, 95% CI=-2.7 to -0.6), SF-36 physical component (β=0.1, 95% CI=0.0 to 0.1) and MHISS (β=-0.2, 95% CI=-0.2 to -0.1) correlated with longitudinal MMO.

Conclusions: Over time, MMO is relatively stable in the majority of SSc patients. Microstomia is seen in 9% and important decrease of MMO in 12% is associated with more severe organ involvement. Even though this concerns only a small subgroup of SSc patients, a significant association with global functioning and HRQoL was demonstrated, underlining the need for treatment strategies improving MMO.

SAT0360 MYOSITIS-SPECIFIC AND MYOSITIS-ASSOCIATED AUTOANTIBODIES IN PATIENTS WITH DERMATOMYOSITIS / POLYMYSITIDIS: COMPARISON BETWEEN LINE BLOT AND ENZYME-IMMUNOASSAY ASSAYS

S. Nakashima, T. Kameda, M. Izumikawa, H. Shimada, H. Ozaki, R. Wakiya, A. Kondou, N. Kadowaki, H. Dobashi. Department of Internal Medicine. Division of Hematology, Rheumatology and Respiratory Medicine, Kagawa University, Kagawa, Japan

Background: MESCUP™ test (enzyme-immunoassay assays; TIF1γ, MDA5, Jo-1, EJ, PL-7, PL-12, and KS; MBL) (MESA) is used for a diagnosis of idiopathic inflammatory myopathies (IMMs) in Japan. On the other hand, EUROLINE myositis Profile 3 (line blot; EUROMMUN) (EURO) can analyze plural Myositis-specific autoantibodies (MSA) and that of EURO haven’t be disclosed.

Methods: We enrolled 58 patients diagnosed PM/DM in our facility. Polymyositis (PM) and dermatomyositis (DM) were diagnosed according to Bohan and Peter’s criteria. Of the MAA and MSA were analyzed using MESA and EURO. In case of MESA (+), MSA (anti-Jo1, anti-PL7, anti-PL12, anti-KS) were identified by specific ELISA. When those results were different, we analyzed by immunoprecipitation. And we analyzed the association between the line autoantibody and clinical features. Results: MSA and MAA were detected in 43/58 (74%) (anti-PL7: 12, anti-Jo1: 7, anti-EJ: 3, anti-PL12: 1, anti-OJ: 0, anti-Ro52: 27, anti-Pm-Scl70: 7, anti-Ku: 6, anti-Pm-Scl100: 1) by EURO. On the other hand, MAA and MSA were detected in 30/58 (52%) (anti-PL7: 9, anti-Jo1: 7, anti-EJ: 4, TIF1γ: 4, MDA5: 3, U1RNP: 3) by MESA. Five patients were MESA (+) and EURO (-). In the case of ARS positive patient, Two of EURO (+) patients was positive in MESA, respectively Jo1 and EJ. Three of MESA (-) patients was positive in EURO. Although MESA(+) and EURO(+) patients had plural MSA and MAA (PL7+Jo1, PL7+PL12, PL7+Ku), MAA and MSA weren’t detected by immunoprecipitation in MESA(-) and EURO(-) patients. Two of patients that detected plural MSA or MAA had rapid progressive ILD.

(association between clinical manifestations and MSA, MAA) All patients with anti-ARS (anti-Jo1, anti-PL7, anti-PL12 and anti-EJ) had ILD. In addition, anti-ARS were associated with arthritis and mechanic’s hands. Anti-MI-2 positive patients didn’t have ILD. Patients detected anti-Pm-Scl75, anti-Pm-Scl100, anti-Ku were almost overlap syndrome. All of Anti-SPR positive patients was PM.

Conclusions: EURO is a convenient and reliable method useful for detection of MAA and MSA. It was suggested the patients of plural antibodies were detected by EURO have unique clinical course in others.

Data in 26 SSc patients (13 with and 13 without esophageal symptoms).

Conclusions: Scleroderma esophagus diagnosed by HRM was present in less than 2/3 of symptomatic patients with SSc and associated only with esophageal dilation (>—5mm) in CT. Although further studies are needed, esophageal dilation on chest CT may be a non-invasive alternative for evaluation of SSc patients with esophageal symptoms.

SAT0362

RISK FACTORS AND OUTCOME OF THAI PATIENTS WITH SCLERODERMA RENAL CRISIS (SRC): A DISEASE DURATION-MATCHED CASE CONTROL STUDY

S. Wangkaew 1, S. Lertthanaphok 1, S. Puntana 1, K. Noppakun 2

1Rheumatology; 2Nephrology. Chiang Mai University, Chiang Mai, Thailand

Background: Data regarding the prevalence, risk factors and outcome of scleroderma renal crisis (SRC) in Asian patients with systemic sclerosis (SSc) are limited.

Objectives: To determine the prevalence, risk factors and outcome of SRC in Thai SSc patients.

Methods: Medical records of all SSc patients, fulfilling the 1980 American College of Rheumatology classification criteria for SSc, seen at the Division of Rheumatology, Maharaj Nakorn Chiang Mai Hospital, Thailand, from January 1990 and December 2015 were retrospectively reviewed. Patients younger than 18 years old or overlapping with rheumatoid arthritis, systemic lupus erythematosus or mixed connective tissue disease were excluded. Cases of SRC were identified based on the international Scleroderma Renal Crisis Study criteria 1. Controls were selected from consecutive SSc patients without SRC from our database that was ranked closest to the cases based on esophageal dilation and matched for disease duration from the first non-Raynaud’s phenomenon, by ±1 year. The ratio for SRC patients to control patients was 1:4.

Results: Of 608 SSc patients seen during the study period, 19 SRC were identified resulting of the SRC prevalence of 3.13% and there were 76 matched controls. Of the 19 cases, mean±SD age and median (IQR1, 3) disease duration was 56.2±13.8 years and 9 (5.0, 16.0) months, respectively. Seventeen patients (89.5%) had dSSc. There were 12 (63.2%) patients with hypertensive renal crisis (HRC) and 7 (36.8%) patients with normotensive renal crisis (NRC). Univariate conditional logistic regression analyses showed that current myositis (OR2.01, 95% CI 1.02 – 3.98, p=0.049), WBC≥10,000 cell/mm³ (OR2.69, 95% CI 0.99 – 7.26, p=0.050), serum albumin <3.0 mg/dl (OR11.08, 95% CI 3.02 – 40.6, p=0.001), and current prednisolone used≥15 mg/day (OR19.36, 95% CI 2.29 – 163.6, p=0.007) were associated with SRC. Digital gangrene tended to show an association with SRC in the univariate analysis (OR8.00, 95% CI 0.72 – 88.2, p=0.090). Variables with p<0.15 in univariate conditional logistic regression analysis were included in the multivariate conditional logistic regression analysis. When multivariate conditional logistic regression analysis was adjusted, digital gangrene (adjusted odd ratio [AOR]31.41, 95% CI 1.16 – 852.23, p=0.041), current prednisolone use≥15 mg/day (AOR31.22, 95% CI 1.59 – 613.85, p=0.024), serum albumin <3 mg/dl (AOR9.97, 95% CI 1.49 – 42.56, p=0.015) and cardiac involve (AOR6.62, 95% CI 0.18 – 40.63, p=0.041) were confirmed to be independent risk factors for SRC. During a median (IQR 1, 3) follow-up of 1 (0, 2) months, 15 (78.9%) patients required hemodialysis, including 9 of 12 (75.0%) patients with SRC and 6 of 7 (85.7%) with NRC. Twelve (63.2%) patients received ACEI, including 9 of 12 (75.0%) patients with SRC and 3 of 7 (42.9%) patients with NRC. Ten (52.6%) patients died, including 5 of 12 patients (41.7%) with SRC and 5 of 7 (71.4%) patients with NRC. Current myositis was an uncommon complication in Thai patients with SSc, but associated with high mortality. Digital gangrene, current prednisolone used≥15 mg/day, serum albumin<3 mg/dl and cardiac involvement were independent risk factors of SRC.

Disclosure of Interest: None declared

sclerosis (SSc) and it substantially contributes to prominent features of the disease such as digital ulcers (DUs). History of DUs (HDUs) has been shown to correlate with disease severity, new cardiovascular events, new DUs and overall poor prognosis [1]. Microvascular abnormalities as assessed by nailfold videocapillaroscopy (NVC) and power Doppler ultrasound (PDUS) have been demonstrated to be predictive of new DUs occurrence [2,3].

**Objectives:** To study the severity of microvascular involvement at the 3rd and 4th finger of the dominant hand in patients with SSc with or without HDUs as assessed by NVC and 22-MHz PDUS.

**Methods:** 100 SSc consecutive patients fulfilling the 2013 EULAR classification criteria were enrolled. PDUS was performed at the 3rd and 4th finger of the dominant hand after exclusion of ulnar artery occlusion (UAO). In case of UAO non-dominant hand was examined. Ultrasound investigation was performed with Esaote MyLab 70 XVG by means of linear array transducer (10–22 MHz). Power Doppler settings were standardized (Doppler frequency 14.3 MHz, Gain 55%, PRF 75 Hz). PDUS measurements included sagittal scan of nailbed and fingertip and capillarity were not significantly associated with the presence of HU. NVC and capillarity density were significantly different in the two groups as shown in the table below:

<table>
<thead>
<tr>
<th>Presence of HDUs</th>
<th>Absence of HDUs</th>
<th>Mean difference (95% CI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Capillarity density</td>
<td>3.023</td>
<td>3.884</td>
</tr>
<tr>
<td>RI</td>
<td>0.740</td>
<td>0.792</td>
</tr>
</tbody>
</table>

**Conclusions:** A significant lower RI of ulnar and radial proper digital arteries reported in patient with HDUs is novel. By contrast PDUS grading of nailfold and fingertip were not significantly different in patients with or without HDUs. The finding of a significant lower capillary number assessed by NVC in patients with HDUs is consistent with previous results [2]. Adequately longitudinal studies exploring the predictive value of PDUS parameters are required to fully ascertain its role in SSc.

**SAT0365 MUSCULOSKELETAL US AND MRI FINDINGS IN JUVENILE SCLERODERMA**

M. Tsinti, V. Dermentzoglou, E. Tsitsami. Pediatric Rheumatology Unit, 1st Department of Pediatrics, University of Athens, Children’s Hospital “Agia Sofia”, Athens, Greece.

**Background:** Musculoskeletal (MS) involvement and clinically evident arthritis occurs in up to 85% of patients with Juvenile Systemic or localized Scleroderma (JSc). It may be the first manifestation preceding even the onset of Raynaud or skin manifestations; patients presenting with arthritis, tenosynovitis or enthesis may suffer from Sc. On the other hand clinical examination often underestimates MS involvement in JSc. US and MRI can help distinguish arthritis with effusion from tendinosis, tendon-sheath synovitis and muscular fascia thickening and enhancement (black arrows), and contractures (thin white arrow) very characteristic of scleroderma, helped identify sclerodermatous musculoskeletal involvement in the absence of skin induration. Focal bone marrow edema depicted as high signal intensity in fluid sensitive sequences (curved arrow) was found in 2 cases; 1 with generalized morphea without apparent overlying skin sclerodermatous lesion, 1 with linear scleroderma with atrophic lesions in all overlying structures.

**Objectives:**

1. To describe the spectrum of MRI and US features in juvenile scleroderma with MS involvement.
2. To provide insight into disease extent and to allow for disease monitoring.
3. To emphasize the role of MRI and US in the diagnostic work-up and the management of juvenile scleroderma.

**Methods:**

1. We describe MRI and color Doppler MSUS findings of clinically affected children with arthritis and/or JSc. MSUS is a feasible and non-invasive method for follow-up of patients in whom disease activity is of interest.
2. MRI and US were performed with a 1.5 T Siemens Avanto scanner (Siemens AG, Erlangen, Germany) and a 28–8 MHz linear transducer with a 13–5 MHz dedicated probe (Aloka SSD–5000, Tokyo, Japan). MSUS and MRI in Juvenile scleroderma led to earlier definition of the diagnosis and assisted the evaluation of disease extension.

**Conclusions:** Musculoskeletal imaging features of juvenile scleroderma involving the skin, fascia, musculature and bones reflect pathomorphologic changes of this rare disorder and enable a complete assessment of the disease extent, including depth of infiltration and disease activity. In the described cases, implementation of MSUS and MRI in Juvenile scleroderma led to earlier definition of the diagnosis and assisted the evaluation of disease progression.

**SAT0366 SMOKING BEHAVIOUR AND THE PROGRESSION OF ORGAN MANIFESTATIONS IN SYSTEMIC SCLEROSIS: A LONGITUDINAL EUROPEAN SCLERODERMA TRIALS AND RESEARCH GROUP STUDY**

V.K. Jaeger, G. Valentini, E. Hachulla, L. Czirjak, E. Siegert, D. Diester, L.M. Bambara, E. Rosato, Y. Allainore, M. Matsuuchi, P. Airo, U. Walker on behalf of EUSTAR co-authors. 1University Hospital Basel, Basel, Switzerland; 2Second University of Naples, Naples, Italy; 3Université de Lille, Lille, France; 4University of Pécs, Pécs, Hungary; 5University Hospital Charité, Berlin, Germany; 6University Hospital Zurich, Zurich, Switzerland; 7University of Verona, Verona; 8Sapienza University of Rome, Rome, Italy; 9Paris Descartes University, Paris, France; 10University of Florence, Florence, Italy; 11Spedali Civili, Brescia, Italy

**Background:** Systemic sclerosis (SSc) is a rare, multisystem autoimmune disorder. It is characterised by generalized microangiopathy, in which hypoxia and oxidative stress have been implicated in its pathogenesis. Tobacco inhalation increases free radicals and strongly promotes vascular damage. So far, data available with regards to a role of tobacco exposure with SSc severity and progression are scarce.

**Objectives:** We aimed to assess the effects of smoking on the speed of worsening of organ manifestations, namely lung involvement (forced vital capacity, FVC; forced expiratory volume, FEV1/FVC ratio; diffusing capacity for carbon monoxide corrected for alveolar volume, DLCO/VA), skin involvement (modified Rodnan skin score; mRSS), and digital ulcers (DU) in the European scleroderma trials and research (EUSTAR) database.

**Methods:**

1. We included 9,885 SSc patients from the EUSTAR cohort with a follow-up visit 12±4 months after their baseline visit and available data on their smoking habits were included.
2. The associations of smoking behaviour (never smokers vs ex-smokers vs current smokers) with the disease manifestations at follow up were assessed after adjusting for potentially confounding covariates using multivariable linear or logistic regression analyses.

**Missing data were imputed using multiple imputations.**

**Results:** Of the 3,023 patients included (mean age 57 years, SD 13; 85% female), 66% stated that they never smoked, 23% were ex-smokers and 11% were current smokers. On average, ex-smokers had smoked for 19.5 years (SD 12) while current smokers smoked for 29.1 years (SD 13). Ex-smokers had smoked on average 17.3 pack-years (SD 20) and current smokers 29.3 pack-years (SD 36). The mean time since smoking cessation in ex-smokers was 15.8 years (SD 12). Smoking was associated with decreased FEV1/FVC ratio (p<0.001), increased mRSS (β=-2,8, p=0.001). Similarly, the DLCO/VA diminished faster in current smoking SSc patients than in never smokers (β=-2,8, p=0.001).
SAT0367 | CAPILLAROSCOPY PATTERNS AMONG SYSTEMIC SCLEROSIS PATIENTS WITH GASTROINTESTINAL INVOLVEMENT AND MALNUTRITION EVALUATED BY SELF-REPORTED QUESTIONNAIRES
Y. Yalcinkaya, Z. Erturk, A.U. Ünal, S. Kaymaz, P. Atagündüz, H. Direskeneli, N. İnanç. Department of Internal Medicine, Division of Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey

Background: Gastrointestinal system (GI) is commonly involved in systemic sclerosis (SSc) beginning after early stages of disease.

Objectives: We aimed to investigate capillaroscopic findings among the SSc patients with GI involvement and malnutrition.

Methods: GI involvement was evaluated by UCLA SCTG CIT 2.0 questionnaire (Khanna D.) (7 multi-item; reflux, distension, soilage, diarrhea, social functioning, emotional wellbeing and constipation) in SSc patients ACR/EULAR classification criteria (2013). To report the nutrition status of the patients “malnutrition universal screening tool (MUST)” (sum of the scores of body mass index, weight loss in last 3–6 months and acute disease effect) scores were calculated. Simultaneously, nail fold video-capillaroscopy (NVC) was performed in all patients to determine ealy, active late scleroderma patterns (Cutolo et al.).

Results: In 58 SSc patients (51 female); the mean age, mean duration of Raynaud’s, non-Raynaud symptom (year) and follow-up (month) were 46±13, 54±50, 10±9 and 7±7, respectively. Limited cutaneous form, positive ANA and anti-Scl70, telangiectases, dysphagia, digital ulcers, lung disease were found in 40 (71%), 10 (17%), 45 (78%), 39 (67%), 33 (57%), 23 (40%) in patients, respectively. Of the NVC patterns, early was found in 16 (28%), active was in 11 (19%), late was in 28 (48%) and normal in 3 (5%). Scores of disease activity, severity and GI were shown to be higher in patients with late pattern. NVC might be useful to predict the severity of GI and malnutrition and allow to direct the patients to required procedures earlier.

SAT0368 | THE PREVALENCE OF OSTEOMYELITIS IN INFECTED DIGITAL ULCERS IN SYSTEMIC SCLEROSIS PATIENTS
Y. Braun-Moscovici 1, Z. Keidar 2, M. Braun 3, D. Markovits 1, K. Toledano 1, V. Tavor 1, F. Sazz Bian 1, A. Roini 1, K. Dolnikov 1, A. Balbir-Gurman 1
1Rheumatology Department, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion; 2Department of Nuclear Medicine, Rambam Health Care Campus Rappaport Faculty of Medicine Technion, Haifa; 3Liver Institute, Belinson Hospital Petach-Tikva, Sacker School of Medicine, Tel Aviv University, Petach-Tikva, Israel

Background: Skin ulcers, particularly digital ulcers occur in at least 50% of systemic sclerosis (SSc) patients (pts) and cause significant morbidity. They are often complicated by local infection which can lead to contiguous osteomyelitis.

Objectives: Our aims were to evaluate the accuracy of clinical diagnosis of osteomyelitis and to assess the sensitivity and specificity of clinical parameters that may improve the precision of the clinical diagnosis.

Methods: We retrospectively analyzed the clinical data of consecutive SSc patients hospitalized for skin ulcers in a tertiary referral center for SSc. Our cohort is part of the EUSTAR cohort. The patients were evaluated by rheumatologists skilled in managing SSc skin lesions. All the patients with infected ulcers and suspected for contiguous involvement of underlying bone had bone scans. All the positive scans were followed with 99m-Technetium-Tc-labeled white blood cells (WBC) scintigraphy, in order to differentiate true osteomyelitis fromacro-osteodystasis or soft tissue infection. We collected demographic data, disease type, extent and severity, routine lab data (Glias, CRP, creat, L. Nat), laboratory protein, CRP, erythrocyte sedimentation rate (ESR), alkaline phosphatase (ALKP), albumin) and wound culture. Each hospitalization was considered a separate event. Statistical analysis: descriptive, student’s T test, Mann-Whitney test.

Results: During the years 2003–2016, 220 SSc pts with skin/digital ulcers were hospitalized in our department for ilomedin treatment (993 hospitalizations). Most of the pts were hospitalized several times due to recurrent ulcers. Ulcer scan was performed in 39 pts (59 admissions) with infected ulcers (32 females, mean (SD) age 48 (15), disease duration 9 (6.6) years, 25 with diffuse SSc, skin suspected cases, WBC scans confirmed osteomyelitis in 18 pts in 23 occasions. Osteomyelitis occurred twice in 5 pts in different locations. No statistically significant differences were found between the group with positive scans and the group with negative scans regarding demographic, clinical and lab data. 9 pts had 25 admissions for infected ulcers, osteomyelitis was confirmed in 75% or the patients with positive Tc bone scans.

Conclusions: The prevalence of osteomyelitis among our SSc pts admitted for digital ulcers was 10%. The prevalence of confirmed osteomyelitis by scintigraphy in clinically highly suspected cases was 39%. Even when contiguous osteomyelitis was suspected by highly skilled rheumatologists, bone scan ruled out the diagnosis in 61% of the cases, thus avoiding unnecessary prolonged antibiotic therapy. No clinical predictors to rule osteomyelitis in or out could be identified.

SAT0369 | HETEROGENEITY IN THE UNDERLYING PATHOGENESIS IN PATIENTS WITH CONNECTIVE TISSUE DISEASE-ASSOCIATED BORDERLINE MEAN PULMONARY ARTERIAL PRESSURE AND ITS DISTINCTIVE HEMODYNAMIC CHARACTERISTICS FROM THOSE WITH NORMAL PULMONARY ARTERIAL PRESSURE
Y. Yamasaki 1, Y. Asari 1, K. Tsuchida 1, K. Suzuki 2, Y.J. Akashi 2, T. Okazaki 2, S. Ozaki 3, H. Yamada 3, Y. Braun-Moscovici 1, Z. Keidar 2, M. Braun 3, D. Markovits 1, K. Toledano 1, V. Tavor 1, F. Sazz Bian 1, A. Roini 1, K. Dolnikov 1, A. Balbir-Gurman 1

Background: Borderline mean pulmonary artery pressure (PAP) (21–24 mmHg) may comprise a transition phase from normal pulmonary hemodynamic condition to pulmonary arterial hypertension (PAH), which is one of the fatal complications in connective tissue diseases (CTD) [1]. The accumulated evidence is not enough to conclude that treatment for PAH in this stage may be associated with improving clinical outcomes. On the other hand, CTD-associated PH is caused by various cardiopulmonary comorbidities. It is possible that borderline mean PAP, like overt PAH, is caused not only by pulmonary vasculopathy but also by cardiac and pulmonary complications [2].

Objectives: To clarify whether patients with borderline mean PAP associated with CTD have distinctive hemodynamic characteristics from those with normal mean PAP and its underlying pathogenesis is heterogeneous as those with manifest PAH.

Methods: We retrospectively investigated 76 CTD patients who underwent right heart catheterization from 2008 through 2016. Of the 76 patients, 25 (33%) and 16 (21%) had manifest PH and borderline mean PAP, respectively. The rest of the 35 patients had normal mean PAP. Systemic sclerosis was the most common
EVALUATIONS OF EXERTION DYSPNEA IN PATIENTS WITH BONE FRACTURE RISK ASSESSMENT IN PATIENTS WITH CLINICAL AND SEROLOGICAL ASSOCIATIONS OF Y. Nobuhara

Results: The values of tricuspid regurgitation pressure gradient (TRPG) were correlated with serum biomarkers in borderline patients with borderline mean PAP (31.1±7.8 mmHg) and normal mean PAP (28.3±6.9 mmHg) (P=0.1572) but its value became significantly higher in patients with borderline mean PAP (39.1±8.0 mmHg) than in those with normal mean PAP (32.8±7.4 mmHg) after exercise echocardiography (P=0.0391). Pulmonary arterial wedge pressure was significantly elevated in patients with borderline mean PAP (12.5±3.1 mmHg) compared with that in normal mean PAP (7±3 mmHg) (P=0.0001) and its value was comparable to those with overt PH, suggesting the heterogeneity on the cause of borderline mean PAP among CTD patients. The clinical course of 10 patients with borderline mean PAP was studied. Five were treated for precipi-capillaroscopic pattern and 2 for interstitial lung disease (ILD). Normalization of mean PAP was seen in 3/4 and 3/3 of the patients treated for precipi-capillaroscopic and postcapillary disease, respectively. Deterioration of TRPG was seen in one patient after receiving pulmonary vasodilators. One with severe ILD developed PH.

Conclusions: The pathogenesis of borderline mean PAP could be clearly distinguished from normal mean PAP, which was heterogeneous as that of manifest PH in CTD patients. Though the clinical course may be altered with appropriate therapeutic intervention, repeated assessment is needed.

SAT0371 EVALUATION OF EXERTION DYSPNEA IN PATIENTS WITH CONNECTIVE TISSUE DISEASE (CTD) BY CPET (CARDIOPULMONARY EXERCISE TESTING) FOR EARLY DETECTING ASSOCIATED PULMONARY HYPERTENSION (PAH)

Y. Nebuhara, Y. Kamei, Y. Fujikawa, T. Nakazawa. Rheumatology, Osaka sakesei nakatsu hospital, Osaka, Japan

Background: Patients with CTD often complain of exertion dyspnea, due to lung diseases, heart diseases, musculoskeletal disorders and/or PAH. Although imaging and physiological tests could reveal pathophysiology, some of them remain unknown. Especially PAH is rarely diagnosed in WHO functional class I or II, because pulmonary vasculopathy (PV) cannot be detected until two-thirds of pulmonary blood vessels deteriorated,1 with cardiac ultrasonography (UCG) or right heart catheterization (RHC) at rest. Pathophysiological considerations suggest that the haemodynamic/mechanical impairment in APH may be observed during exercise before the disease becomes evident at rest.2,3 We evaluated exertion dyspnea of unknown origin to find early PAH with CPET.

Objectives: We determined the PAH in patients who complained of exertion dyspnea and tried to detect early PV.

Methods: From June 13th in 2015 to October 28th in 2016, we performed CPET and evaluated their clinical state in 28 patients, 17–80 years old (mean 26.1+18.8 years), 5 mixed connective tissue disease (MCTD), 15 SSC, 3 SLE, 2 Sjogren’s syndrome, 3 dermatomyositis. We undertook UCG, pulmonary function testing (PFT), 6-minutes walk test, and nailfold capillaroscopy by Cuto’s method.4

Results: Twenty cases presented decreased peak VO2. VE/VCO2 ratio, which represented increased ventilation-perfusion mismatch, elevated in 12 cases. 8 cases, with decreased peak VO2 but normal VE/VCO2, were regarded that muscle weakness mainly induced exertion dyspnea, and advised exercise. Twelve cases with decreased peak VO2 and elevated VE/VCO2 were estimated to have APH or/and interstitial lung disease (ILD). Seven of them underwent RHC and 1 case was classified as PAH, and another 1 case as postcapillary PHT. A 34 years MCTD woman without ILD showed an active capillaroscopic pattern, her peak VO2 decreased (13.9±7.8 ml/kg/min.) and nadir VE/VCO2 elevated (39). Although her mean PAP was normal, we suspected she had early PV and administered PDE5 inhibitor to her and her dyspnea had gone soon and CPET parameters improved. CPET was also useful for early detections of therapeutic gains in APH. A SSC woman, diagnosed as APH by RHC, was performed CPET only 9 days after administration of PDE5 inhibitor. Her peak VO2 decreased (13.3±16.4 ml/kg/min.) and nadir VE/VCO2 decreased (43.4 to 38.9) promptly. Thirteen patients showed an early capillaroscopic pattern, 7 an active pattern and 3 a late pattern. Median values of minimum VE/VCO2 ratio significantly differed (p<0.05) in the three capillaroscopic groups, being progressively worse from early to late capillaroscopic pattern.

Conclusions: CPET was useful for early diagnosis in every patient safely. Although more research is required, CPET may provide valuable information notably in patients with PAH.

SAT0372 CLINICAL AND SEROLOGICAL ASSOCIATIONS OF ANTI-BICD2 AUTOANTIBODIES TO BICD2 AS A NOVEL MARKER FOR SYSTEMIC SCLEROSIS

M. Mahler 1, C. Bentov 1, J. Milo 1, M. Hudson 2, H.-D. Zucht 3, P. Budde 4, D. Wirtz 4, J. Schulte-Pelkmann 4, M. Choi 4, M. Fritzier 4, 1Research and Development, Inova Diagnostics, San Diego, CA, United States; 2Department of Medicine, McGill University, Quebec, Canada; 3Protogen, Dortmund, Germany; 4Cumming School of Medicine, University of Calgary, Calgary, Canada

Background: Anti-nuclear antibodies (ANA), which are present in approximately 90% of systemic sclerosis (SSc) sera, play an important role in establishing the diagnosis and predicting prognosis of SSc. Recently, a novel autoantibody has been described in SSc patients targeting Cytoskeleton-Like Bicaudal D Protein Homolog 2 (BICD2).

Objectives: The aim of this study was to assess the prevalence and titers of anti-BICD2 antibodies in SSc and controls and to study the clinical associations of this new antibody.

Methods: A total of 502 samples from SSc patients enrolled in the Canadian Scleroderma Research Group (CSRG) cohort were included in this study. Clinical associations were assessed either as anti-BICD2 antibody positivity
with and without other autoantibodies present using 451 SSc patients with complete dataset. Autoantibodies to several scleroderma-related autoantibodies were detected using commercial or research use only kits (Inova Diagnostics, San Diego, USA). P-values below 0.05 were considered significant. 

**Results:** The sensitivity and specificity of anti-BICD2 antibodies were determined as 22.1% and 99.0%, respectively. Receiver operating characteristic (ROC) analysis showed an area under the curve of 0.79 (95% CI 0.75–0.84). The likelihood (LR) and odds ratios (OR) were 17.7 (LR+) and 0.8 (LR-) and 20.4 (OR). The prevalence of all these autoantibodies was equally distributed between limited diffuse form of SSc (22.8% and 24.0%). When SSc patients without the classification criteria markers anti-Scl-70, anti-Centromere and anti-RNA Pol III negative (n=184) were compared with controls, similar performance was obtained as seen classification criteria markers anti-Scl-70, anti-Centromere and anti-RNA Pol III (n=184) were compared with controls, similar performance was obtained as seen.

Several statistically relevant clinical associations were found for anti-BICD2 as summarized in table 2 below.

**Conclusions:** Our data confirm the presence of anti-BICD2 antibodies in SSc patients that may help to differentiate SSc from other systemic autoimmune rheumatic diseases and to stratify SSc patients into more defined subsets of the disease.

SAT0373 EVALUATION OF AMERICAN COLLEGE OF RHEUMATOLOGY PROVISIONAL COMPOSITE RESPONSE (CRiSS) INDEX IN THE FASCIINATE TRIAL

D. Khanna1, V. Berrocal1, C. Denton2, A. Jaheris3, H. Spotwood4, C. Lin5, J. Siegel6, D. Menchaca, Guadalajara, Mexico; 13Rheumatology, Oslo University Hospital, Oslo, Norway; 14Vascular Medicine, Swedish University Hospital, Göteborg, Sweden; 15Rheumatology, University Hospital of Birmingham, Birmingham, United Kingdom; 16Department of Medicine, University of British Columbia, Vancouver, Canada; 17Department of Medicine, Mayo Clinic, Rochester, United States; 18Clinical Immunology and Rheumatology Unit, University Hospital of Trieste, Trieste, Italy; 19Department of Internal Medicine, University of Coimbra, Coimbra, Portugal; 20Department of Medicine, University of Oxford, Oxford, United Kingdom; 21Department of Rheumatology, University of Southern California, Los Angeles, California; 22Rheumatology, University of Gothenburg, Gothenburg, Sweden; 23Rheumatology, University of Lübeck, Lübeck, Germany; 24Rheumatology, University of Athens, Athens, Greece; 25Rheumatology, Fondazione IRCCS Istituto Auxologico Italiano, Milan, Italy; 26Rheumatology, Federal University of Pelotas, Pelotas, Brazil.

**Background:** Treatment with tocilizumab (TCZ) in early systemic sclerosis (SSc; FaSScinate trial) resulted in consistent, but not statistically significant, improvements in skin sclerosis (mRSS) at wks 24 and 48. CRiSS index has been proposed as a composite index for trials in SSc2. CRiSS is a 2-step process that assigns a probability of improvement for each subject ranging from 0.0 [no improvement] to 1.0 [marked improvement]. Step 1 assesses clinically meaningful disease activity in cardio-pulmonary-renal involvement and assigns a probability of 0.0. For remaining subjects, 5 variables are used to calculate probability of improvement. These are: FVC%, mRSS, patient (PT GA) and physician globals (MD GA), and HAQ-DI.

**Objectives:** To assess the performance of CRiSS index in the FaSScinate trial.

**Methods:** In FaSScinate, pts <18 y with active SSc were randomized 1:1 to TCZ or placebo (PBO) for 48 wks. Step 1 CRiSS was captured using review of serious adverse event data. Non-parametric Wilcoxon test was used to assess significant differences between the CRiSS scores in both arms. Analyses were carried out for subjects who had complete data at baseline and 24 weeks and at baseline and 48 weeks.

**Results:** 87 pts (43 TCZ, 44 PBO) were enrolled. Baseline characteristics were similar between arms. 4 subjects in the PBO group and none in TCZ met the predefined definition of worsening in Step 1 and were given a score of 0. For remaining subjects, we calculated probability score for each subject. Using CRiSS as a continuous measure, the median score was statistically significant favoring TCZ at wk 48.

**Conclusions:** In this post-hoc analysis, CRiSS index was able to discriminate TCZ from PBO, supporting its validity in an independent cohort.

SAT0375 | METABOLOMICS OF SERA REVEALS POTENTIAL BIOMARKERS OF SKIN FIBROSIS IN SYSTEMIC SCLEROSIS THAT CORRELATE WITH PRO-FIBROTIC GENE EXPRESSION IN SKIN BIOPSIES
1 Clinical Immunology, Sanjay Gandhi Post Graduate Institute of Medical Sciences; 2Centre for Biomedical Research, Lucknow, India

Background: There is an unmet need for biomarkers in Systemic Sclerosis (SSc). Despite its shortcomings, the modiﬁed Rodnan skin score (mRSS) has remained the standard disease assessment tool for SSc. Expression of certain genes, cartilage oligomeric matrix protein (COMP), thrombospondin-1 (THS1), interleukin-1α (IL1α) and collagen 1 (COL1A1), and, more recently, Tenascin-C (TNSC) have been shown to correlate with skin ﬁbrosis. However, assessment of the expression of these genes requires a skin biopsy. Hence, we used an open-ended approach to identify a serum-based biomarker of SSc.

Objectives: To identify small molecules in serum that correlate with mRSS and proﬁbrotic genes that are upregulated in skin of SSc patients.

Methods: We obtained serum and skin biopsies from 25 consenting adult patients with SSc and serum from 25 age- and sex-similar controls. mRNA levels of ﬁve genes: COMP, THS1, IFI44, SIG1, and TNSC were estimated as fold-changes relative to glyceraldehyde 3-phosphate dehydrogenase (GAPDH). Glyceroldehyde 3-phosphate dehydrogenase (GAPDH), a housekeeping gene. H^1NMR (Nuclear Magnetic Resonance) based metabolomics studies were performed on the sera using standard protocols. Principal component analysis (PCoA) and Partial Least Squares Discriminant Analysis (PLSDA) were used to delineate metabolites that were different between patients and healthy controls. The signiﬁcance of associations (α) of the metabolites with mRSS and the fold-expression of the ﬁve pro-fibrotic genes were estimated.

Results: H^1NMR based metabolomics identiﬁed 126 peaks that were different between patients and controls. Out of these, the levels of glycine had the best correlation with pro-fibrotic gene expression (p=0.5, p<0.05 for IFI44; p=0.04, p<0.05 for SIG1).

Conclusions: Glycine was shown to have a signiﬁcant correlation with proﬁbrotic gene expression in serum samples from SSc patients, as well as with the mRSS score. This suggests that serum glycine levels may be useful as a potential biomarker for skin ﬁbrosis in SSc.

SAT0376 | ANTI-NT5C1A AUTOANTIBODIES ARE FREQUENT IN JUVENILE MYOSITIS AND ASSOCIATED WITH INCREASED ILLNESS SEVERITY
1Muscle Disease Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS)/National Institutes of Health (NIH); 2Environmental Autoimmunity Group, National Institute of Environmental Health Sciences (NIEHS)/National Institutes of Health (NIH); 3Department of Neurology, University of Oklahoma Health Sciences Center, Oklahoma City, United States

Background: Autoantibodies (Abs) against 5'-nucleotidase, Cytosolic 1A (NT5C1A) have been portrayed as a potential diagnostic aide in distinguishing inclusion body myositis (IBM) and polymyositis (PM) in adults. However, 46% of dermatomyositis (DM) patients also have Abs to NT5C1A.

Objectives: The prevalence and clinical features of anti-NT5C1A Abs in juvenile-onset myositis (IIM) patients is unknown, so we sought to examine this in a large cohort.

Methods: We screened 384 juvenile IIM patients meeting probable or deﬁnite Bohan and Peter criteria for anti-NT5C1A Abs by immunoblotting for the full length NT5C1A protein in transfected and non-transfected lysates. Clinical characteristics and HLA typing were compared between juvenile IIM patients who were anti-NT5C1A positive (Ab+) and those who were anti-NT5C1A negative (Ab-).

Results: In this cohort, 29% (103) of juvenile DM, 15% (3) of juvenile PM, and 37% (15) of juvenile overlap myositis patients tested positive for anti-NT5C1A Abs. Compared with anti-NT5C1A Ab- patients, anti-NT5C1A Ab+ juvenile IIM patients showed a similar distribution of race, gender, and association with myositis-specific Abs. However, NT5C1A Ab was associated with anti-p155/140 Abs (p=0.05). The only observed clinical difference was an increased frequency of V- or shaw-sign rashes ever present (44% vs. 26%, p=0.002). Disease severity was increased in anti-NT5C1A Ab+ patients, based on more frequent hospitalizations (p<0.001), more medications used (p<0.001), and more treatment trials per year (p<0.001). Additionally, pulse steroids (p<0.001) and intravenous immunoglobulin therapy (p=0.008) were prescribed more frequently in anti-NT5C1A Ab+ than Ab- patients. The HLA alleles DRB1*07 (20% vs. 9%, p<0.05) and DQA1*0201 (21% vs. 7%, p<0.01) were present more frequently in anti-NT5C1A Ab- compared to Ab+ patients.

Conclusions: Anti-NT5C1A Abs are commonly present in juvenile DM and juvenile overlap myositis patients, and are present more frequently in patients with anti-p155/140 Abs, but are also seen in association with other myositis specific Abs. Consistent with data in adult IIM patients, anti-NT5C1A Abs have few distinguishing clinical features in juvenile myositis, but are associated with increased illness severity marked by increased hospitalizations and receipt of additional therapy.

**SAT0377 RELIABILITY OF A NEW AUTOMATED SYSTEM FOR ABSOLUTE CAPILLARY NUMBER COUNTING (AUTOCAPI) ON SYSTEMIC SCLEROSIS NAILFOLD VIDEOCAPILLAROSCOPIC IMAGES**

M. Cutolo 1, K. Melsen 2, A.C. Trombetta 1, C. Pizzorni 1, E. Deschepper 3, A. Sulli 1, V. Smith 4.
1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy; 2Department of Internal Medicine, Faculty of Medicine and Health Sciences; 3Department of Public Health, Biostatistics Unit; 4Department of Internal Medicine, Faculty of Medicine and Health Sciences; Department of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium

**Background:** Nailfold capillary density is a useful measure in systemic sclerosis (SSc) classification and evaluation. Its manual detection may be time-consuming, hampering its use in largescale investigations. We evaluated a new automated system to assess the absolute nailfold capillary number.

**Objectives:** To attest the instrumental reliability of automatic counting in SSc patients using nailfold video capillaroscopy (NVC) images.

**Methods:** 75 NVC random images, from SSc patients, were blindly analyzed by four raters (2 less and 2 more experienced; raters: 1,2,3,4) from two European centers. Each rater was asked to define the region of interest (ROI) on the NVC image in order to manually count the number of capillaries, according to the following instructions: upper bound placed on top of the longest capillary head and lower bound placed on half of the length of that longest capillary (figure 1); if the common branch of an abnormal shape (neangiogenesis) is in ROI it is counted as being one; if the common branch is out of ROI it is counted as separate capillaries; if the capillary is on the edge of the vertical line of ROI, it is only counted when the head of the capillary is half in ROI; if the capillary head is on the edge of lower bound, it is counted as soon as the “head” part is in the ROI; all “heads” in the ROI are counted (not only distal row). The dedicated automated system (AUTOCAPI-ds medica, IT) also counted the number of capillaries in the same ROI (figure 1). Reliability between the manual and automatic counting was investigated per rater through intraclass correlation coefficient (ICC) and reported with 95% confidence interval (CI). External validation was obtained by multi-rating tests and laboratory tests (antibody profile, RF, CRP, Creatine phosphokinase) and disease activity (by Valentini index) were done.

**Results:** By multiple logistic regression analysis taking into account all clinical and laboratory variable, we found that MRI bone marrow oedema of the hand was associated and probability for the occurrence of MRI bone marrow oedema was higher for the SSc pts with digital ulcers (OR=6.081;95%IP:1.295–28.550; p<0.05), HAQ<1.5 (OR=6.448; 95%IP:1.714–24.257; p<0.01) and active disease (OR=3.377; 95%IP:1.175–9.706; p<0.05).

**SAT0379 NAILFOLD CAPILLAROSCOPY FINDINGS IN PATIENTS WITH INFLAMMATORY MYOPATHY AND/OR SPECIFIC OR ASSOCIATED ANTIBODIES**

A.M. Milian Arciniegas 1, M.A. Martinez 2, A. Baucells 2, C. Juarez 2, L. Martinez 2, H.S. Park 1, B. Magallares 1, A. Laiz 1, P. Moya 1, J.M. Llobet 1, C. DiazTorres 1, I. Castellvi 1.
1Rheumatology; 2Immunology, Hospital de Sant Pau, Barcelona, Spain

**Background:** Nailfold videocapillaroscopy (NVC) is an easy, fast and non-aggressive tool, useful in the study of autoimmune diseases. The use of NVC in inflammatory myopathy (IM) is not clearly established.

**Objectives:** 1. To evaluate capillaroscopic findings in patients with IM and/or with presence of specific or associated antibodies with this pathology. 2. To analyze possible relationships with clinical characteristics of the patients.

**Methods:** Retrospective review of a cohort of patients with IM and/or with presence of specific or associated antibodies, followed in Rheumatology Unit of a University Hospital. Patients underwent a NVC at 200x, being evaluated for the presence of: loss of capillary density, enlarged and giant capillaries, ramified capillaries, haemorrhages, thrombosis, tortuous capillaries, avascular areas, disorganization of capillary architecture and subpapilar venous plexus. The following variables were also collected: sex, age, active smoking, muscle weakness, CK elevation at diagnosis, compatible muscle EMG and biopsy, skin findings, cardiac disease, dysphagia, lung disease, Raynaud’s phenomenon, cancer history and overlap syndromes. For the comparison of qualitative and/or quantitative variables Fisher’s exact Test or T-test was performed when necessary.

**Results:** Twenty patients were included at least one NVC (45% with 2), 65% female, with a mean age of 58 years ±11.6 were included. The characteristics of the patients are detailed in table 1.

- 65% of patients had some capillaroscopic alteration. The findings in NVC-1 and NVC-2 were: loss of capillary density 30% and 33%, tortuous capillaries 90% and 89%, enlarged capillaries 40% and 45.6%, giant capillaries 65% and 66.7% (giant 30% and 30%), ramifications 40% and 55.6%, disorganization 10% and 33%, haemorrhages 25% and 44%, thrombosis 20% and 0%, avascular areas 25% and 22%, visible venous plexus 40% and 55%.

**Disclosures of Interest:** None declared

density (p<0.02) and haemorrhages (p<0.01) in the initial NVC, as well as the presence of ramifications in the control NVC (p<0.05). It was observed that patients with normal capillary organization presented better value of FVC (p<0.01), TLC (p<0.01), and lower FEV1/FVC ratio (p<0.02), the latter finding also found in control NVC (p<0.03). As additional data, we found that patients with anti-Ku+ presented better values of FVC (p<0.04) and TLC (p<0.05), but although they all had normal capillary organization, the association of this antibody with NVC was not statistically significant. We also did not find a statistically significant relationship between the alterations in NVC and the presence of Raynaud’s phenomenon, the other clinical variables, cancer history and the presence of overlap syndromes.

Conclusions: Patients with capillary disorganization in NVC showed worse values of FVC, TLC and FEV1/FVC. We found a statistically significant association between esophageal disease and haemorrhages, loss of capillary density and ramifications. Prospective studies with larger sample sizes are required to define the usefulness of NVC in the diagnosis, prognosis and follow-up of these patients.

SAT0380 | CLASSIFICATION, CATEGORISATION AND ESSENTIAL ITEMS FOR DIGITAL ULCER (DU) EVALUATION IN SYSTEMIC SCLEROSIS (SSC): A DESSCIPHER/EUSTAR SURVEY

J. Blagićević1,2,3, L. Cometi1, G. Abignano3,4, S. Guiducci1, S. Bellando-Randone1, D. Hüscher2, J. Aveuca3, L. Czirjak4, C. Denton8, O. Distler5, M. Ferri9,10, V.K. Jaeger11, V. Lóránd12, B. Maurer13, S. Nihytanainen6, G. Riemekasten17, L. Siegert13, G. Valentini14, S. Vettori14, U. Walker15, U. Müller-Ladner10, Y. Allanore16, F. Del Galdo3,4, M. Matucci-Cerinic1 on behalf of DeSScipher and 82/194 EUSTAR centres (42.3%) completed the usefullness of the existing DU classification (DU due to DPS, to loss of tissue, to mRSS), DU due to episodic (p<0.01), recurrent (p<0.001) and chronic (p<0.005). A positive correlation was observed in SSC patients between DT and the presence of overlap syndromes.

Conclusions: DU in episodic, recurrent and chronic.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.6815

SAT0381 | CORRELATION BETWEEN THREE DIFFERENT METHODS TO ASSESS DERMAL THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS WITH DIFFERENT PATTERNS OF NAILFOLD MICROANGIOPATHY

The aim of this study was to identify possible correlations between US, mRSS and PST to evaluate DT in SSC patients with different patterns of nailfold microangiopathy. This study demonstrates a relationship between different methods to evaluated cutaneous involvement in SSC patients (6). Several studies have reported the capability of high frequency skin ultrasound (US) to reflect the overall severity of the skin damage in SSC patients (4–5). The plicometer skin test (PST) is another method to evaluated cutaneous involvement in SSC patients (6).

Objectives: The aim of this study was to identify possible correlations between US, mRSS and PST to evaluate DT in SSC patients with different patterns of nailfold microangiopathy.

Methods: Sixty-three SSC patients (mean age 64±11SD years, mean disease duration 7±6 years, 43 lSceSSc and 20 dcSSc) and 63 sex and age matched healthy subjects were enrolled after written informed consent. All subjects were assessed by mRSS, US and PST to evaluate the DT in the seventeen skin areas of the body usually evaluated by mRSS (zygoma, fingers, hands, dorsum of hands, forearms, arms, chest, abdomen, thighs, legs, feet) (1–6). Nailfold videocapillaroscopy (NVC) was used to assess the proper pattern of microangiopathy and to calculate the microangiopathy evolution score (MES) (7–8). Statistical evaluation was performed by non-parametric tests.

Results: As expected, the group of SSC patients had a statistically significant higher DT, as evaluated by the three methods, at level of all areas when compared to the control group (p<0.0001). All methods demonstrated a progressively higher DT in patients with "Late" vs. "Active" vs. "Early" pattern of nailfold microangiopathy (p<0.005), and a positive correlation was observed with MES (r=0.71 p<0.0001). A positive correlation was observed in SSC patients between the method to evaluate DT (PST vs mRSS r=0.98, p<0.0001; PST vs US r=0.53, p<0.0001; US vs mRSS r=0.53, p<0.0001).

Conclusions: This study demonstrates a relationship between different methods to assess DT (US, mRSS and PST) in SSC patients and a relationship between skin damage and microangiopathy impairment.

SAT0382 | PROSPECTIVE STUDY TO ASSESS THE VALUE OF THE SKIN THICKNESS ASSESSMENTS IN SSC PATIENTS WITH PROGRESSIVE DIGITAL ULCE
Changes in volumetric bone mineral density and bone microarchitecture in patients with ankylosing spondylitis: A five-year prospective study using HRpQCT

Background: Studies have demonstrated increased prevalence of osteoporosis in patients with ankylosing spondylitis (AS) in the hip and lumbar spine assessed by conventional DXA but the peripheral skeleton is less studied. The peripheral skeleton can be studied in detail by high-resolution peripheral quantitative computed tomography (HRpQCT) demonstrating data of the volumetric bone mineral density (vBMD) and bone microarchitecture. We have previously shown that patients with AS from Western Sweden had lower vBMD measured by HRpQCT in radius and tibia compared with healthy controls [1]. No prospective study in this matter has been published in AS.

Objectives: To investigate changes over 5 years in the peripheral vBMD and microarchitecture in patients with AS.

Methods: HRpQCT of ultra-distal radius and tibia was performed in male AS-patients (NY criteria) at baseline and at the five-year follow-up. The patients were also assessed with BASDAI and BASFI. The images had common regions.

Results: Of the 69 patients included at baseline 57 (83%) patients were re-examined at the five-year follow-up. Baseline characteristics of the 57 patients (median [IQR]: age 48 (35 to 61) years, symptom duration 21 (11 to 34) years, ESR 10 (5 to 17) mm/h, CRP 3 (1 to 7), ASDASCRP 1.8 (1.3 to 2.8) and BASDAI 2.3 (1 to 4.2). 23% used TNF-inhibitors, 75% used NSAIDs and 2% bisphosphonates. All measurements at baseline had good quality and matched images had common regions >80%. The radius of 12 patients had to be excluded due to insufficient quality. At tibia, the total, cortical and trabecular vBMD decreased significantly. In the microarchitecture an increase in the trabecular separation was seen (Table). Changes in vBMD were negatively and significantly correlated; Spearman’s correlation coefficient between -0.3 and -0.4, to Δ-values (difference between follow-up and baseline) for ESR, CRP (cortical vBMD), ASDASCRP (total vBMD and cortical vBMD) and BASDAI (total vBMD). At radius, no significant change in vBMD was observed; however, less power for analyses of radius. An increase was seen in the cortical thickness and the trabecular number while the trabecular thickness decreased (Table). Changes in cortical vBMD was negatively and significantly correlated, r = -0.3, to Δ-ASDASCRP.

Table.

Conclusions: Over five years, this group of male patients with AS decreased in the vBMD of tibia, both trabecular and cortical. Even though there were alterations in the microarchitecture, no significant change in vBMD of radius was seen. Increases in inflammatory markers and disease activity had a negative impact on the cortical vBMD. The difference in the development of vBMD and microarchitecture in loaded and unloaded skeleton as well as factors associated with the changes needs to be further investigated.

OBJECTIVES: 1) To assess the future risk of newly recorded MI and CVA events among incident cases of AS compared to non-AS controls from the general population by utilizing physician billing, medication, and hospitalization data that covers the entire province of British Columbia (BC), Canada.

METHODS: Our data includes all outpatient visits and hospitalizations (1990–2012) and all residents of BC (1996–2012) for all BC residents. We conducted a retrospective matched cohort study of all patients >18 years of age satisfying the following criteria: 1) two ICD-9 or 10 codes (720.0 or M45) for AS at least two months apart and within a 2-year period by any physician or hospitalization; 2) all AS cases had at least a 7-year run-in period before the 1st ICD code for AS in order to consider the case as incident. Each AS patient was matched with up to 10 controls by birth year, sex, and entry cohort time. The outcomes were a newly recorded MI (ICD-9-CM: 410 or ICD-10-CM: I21) or CVA (ICD-9 codes: 433–434, ICD-10 codes: I63–I68) event from hospital or death certificates. We estimated incidence rate and rate ratios (with 95% CI) for each ICD code using a Cox proportional hazard model.

RESULTS: 7,107 adult patients (48.7% female, mean age of 45.8 yrs), 7,148 and 7,107 were free of previous CVA/MI, respectively. The age-, sex-, and entry-time-matched RR for CVA was 1.60 (95% CI, 1.25–2.03) and MI was 1.52 (95% CI, 1.24–1.85). When adjusted for cardiovascular risk factors (obesity, angina, COPD, hospitalizations in year before index date, Charlson’s comorbidity index, diabetes, cardiovascular medication, HRT, contraceptives, fibrates, statins, NSAIDs, and Cox-2 inhibitors), the estimated RR was 1.34 (1.04–1.73) for CVA and 1.21 (0.98–1.49) for MI.

Table 1. Relative risk of incident CVA and MI according to AS status

Conclusions: This large population-based study demonstrates an increased risk of CVA, but not for MI. These findings support that increased monitoring for this potentially fatal outcome and its modifiable risk factors is warranted for AS patients.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.8544
**RESULTS:**
The final list was produced. Support the recommendations, items without sufficient basis were removed, and for the management of comorbidity launched by the same panel, a list of Not to do recommendations was issued. A multidisciplinary group was selected [10 rheumatologists, 1 internist, 11 cardiologists, 11 gastroenterologists, and 11 pneumologists].

**Objectives:**
To recognize what prescriptions, risk assessments, or preventive aids of the GECOAx project, the importance of avoiding certain situations was highlighted.

**Methods:**
A summary list of Not to do recommendations (Table 1) was issued. A multidisciplinary group was selected [10 rheumatologists, 1 internist, 11 cardiologists, 11 gastroenterologists, and 11 pneumologists].

**Results:**
We recruited 183 patients diagnosed with IB (57.4% women), 117 with CD and 66 with UC, with a mean age at diagnosis of 37.0±14.0 years old; 29 of them have axial affection and 51 peripheral affection, and simultaneously in 22 cases. We observed no statistical differences in axial or peripheral affection according to the IBD diagnosis. 79 cases were on biological therapy, and these treatments were conducted by Rheumatology in 44% of cases and by Digestive Department in the 66% of cases. We observed that patients with axial affection present higher probability that the treatment has been conducted by Rheumatology (P<0.007), and broken down axial affection AS diagnosis had the most probability to be conducted by Rheumatology (n=36 P=0.019). Related to peripheral manifestations, uveitis diagnosis had the most probability to be conducted by Rheumatology (n=14 P=0.037).

**Conclusions:**
In our patient series with IB and musculoskeletal manifestations, the most common were peripheral affection. Among patients with IB and axial and/or peripheral manifestation, 44% were conducted by Rheumatology, and are cases with axial predominance, where IBT treatment does not improve musculoskeletal disease and a primary spondyloarthropathy treatment is needed.

**Disclosure of Interest:**
None declared.

Dalmàs 1, M.D. Martín-Arranz 1,2.

**Background:**
Crohn’s disease (CD) and ulcerative colitis (UC) are the main entities of inflammatory bowel disease (IBD). Both present extraintestinal manifestations that do not always depend on the IBD activity. The most common manifestations involve the musculoskeletal system and they are included in the seronegative spondyloarthropathy group. If there is active or known IBD, treatment of this is priority because it usually improves joint disease. However, joint disease can also have an independent course of the intestinal manifestations as in patients with IBD and anklyosing spondylitis (AS).

**Objectives:**
To analyze the prevalence of extraintestinal manifestations in IBD patients and treatment provided.

**Methods:**
Retrospective observational analysis of IBD patients that have been remitted to the rheumatology department of HUP La Fe with musculoskeletal manifestations. Demographic, clinical and treatment data of patient were collected. Biostatistical analysis with R (3.3.2) was performed.

**Results:**
We recruited 183 patients diagnosed with IB (57.4% women), 117 with CD and 66 with UC, with a mean age at diagnosis of 37.0±14.0 years old; 29 of them have axial affection and 51 peripheral affection, and simultaneously in 22 cases. We observed no statistical differences in axial or peripheral affection according to the IBD diagnosis. 79 cases were on biological therapy, and these treatments were conducted by Rheumatology in 44% of cases and by Digestive Department in the 66% of cases. We observed that patients with axial affection present higher probability that the treatment has been conducted by Rheumatology (P<0.007), and broken down axial affection AS diagnosis had the most probability to be conducted by Rheumatology (n=36 P=0.019). Related to peripheral manifestations, uveitis diagnosis had the most probability to be conducted by Rheumatology (n=14 P=0.037).

**Conclusions:**
In our patient series with IB and musculoskeletal manifestations, the most common were peripheral affection. Among patients with IB and axial and/or peripheral manifestation, 44% were conducted by Rheumatology, and are cases with axial predominance, where IBD treatment does not improve musculoskeletal disease and a primary spondyloarthropathy treatment is needed.

Diffusion Weighted Imaging (DWI) is a new Magnetic Resonance Imaging (MRI) sequence proposed for spondyloarthritis (SpA) diagnosis. Whether it is more useful than the traditional short tau inversion recovery (STIR) sequence in disease diagnosis had not been evaluated.

Objectives: By comparing with traditional STIR sequence in a group of back pain patients newly referred to rheumatology clinics, we evaluated the usefulness of DWI in SpA diagnosis at different stages.

Methods: All new patients referred to the rheumatology clinics with persistant back pain were recruited. DWI and STIR MRI were performed. Conventional radiographs of the pelvis were assessed according to the modified New York criteria for ankylosing spondylitis. Bone marrow edema (BME) and active sacroiliitis according to the ASAS definition were evaluated in STIR and DWI by two independent observers.

Results: One hundred and thirty-three patients were recruited. Ninety patients (67.7%) had a clinical diagnosis of SpA. Average back pain duration was 8.5±8.9 years. The presence of Human Leukocyte Antigen (HLA) B27 was found in 42.9% of the study population. Inter-observer correlations were excellent (STIR 95.4%, p<0.0001; DWI 69.5%, p<0.0001). DWI was found to be comparable to STIR in disease diagnosis (sensitivity DWI 34.1% vs STIR 34.3%; specificity DWI 85% vs STIR 93.8%) and when applied to the Assessment of SpondyloArthritis international Society (ASAS) criteria for axial SpA (sensitivity DWI 78.9% vs 76.7%; specificity DWI 95.6% vs 78.9%). DWI is better than STIR in non-radiographic axial SpA group (sensitivity DWI 37.8% vs STIR 33.8%; specificity DWI 85.3% vs STIR 95.6%). In the group with disease duration less than 3 years, sensitivity DWI 78.9% vs STIR 63.6% (p<0.001) was better compared to longer than 3 years. When applied to the Assessment of SpondyloArthritis in Cardiovascular Disease (ASCO) criteria for axial SpA, patients with lower disease activity scores tended to experience poorer well-being and quality of life. Although both groups represent different aspects of the same disease, they respond similarly to treatment.

The diagnostic accuracy of existing grading criteria of sacroiliac joint CT in ankylosing spondylitis

D Gao, K Li, Y Wang, J Zhu, J Zhang, F Huang, Rheumatology, Chinese PLA General Hospital, Beijing, China

Background: Imaging modalities are essential for the diagnosis of ankylosing spondylitis (AS) due to the absence of specific clinical manifestations. Sacroiliac Joint (SIJ) CT has been used to identify sacroiliac for decades with a higher diagnostic accuracy than radiography in detecting structural changes, and not reducing the specificity like MRI. However, no well-accepted grading system for SIJ CT existed.

Objectives: We evaluated the reliability of 3 grading criteria of sacroiliac CT in SIJ and compared them with the SARA clinical activity score of AS patients.

Methods: In the 6 months of the study, CT scans were sent to a radiology center for grading. Three radiologists independently graded the CT scans. Internal consistency reliability analysis was performed using reliability statistics of the unweighted average kappa.

Results: A total of 2714 patients had received CT scanning for any reasons with complete SIJ structures displaying between June 2012 and December 2015 were included. The CT scans were read by 2 rheumatologists together who had received the same training in radiology. Patients with sacroiliitis were selected and bilateral SIJs of each patient were evaluated separately by the 1984 modified New York (mNY) criteria, the criteria proposed by Lee (Lee criteria) and the criteria from Innsbruck workshop report (Innsbruck criteria) respectively. The grading differences among these criteria were analyzed.

Lumbar flexion-relaxation phenomenon in patients with axial spondyloarthritis

C Aranda-Valera1, J.L. Garrido-Castro2, A.M. Galisteo1, J. Peña-Amaro1, C. González-Nava3, F. Font-Ugalde2, E. Collantes-Estevez1, University of Córdoba; 1Maimonides Institute for Biomedical Research of Córdoba, Cordoba, Spain

Background: Surface electromyography (sEMG) has been used in several studies to assess muscle activity in patients with low back pain (LBP). It has also been analyzed the lumbar flexion-relaxation phenomenon (FRP) defined by reduced erector spinae muscles (ES) muscle myoelectric activity during full trunk flexion in healthy individuals. FRP is observed through the flexion relaxation ratio (FRR). In LBP patients, this relaxation, compared to the peak reached at the flexion phase, is smaller and even non-existent. There are very few studies that analyze this effect in patients with Axial Spondyloarthritis (axSpA).

Objectives: To evaluate muscular activity at the erector spinae muscles using sEMG in patients with axSpA before and after FRP.

Methods: 39 subjects were included: 25 patients with axSpA (49.3±5.6 years, 75% men) and 14 healthy subjects (46.7±8.7 years, 71% men) as control group. Demographic data, conventional metrology, advanced metrology using motion capture (UCOTrack) and PRO questionnaires were collected. Electrodes were placed on left and right side, at L4-L5 level and separated 2cm from the spinous process, on the ES. Muscle activity values were obtained in 4 phases (standing, flexion, relaxation and extension). With the values of flexion and relaxation, the FRR index and its inverse 1/FRR were calculated. Student t tests were used for differences between groups.

Results: There were no significant differences between the right and left sides of the measurements at ES, so mean values were considered for the analysis. There were also no significant differences in age and gender between the control group and patients. Results obtained in each of the phases are shown in the graph. The FRP appeared in healthy individuals, but not in patients, as show the FRP line in the graph: in axSpA, sEMG values at the Flexion phase are above values at the stand phase, and in control group is the opposite, so there is a truely relaxation. There were significant differences between patients and control group in flexion, relaxation, and in the FRR and 1/FRR ratios.

Conclusions: In our study, there were differences between healthy and patients with axSpA in the FRP, as in other studies with LBP patients. The 1/FRR index shown the best results in correlation with other parameters and it was where major differences between groups appeared. There was good correlation with the patient global score (BASG) and with the functional BASFI index, so assessment with sEMG could be an objective and quantitative test to evaluate the patient's functional status. It would be very interesting to analyze, in future studies, the sensitivity to change to treatments which would give us a good indicator to assess their effectiveness.

DOI: 10.1136/annrheumdis-2017-eular.2173
Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic diseases which mainly affects the spine and sacroiliac joint. So far, the pathogenesis of AS remains elusive, making it difficult to improve early diagnosis and treatment. Proteomics is a new enabling technology to screen disease associated proteins which can be used in diagnostics or therapeutics.

Objectives: The surface-enhanced laser desorption ionization/time of flight mass spectrometry (SELDi-TOF-MS) and protein chip screening specific biomarkers in serum of patients with ankylosing spondylitis (AS) are used to diagnose and assess the disease as well as to anticipate the program of disease.

Methods: The serum samples of 69 AS patients, 10 rheumatoid arthritis (RA) and 12 patients with ankylosing spondylitis (AS) are used to diagnose and assess the disease.

Results: The contents of 30 proteins were significantly different. Of these proteins, 14 were up-regulated and 13 were down-regulated in the AS patient. The diagnostic model made up of 10259, 7972, 2048, 2154 and 2954 could be used to distinguish AS from RA, which the sensitivity and specificity were 100% and 100% respectively.

Conclusions: The protein fingerprinting set up by SELDI-TOF-MS could screen new biomarkers in AS, which is expected to become a screening platform in diagnosis and assessment of disease.

left HJ (Table 1). There were no statistical differences between MRI symptoms of the impairment HJ and US symptoms of coccyx at baseline and after 2 years (Table 2).

Radiographic progression (BASRI-hip > 1 stage) after 2 years follow-up founded in 7 (31.8%) pts with MRI symptoms of the impairment HJ. There are radiographic progression from baseline to bilateral HJ stages (7.99%) pts. from sacrifice stage 1 to bilateral stage 2 in 2 (28.6%) pts. Mean NSAID index in pts with radiographic progression (31.8%) amount 62.2%, while in pts without radiographic progression – 72.5% (p>0.2).

Conclusions: 1. In patients with early axial spondyloarthritides in two years of observation radiographic progression observed in 31.7%, pts independent on regular intake of NSAIDs. 2. Further studies of the impairment HJ are required in patients with axial SpA.

D. Poddubnyy 1, R.D. Inman 2, J. Sieper 3, S. Akar 3, S. Muñoz-Fernández 4, M. Hönig 5, 1. Charité Universitätsmedizin Berlin, Berlin, Germany; 2. Toronto Western Hospital, Toronto, Canada; 3. Izmir Katip Celebi University School of Medicine, Izmir, Turkey; 4. Hospital Universitario Infanta Sofía, Universidad Western Hospital, Toronto, Canada; 5. AbbVie, Ljubljana, Slovenia

Background: Previously, some differences between non-radiographic and radiographic axial spondyloarthritis (axSpA) – such as a higher prevalence of females and a lower level of acute phase reactants in non-radiographic axSpA (nr-axSpA) – have been reported in national observational studies, mostly from Europe.

Objectives: To compare demographic and clinical characteristics of patients (pts) with nr-axSpA and radiographic axSpA (ankylosing spondylitis, AS) in a large multinational cohort of pts with recently diagnosed axSpA.

Methods: PROOF is a large prospective observational study. Among all consecutive pts of 29 countries, the pts with axSpA fulfilling ASAS classification criteria were only if diagnosed ≤ 1 year prior to study enrolment. Investigator’s confidence with the diagnosis of axSpA was ascertained on a numeric rating scale (NRS 0–10) at enrolment and end of follow-up. At baseline, demographic and clinical data related to the diagnosis, disease activity, quality of life and work productivity, as well as conventional radiographs of the sacroiliac joints were collected. Classification as nr-axSpA or AS was based on the results of the assessment of sacroiliac radiographs. Available radiographs were assessed first by a local reader and then by a central reader according to the grading system of the modified New York criteria.

In the case of a disagreement in the classification (nr-axSpA or AS), the radiograph was evaluated by the 2nd central reader, who was blinded to the previous assessments and the final classification was made based on the decision of 2 out of 3 readers.

Results: Of the 2126 pts enrolled in PROOF, 1281 (60.3%) pts were classified to AS and 845 (39.7%) as nr-axSpA. The confidence with the diagnosis of axSpA was ascertained on a numeric rating scale (NRS 0–10) at enrolment and end of follow-up. At baseline, demographic and clinical data related to the diagnosis, disease activity, quality of life and work productivity, as well as conventional radiographs of the sacroiliac joints were collected. Classification as nr-axSpA or AS was based on the results of the assessment of sacroiliac radiographs. Available radiographs were assessed first by a local reader and then by a central reader according to the grading system of the modified New York criteria.

In the case of a disagreement in the classification (nr-axSpA or AS), the radiograph was evaluated by the 2nd central reader, who was blinded to the previous assessments and the final classification was made based on the decision of 2 out of 3 readers.

Results: Of the 2126 pts enrolled in PROOF, 1281 (60.3%) pts were classified to AS and 845 (39.7%) as nr-axSpA according to investigators. The confidence with the diagnosis of axSpA was ascertained on a numeric rating scale (NRS 0–10) at enrolment and end of follow-up. At baseline, demographic and clinical data related to the diagnosis, disease activity, quality of life and work productivity, as well as conventional radiographs of the sacroiliac joints were collected. population. We found that AS was more active in patients who were diagnosed as IDA. We suggest that AS activity may cause mucosal inflammation and subsequently may result as IDA. Also we found that mucosal inflammation in AS patients is not related to NSAIDs because there was no difference about mucosal lesions between NSAID taking and non-NSAID taking group. No study was met in the literature concerning AS and IDA. Our findings should be supported by further studies.

SAT0397 RISK FACTORS FOR DEVELOPMENT AND PERSISTENCE OF CHRONIC WIDESPREAD PAIN, IN ANKYLOSING Spondylitis and undifferentiated SPONDYLOARTHRITIS

E. Moger 1, E. Lindqvist 1, A. Bremander 2,3, S. Bergman 2,4.

To study the development of CWP in patients with SpA, and to predict the outcome.

Objectives:
- To study non-steroidal anti-inflammatory drugs (NSAIDs) for rheumatic diseases: the EVIDENCE study of European routine practice.
- To analyze frequency of anemia of inflammation in patients with ankylosing spondylitis requiring anti-TNFα drugs and therapy-induced changes.

Methods:
- A cohort study with baseline and 2.5-year follow-up postal surveys.
- 644 patients (47% women) with ankylosing spondylitis (AS) and undifferentiated spondyloarthritis (SpA) answered both surveys, and were categorized as no chronic pain (NCP), chronic regional pain (CRP), and CWP.
- Logistic regression analyses, with CWP as the main outcome were performed. Due to multicollinearity, each risk factor candidate (disease duration, BMI, smoking, and different patient-reported outcome measures; PROMs) were analysed in separate logistic regression models together with a base model (age, sex, and SpA-subgroup).

Results:
- At follow-up, prevalence estimates for NCP, CRP and CWP were similar to those at baseline, but 38% of the patients had transitioned between the groups. A large group, 72% of the patients with initial CWP, also reported persistent CWP at follow-up (Figure). Risk factors (OR and 95% CI) for development of CWP from initial NCP/CRP were more pain regions (1.36; 1.20–1.53), pain intensity (1.35; 1.20–1.52), fatigue (1.25; 1.13–1.38), global health (1.35; 1.19–1.54), EQ-5D (0.50; 0.40–0.60), BASDAI (1.25; 1.07 – 1.45), BASFI (1.32; 1.16 – 1.50), ASAS pain (0.97; 0.96 – 0.99), ASAS symptom (0.98; 0.97 – 0.99), and HADb (1.10; 1.02 – 1.19). The risk factors for persistent CWP compared to patients transitioning to NCP or CRP, were similar to those predicting development of CWP, but in addition, also higher age (1.02; 1.00–1.04), and female sex (1.82; 1.06–3.10), predicted the outcome.

Conclusions: The total prevalence of CWP did not change over the study-period, although a substantial transition between the pain-groups were found. More pain regions, higher pain intensity, fatigue and worse self-reported health predicted the development into CWP, and persistent CWP. Also, higher age and female sex were risk factors for persistent CWP in SpA. Special attention in patients who report increased pain and related symptoms is essential, to early identify the development of CWP in patients with SpA.

SAT0398 PREGNANCY OUTCOMES IN KOREAN WOMEN WITH ANKYLOSING SPONDYLOPHTHYSIS

E.H. Park 1, J.K. Jun 2, S.M. Lee 3, Y.W. Song 3, E.B. Lee 1, 1Division of Rheumatology, Department of Internal Medicine; 2Department of Obstetrics and Gynecology, Seoul National University College of Medicine, Seoul, Korea, Republic Of

Background: Ankylosing spondylitis (AS) is a chronic, systemic, inflammatory disease that primarily affects the sacroiliac joints and spine. Despite overwhelming prevalence of AS in men, it can also occur in women. Since AS mainly affects the sacroiliac joints, a special attention should be paid to the normal labor and pregnancy outcomes in these female patients. However, very little is known about the impact of AS on pregnancy outcomes due to rare occurrence of the disease in women.

Objectives: To investigate the pregnancy outcomes in Korean female patients with AS.

Methods: All of the 27 deliveries from 20 AS female patients who had been cared at Seoul National University Hospital between February 1994 and June 2016 were retrospectively evaluated through medical record review. After matching the sacroiliac joints of the AS women with the pregnancies of the control group on a 1 to 4 ratio based on maternal and gestational age, pregnancy outcomes of AS patients were compared with those of the control group. Pregnancy outcomes included cesarean section (CS) rate, preterm birth, low birth weight infant, fetal growth restriction (FGR), fetal malformations and pre-eclampsia. Each pregnancy was considered as a separate observation, and outcomes between the groups were compared by regression models estimated using Generalized Estimating Equations (GEEs) to account for the matched nature of the data. For zero events in either group in which GEE models do not converge, Fisher’s exact test or Chi-square test were used.

Results: Cesarean section (CS) was performed in 44.4% of deliveries among women with AS compared with 20.4% in controls (p=0.002) (Table 1). The indications of CS included previous uterine surgery, breech position, placenta previa, placental abruption, fetal distress, and cephalopelvic disproportion (CPD). Caesarean section (CS) was performed in 1 case (8.3%) of AS women, while there was no case in the controls (p=0.353). Interestingly, the severity of sacroiliitis in AS patients did not show any association with CS (p=0.342). Women with AS had a higher frequency of LBW compared to the controls (22.2% vs 8.3%, p=0.024). However, there was no statistically significant difference in other adverse pregnancy outcomes, including preterm birth, FGR, fetal malformations, and pre-eclampsia.

*P value calculated from regression models estimated using GEEs to account for the matched nature of the data.

Conclusions: Although pregnant women with AS are concerned about CPD during their labors due to the involvement of the sacroiliac joints, vaginal deliveries
can be tried in patients with AS. The obstetric and perinatal outcomes in women with AS were also comparable to normal pregnant women. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.12511

SAT0399 | HEADACHE AS A CLINICAL COMPLAINT AT INITIAL PRESENTATION AND DURING THE DISEASE COURSE IN PATIENTS WITH SPONDYLOARTHRITIS INDICATES CONCOMITANT / SECONDARY FIBROMyalGia

E. Roussou, M. Karella, A. Georgiou. Rheumatology, Barking, Havering and Redbridge University Hospitals NHS Trust, London, United Kingdom

Objectives: To evaluate the symptom of headache as being able to clinically distinguish associated secondary fibromyalgia in patients with spondyloarthopathies (SpA). To compare the incidence of MSK complaints (related to SpA) in patients with headache to those that did not. To assess headache during the SpA disease course.

Methods: Registry data from 776 patients seen in clinic with SpA were analysed with reference to headache as symptom at presentation. The data of those patients presented with headache were compared with data of those patients who did not report headache with regards to demographics and disease characteristics. In addition, other MSK complaints, fatigue and pain during disease course were also analysed.

Results: From a total of 776 patients (m: f=265:508) age 48.3 (SD +14.1), 13 were excluded as no answer was recorded. 117/ 763 patients (15.08%) representing 28 males and 89 females (23.9% vs 76.1% ratio 1:3.1) reported headache at disease onset.

During the disease course, 13 patients out of the initial 117 did not record an answer to the question and were excluded. From remaining 104 patients, 95 patients (91.3%) continued to describe headache as a symptom. From those not reporting headache as initial symptom, (n=659) 148 did not answer and were excluded. From the remaining 511 patients, 194 (37.9%) reported headache during the disease course.

From those not reporting headache during the disease course, (n=659) 148 did not answer and were excluded. From the remaining 511 patients, 194 (37.9%) reported headache during the disease course. From those patients who did not have headache at disease onset, 38% report headache during the disease course. From those patients who did not have headache at presentation, 38% report headache during the disease course. Patients presenting with headache at presentation worse disease, more fatigue and a greater percentage describe pain at pressure points and MSK system.

Conclusions: Headache can clinically represent secondary FM among SpA patients. A proportion of patients (representing 15%) report headache at presentation. The majority of those patients (>90%) continue to describe headache during the disease course. From those patients who did not have headache at presentation, 38% report headache during the disease course. Patients describing headache at presentation have more MSK complaints at presentation.

SAT0401 | PREVALENCE OF ULTRASONOGRAPHIC LOWER AND UPPER ENTHESITIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

G. Cuomo 1, M. Zappia 2, M. Verde 1, D. Sgambato 2, M. Romano 2, 1 Dipartimento Assistenziale Integrato di Medicina Interna, UOC Medicina Interna - Università degli Studi della Campania - Luigi Vanvitelli; 2Dipartimento di internistica Clinica e Sperimentale, Università degli studi della Campania - Luigi vanvitelli, Napoli, Italy

Background: Spondyloarthritis (SpA) occurs in up to 20% of patients with inflammatory bowel disease (IBD) [1]. Symptomatic enthesitis is a characteristic feature of SpA and represents an early sign of SpA [2]. The prevalence of enthesitis in patients with IBD is not known.

Objectives: This study was designed to evaluate whether patients with IBD showed an increased prevalence of enthesal involvement, even in the absence of clinical symptoms.

Methods: Thirty-five IBD patients (25 M and 10 F, median age 41 yrs), 25 with Crohn’s disease (CD) and 10 with ulcerative colitis (UC), all with moderate intestinal activity, and 22 (13 M and 12 F, median age 44 yrs) control subjects with irritable bowel syndrome underwent a thorough clinical evaluation followed by entheses ultrasonography of upper limb (shoulder) and lower limb (quadriceps, proximal and distal rotuleus, Achilles tendon and plantar fascia).

The Madrid sonographic entheses index (MASEI) was used to score enthesopathies [2]. Correlation between IBD features (type, duration and 22, and 23 patients) and statistical analysis was performed using the Chi-Square test.

Conclusions: The remarkable finding in this study is that half of patients with AxSpA had a history of whiplash injury. These results suggest that trauma may influence the course of AxSpA through the immunological system or hypothalamic-pituitary-adrenal axis.

Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.3953

SAT0400 | IS WHIPLASH INJURY A TRIGGERING OR EXACERBATING FACTOR FOR AXIAL SPONDYLOARTHRITIS?

F. Urano, S. Ono, R. Hara, M. Yasumura, T. Muramatsu, S. Suzuki. Arthritis and Lupus Center, J a Nagano Kosei en Shinonoi General Hospital, Nagano City, Japan

Background: Axial spondyloarthritis (AxSpA) can be triggered by infection and environmental factors, and some cases involve trauma. Whiplash injury in a traffic accident may lead to exacerbation of symptoms of AxSpA.

Objectives: The aims of this study are to survey the prevalence of trauma before or after onset of AxSpA and to examine the prevalences of neck trauma and other trauma in patients with a history of AxSpA.

Methods: The patients completed a questionnaire, and clinical presentation, inflammatory markers (ESR, CRP), radiographs, MRI of sacroiliac joints, Bath and ankylosing spondylitis disease activity index (BASDAI), Bath ankylosing spondylitis functional index (BASFI), and Bath ankylosing spondylitis metrology index (BASMI) were assessed. Onset of symptoms was evaluated using European criteria for spondyloarthritis and patients were asked about mechanical stress (spinal trauma, extremity trauma, and internal organ injury). Patients with rheumatoid arthritis (RA) were included as controls and underwent the same evaluation. Patients with neck trauma were divided into four groups based on a short (<3 years) (group A) or long (>3 years) (group B) period between disappearance of trauma symptoms and onset of inflammatory back pain (IBP); continuous IBP after trauma (group C); and a gradual change from minor symptoms to severe IBP after trauma (group D).

Results: The subjects were 124 patients with AxSpA and 102 with RA. Trauma occurred at a significantly higher rate in patients with AxSpA than in those with RA (66 (53.2%) vs. 12 (11.8%), p<0.0001). Neck trauma was also significantly more frequent in patients with AxSpA (63 (53.2%) vs. 9 (8.8%), P<0.001) (Table 1). There were no significant differences in clinical background between patients with AxSpA with and without trauma (Table 2). Regarding the period from neck trauma to onset of IBP in patients with AxSpA, there were 4 (6.3%), 22 (34.9%), 14 (22.2%), and 23 (36.3%) cases in groups A, B, C, and D, respectively.

Conclusions: The remarkable finding in this study is that half of patients with AxSpA had a history of whiplash injury. These results suggest that trauma may influence the course of AxSpA through the immunological system or hypothalamic-pituitary-adrenal axis.

activity), age, sex and MASEI score was assessed with nonlinear Spearman's rho. Significance of differences was assessed by chi-square test. The level of statistical significance of differences was set at p<0.05.

**Results:** All of 35 patients with IBG presented at least one entheses alteration with a mean MASEI of 5.43 (thickness 57.1%, enthesisophyseal 42.8%, bursitis 0%, erosion 1%, PD abnormalities 14.2%) vs 3 patients of control group (enthesisophyseal 14%) (p=0.001).

**Conclusions:** 1) IBG patients showed a significantly higher prevalence of early entheses involvement, even in the absence of clinical symptoms; 2) the entity of entheses alteration as assessed by MASEI did not correlate with type, duration and activity of IBG; 3) age was the only variable which significantly correlated with ultrasonographic entheses involvement; 4) we speculate that IBG patients should undergo ultrasonography evaluation of entheses and, if any alteration, be followed up for early detection of SpA.

**SAT0402**  
**FREQUENCY AND HLA PHENOTYPE OF REACTIVE ARTHRITIS, UVEITIS, AND CONJUNCTIVITIS IN JAPANESE PATIENTS WITH BLADDER CANCER FOLLOWING INTRAVESICAL BCG THERAPY: A 20-YEAR, TWO-CENTER RETROSPECTIVE STUDY

**H. Nishikawa**  
[1] Hoshikawa1 Y. Taniguchi1 Y. Kiose1 Y. Yoshinaga2 Y. Terada1  

**Background:** Intravesical instillation of Bacillus Calmette-Guérin (BCG) is used as an effective immunotherapy of bladder cancer. However it may have, as an adverse event, a reactive arthritis (ReA) and the frequencies are known as about 0.5 to 1% in Western countries.

**Objectives:** To evaluate the frequencies and HLA phenotype of reactive arthritis (ReA), uveitis, conjunctivitis and other adverse events in Japanese patients with bladder cancer following BCG therapy.

**Methods:** The clinical findings of Japanese patients who received BCG (n=555 [250 and 305 in Kochi Medical School Hospital (KMSH) and Kurashiki Medical Center (KMC), respectively]) for bladder cancer from March 1997 to February 2016 were retrospectively assessed, with specific attention to patients with ReA and conjunctivitis/uveitis. We also looked at human leukocyte antigen (HLA) phenotypes of patients with ReA.

**Results:** Patient age was 73±10 and 70±11 years and male/female ratio was 198/52 and 240/65 in KMSH and KMC, respectively. 91/555 (16.4%), 121/555 (21.8%), and 196/555 (35.3%) of all enrolled patients presented with fever, haematuria, and dysuria, respectively. Of the 555 cases, ReA, uveitis and conjunctivitis were revealed in 11/555 (2.0%), 4/555 (0.7%) and 33/555 (5.9%), respectively. The frequency and the protocol of BCG therapy were stable over the 20 years. Notably, HLA-B27, -B35, -B39 and -B51 positivity was more frequent in ReA patients (9.1%, 36.3%, 36.3% and 63.6%, respectively) (p<0.05) than in healthy subjects without ReA.

**Conclusions:** Of BCG treated Japanese patients exceeds that in Western countries. HLA phenotype, especially HLA-B51 and -B39 alleles in addition to -B27, may be a risk factor in iBCG-induced ReA in Japanese patients.

**SAT0403**  
**ARTERIAL HYPERTENSION IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS – RESULTS OF 10-YEARS FOLLOW-UP

**I.Z. Gaydukovs, A. Aparikna, E. Chkondkaryan, A. Rebrov. Hospital Therapy, Saratov State Medical University, Saratov, Russian Federation**

**Background:** Spondylarthropathy (SpA) (ankylosing spondylitis (AS) and psoriatic arthritis (PsA) are associated with increased cardiovascular risk [1]. Destabilization of arterial pressure in chronic inflammation and anti-inflammatory treatment could be one of the reasons of early cardiovascular events onset.

**Objectives:** The purpose of this work is evaluate the occurrence and risk of arterial hypertension (AH) onset in patients with AS and PsA.

**Methods:** 663 patients were involved in the study: AS patients fulfilled mNew-York criteria (1984). PsA patients fulfilled CASPAR criteria (2006). Study included cross-sectional analysis where 159 AS and 85 PsA patients participated, and 10-year prospective follow-up part, included 278 AS patients, 109 PsA patients. 276 patients were excluded due to lose the follow-up. In follow-up part of the study were involved SpA patients without AH at baseline. 182 healthy volunteers participated in the study like controls, 32 of them lost the follow-up. New cases of AH were registered during 10 years. Statistics was performed in SPSS17 and GraphPadPrizm. All the results were adjusted to cardiovascular risk factors.

**Results:** Characteristics of the patients and controls with 10-years follow-up are presented in table 1.

**Table 1. Baseline characteristics of the patients, involved in the study**

**AS, ankylosing spondylitis; PsA, psoriatic arthritis; “–”, absence of data.** p<0.001 for the difference with controls.

The relative risk (RR) of AH onset in patients with AS compared to healthy individuals is 2.22 (95% confidential interval (CI) 1.59 - 3.1); RR in PsA patients is 3.08 (95% CI 2.19 - 4.03), difference between risk of AH development in PsA and AS is significant, p<0.0001. Median to new AH cases in AS and PsA is 10±2.57 years from the first SpA symptoms appearance.

**Conclusions:** AH is frequently presented in PsA patients than in AS. Risk of new AH onset in patients with AS and PsA is superior compared with the healthy individuals. The number of new cases of hypertension increases with time, and in 10 years from diagnosis half of PsA/AxS patients without cardiovascular disease will be in the risk of hypertension.

**RELATIONSHIP OF SCLEOSTIN AND DICKKOPF-1 SERUM LEVELS WITH DISEASE ACTIVITY AND INFLAMMATORY MRI LESIONS IN PATIENTS WITH SPONDYLOARTHROSIS**

**I. Shyrnykura1, O. Iaremkenko1, D. Fedkov1, K. Iaremkenko1, B. Bogomolots National Medical University; 2Olexandrivska Kyiv City Hospital, Kyiv, Ukraine**

**Background:** Dickkopf-1 (Dkk-1) and sclerostin (Scl) are likely to play important roles in the process of ankylosis in Spondylarthropathy (SpA) [1]. Their serum levels are associated with the formation of new syndesmophytes [2]. But the relationship between these biomarkers and disease activity including active inflammatory lesions in sacroiliac joints (SIJ) on magnetic resonance imaging (MRI) still not clear.

**Objectives:** To estimate the relationship between the SIJ and Dkk-1 and sclerostin serum levels and active inflammatory MRI lesions in SpA, disease activity and functional status.

**Methods:** Serum levels of ScI and Dkk-1 (pmol/l; ELISA) were measured at baseline in 79 cases with SpA. Mean age of pts (63.3% male) was 75.1±13.3, mean disease duration – 10.7±9.44 yrs. Radiological sacroiliitis defined according to Kellgren grade was: 0 – 1.6%, I – 22%, II – 49.2%, III – 13.6% and IV – 13.6%.

**Results:** Disease duration, years (M±SD) 13.7±10.03 14.8±14.4 – 0.001 for the differ-

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.6325
In SpA pts with lower activity by SPARCC score significant correlation between Dkk-1 and inflammatory lesions in SIJ (r=0.400, p=0.043) and a negative correlation between Dkk-1 and BASDAI (r=-0.513, p=0.017) were found. There was no correlation between Scl and Dkk-1 levels among all pts and different subgroups.

Conclusions: Scl level is significantly higher in pts with lower disease activity by SPARCC MRI SIJ score and ASDAS-CRP Dkk-1 significantly correlates with disease activity due to CRP level and SPARCC score, but not to BASDAI.

SAT0405 | CLINICAL, BIOLOGICAL AND GENETIC FACTORS, PREDICTORS OF TREATMENT NONRESPONSE TO TNF INHIBITORS (TNFi), IN ANKYLOSING SPONDYLITIS (AS) AND PSORIATIC ARTHRITIS (PSA)
J. Pole y La Borda, J. Campos, J. Sanz, J. Muñoz, A. Sánchez. Reumatología, Instituto de Investigación Biomédica, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain

Background: TNF inhibitors (TNFi), effective in controlling the activity of spondyloarthritis, but there is a proportion of patients, who have to stop treatment due to its ineffectiveness or to the appearance of adverse events. In addition, these therapies imply high economic costs. To identify predictors of response, would help us to make decisions and to improve the risk/benefit ratio, in patients candidates who are candidates to initiate TNFi.

Objectives: To determine clinical, biological and genetic predictors of nonresponse to treatment with TNFi in patients with AS and PsA.

Methods: We analyzed 118 patients [49 AS and 69 PsA (24 axial and peripheral involvement and 45 only peripheral)], under treatment or who were to start treatment with TNFi. Data were collected before the start of the TNFi and at the last scheduled visit to the Rheumatology Service of the Hospital Puerta de Hierro, during the period 2013–2014. A clinical response was defined as the reduction ≥50% of the initial BASDAI, in patient with axial involvement, and if the final DAS 28 PCR was <2.6, in those patients with only peripheral involvement. A total of 73 men and 45 women, mean age 53±11.2 years, and a median duration of illness of 15 years (IQR 10–23) were included. The baseline ESR and CRP were (10 mm/hr IQR 5.0–27.0 and 2mg/l IQR 0.0–9.0) respectively. The mean and SD of BASDAI, DAS28 CPR and BASFI were (6.0±1.9, 3.0±0.6 and 5.4±2.5) respectively. An univariate analysis was performed using a Cox proportional hazard regression model which included: Smoker status, axial pain, peripheral arthritis, sacroiliitis, IBD, uveitis, psoriasis, HLA B27, VSG, PCR, BASFI, BASFI, the number of TNFi and 45 single nucleotide polymorphism (SNPs) previously reported to be associated with response to TNFi; SNP genotyping was performed using de Sequenom MassARRAY platform.

Results: A trend of significance (P<0.065) for the association between DKK-1 and BASDAI (HR 1.80, P=0.001), BASFI (HR 1.47, P=0.001) and the number of TNFi used (P<0.001). There was a trend of significance (P<0.10) for females, with a 2.13-fold lower response rate than males (P=0.065). The SNPs associated were: rs4240847 of the MAPKAPK2 gene (allele T, HR 1.47, P=0.035). The multivariable analysis showed in the following table:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Private Hazard Ratio</th>
<th>95% CI Hazard Ratio</th>
<th>Lower</th>
<th>Upper</th>
</tr>
</thead>
<tbody>
<tr>
<td>BASFI at the start of treatment</td>

SAT0406 | PREVALENCE OF VERTEBRAL FRACTURES IN AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW OF OBSERVATIONAL STUDIES
J. C. Nieto-González 1, R. Cubero 2, S. Castañeda 3, J. Ramírez 4, L. Carmona 5
1 Rheumatology, Hospital G.U. Gregorio Marañón; 2 Statistics, Instituto de Salud Musculoesqueletica; 3 Rheumatology, Hospital la Princesa, Madrid; 4 Rheumatology, Hospital Clinic, Barcelona, Spain

Background: Some studies have described a higher rate of osteoporosis in axial spondyloarthritis (AxSpA). However, there are still some doubts about whether vertebral fractures (VF) should be a concern in AxSpA patients.

Objectives: To evaluate the prevalence and incidence of VF in AxSpA.

Methods: A systematic review was performed in Medline, Embase and Cochrane Library databases limited to studies published from Jan/2006 to Dec/2015 in Spanish, Italian and English. Search strategy combined synonyms of AxSpA, vertebral fractures, plus a filter study type. We selected cross-sectional or longitudinal studies estimating the prevalence and/or incidence of VF in adult AxSpA patients.

Results: The search retrieved 3944 references which after screening by title and abstract ended in 90 studies to study in depth. Finally, 12 studies were included. The majority of the studies evaluated the VF prevalence, and only 2 studies evaluated the incidence of VF. Prevalence estimates depended on VF definitions, varying between 4.1% (clinically diagnosed VF) and 32.4% (morphometric fracture by Genant definition). Table 1 shows all studies included and their data.

Conclusions: The published studies that focus on VF in AxSpA are very heterogeneous, but in general showed a slight increase in the VF prevalence. More studies are needed focused on VF incidence in AxSpA.

Disclosure of Interest: None declared

Abstract SAT0406 – Table 1
RISE IN THE DIAGNOSIS OF NON-RADIOGRAPHIC FORM OF AXIAL SPONDYLOARTHROPATHY IN NORTHERN ISRAEL OVER TIME

K. Zilber, S. Ginsberg, D. Rimar, M. Rozenbaum, N. Boulman, L. Kaly, A. Wisiat, N. Jaries, I. Rosner, G. Slobochin. Rheumatology, Bnai Zion Medical Center, Haifa, Israel

Background: Approach to the diagnosis of axial spondyloarthritides (axSpA) has changed in the last decade, with the aim of diagnosing the disease in its early form.

Objectives: The objective of this study was to explore change in the diagnostic pattern of axSpA in Northern Israel over the last 15 years.

Methods: Patients with the clinical diagnosis of axSpA from six rheumatology practices affiliated with the Rheumatology Unit of the Bnai Zion Medical Center in Haifa, Israel were included to the study. Ankylosing Spondylitis (AS) was diagnosed in the presence of sacroiliitis grade 2 or more on X-ray films; all other patients were considered as having non-radiographic axSpA. All patients were subdivided by time periods to 5 groups, and percentages of patients diagnosed in the non-radiographic stage of the disease, as well as patient demographic data were compared using exact Fisher test.

Results: One hundred twenty five patients were subdivided to 5 groups by periods of diagnoses (before 2000, 2001–2004, 2005–2008, 2009–2012, 2013–2016). Gradual increase in a proportion of patients diagnosed with non-radiographic axSpA was observed over years, with statistical significance achieved in 2013–2016 (<p>0.05) (Fig 1). Patients’ gender and age distribution did not differ significantly among the groups.

Conclusions: Progressive increase in the proportion of patients diagnosed with non-radiographic form of axSpA over years was observed in this study. This finding, made on the basis of real life data, reflects change in the diagnostic approach to spondyloarthritides during the last decades.

POSITIVE CORRELATION BETWEEN INFLAMMATION ON SACRIOCILIAC JOINT MRI AND SERUM C-TERMINAL TEOPEPTIDE OF TYPE-I COLLAGEN IN ANKYLOSING SPONDYLITIS BUT NOT IN NON-RADIOGRAPHIC AXIAL SPONDYLITIS

K.Y. Kang1, Y.S. Hong2, J.H. Ju3, S.-H. Park3. 1Division of Rheumatology, Internal Medicine, Catholic University of Korea, seoul; 2Catholic University of Korea, Incheon; 3Catholic University of Korea, seoul, Korea, Republic Of

Background: The MRI-determined inflammatory score was suggested as a functional index, or MRI-determined SIJ inflammation. Erythrocyte sedimentation rate, C-reactive protein, and ASAS correlated with MRI inflammatory scores in nr-axSpA but not in AS. sCTX-I correlated with MRI-determined SIJ inflammatory scores in AS only. BASDAI and BALP levels did not associate with MRI inflammatory scores in either group. Multivariate analysis showed that sCTX-I associated independently with MRI inflammatory score in AS (<p>0.047, p=0.038).

Conclusions: Inflammatory markers and ASDAS correlated with active sacroiliitis on MRI in nr-axSpA only. In AS, only sCTX-I correlated with active inflammation on SIJ MRI. sCTX-I may be useful as a marker of objective inflammation in AS.

HLA-B27 ROLE IN ANKYLOSING SPONDYLITIS PHENOTYPE: RESULTS FROM THE REGISPONSER DATABASE

M. Arevalo1, P. Font2, M. Moreno2, D. Ruiz3, M. Castro2, P. Carreto3, M. Larrosa1, E. Collantes1 on behalf of REGISPONSER group.

1Rheumatology, Parc Taulí Hospital Universitari. Institut d’Investigació i Innovació Parc Taulí I3PT. Universitat Autònoma de Barcelona. Sabadell, Spain; Sabadell; 2Rheumatology, Hospital Universitario Reina Sofia/IMIBIC/Universidad de Córdoba., Córdoba; 3Genery MyC y Valladolid East Area, Valladolid, Spain

Objectives: To assess if there are different phenotypical patterns of Ankylosing Spondylitis (AS) patients depending on the positivity or negativity of HLA-B27.

Methods: This is a multicentric, observational, transversal and descriptive study of AS patients from the spanish database REGISPONSER. We compared HLAB27 positive and HLAB27 negative patients regarding clinical and demographical data, disease activity and structural damage. In order to assess disease activity we used the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and acute phase reactants (VSG and PCR). Functional disability was measured by Bath Ankylosing Spondylitis Functional Index (BASFI), and structural damage by Bath Ankylosing Spondylitis Radiology Score (BASRI). For qualitative variables we used the Chi square test and for quantitative ones the t test. An univariate
and multivariate comparative analysis was performed, in order to define which variables were related to the negativity or positivity of HLAB27.

Results: Data of 1235 AS patients were analysed. Of them 1029 (83.3%) were HLAB27 positive and 206 (17.7%) HLAB27 negative. 924 (74.8%) were men. AS patients with HLAB27+ presented significantly more familiar history of spondyloarthropathy (p=0.002), axial pain, enthesopathy, enthesis, no radiological signs and diagnosis (p<0.001), with a longer disease duration (p=0.037) and a trend to a higher percentage of uveitis compared to those with HLAB27−. On the other hand, AS patients with HLAB27+ also presented significantly more peripheral arthritis (p=0.002), dactylitis (p=0.001) and extraarticular manifestations (p<0.001), presenting no radiological signs of the disease (p<0.001) compared with those of HLAB27−. AS patients with HLAB27+ also presented higher scores of BASDAI and BASFI (p=0.047 and p=0.005 respectively). The study didn’t show differences between both groups of patients regarding sex distribution, age at diagnosis, family history of inflammatory arthritis (p>0.05), age at diagnosis (OR 0.97, IC95% 0.96–0.98, p<0.001), the presence of dactylitis (OR 0.16, IC95% 0.05–0.56, p=0.004), extraarticular manifestation specially IBD (OR 0.22, IC95% 0.12–0.40, p=0.001) and peripheral arthritis (OR 0.53, IC95% 0.32–0.89, p=0.016) were the variables independently associated with the presence of HLAB27.

Conclusions: The presence of HLAB27 in AS patients is associated to an earlier disease onset, a higher frequency of familiar history of spondyloarthropathy, and a lower frequency of dactylitis, extraarticular manifestations and peripheral arthritis.

**SAT0411** CORRELATION BETWEEN DISEASE ACTIVITY SCORES AND QUALITY OF LIFE IN SPONDYLOARTHITIS

Background: Spondyloarthritides (SpA) is a group of chronic inflammatory rheumatism and it is known to be one of the leading causes of disability.

Objectives: This study aimed to investigate the quality of life and the psychological disorders (depression, anxiety and insomnia) in patients with SpA.

Methods: A total of 60 patients were included with the diagnosis of SpA meeting the Amor and New York modified criteria, in a prospective study. In a questionnaire, the characteristics of the disease and sociodemographic patient were collected. Also psychiatric assessment was done using the insomnia severity index score (ISI) and the Hospital Anxiety and Depression scale (HAD). In addition, patients answered to the Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire and the SF-12.

Results: The sex-ratio (men:women) was 3.28 (46/14), the average age was 37.95 years (18–70). The average duration of disease progression was 11.5 years (1–30). The mean value of the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) was 5.11 and the Bath Ankylosing Spondylitis Functional Index (BASFI) was 5.22. Uveitis was reported in 11.7% of patients, otoporosis in 35%, enthesis in 36.7% and coxitis in 36.7%. 78.3% of patients received NSAID and 30% were treated with biotherapy. On the psychological level, 25% of patients had an anxiety, 20% had depression. According to the ISI, 35% of patients had sub threshold insomnia, 20% had moderate insomnia and 10% had severe insomnia. The mean value of the ASQoL was 9 (0–16). The mean value of the physical health was 37.13 (19.34–60.41) and for the mental health was 41.65 (14.9–60.35). A significant positive correlation was found between the disease activity and the ASQoL (p<0.001), the physical health (p<0.001) and the mental health (p=0.002). Also, we found a significant positive correlation between the BASDAI and depression (p=0.01) and insomnia (p=0.001).

Conclusions: SpA is a chronic inflammatory disease that contributes to significant physical disability. It decreased quality of life in a significant number of patients. The treatment of those patients must consider the improvement of quality of life, as part of a global approach.

Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.6394

**SAT0412** ASSOCIATION BETWEEN SMOKING WITH SPINAL LEVEL OF STIFFNESS AND FUNCTIONAL LIMITATION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbraa 1, J. Chacón-García 1, J. Graciacos-Masmità 2, D. Galvez-Ruíz 1, V. Navarro-Compan 3, C. Blanch-Mur 4, E. Collantes-Estevez 2, P. Zarco-Montejo 5, O. Brace 1, 1Universidad de Sevilla, Seville; 2, Parc Taulí, Sabadell; 3Universidad de la Paz, Madrid; 4Novartis, Barcelona; 5Universidad de Córdoba, Córdova; 6Fundación Alarcon, Madrid, Spain

Background: Smoking has been associated with greater disease activity and radiographic progression in patients with axial spondyloarthritis (axSpA). In addition, radiographic damage has been linked to greater functional limitation. However, clarification is still being sought as to whether or not this association exists.

Objectives: To investigate the association between smoking and both the area of spinal stiffness and functional limitation in patients with axSpA.

Methods: A sample of 680 patients diagnosed with axSpA was interviewed between 2016 as part of the Spanish Atlas, which aims to promote early referral and improve healthcare and the use of effective treatments in patients with axSpA. Tobacco consumption was recorded as: Smoker (62.4%), Occasional Smoker (8.9%) and Non-Smoker (28.7%). Spinal stiffness was assessed in the three different vertebral areas: cervical, dorsal and lumbar. To determine the degree of functional limitation we used a composed index which includes the sum of the degree of limitation in the 18 daily activities well established (dressing, grooming, bathing, tying shoelaces, moving around the home, stairs, getting to/out of bed, toilet, shopping, preparing meals, eating, cleaning, walking, using public transportation, going to the doctor, driving, physical exercise, sexual relations) using an ordinal variable (0=noone, 1=little, 2=moderate and 3=moderate).

A descriptive analysis was used to compare the level of stiffness (chi-squared test) in the different groups of smokers consumptions. Regression analysis was also used to assess the relation between smoking and degree of limitation (0–54).

Results: 53% were females, mean age 46 years and 77.1% were HLA-B27+.

The percentage of patients with stiffness in the lumbar region was significantly higher in habitual/occasional smokers than in non-smokers (89.0%, 93.8%, 83.5% respectively; p<0.01) (Table). The mean level of functional limitation increased with tobacco consumption, although this difference was not statistically significant (47.9±12.1 vs. 45.1±11.5 vs. 44.8±13.7 respectively; p=0.2). However, regression analysis showed a statistically significant correlation between smoking and functional limitation (r=0.096; p=0.02).

Declaration of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.6519

**SAT0413** INFECTIOUS PROFILE IN A TUBERCULOSIS-ENDEMIC POPULATION WITH SPONDYLOARTHROPATHIES

M.A. Alzate 1, 2, F. Ramírez 2, F. Vargas 2, D. Hernández-Parra 1, J.C. Salazar-Urbe 3, P. Ortíz-Salazar 1, R. Pineda 1 on behalf of Artmedica IPS, Medellin, Colombia. 1Clinical information group; 2Rheumatology division, Artmedica IPS; 3School of Statistics, Faculty of Sciences, National University of Colombia, Medellin, Colombia

Background: Screening latent tuberculosis (TB) and other opportunistic infections in patients with spondyloarthropathies (SpA) with biologic or immunosuppression therapy is important in highly endemic populations (1,2).

Objectives: To assess the prevalence of latent and active TB, hepatitis B, hepatitis C and HIV among patients with spondyloarthropathies (SpA) by means of CHI-square tests, Mann-Whitney test, and logistic regression analyses.

Methods: A cross-sectional study was conducted in 621 patients with SpAs, in whom TB, hepatitis B, hepatitis C, HIV and syphilis screening was analyzed based on type of diagnosis. Differences among immunomodulatory therapies were assessed. Statistical association was examined by means of CHI-square tests, Mann-Whitney test, and logistic regression analyses.

Results: The prevalence of latent and active TB in this cohort were 63.1%, 2.9%, respectively. Significant differences were found in proportions of latent and active TB among types of SpAs, indicating a positive association with AS. A high
Spondyloarthropathies (SpAs) are a group of auto-inflammatory diseases with overlapping symptoms, that include ankylosing spondylitis (AS), psoriatic arthritis (PsA), undifferentiated spondyloarthropathy (Und SpA), enteropathic arthropathies, and reactive arthritis (1). Historically, SpAs have been viewed as diseases that predominantly affected men (2).

Objectives: To analyze the influence of gender on disease patterns and therapeutic approach in a large cohort of Colombian patients with SpAs.

Methods: A cross-sectional study was conducted in 621 patients with SpAs, in whom clinical and therapeutic characteristics were analyzed based on gender. Statistical association was examined by means of Chi-square tests, Mann-Whitney test, and logistic regression analyses.

Results: The male-to-female ratio was 1.1:1 in this cohort. Younger age at diagnosis was found in males. AS was the most frequent disease (54.7%), followed by PsA (35.7%), and undifferentiated SpA (9.5%). The male gender was positively associated to the presence of AS (OR 2.29 95%IC 1.31–4.04), sacroilitis (OR 3.46 95%IC 1.82–6.56), HLAB27 positivity (OR 1.95 95%IC 1.31–2.91), low back pain (OR 1.85 95%IC 1.34–2.54) and axial involvement (OR 1.98 95%IC 1.42–2.77). According to the therapeutic profile, female gender was positively associated to the use of conventional DMARD therapy (i.e., methotrexate [p=0.03], leflunomide [p=0.0057], chloroquine [p=0.013]), while male patients were more associated to the use of biologic therapy.

Conclusions: In this Colombian large sample with SpA, male patients have a younger onset of disease, higher proportion of axial involvement, HLAB27 positivity, evidence of radiographic sacroiliitis and higher use of anti-TNF therapy. References:

HLA-B27 positive. In total, 254 (66%) patients started TNF-α inhibitors and 139 (34%) patients received conventional treatment. Patient characteristics were comparable between both groups, except higher disease activity, more often peripheral arthritis, and worse physical functioning in patients starting TNF-α inhibitors. NSAID use and disease activity reduced significantly after starting TNF-α inhibitor and remained low and stable during follow-up. In the conventional treatment group, disease activity was low and NSAID remained stable at all visits. GEE analysis over time showed that NSAID use was significantly associated with disease activity (Table 1). In the TNF-α inhibitor group, a significant association of all NSAID parameters with ASDAS was found: NSAID use yes vs. no, \( \alpha \), GEE analysis over time showed that NSAID use was significantly associated with treatment group, disease activity was low and NSAID remained stable at all visits. 

**Table 1. Association between ASDAS and NSAID use over time in AS patients.**

**Conclusions:** In this observational cohort of established AS patients, NSAID use over time was significantly associated with ASDAS, which was most pronounced in the TNF-α inhibitor group, a significant but less prominent association of NSAID parameters with disease activity in the conventional treatment group, a significant but less prominent association of NSAID parameters with clinical parameters (ASAS 5/6/4/3/2/1), and the combination of NSAID use and disease activity in the conventional treatment group, a significant but less prominent association of NSAID parameters with clinical parameters (ASAS 5/6/4/3/2/1).

**SAT0417** | GRADUAL PROGRESSIVE CHANGE TO EQUAL PREVALENCE OF ANKYLOSING SPONDYLITIS AMONG MALES AND FEMALES IN SWITZERLAND: DATA FROM THE SWISS ANKYLOSING SPONDYLITIS SOCIETY (SVMB)

H. Baumberger, 1M. A. Khan 2, PhD. First president of, Schweizerische Vereinigung Morbus Bechterew, Zurich, Switzerland; 2Professor Emeritus of Medicine, Case Western Reserve University, Cleveland OH, United States

**Background:** Classic ankylosing spondylitis (AS) with radiographic sacroiliitis has long been considered to be more common in men than women. But this difference has gradually decreased with increasing recognition of this condition in women so that the more recent data suggest a range of 2:1 to 1:1 ratio in favor of men [1].

**Objectives:** To document greater disease recognition in women during the last 30 years in Switzerland as reflected by AS patient membership in the Swiss Ankylosing Spondylitis Society (SVMB) since its foundation in 1978 [2].

**Methods:** We reviewed the Society's quarterly newsletters that have kept record since 1980 not only of the number of members, but also the percentage of males and females AS patients. We calculated yearly AS patient membership and also change in the male/female patient ratio (M:F).

**Results:** There has been a progressive decline in the M:F ratios since 1980 as shown in the Figure. There were 44 female forming 28% of the patient population, with a M:F ratio of 2.57 in 1980. At the end of 2016, there are 1731 females forming 49% of the total number of patients, and the M:F ratio is now 1.03.

**Conclusions:** AS is now being recognized as often in females as in males, as reflected in the membership of SVMB over the last 36 years. There can be various reasons for this observation, one of them being the availability of better imaging tools to recognize AS/axial spondyloarthritis (axSpA), especially among women whose disease is clinically and radiologically less pronounced and is therefore often overlooked [2]. For example, the use of MRI (for early detection of spinal inflammation) and the ASAS criteria have resulted in > 50% females in a German cohort of patients with nonradiographic axSpA [3]. SVMB has played a major role in achieving greater disease recognition in Switzerland by increasing disease awareness and educating patients and their families, the general public, the governing bodies and the allied health professionals about AS, and by interacting closely with rheumatologists. Other possible factors influencing our data include: women outliving men, forming a little greater percentage of the general population, and possibly more likely to join patient self-help groups and societies. We did not investigate any gender difference in disease severity and clinical presentation. In conclusion, AS/axSpA almost equally afflicts men and women in Switzerland.

**SAT0418** | ANXIETY AND DEPRESSION ON DISEASE ACTIVITY AND QUALITY OF LIFE OF SPONDYLOARTHRITIS PATIENTS UNDER BIOLOGIC THERAPIES

N. Madeira 1, J. Borges 1, A. Cardoso 2, L. Miranda 1, F. Barcelos 1, C. Miguel 1, C. Silva 1, S. Fernandes 1, R. Trincão 3, D. Medeiros 1, R. Campanilho-Marques 1, H. Santos 1, R. Leitão 1, A. Faustino 1.

**Background:** Rates of anxiety and depression in ankylosing spondylitis (AS) or related spondyloarthritis (SpA) range from 5 to 70% and are more prevalent in females than males. It is not clear whether this is due to the disease or other factors such as socioeconomic status. This study aimed to evaluate disease activity and quality of life (QOL) among AS or SpA patients with and without anxiety or depression.

**Objectives:** The aim of this study was to evaluate the association of anxiety and depression with disease activity and QOL parameters in AS and related spondyloarthropathies (SpA). Also, to compare the disease experience of ANXIETY and DEPRESSION on DISEASE ACTIVITY AND QUALITY OF LIFE OF SPONDYLOARTHRITIS PATIENTS UNDER BIOLOGIC THERAPIES.

**Methods:** We conducted a cross-sectional analysis of 771 patients with AS or related spondyloarthropathies. Anxiety and depression were measured using the Hospital Anxiety and Depression Scale (HADS). Disease activity was assessed using the BASDAI and ASDAS. QOL was evaluated using the SF-36 and EQ5D. Statistical analysis was performed using logistic regression.

**Results:** Anxiety and depression were more prevalent in women than in men (64% vs. 36%) and in patients with radiographic sacroiliitis (76% vs. 24%). Anxiety and depression were associated with higher disease activity (BASDAI, ASDAS) and lower QOL (SF-36, EQ5D). Treatment with biologics was associated with lower anxiety and depression.

**Conclusions:** Anxiety and depression are common in AS and related spondyloarthropathies. They are associated with higher disease activity and lower QOL. Treatment with biologics is associated with lower anxiety and depression.
Objectives: To assess disease activity and quality of life in anxious and depressed SpA patients.

Methods: Observational, retrospective, cross-sectional study of SpA patients on bDMARDS, registered at Reuma.pt, Portuguese Rheumatology registry, with ≥1 clinical evaluation from November 2015 to July 2016. Demographic and clinical outcomes including BASDAI, BASFI, ASDAS, BASDI, DAS 28–3V, ESR in peripheral psoriatic arthritis, tender and swollen 44 joints count (TJC, SJC), patients’ pain and global assessments, physician’s global assessment, CRP, ESR, ASO, EQ-5D, FACIT-F for fatigue and HADS scale with 2 domains, HADS-A for anxiety and HADS-D for depression (a cutoff of 0 defining these symptoms), were collected. Statistical: Mann-Whitney test, p<0.05, SPSS® v.17.

Results: 160 patients were included, 41.9% were male, with mean current age 50.7±11.9, age at diagnosis 36.9±11.96, at 1st bDMARD 46.2±11.8, time from diagnosis 18.5±10.3. Years. The mean DAS 28–3V ESR was 3.2±1.4, BASDAI 2.98±2.2, BASDI 2.4±1.5, BASFI 2.68±2.26, BASMI 3.36±1.7, patient’s global assessment 28.9±6.1, physician’s global assessment 14.5±15.2, ESR 18.8±18.1 mm/h, CRP 6.7±16.01 mg/L, ASQol 6.2±6.5, FACIT-F 37.2±10.1 and EQ-5D 0.417±0.19. The mean HADS-A was 5.96±4.01 and HADS-D was 5.05±4.1 (HADS-A ≥8 in 39.5% and HADS-D ≥8 in 28.3% patients). Comparison of anxious vs non-anxious and depressive vs non-depressive groups appears on table 1.

Conclusions: These results suggest that anxious and depressed patients may have higher disease activity, more functional limitations and worse quality of life. These symptoms should not be underestimated, but instead, they should be controlled to achieve clinical improvement.

**SAT0419** SIMILARITIES AND DIFFERENCES BETWEEN HLA B27 POSITIVE AND HLA B27 NEGATIVE SPONDYLOARTHRITIS: RESULTS FROM THE ESPERA COHORT

P. Serrano 1,2, V. Navarro-Compañ 1, S. Rodríguez 1, M. Fernández 4, P. Zarco 5, E. de Miguel 2
1Universidad Autónoma; 2Hospital la Paz, IdiPaz, Madrid; 3Hospital Nuestra Señora de Valme, Sevilla; 4Hospital Guadalajara, Guadalajara; 5Hospital Fundación Alcorcón, Madrid, Spain

**Background:** The diagnostic relevance of HLA B27 for spondyloarthritis (SpA) vs non-anxious and depressive vs non-depressive groups appears on table 1.

**Objectives:** To investigate the influence of HLA B27 status on disease manifestations in patients with recent-onset SpA.

**Results:** A total of 291 patients (75% B27+ and 25% B27-) were classified as axial SpA (86% [33% B27+ and 67% B27-] as peripheral SpA. Results (mean –standard deviation- and relative frequencies) are presented in the table. In axial SpA, B27+ patients were younger, more frequently males and with a family history of SpA while B27- patients had more frequently psoriasis, IBD and poorer quality of life. In peripheral SpA, B27- had more frequently psoriasis and reported higher BASDAI.

**Conclusions:** In patients with SpA, HLA B27 status influences on the presentation of the disease. In axial SpA, the presence of B27 is associated with an earlier onset, male predominance and more frequency of family history of SpA. In peripheral SpA, the presence of B27 is linked with lower subjective parameters of disease activity. In both, axial and peripheral SpA, the absence of B27 is associated with psoriasis, IBD and poorer quality of life.

SAT0421

FAT MASS NEGATIVELY AFFECTS THE RESPONSE TO TNF-α BLOCKERS IN ANKYLOSING SPONDYLITIS PATIENTS

S.E. İbşez Vodnizza 1,2, M.T. Nurmohamed3,4, J.M. Visman 3, J.C. van Denderen3, W.F. Lems3,4, I.E. van der Horst-Bruinsma 4,1

1Rheumatology Department, Clinica Alemana de Santiago; 2Rheumatology department, Hospital Padre Hurtado, Santiago, Chile; 3Amsterdam Rheumatology and Immunology Center, Reade; 4Amsterdam Rheumatology and Immunology Center, VU University Medical Center, Amsterdam, Netherlands

Methods: All AS patients with vitamin D level of < 20 ng/ml who consecutively attended the outpatient rheumatology clinic were enrolled. C-reactive protein, erythrocyte sedimentation rate, Bath AS disease activity index (BASDAI), Bath AS Functional Index (BASFI), TNF-α, IL-1, IL-6, ADMA, symmetric dimethylarginine (SDMA), NG-monomethyl-L-arginine (LNMMA), arginine, arginine/ADMA ratio and citrulline levels were analyzed when vitamin D level was < 20 ng/ml and ≥ 20 ng/ml after replacement.

Results: The study population was represented by 82 patients, 48 women (59%), mean age 39 years old and mean disease duration 5.5 years. When vitamin D levels were increased to normal levels, levels of IL-1 (4.8±9.7 and 3.1±4.0 p=0.001), IL-6 (7.1±14.1 and 4.7±2.1 p=0.009), ADMA (0.8±0.2 and 0.4±0.2 p=0.001), SDMA (0.9±0.2 and 0.4±0.2 p=0.001), LNMMA (0.08±0.02 and 0.06±0.02 p=0.001), arginine (385.8±160.4 and 269.5±79.0 p=0.001) and citrulline (91.5±34.3 and 75.3±23.5 p=0.001) were reduced. Levels of arginine/ADMA ratio was increased (498.7±136.5 and 576.7±170.7 p=0.001) (Table 1). Also BASDAI, BASFI and erythrocyte sedimentation rate were decreased but it was statistically meaningless. In Pearson correlation analysis, ADMA, SDMA, LNMMA, arginine and citrulline were negatively correlated with vitamin D levels. Multiple regression analysis showed that SDMA, arginine and citrulline were significantly related with vitamin D levels. Negative correlation between ADMA and vitamin D levels was shown in Figure 1

*aControlled for gender, age, years with symptoms, days of follow up, use of DMARDs and NSAIDS and baseline outcome value. **Percentiles according to the reference population tables, stratified by age and gender. *Only for patients with a BASDAI ≥ 4 at baseline. CRP = C-reactive protein, ASAS = Ankylosing Spondylitis Disease Activity Score, BASDAI = Bath Ankylosing Spondylitis Disease Activity Index, MCI = minimum clinically important improvement, FMI = Fat Mass Index.

Conclusions: Vitamin D replacement in AS with low vitamin D levels improves antioxidant status via ADMA pathway and shows anti-inflammatory effects on IL-1 and IL-6. In literature, there is no other study investigating the effects of increased vitamin D levels on disease activity, inflammatory parameters and ADMA pathway in AS.

SAT0422

EFFECTS OF VITAMIN D REPLACEMENT ON THE DISEASE ACTIVITY AND INFLAMMATORY PARAMETERS SUCH AS IL-1, IL-6, TNF-α, ASYMMETRIC DIMETHYLARGININE (ADMA) AND ARGinine/ADMA RATIO IN ANKYLOSING SPONDYLITIS

S. Ergülü Esen1, S. Yilmaz2, L. Kebapcilar3, A. U nú4, S.H. Ipeki3, A. Abusoglu4, I. Rheumatology, Internal Medicine, Konya Education and Research Hospital; 2Rheumatology, Internal Medicine; 3Endocrinology and Metabolic Diseases, Internal Medicine; 4Biochemistry, Selcuk University, Konya, Turkey

Background: Asymmetric dimethylarginine (ADMA) levels in AS patients were found to be higher than controls (1). The relationship between vitamin D level and disease activity was shown in AS (2). But the effects of vitamin D replacement on the disease activity, inflammatory parameters and ADMA pathway were not investigated in AS.

Objectives: To determine the effects of vitamin D replacement on the disease activity, inflammatory parameters and ADMA pathway in AS.

Methods: All AS patients with vitamin D level of < 20 ng/ml who consecutively attended the outpatient rheumatology clinic were enrolled. C-reactive protein, erythrocyte sedimentation rate, Bath AS disease activity index (BASDAI), Bath AS Functional Index (BASFI), TNF-α, IL-1, IL-6, ADMA, symmetric dimethylarginine (SDMA), NG-monomethyl-L-arginine (LNMMA), arginine, arginine/ADMA ratio and citrulline levels were analyzed when vitamin D level was < 20 ng/ml and ≥ 20 ng/ml after replacement.

Results: The study population was represented by 82 patients, 48 women (59%), mean age 39 years old and mean disease duration 5.5 years. When vitamin D levels were increased to normal levels, levels of IL-1 (4.8±9.7 and 3.1±4.0 p=0.001), IL-6 (7.1±14.1 and 4.7±2.1 p=0.009), ADMA (0.8±0.2 and 0.4±0.2 p=0.001), SDMA (0.9±0.2 and 0.4±0.2 p=0.001), LNMMA (0.08±0.02 and 0.06±0.02 p=0.001), arginine (385.8±160.4 and 269.5±79.0 p=0.001) and citrulline (91.5±34.3 and 75.3±23.5 p=0.001) were reduced. Levels of arginine/ADMA ratio was increased (498.7±136.5 and 576.7±170.7 p=0.001) (Table 1). Also BASDAI, BASFI and erythrocyte sedimentation rate were decreased but it was statistically meaningless. In Pearson correlation analysis, ADMA, SDMA, LNMMA, arginine and citrulline were negatively correlated with vitamin D levels. Multiple regression analysis showed that SDMA, arginine and citrulline were significantly related with vitamin D levels. Negative correlation between ADMA and vitamin D levels was shown in Figure 1

SAT0423

INCREASED PREVALENCE OF EXTRA-ARTICULAR MANIFESTATIONS AMONG INDIVIDUALS WITH ANKYLOSING SPONDYLITIS IN CANADA: RESULTS FROM THE RHUMADATA® MULTICENTRE REGISTRY

S. Szabo1, S. Chebah2, L. Coupal3, D. Chouquette1, 3Broadstreet HEOR, Vancouver; 2Novartis Pharmaceuticals Canada; 3Institut de Recherche en Rhumatologie de Montréal, Montreal, Canada

Background: Among populations with ankylosing spondylitis (AS), the frequency and severity of extra-articular manifestations (EAMs) vary widely, due to underlying geographic and genetic differences, individual characteristics, and the impact of treatment with anti-tumour necrosis factor (TNF) agents. The frequency of EAMs

Scientific Abstracts
Saturday, 17 June 2017 931
among Canadians with AS has not previously been examined, using data from a large clinical registry.

**Objectives:** To estimate the prevalence of EAMs, including uveitis, inflammatory bowel disease (IBD), dactylitis, and enthesitis, in a population of Canadians undergoing active management for AS.

**Methods:** This retrospective cohort study used RHUMADATA®, a multicentre registry developed by rheumatologists of the IRMM and Centre d’ostéoporose et de rhumatologie de Québec to evaluate the effectiveness and safety of rheumatologic therapies. Up to 15 years of real-world observational data on the broad set of patients treated in clinical practice are available. The proportion with EAMs was estimated according to type. The frequency of EAMs was compared according to age at cohort entry (<40 vs >40 years), sex, AS severity (by BASDAI score), and status of treatment with anti-TNFs (anti-TNF-naive, anti-TNF-treated [without switching], and anti-TNF treated [with switching]).

**Results:** Median (SD) age at cohort entry was 39.0 (12.6) years, and 60.0% were male. Of the 944 patients, 268 (28.4%) were ever diagnosed with an EAM over a median of 9.66 (10.58) years of follow-up. Prevalence was 14.7% for uveitis, 5.8% for IBD, 4.3% for dactylitis, and 9.0% for enthesitis (Table). The proportion with EAMs was: slightly higher among females versus males (31.0% vs. 26.7%), among older versus younger patients (29.5% vs. 25.9%), among those with more severe disease (from 29.2% [mild AS] vs. 34.1% [severe AS]), and among anti-TNF treated patients (18.8% [anti-TNF-naive] vs 47.0% [treated with anti-TNFs, with switching]).

**Conclusions:** Underdiagnosed axial disease is frequent in PsA, women having higher risk and IBD criteria being less sensitive in women. More complex patients (eg with higher enthesitis and peripheral arthritis) have a higher risk of being underdiagnosed. These patients are less frequently treated with biologic treatments, which could be the right treatment choice if were diagnosed. Axial disease needs to be ruled out using imaging modalities, even if back pain does not clinically suggest an inflammatory pattern.

**AXIAL DISEASE IN PSORIATIC ARTHRITIS: BURDEN OF UNDERDIAGNOSED DISEASE AND RISK FACTORS IN REAL LIFE**

S.Z. Aydin1, U. Kalyoncu2 on behalf of the PsART study group. 1University of Ottawa, Ottawa, Canada; 2Hacettepe University, Ankara, Turkey

**Background:** The frequency of axial disease in Psoriatic Arthritis (PsA) is around 24–78% with additional patients with subclinical disease who have spondylitis-like changes or sacroiliitis in the absence of clinical findings. Despite that most of the physicians do not perform routine imaging with the argument that subclinical changes or sacroiliitis in the absence of clinical findings. Despite that most of the physicians do not perform routine imaging with the argument that subclinical disease has no effects on management decisions.

**Objectives:** To examine barriers for diagnosing axial disease in PsA and its implications in real life.

**Methods:** PsART (Psoriatic Arthritis Registry of Turkey) is a prospective, multicentre registry where PsA patients are consecutively recruited. Radiographs of the spine and sacroiliac joints were scored by one central reader, whenever available. Patients with axial disease according to the physician were compared with patients with imaging findings of Bacchus disease when appropriate.

**Results:** Among 1195 patients, 35% had axial disease according to the physician who were more frequently men (41.2% vs 32.2%; p=0.04), younger (44.4 (12.2) vs 47.7 (11.8); p=0.04), and inflammatory back pain (44.6% vs 34%; p=0.001), more on anti TNFs (37.1% vs 29.4%; p=0.01) and had more nail involvement (49.9% vs 43.2%; p=0.03). Within the IBD criteria, the ASAS criteria had the lowest sensitivity (59.7%) which was even lower in women (53.1%). Forty-nine (15.7%) patients were classified as having axial disease according to the rheumatologist despite not fulfilling any of the IBP criteria which was more frequent for women (21.1%) than men (8.2%; p=0.002). Among 71 patients that had syndesmophytes, 20 patients (28.2%) were not classified as having axial disease according to the physician. This higher was for women (15/42, 35.7%) then men (5/29, 17.2%). There were 126 patients who had sacroiliac fulfilling the ASAS criteria, despite being categorized as having axial disease by the clinician. The risk of being underdiagnosed was higher for women (30.8% vs 18.4%; p=0.003). These patients had higher Leeds enthesis scores, tender and swollen joint counts (table) and were less using anti-TNF medications (14.6% vs 38.7%; p=0.001).

The PROs and the physician global assessment were similar, suggesting a similar disease activity stage according to the patients and physicians in diagnosed and undiagnosed groups.

SAT0426  HIGH LEVELS OF EMPLOYMENT BUT PERSISTING WORK PLACE IMPAIRMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS ON BIOLOGIC THERAPY

SAT0427  ASAS HEALTH INDEX: VALIDITY AND RELIABILITY IN ARGENTINEAN PATIENTS WITH SPONDYLOARTHRITIS

SAT0428  WHICH CRITERIA FOR INFLAMMATORY BACK PAIN IN SPONDYLOARTHRITIS ARE OPTIMAL? DATA FROM THE SCREENING FOR AXIAL SPONDYLOARTHRITIS IN PSORIASIS, IRRITIS, AND COLITIS STUDY (SASPIC)

Background: Criteria for inflammatory back pain (IBP) in spondyloarthritis (SpA) include the Calin, Berlin, and Assessments in SpA International Society (ASAS) criteria, although no studies have undertaken comparative validation to determine which are optimal versus the rheumatologist expert opinion gold standard assessment.

Objectives: We aimed to compare IBP criteria in unselected patients presenting with undiagnosed back pain to rheumatology practice.

Methods: The Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis Study (SASPIC) is aimed at the development and validation of a triage strategy for detection of axial SpA in patients presenting with undiagnosed back pain. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any of one psoriasis, acute anterior uveitis, or colitis diagnosed by the relevant specialist undergo routine clinical evaluation by a rheumatologist for axial SpA. The rheumatologist then uses the presence or absence of IBP (defined as ≤5 or ≤5 on 0–10 scale, respectively) and axial SpA (yes/no) after the clinical evaluation and review of labs (B27, CRP) and imaging (x-ray, MRI). Clinical and laboratory data, radiographs and MRI scans are also assessed centrally for diagnosis of axial SpA (yes/no). We assessed sensitivity and specificity of each
of the IBP criteria for diagnosis of IBP according to the local rheumatologist, diagnosis of axial SpA by local rheumatologist, diagnosis of axial SpA by central assessment, and concordant diagnosis of axial SpA by both local and central assessment.

Results: We recruited 185 patients (48.6% male, mean age 27.6 years, mean back pain duration 7.0 years) with iritis (30.3%), psoriasis with arthritis (34.9%), Crohn’s disease (18.9%) and ulcerative colitis (18.9%). IBP and/or axial SpA were considered present in 65.2% and 47.3%, respectively, of all patients by the local rheumatologist. By central assessment axial SpA was considered present in 32.7% whilst among patients with a concordant diagnosis by both local and central assessment 37.2% were considered to have axial SpA. Sensitivity was comparatively high for all IBP criteria but specificity was poor. The Berlin criteria consistently performed best when the Calin criteria consistently performed worst (Table).

SAT0429 | THE PERFORMANCE OF MAGNETIC RESONANCE IMAGING USING THE VIBE TECHNIQUE TO DETECT STRUCTURAL CHANGES IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS IN COMPARISON TO CONVENTIONAL RADIOGRAPHY AND COMPUTED TOMOGRAPHY

X. Baraliakos 1, F. Hoffmann 1, X. Deng 2, Y. Wang 3, F. Huang 4, J. Braun 5
1 Rheumatology, Ruhrgebet, Henne, Germany; 2 Department of Rheumatology, Chinese PLA General Hospital, Beijing, China

Background: Magnetic resonance imaging (MRI) is the gold standard for detection of inflammation in the sacroiliac joints (SIJ) of patients (pts) with axial spondyloarthritids (axSpA), while for chronic, structural changes (erosions, sclerosis and ankylosis) conventional radiographs (CR) and computed tomography (CT) are often preferred. The 3D volumetric interpolated breath-hold sequence (VIBE) is an MRI technique, easy to acquire in daily practice, that can visualize cartilage especially well because of its good contrast to synovial tissue.

Objectives: To compare the ability of the VIBE technique to detect structural changes in comparison to CR and CT in SIs of axSpA patients in relation to symptom duration and age.

Methods: Complete sets of MRI (T1 and VIBE techniques), CT and CR of SIs of 109 AS patients were available. Two readers evaluated all images independently, blinded to demographic data and in separate, 82% HLA-B27+, 58 pts (53%) had a disease duration <3y. Agreement for positive and negative findings between MRI and CT was generally high (ICC=0.979–0.997). Overall, MRI detected significantly more SIJ erosions in pts <45y (n=134) and in pts with disease duration <3y (n=125) as compared to CT (n=91, p=0.002 and n=90, p=0.003, respectively) and in pts with age <45y (n=61, p<0.001) as compared to CR, while there were no differences between MRI and CT in pts >45y or disease duration >3y. Linear regression analysis showed that the sensitivity of MRI was superior in the disease duration ≤45y (n=134) but weak in pts >45y (B=0.032, p=0.001). However, CT detected significantly more SIJ half erosions in all subgroups and more SIJ with sclerosis in pts with disease duration <3y (n=64 vs. n=37, respectively, p=0.006), and it also detected more so with sclerosis in pts <45y (n=67 vs. n=38, p=0.001) and disease duration >3y (n=64 vs. n=40, p=0.003) as compared to MRI, while no differences were found in the assessment of ankylosis.

Conclusions: MRI in the T1 and VIBE technique is more sensitive in the detection of erosions as compared to CT and CR in axSpA pts with short disease duration and younger age. This is due to its ability to identify structural damage in the SIJ cartilage that has not yet extended to the underlying bone. These differences are not found in pts with longer disease duration or older age. This data suggests a more prominent role for MRI also for the early detection of structural changes in the SIJ of axSpA pts.

SAT0430 | THE RELATIONSHIP BETWEEN EXOSOMAL miRNA21-5P AND ANKYLOSING SPONDYLITIS

Y. Huang, T. Li, Z. Huang, W. Deng, S. Zheng, Z. Huang. Guangdong No. 2 Provincial People’s Hospital, Guangzhou, China

Background: Ankylosing Spondylitis (AS) affects human health seriously, which is difficult to diagnose in the early stages. It is reported that MicroRNAs (miRNAs) may serve as novel biomarkers for AS. Exosome can function as vehicles to deliver miRNAs in body fluids including saliva and plasma. Our previous study shows that exosomal miRNA21–5P is higher expressed in AS patients, compared with healthy subjects. However, the relationship between exosomal miRNA21–5P and AS has yet to be determined.

Objectives: The aim of the present study is to explore the relationship between exosomal miRNA21–5P and AS.

Methods: AS patients who fulfilled the modified New York criteria were enrolled in our study. Healthy subjects were also enrolled as control group. BASDAI, BAVSI, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were evaluated. Quantitative reverse-transcription PCR (qRT-PCR) was used to confirm the expression of exosomal miRNA21–5P, and receiver-operator characteristic (ROC) curve was used to evaluate the diagnostic value of exosomal miRNA21–5P for AS. According to the cut off value, AS patients were divided into exosomal miRNA21–5P low value group (<cut off value) and exosomal miRNA21–5P high value group (>cut off value), and the difference of AS patient’s clinical characteristics between the two groups were explored.

Results: Twenty healthy subjects and 64 AS patients were enrolled in the study. The qRT-PCR results indicated that the expression level of exosomal miRNA21–5P in AS patients was (2.041±0.975) times higher than that of healthy subjects. ROC curve analysis showed that exosomal miRNA21–5P had significant diagnostic value for AS with the AUC of 0.809 (CI95%; 0.691–0.921). In addition, the cut off value was 1.310, with the specificity of 80.0% and sensitivity of 76.32%. According to the cut off value of exosomal miRNA21–5P, AS patients were divided into the low exosomal miRNA21–5P group (<1.310) and the high exosomal miRNA21–5P group (>1.310). Among the 38 AS patients, 12 cases were in the low exosomal miRNA21–5P group and 26 cases were in the high exosomal miRNA21–5P group. Comparations of the clinical characteristics of the two groups showed that BASDAI, BAVSI, CRP and ESR were significantly increased in exosomal miRNA21–5P high value group.

Conclusions: Exosomal miRNA21–5P was significantly increased in AS patients, which may be used as a biomarker for AS.

DOI: 10.1136/annrheumdis-2017-eular.6836

SAT0431 | THE RELATIONSHIP OF SEASONAL VARIATION, THE ONSET AND THE SYMPTOMS OF ANKYLOSING SPONDYLITIS MEASURED BY SELF-ADMINISTRATED QUESTIONNAIRES IN CHINESE PATIENTS

Y. Jiang, M. Yang, Z. Lin, Q. Wei, S. Cao, J. Gu. Rheumatology, the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease which mainly results in pain, functional limitation and even less life expectancy. Seasonal variation was found in rheumatoid arthritis and gout [1,2]. No reports had been focused on seasonal variation of AS onset or symptoms in AS patients.

Objectives: Our study was to investigate the relationship of seasonal variation and the onset and symptoms of AS in Chinese patients.

Methods: Adult AS patients diagnosed with the modified New York criteria for AS whose disease duration was over 2 years were enrolled from several provinces all over China. Participants were required to complete a set of questionnaires and examinations, including demographic and clinical information. Questions included ‘in which season(s) did you have the initial symptoms of AS’, and ‘in which season(s) were the symptoms aggravated/improved’. The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis.

Results: Of all the 859 AS patients, 75.1% were male patients. 47.8% were married. Mean age was 30.60±9.50 years. Mean disease duration was 7.43±6.92 years. 27.7% of the patients had an onset of the disease in summer, while the lowest incidence happened in autumn (12.5%, p<0.05). 29.6% of the patients could not recall the exact season. 29.5% of the patients’ symptoms got worse in winter,
while only 2.6% of the patients felt worse in autumn, in comparison of 10.3% in winter and 6.0% in summer. 24.4% of the patients felt relieved in summer, while only 2.6% felt better in spring, with a overall 2.7% felt better in spring, with a lower rate of the first in autumn.

Conclusions: More patients had an onset of AS in summer, compared to other seasons. More patients felt worse in winter and better in summer. Nearly half of AS patients considered that there were no seasonal differences in the deterioration or improvement of the symptoms.

SAT0432 | CORRELATION BETWEEN THE SPINAL MRI FINDINGS AND NEW BONE FORMATION FACTOR (DKK-1) IN PATIENTS WITH SPONDYLOARTHRITIS

Z. Zhao, G. Wang, Y.Y. Wang, J.S. Yang, J. Zhu, F. Huang. Rheumatology. Chinese PLA General Hospital, Beijing, China

Background: Recent prospective data suggest that spinal inflammatory damage in patients with ankylosing spondylitis will eventually convert into fat. In these complex inflammatory lesions, bone formation and inflammation are not synchronized. The molecular basis responsible for new bone formation in SpA patients is still unclear. Serum level of dickkopf-1 (Dkk-1), the natural inhibitor of Wnt protein, is a main factor in limiting new bone formation.

Objectives: In this study, we aimed to assess the correlation between the secreted protein Dkk-1 and abnormal findings on spinal MRI through a prospective study of SpA.

Methods: Thirty patients with active axial SpA (axSpA) who fulfilled the ASAS axSpA criteria were enrolled. All patients received an injection of recombinant human TNF receptor-antibody fusion protein (YISAIPU) at a dosage of 50 mg/week for 6 months. Patient report outcome measure questionnaires and physical examination, blood tests were completed according to the study protocol. All patients were scored for bone marrow edema and fat infiltration on spinal MRI using the SPARCC scoring system by two blinded reviewers.

Table 1. Clinical indexes, serum Dkk-1 and spine imaging scores before and after treatment.

Conclusions: Our findings show that biological therapy in patients with RA or AS is associated with a 13 to 35 fold increase in prevalence of PPP. While the prevalence of biological-associated PV is lower than the prevalence of PV in the general population. In this study PV and PPP are different from each other regarding prevalence, time to onset and consequences for biological treatment, and therefore should be considered as separate entities.

**SAT0434** NETWORK META-ANALYSIS ON THE EFFICACY OF NOVEL THERAPEUTIC AGENTS IN PATIENTS WITH PSORIATIC ARTHRITIS

T.T. Cheung, M.F. Tsoi, Y. Fei, C.S. Lau, B.M.Y. Cheung. Medicine, The University of Hong Kong, Hong Kong, Hong Kong

**Background:** Novel therapeutic agents are more effective than DMARDs in the management of psoriatic arthritis. However, direct comparisons of efficacy between these novel therapeutic agents are lacking.

**Objectives:** This network meta-analysis aims to compare the relative efficacies between different novel therapeutic agents.

**Methods:** Literature searching was conducted in MEDLINE, EMBASE, Scopus, ISI Web of Science, Cochrane Library, Clinicaltrial.gov and recent rheumatology conference abstracts up to Nov 2016. 2 independent researchers analysed the articles. For inclusion, randomised, placebo-controlled trials must report the proportion of patients achieving ACR20, ACR50, ACR70 and PASI75 responses. The outcomes of this network meta-analysis were the proportion of patients achieving ACR20, ACR50, ACR70 and PASI75 responses with reference to placebo and etanercept.

Results were analysed using random effect model by R statistics (version 3.3.1) with statistical package netmeta (version 0.9–2). The heterogeneity of the study results was determined by the I² statistics.

**Results:** 18 trials were included into this study. In general, all novel therapeutic agents demonstrated superior efficacy than placebo. With reference to etanercept, apremilast and ustekinumab were associated with less proportions of patients achieving ACR20 response (odds ratio [95% confidence interval]: golimumab: 3.51 [0.44–28.2]; adalimumab: 0.33 [0.13; 0.86]; 5mg Tofacitinib BID: 0.25 [0.08; 0.81]; 45mg Ustekinumab: 0.26 [0.09; 0.75]; 30mg Secukinumab 0.77 [0.21; 2.80]; 30mg Apremilast: 0.24 [0.09; 0.63]; 20mg Apremilast BID: 0.18 [0.07; 0.49]; Placebo: 0.10 [0.04; 0.22]; 0.09 [0.03; 0.35]).

Conclusions: Apremilast and ustekinumab were less efficacious than etanercept in terms of ACR20 response. All the novel therapeutic agents demonstrated comparable efficacies in terms of ACR50, ACR70 and PASI75 responses.

**SAT0435** IL17 CORRELATES POSITIVELY WITH TGF-BETA 1 AND DKK1 AND INVERSELY WITH BMP2 AND 4 IN SYNOVIAL MEMBRANE OF PATIENTS WITH PSORIATIC ARTHRITIS

**Background:** Immune and non-immune cells contribute to the pathology of chronic arthritis and they can contribute to tissue remodeling and repair as well as disease progression. An important role for their products such as TGF-beta 1, IL17 or BMPs has been suggested in homoeostatic and remodeling mechanisms in arthritis. BMP signaling could have an anti-inflammatory role in the control and maintenance of low levels of pro-inflammatory factors in healthy joints or the early stage of RA.

**Objectives:** To analyze and compare serum levels, gene expression and immunohistochemistry (IHC) in synovial membrane of inflammation and bone destruction/regeneration biomarkers in patients with psoriatic arthritis (PsA), undernourished seronegative arthritis (USA), Osteoarthritis of the knee (kOA) and ankylosing spondylitis (AS).

**Methods:** We recruited 45 consecutive patients with chronic knee arthritis referred for undergoing arthroscopies (17 PsA, 12 USA, 12 kOA, 4 AS). Synovial membrane was processed for IHC analysis and quantification of mRNA expression. Synovial levels of TGF-beta 1, IL6, IL17 and IL22, DKK1, Sclerostin, BMP2, BMP4, Wnt1 and Wnt5a were measured (ELISA). We analyzed and compared these data with the demographic, clinical, analytical and radiological characteristics of the patients. Data were analyzed using the SPSS version 17.0 software and statistical significance was defined as P<0.05.

Conclusions: Synovial membrane samples from 41 patients were collected for biomechanical, IHC and RNA extraction from 29 patients for mRNA expression and flow cytometry from 38 patients for protein levels measurement. IL17 gene expression was higher in PsA patients (p=0.027) and correlated positively with DKK1 (r=0.424, p=0.022) and negatively with BMP2 (r=-0.396, p=0.030) and BMP4 (r=-0.472, p=0.010). IL17 reactivity for TGF-beta 1 in synovial tissue was higher in patients with psoriatic arthritis compared to placebo (p=0.010) and correlated positively with IL17 (r=0.389, p=0.012) and DKK1 (r=0.388, p=0.012). Moreover, serum levels of TGF-beta 1 were significantly increased in PsA with erosions (p=0.044).

**SAT0436** DURABILITY OF APREMILAST RESPONSE IN PATIENTS WITH PSORIATIC ARTHRITIS: LONG-TERM (208-WEEK) RESULTS FROM THE PALACE 1 TRIAL

A. Kavanaugh 1, D.D. Gladman 2, J.J. Gomez-Reino 3, S. Hall 4, E. Lespesailles 5, P.J. Mease 6, G. Schett 7, M. McInraith 8, N. Delev 9, M. Paris 9, L. Teng 9, J. Wollenhaupt 9, 1UCSD School of Medicine, La Jolla, United States; 2Toronto Western Research Institute, Toronto, Canada; 3Hospital Clinico Universitario, Santiago, Spain; 4Monash University, CabiriniHealth, Melbourne, Australia; 5University of Orleans, Orilians, France; 6Swedish Medical Center and University of Washington School of Medicine, Seattle, United States; 7University of Erlangen-Nuremberg, Erlangen, Germany; 8Celgene Corporation, Summit, United States; 9Schön Klinik Hamburg Elbe, Hamburg, Germany

**Background:** Optimizing treatment choice in psoriatic arthritis (PsA) necessitates an understanding of the long-term effects of therapies across varied manifestations of this complex disease. Data from 4 years of apremilast (APR) treatment in PALACE 1 were used to examine disease control across markers of active inflammation, such as SJC, as well as improvements in patient (pt) functionality, as assessed using the HAQ-DI.

**Objectives:** Evaluate long-term outcomes with APR treatment after ≥1 DMARD or biologic in pts with active PsA.

**Methods:** Pts were randomized (1:1:1) to placebo (PBO), APR 30 mg BD (APR30), or APR 20 mg BD (APR20). The PBO-controlled phase continued to Wk 24, at which time all remaining PBO pts were re-randomized to APR30 or APR20.
Conclusions: APR30 demonstrated sustained, clinically meaningful improvements in signs and symptoms of PsA, physical function, and associated psoriasis over 208 wks. APR30 continued to demonstrate a favorable safety profile and was generally well tolerated.

SAT0438  PSORIATIC ARTHRITIS AND NODAL OSTEOARTHRITIS CAN BE DIFFERENTIATED USING HAND RADIOGRAPHS: A NOVEL METHOD

S. Bahadur1, A. Zavareh2, C. Hughes3, R. Mandegaran3, S. Subesinghe3, B. Kirkham1, 1Rheumatology; 2Radiology; 3Guys and St Thomas Trust, London, United Kingdom

Background: One of the difficulties of rheumatology practice is the differentiation of Psoriatic Arthritis (PsA) and Nodal Osteoarthritis (NOA) in some patients with distal interphalangeal joint involvement. MRI and ultrasound imaging, have recently been demonstrated to be very valuable in some cases (1,2). This differentiation is critical, as treatment for these debilitating conditions is completely different.

Objectives: To establish a scoring system of radiographic joint and soft tissue features to differentiate PsA from NOA.

Methods: We devised a scoring system for hand radiographs of interphalangeal joints, soft tissue and bone features, allocated major and minor weighting. The scoring system was then tested in a single blind analysis of hand radiographs from 48 patients with PsA, 50 with NOA and 1 with RA (incorrectly classified as PsA at study entry) seen between 2008 and 2016. Anonymised patient images were assessed by a Musculoskeletal (MSK) Radiologist, blind to clinical information. Radiological diagnosis was then compared with clinical diagnosis. We taught the method to 2 rheumatology and 1 radiology trainees over 1 hour, who then independently assessed the same radiographs.

Results: The MSK radiologist reported normal hand radiographs in 5 patients. Of the remaining 53 patients, the scoring system correctly allocated 100% of images into PsA, NOA or RA. Notably, 2 patients with NOA who subsequently developed PsA several years later, and 1 patient with seropositive RA, initially misclassified as PsA, were correctly identified by the MSK radiologist.

Conclusions: We taught the method to 2 rheumatology and 1 radiology trainees over 1 hour, who then independently assessed the same radiographs.

SAT0439  INTEGRATED SAFETY SUMMARY OF TOFACITINIB IN PSORIATIC ARTHRITIS CLINICAL STUDIES

G. Burmester1, O. FitzGerald2, K. Winthrop2, G. Williams3, V.F. Azevedo5, W.F.C. Rigby5, K. Kanik7, C. Wang7, P. Biswas8, T. Jones9, S. Menon7, N. Palmetto3, R. Rojo1, 1Charité - University Medicine Berlin, Berlin, Germany; 2Department of Rheumatology, St. Vincent’s University Hospital, Dublin, Ireland; 3Oregon Health and Science University, Portland, OR; 4Williams Cancer Drug Consulting LLC, Wayne, NJ, United States; 5Universidade Federal do Paraná, Curitiba, Brazil; 6Geisel School of Medicine at Dartmouth, Lebanon, NH; 7Pfizer Inc, Groton, CT; 8Pfizer Inc, New York, NY; 9Pfizer Inc, Collegeville, PA, United States

Background: Tofacitinib is an oral Janus kinase inhibitor under investigation for psoriatic arthritis (PsA).

Objectives: To describe the safety profile of tofacitinib from integrated Phase (P)3 and long-term extension (LTE) studies.

Methods: Data were analysed for patients (pts) who received ≥1 dose of tofacitinib 5 or 10 mg BID or placebo (PBO), integrated across 2 P3 studies (OPAL Broaden [12 months; NCT01877668], OPAL Beyond [6 months; NCT01824399]) and 1 LTE study (OPAL Balance [ongoing, database not locked; NCT01976364]). Common adverse events (AEs; occurring in ≥2% of tofacitinib pts in any group) were analysed in the PBO-controlled portion (Months 0–3) of the P3 studies (Cohort 1 [C1]). Serious AEs (SAEs) and discontinuations due to AEs were analysed over 12 months in pts randomised to tofacitinib 5 or 10 mg BID in P3 studies (Cohort 2a [C2a]; pts randomised to PBO were excluded from this analysis. Deaths and AEs of special interest (serious infections [SI], herpes zoster [HZ], opportunistic infections [OI]) including HZ, major adverse cardiac events [MACE], malignancies, non-melanoma skin cancer [NMSC]) were evaluated in all tofacitinib-treated pts in the P3 and LTE studies (Cohort 3 [C3]). Incidence rates (IR; pts with events/100 pt-years [PY]) and 95% confidence intervals are reported. Laboratory results will be reported in future publications.

Results: C1 included 474 tofacitinib- and 236 PBO-treated pts; C2a included 474 tofacitinib-treated pts, and C3 included 783 tofacitinib-treated pts (exposure: 776 PY). Nasopharyngitis (5.9%) and headache (8.5%) were the most commonly reported AEs at Month 3 in pts receiving tofacitinib 5 or 10 mg BID, respectively (Table). In pts randomised to tofacitinib 5 or 10 mg BID, over 12 months (C2a), the IRs for SAEs were 7.92 (4.09, 13.84) and 8.11 (4.19, 14.17), respectively. Discontinuation due to AEs occurred in 11 (4.6%) and 11 (4.7%) pts randomised to tofacitinib 5 and 10 mg BID, respectively. The IRs for SIs of 17.5 (3.68, 13.08), respectively, over 12 months (C2a). Across all tofacitinib-treated pts in the P3 and LTE studies (C3), SIs occurred in 11 pts (1.4%; IR 1.40 [0.70, 2.50]). HZ was reported in 16 pts (2.0%; IR 2.05 [1.17, 3.33]) receiving tofacitinib. All 3 cases of multidermalar HZ were adjudicated as OIs; these were the only OIs (0.2%; IR 0.38 [0.08, 1.11]). In C3, 2 deaths occurred (0.3%; IR 0.25 [0.03, 0.91]); all were considered unrelated to the study drug. MACE were reported in 3 pts (0.4%; IR 0.38 [0.08, 1.11]), malignancies (excluding NMSC) in 5 pts (0.6%; IR 0.63 [0.21, 1.48]) and NMSC in 4 pts (0.5%; IR 0.51 [0.14, 1.30]).

Conclusions: Tofacitinib was well tolerated in pts with PsA, with a safety profile consistent to that seen in RA; no new risks were identified. Longer-term follow-up and larger pt populations will provide further information on the safety profile of tofacitinib in pts with PsA.

SAT0440  DO DEPRESSION AND ANXIETY INFLUENCE THE CHANCE OF REMISSION IN PATIENTS WITH PSORIATIC ARTHRITIS? REAL LIFE DATA FROM THE NOR-DMARD STUDY

B. Michelsen1,2, E.K. Kristianslund1, K.M. Fagel1, E. Lie1, H.B. Hammer1, G. Haugeberg1,2,3, T.K. Kvien1, 1Rheumatology; 2Radiology; 3Guys and St Thomas Trust, London, United Kingdom

Background: Depression and anxiety are frequent comorbidities in psoriatic arthritis (PsA). The potential influence of depression/anxiety on achievement of remission remains unexplored.

Objectives: To investigate the predictive value of baseline depression/anxiety on the likelihood of achieving remission in PsA, as well as the associations between
baseline depression/anxiety and the components of the remission criteria at follow-up.

Methods: From the prospective multi-center observational NOR-DMARD study we included PsA patients starting first-time methotrexate/tumor necrosis factor inhibitors between year 2006 and 2012. The following criteria for depression/anxiety were assessed: 1) the Medical Outcomes Survey Short Form-36 (SF-36) Mental Health subscale (MH); 2) SF-36 Mental Component Summary score (MCS); 3) The predictive value of baseline depression/anxiety on remission at 3 and 6 months was explored in prespecified logistic regression models adjusted for age, sex, disease duration and smoking, and the associations between baseline depression/anxiety and the components of the remission criteria at follow-up in prespecified multiple linear regression models adjusted for age, sex, disease duration and smoking.

Results: 805 PsA patients were included (mean (SD) age 48.0 (12.4) years, median (25th-75th percentile) disease duration 1.0 (0.07–6.8) years, 50.8% females, 28.6% current smokers). According to the SF-36MH;SF-36MCS;38 criteria 15.6/25.2% of the patients had depression/anxiety at baseline, respectively. Lower percentages of patients with vs. without baseline depression/anxiety achieved remission at 6 months (unadjusted analyses:figure). Patients with baseline depression/anxiety had consistently lower point estimates for achievement of remission at follow-up, but did not reach significance for all the analyses (adjusted analyses: table).

Baseline depression/anxiety was associated with increased patient’s global assessment and joint pain at follow-up, but not with swollen joint count or levels of acute phase reactants.

Objectives: To investigate the merits of different potential remission definitions using data from the PRESTA study.

Methods: Remission was investigated for disease activity index for PsA for 3 definitions: very low disease activity (VLDA), Disease Activity in PsA (DAPSA), and clinical (c)DAPSA. VLDMA index was defined as 7/7 met criteria of the minimal disease activity (MDA) cut-off points: tender joint count (TJC) ≤ 5, swollen joint count (SJC) ≤ 7, psoriasis activity and severity index (PASI) ≤ 1, patient global visual analog scale (PtVAS) ≤ 20mm, Pt pain VAS ≤ 15mm, health assessment questionnaire (HAQ) ≤ 0.5, tender enthesal point ≤ 1. VLDMA remission was defined as VDCA ≤ 4 (TJC, SJC, physician global VAS [cm], Pt VAS [cm], C-reactive protein [CRP]) and cDAPSA remission was defined as cDAPSA ≤ 4 (DAPSA without CRP).

Results: At Week 24, the proportion of patients achieving remission was 9.6%, 31.0%, and 34.7% for VLDMA, and cDAPSA remission, respectively. Discordance between VLDMA and DAPSA or cDAPSA remission was 21.7% or 25.1%, respectively. Only 0.2% of the patients that achieved VLDMA did not achieve DAPSA remission and 21.5% vice versa (Kappa coefficient 0.38) and 0.0% in the case of cDAPSA remission and 25.1% vice versa (Kappa coefficient 0.33). At the end of the study, residual levels of dactylitis and enthesitis appeared to be similar among all definitions (all ≤3.0%); however, patients achieving DAPSA and cDAPSA remission had higher proportions of patients with PASI > 3 versus patients achieving VLDMA remission (PASI > 2.5: VLDMA 0.0% vs DAPSA 4.6% vs cDAPSA 47.2%; PASI ≥ 10: VLDMA 0.0% vs DAPSA 5.8% vs cDAPSA 6.4%).

Raised CRP values (upper limit of normal >8.9 mmol/L) were 7.8%, 4.8%, and 7.3% for VLDMA, DAPSA, and cDAPSA, respectively.

Conclusions: VLDMA remission is a more stringent target than DAPSA and cDAPSA remission, with the advantage of including an measurement for psoriasis. Therefore, VLDMA is more useful than DAPSA or cDAPSA in assessing a remission state in patients with PsA and extended skin lesions. Measurement of CRP levels does not appear to provide further information on current disease activity level in these patients and exclusion of this laboratory marker should facilitate remission assessment in clinical practice.

measurement. As cost data were not normally distributed, standard errors (SEs), 95% confidence intervals (CIs) and P-values were estimated by bootstrap resampling (10,000 samples).

**Results:** Data were available for 95 PsA patients (female: n=43). Mean HAQ-DI score was 0.81 (SE 0.08); mean age at HAQ-DI measurement was 56.8 (SE 1.04). Mean total usual healthcare costs, excluding medication costs, were €1,588 (SE 172.3). Regression modelling indicated that a 1-point increase in HAQ-DI score was associated with an increase in total costs, excluding medications, of £547.49 (SE 222.7; 95% CI 191.1–1,103.8; P=0.004) (Table). Subgroup analyses suggested trends for higher cost increases within the lower HAQ-DI cohort (HAQ-DI ≤1) and for those with greatest disease duration (>10 years). Costs associated with secondary care consultations seemed to be the primary factor in the association between HAQ-DI and total costs.

**Conclusions:** Models incorporating total healthcare costs were highly significant; this association appears to be driven mainly by secondary care consultation costs. Costs in this study were similar to previous studies in RA populations. A study limitation was that only direct medical costs were considered, which may underestimate the true burden of PsA on healthcare systems and the wider society.

**SAT0443 IDENTIFICATION OF PREDICTORS OF MINIMAL DISEASE ACTIVITY IN EARLY PSORIATIC ARTHRITIS**

A. Zabolli1, L. Idolazzi2, L. Quattruccio1, M. Sartori1, A. Fassio2, F. Zuliani1, A. Fassio2, L. Idolazzi1, O. Viapiana, C. Benini, E. Vantaggiato, M. Rossini1, D. Gatti1, M. Rossini2, S. De Vita1, D. O. Perilli1, S. De Vita1, Department of Medical and Biological Sciences, Rheumatology Clinic, “Santa Maria della Misericordia” University Hospital, Udine, Italy, Udine.

**Background:** Psoriatic arthritis (PsA) is a systemic inflammatory disease with articular and extra-articular features, the disease activity ranges from mild oligoarthritis to destructive polyarthritis. Hence, establishing the prognosis of a patient with PsA is very important to better define the treatment strategy. Furthermore, minimal disease activity (MDA) is a validated composite outcome measure since it correlates well with long-term outcomes (e.g. development of joint damage)1. The aim of our study was to explore the short-term effects of secukinumab on bone.

**Methods:** Consecutive PsA patients attending the outpatient Early Arthritis Clinic in Udine or Verona in the last two years, were assessed. All the included patients had: I) CASPAR score ≥2; II) new diagnosis of PsA III) a complete clinical data and follow-up of at least 12 months. The GRAPPA recommendations on the management of PsA were followed. Statistical analysis included T-test, ANOVA and Pearson’s test in order to find possible predictors of MDA.

**Results:** Eighty-one early PsA patients were included in the study. 47/81 (58.2%) reached MDA at 12 month of follow up; 68/81 (83.9%) were in c-DMARDs while 11/81 (13.6%) were in b-DMARDs. Two variables at baseline were selected according to the groups based on achievement of MDA. These were: 1) lower LEI score was significantly lower at baseline in patients reaching MDA (0.43 Vs 0.86, p=0.001); and 2) a lower baseline CRP (1.2 mg/dl vs 2.8 mg/dl, p=0.008). Of note, neither the baseline disease activity evaluated with DAPSA nor the time to referral were selected by statistical analysis.

**Conclusions:** Baseline lower LEI score and lower CRP were identified as clinical predictors of MDA after 12 months of treatment in PsA. Therefore, patients with a more active enthesitis or higher inflammation may have a less responsive disease. This may be relevant to select proper treatments at baseline, and indirectly confirms that enthesitis is a key therapeutic target in PsA.

**SAT0445 DETECTION OF PSORIATIC ARTHRITIS AT EARLY ONSET: A MULTI-PROTEOMIC APPROACH TO DEVELOPING A NEW BLOOD TEST**

A.F. Mc Ardle1, A. Szentpetery2, S. De Rook3, B. Hernandez1, O. FitzGerald4, S.R. Pennington1, 1School of Medicine and Medical Sciences, University College Dublin; 2Rheumatology, St. Vincents University Hospital, Dublin 4, Ireland; 3Wilhelmina Kinderziekenhuis, Hospital, Utrecht, Netherlands; 4Rheumatology, St. Vincents University Hospital, Dublin 4, Ireland

**Background:** Psoriatic Arthritis (PsA) is an inflammatory arthritis (IA) frequently associated with psoriasis. Clinically, it is a complex heterogeneous disease and there are no diagnostic tests or criteria [1]. At first presentation, PsA may resemble other disease types - especially rheumatoid arthritis (RA), Making an accurate and early diagnosis is particularly important to ensure that individual patients receive effective and safe medication and so optimise long-term patient outcomes. Thus, it is widely acknowledged by physicians and patients alike that a new diagnostic test is urgently needed to facilitate the early and specific diagnosis of PsA [2].

**Objectives:** To (i) identify and verify candidate biomarkers with the potential to segregate patients with PsA from those with RA; and (ii) explore the value of combining different proteomic discovery platforms.

**Methods:** Serum samples were obtained from a cohort of 64 patients (32 PsA (<12 months); 32 RA defined as disease onset <12 months, and DMARD naïve). Individual baseline samples were analysed with label free LC-MS/MS (n=64), the Luminex xMAP (n=62) and an aptamer based platform called SOMAscan (n=36). The random forest test was applied to each individual data set as well as to a combined-matched data set (n=36). To verify MS data, a multiple reaction monitoring (MRM) assay was developed for 54 of the most discriminatory proteins to be applied to both pooled (PsA n=9, RA n=9) and individual patient samples (n=64).

**Results:** In this study, it was possible to quantify 387, 48 and 1129 proteins from LC-MS/MS, Luminex and SOMAscan analysis, respectively. Proteins with the ability to segregate PsA patients from those with RA were identified by random forest analysis; LC-MS/MS (AUC 0.94), Luminex (AUC 0.69) and SOMAscan (AUC 0.73). The application of the random forest model to the (i) combined data and (ii) MRM data set is part of ongoing work.

**Conclusions:** To date, statistical analysis revealed LC-MS/MS identified proteins were the most discriminatory. An MRM assay has been developed to top the 54 LC-MS/MS proteins and this assay has been applied to the discovery cohort (data analysis ongoing). The assay will next be applied to additional evaluation cohorts that include patients with spondyloarthropathy and psoriasis. Discriminatory proteins verified here represent candidates for inclusion in a blood based multi-analyte test that could ultimately be used in the diagnosis of PsA.

**SAT0445 SHORT-TERM EFFECTS OF SECUKINUMAB ON BONE TURNOVER MARKERS AND WNT SIGNALING PATHWAYS IN PATIENTS WITH PSORIATIC ARTHRITIS**

A. Fassio1, L. Idolazzi2, O. Viapiana, C. Benini, E. Vantaggiato, M. Rossini2, D. Gatti1, Rheumatology, Aouli Verona Reumatologia, Verona, Italy

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory disease characterized also by increased levels of cells producing IL-17 [1], and these levels have been shown to correlate with measures of disease activity and structural damage and bone loss [2]. Secukinumab is a monoclonal antibody licensed with the treatment of PsA which selectively binds to and neutralizes interleukin-17 (IL-17). Currently, data about the effects on the activity of either bone-reabsorbing cells and bone-forming cells secondary to the inhibition of the IL-17 pathway are completely absent.

**Objectives:** The aim of our study was to explore the short-term effects of secukinumab on bone turnover markers and Wnt signaling pathways in patients with PsA.

**Methods:** We enrolled 28 patients with PsA, classified with the CASPAR criteria and 43 healthy controls (HC). For the PsA group DAS28 was recorded and serum samples were stored at baseline and then at the first, third and the sixth month of therapy. Intact N-propeptide of type 1 collagen (PINP) and C-terminal
IXEKIZUMAB IMPROVES PATIENT-REPORTED OUTCOMES IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND PREVIOUS INADEQUATE RESPONSE TO TUMOUR NECROSIS FACTOR-INHIBITORS

A. Kavanaugh1, R. Vender2, J. Birt3, D.H. Adams2, O. Benichou4, C.-Y. Lin5, P. Nash1.1 -Univ of CA San Diego Health System, La Jolla, United States; 2Dermatins Research Inc., Hamilton, Canada; 3Eli Lilly and Company, Indianapolis, United States; 4University of Queensland, Brisbane, Australia

Background: Ixekizumab (IXE), a monoclonal high affinity antibody that selectively targets interleukin-17A, was superior to placebo (PBO) in achieving clinical responses and improving health related quality of life (HRQoL) for psoriatic arthritis (PsA) patients who were biologic-naive.1 Herein, results are presented from a phase 3 trial (SPIRIT-P2; NCT02349295) with IXE in patients with active PsA and previous inadequate response to tumour necrosis factor-inhibitors (TNF-ı).

Objectives: To explore the impact of IXE on patient reported HRQoL outcomes up to 24 weeks (wks) in patients with active PsA.

Methods: In this phase 3, multicentre, double-blind study, 363 adult patients with active PsA were randomly assigned in the ratio of 1:1:1 to subcutaneous administration of either 80-mg IXE every 4 wks (Q4W; N=122) or every 2 wks (Q2W; N=123) following a 160-mg starting dose at Wk 0 or PBO (N=118). All patients entering the study had an inadequate response to one or two TNF-ı or were intolerant to TNF-ı. At baseline and Wk 24, HRQoL was measured by the Short Form-36 Health Survey (SF-36) Physical Component Summary (PCS) and Mental Component Summary (MCS), European Quality of Life 5 Dimensions Visual Analog Scale (EQ-5D VAS), Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP; absenteeism; presenteeism, work productivity, and activity impairment), the tich Numeric Rating Scale (NRS), and the Dermatology Life Quality Index (DLQI), Iitch NRS, DLQI, and Psoriasis Area Severity Index (PASI) responses were assessed in patients with baseline psoriatic lesion involving ≥3% body surface area (BSA; N=203). Treatment comparisons were made by a mixed model for repeated measures for continuous data and by a logistic regression model for categorical data with missing values imputed by nonresponder imputation.

Results: Mean baseline (±SD) scores for HRQoL measures indicated impaired physical and mental function, quality of life, and work productivity (Table). At Wk 24, clinical efficacy was shown by 50.6% and 58.1% of IXE-treated patients achieving ACR20 and PASI75 responses, respectively. Patients receiving IXE (Q4W or Q2W) reported significantly greater improvements in SF-36 PCS and MCS, EQ-5D VAS, and WPAI-SHP (presenteeism, work productivity, and activity impairment) than patients treated with PBO (Table; p<.05). For PsA patients with co-morbid psoriasis (≥3% BSA), IXE treatment (Q4W or Q2W) resulted in significantly greater improvements in Iitch NRS and DLQI than PBO treatment (Table; p<.001). Finally, 51.5% of IEXEQ4W patients and 50.0% of IEXEQ2W patients reached a DLQI total score of 0 or 1 at Wk 24, which is significantly greater than patients treated with PBO (9.0%, p<.001).

Conclusions: In patients with active PsA and previous inadequate response to TNF-ı, IXE provided significant improvement through 24 wks in all joint and skin associated HRQoL outcomes, including physical and mental function, quality of life, work productivity, DLQI, and Iitch.

SAT0446
Background: To date, published studies suggest that a significant proportion of patients with Psoriatic Arthritis (PsA) present asymptomatic sacroiliitis; that is to say, an inflammatory back pain (IBP) absence. This fact could account for the underdiagnosis of axial involvement in these patients (1).

Objectives: To evaluate the prevalence of radiographic sacroiliitis in patients with PsA and to determine its association with clinical, analytical and demographic factors.

Methods: A cross-sectional, observational, and uncentre study in which clinical, analytical and demographic data from 359 patients belonging to a PsA monotherapy (PsA) were collected. The x-ray image performed showed sacroiliitis in 127 patients (35.4%). Univariate analysis showed that radiographic sacroiliitis is predominantly associated to the presence of IBP, the positive HLA-B27 antigen and psoriatic cutaneous involvement greater than 25%. The multivariate analysis showed that radiographic sacroiliitis in these patients is predominantly associated to the presence of IBP, the positive HLA-B27 antigen and gender (men). However, sacroiliitis is not associated to the onset age of PsA (p=0.05).

Conclusions: The prevalence of radiographic sacroiliitis in our population is 35.4%, higher than in other series due to the fact that the sacroiliac x-ray images were performed on all patients, regardless of the clinical. The radiographic sacroiliitis in patients with PsA is related to the presence of IBP, HLA-B27 antigen and gender. However, the time of evolution of arthropathy and the onset age of PsA are not related to sacroiliac radiographic involvement.

SAT0449 SEX, METABOLIC CO-MORBIDITIES AND LINE OF THERAPY PREDICT TNF-INHIBITOR THERAPY PERSISTENCE IN PSORIATIC ARTHRITIS: A RETROSPECTIVE COHORT STUDY

W. Ye 1, T. Gururaman 1, C. Stober 2, E.E.P. Hut 1, D.R. Jadon 1, 2, School of Clinical Medicine, University of Cambridge, 2Department of Rheumatology, Cambridge University Hospitals, Cambridge, United Kingdom

Background: Although tumour necrosis factor-alpha inhibitor (TNFi) therapy has proven efficacy in the management of psoriatic arthritis (PsA), relatively little is known about predictors of TNFi persistence. Such knowledge would assist the application of stratified medicine.

Objectives: To determine baseline clinical characteristics associated with TNFi persistence in patients receiving their first-line, and to compare TNFi persistence in first versus second-line users.

Methods: A retrospective cohort study was performed of all patients with PsA attending a single-centre between 2003–2016. Demographic, clinical and laboratory characteristics were compared with TNFi persistence, using Kaplan-Meier survival analysis and multivariable Cox proportional hazards models.

Results: A total of 188 PsA cases had used TNFi therapy as first-line over a period spanning 7.820 person months; 46% male; mean age at TNFi initiation 47.27 (SD 11.36) years; median disease duration at initiation 11 (IQR 7.16) years. Etanercept was used by 102 and adalimumab by 86. Concomitant DMARDs were used by 121/186 (65%) and 87/186 (46%) had metabolic co-morbidities (hypertension, dyslipidaemia, type-2 diabetes, obesity). TNFi therapy was terminated in 65/188 (35%) of cases (35% due to primary inefficacy, 22% secondary inefficacy, 43% adverse events), with a median duration of TNFi persistence of 26.5 (IQR 10.5, 62.0) months. Multivariable Cox proportional hazards modelling found the following parameters at TNFi therapy initiation to be associated with shorter (poorer) TNFi persistence in first line users: female sex (hazard ratio, HR 2.57; 95% CI 1.05, 6.12; p=0.04), presence of metabolic co-morbidity (HR 2.65; 95% CI 1.24, 5.69; p=0.01); with a non-significant statistical trend towards younger age at TNFi initiation (HR 0.94; 95% CI 0.88, 1.00; p=0.06) and older age at PsA onset (HR 1.05; 95% CI 0.99, 1.12; p=0.08). Parameters not statistically associated with TNFi persistence included: choice of TNFi agent (adalimumab vs. etanercept), concomitant DMARD/methotrexate use, tender/swollen joint counts, patient global assessment (PGA) of disease activity, CRP, ESR and disease duration. Of 32 cases proceeding to a second TNFi (19 adalimumab, 13 etanercept), persistence was 14/32 (44%) over 954 person months. TNFi failure was two-fold more likely in second versus first-line users (HR 2.02; 95% CI 1.20, 3.42; p=0.009) [Figure 1], with no significant contribution from other co-variables.

Conclusions: Patients with PsA who are female and have metabolic co-morbidities appear to be more likely to fail first-line TNFi therapy. Contrary to observations in rheumatoid arthritis, and somewhat challenging the few studies in PsA, choice of TNFi agent (humanised monoclonal antibodies vs. TNFi) and is poorly diagnosed. Careful identification of IBP together with MRI of SIJs will help to better define spinal involvement.

SAT0451 THE ONE-YEAR RADIOGRAPHIC PROGRESSION AND MINIMAL DISEASE ACTIVITY IN EARLY PSORIATIC ARTHRITIS PATIENTS TREATED ACCORDING TO TREAT-TO-TARGET STRATEGY (RESULTS OF AN ONGOING OPEN-LABEL REMARCA STUDY)

E. Loginova, T. Korotaeva, A. Smirnov, A. Koltakova, D. Karateev. V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Treat-to-target (T2T) strategy has benefit in early psoriatic arthritis (PsA) treatment, its influence on radiographic progression has limited data.

Objectives: To investigate radiographic outcomes and minimal disease activity (MDA) after 1-year of T2T strategy in patients with PsA.

Methods: 40 (M:18/F:22) DMARD-naive pts with active PsA, according to the CASPAR criteria, mean age 38.4±11.1 yrs., Psa duration 11.9±6.6 months, psoriasis duration 73.8±84.6 months, median DAS 3.8 [3.2; 4.7] from the open-label REMARCA study were included. At baseline all pts were treated by Methotrexate (MTX) subcutaneous (s/c) 20–25 mg/week. Pts that still had medium or high activity after 3–6 months under MTX (MDA) therapy were added to biologic therapy (MTX+ biologic therapy (BT) - anti-TNF or Ustekinumab (s/c)). In the end of the study, 19 pts were treated by MTX-monotherapy. At baseline and after 1-yr. of treatment PsA activity index and digital radiographs of hands and feet were performed. All images were scored according to Sharp/van der Heijde (Sh.-v.d. H) method by a blinded musculoskeletal radiologist. Median total score (TS Sh.-v.d. H) = total erosion score (TES) + total narrowing score (TNS), the proportion of pts with erosion increased up to 26 pts (65%). The median TS Sh.-v.d. H significantly increased from 91.5 [72–108.5] to 91.5 [73.5–111.5] (W-test, p<0.01), TES from 2 [0–4.5] to 2.5 [0–5] (W-test, p<0.05) and TNS from 85 [69–105] to 87 [71–97] (W-test, p<0.05). There was no significant difference between the treatment groups in the value of TS Sh.-v.d. H (W-test p>0.05).

25 of pts (62.5%) had reached MDA by 1 yr. In pts who did not reach MDA (n=15) by 1 yr. TES was significantly higher at baseline compare to those who reached MDA, 3 [2–9] and 0 [5–3] accordingly (U-test, p<0.05). In the group of pts who did not reach MDA 1 yr. treatment was significantly higher (table). In 29 of 40 pts (72.5%) there was no X-ray progression considering both erosion and joint space narrowing. 13 of them (45%) were treated by MTX and 16 pts (55%) by MTX+BT. Negative X-ray progression was found in 11 out of 40 pts (27.5%); 6 of them (54.5%) were treated by MTX and 5 pts (45.5%) by MTX+BT.

Conclusions: Patients with PsA who are female and have metabolic co-morbidities appear to be more likely to fail first-line TNFi therapy. Contrary to observations in rheumatoid arthritis, and somewhat challenging the few studies in PsA, choice of TNFi agent (humanised monoclonal antibodies vs. TNFi) and is poorly diagnosed. Careful identification of IBP together with MRI of SIJs will help to better define spinal involvement.

SAT0405 SILENT AXIAL DISEASE IN THE RUSSIAN COHORT OF EARLY PERIPHERAL PSORIATIC ARTHRITIS PATIENTS

E.E. Gubard V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Axial involvement in early psoriatic arthritis (pPsA) patients (pts) is not well studied so far and has not been studied properly. Magnetic resonance imaging (MRI) of sacroiliac joints (SIJs) helps to better define spinal involvement in pPsA.

Objectives: to study the prevalence of axial involvement in peripheral pPsA pts. Methods: 89 pts (M/F=42/47) with peripheral pPsA according to CASPAR criteria were included; mean age 36.5±10.9 yrs. disease duration 12.1±11.0 mo., disease activity index (DAS) 5.2±2.8, CRP 161 [6.6; 31.0] mg/l, ESR 22.5±19.2 mm/h. All patients were evaluated for the presence of inflammatory back pain (IBP) as ASAS criteria. In pts having IBP disease activity was also measured according to BASDAI. The examination included X-ray of sacroiliac joints (SIJs) (pelvic radiograph), HLA B27 antigen, MRI of SIJs was performed in 79 pts, both with and without IBP, on Signa Ovation 0.35T. Bone marrow edema on MRI (STIR), considered as active MRI sacroilitis (MRI-SI), was evaluated by an experienced musculoskeletal radiologist. MRI of SIJs was performed in 79 pts, of which 58 had IBP disease activity according to BASDAI was 4.5±1.6. Correlation has been detected between MRI-SI and IBP; among the group of pts having MRI-SI IBP was observed in 92.9% cases while out of the group of patients without MRI-SI in 54.9% cases (p<0.0002). An association was found between MRI-SI and long-term IBP (p=0.003) as well as between MRI-SI and short-term IBP (p<0.001). Moderate correlation has been detected between the presence of MRI-SI and IBP (p=0.038). It's worth noticing that among the group of pts having MRI-SI 15 (19.2%) pts never had IBP before. And among the 15 pts having ndMRI-SI, 6 (40.0%) pts never had IBP before. No association was found between the presence of MRI-SI/IBP-R/SI and HLA B27 status.

Conclusions: in the Russian cohort of early peripheral psoriatic arthritis pts, careful examination quite often revealed high prevalence of axial involvement: 65% of pts had IBP (moreover, more than half of them (60%) had short-term IBP), 35% of pts had MRI-SI, half of the pts had R-SI, one third of the pts had definite SI-R. A significant number of patients (40%) developed 2 grade changes in one SIJ without previous IBP. An association was found between IBP and SI revealed by any of the visualization methods used. No association has been detected between the presence of MRI-SI or R-SI and HLA B27 status. These data indicate that in peripheral pPsA pts axial involvement is often asymptomatic and is poorly diagnosed. Careful identification of IBP together with MRI of SIJs will help to better define spinal involvement.

SAT0452

INFLUENCE OF ANTIRHEUMATIC THERAPY ADMINISTERED IN ACCORDANCE WITH “TREAT TO TARGET” PRINCIPLES ON HEART RATE VARIABILITY AND CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH ACTIVE EARLY PSORIATIC ARTHRITIS

E. Markelova, D. Novikova, T. Korotaeva, E. Loginova, I. Krillova, L. Denisov, D. Karateev. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Psoriatic arthritis (PsA) is an inflammatory arthropathy, which is associated with range of co-morbid diseases and risk factors, such as dyslipidemia, obesity, metabolic syndrome, cardiovascular disease (CVD). Lower heart rate variability (HRV) is a well-established risk factor for CVD and all-cause mortality in the general population.

Objectives: to study dynamic of traditional risk factors (TRF) of CVD and parameters of HRV during antirheumatic therapy, administered in accordance with “Treat to target” principles in PsA pts.

Methods: 44 (F:21) DMARD-naïve PsA pts, according to the CASPAR criteria, age 36 [27; 46] years (yrs.), PsA duration – 6 [4; 8] yrs, DAS 4.06 [3.51; 4.74]. TRFs of CVD were assessed according to ESC (2016): arterial hypertension (AH) – 11 (22.9%) pts, obesity (body mass index >30kg/m2) – 11 (22.9%), dyslipidemia – 11 (22.9%), abdominal obesity – 14 (29.2%), diabetes – 31 (64.5%), family history of early CVD – 6 (12.5%), menopausal status – 5 (10.4%), smoking - 16 (33.3%). All pts were assessed for ECG, 24-h ECG monitoring, carotid ultrasound imaging. Antihypertensive therapy received all pts with AH. Metohotrexate (MT) therapy was started in all pts with an escalation of the dose up to 25 mg/week subcutaneously. In case of no remission 3 months later, MT was added with biologic therapy: Adalimumab, Certolizumababep, Ustekinumab. 23 subjects were assessed after 18 months of therapy.

Results: After 18 months of therapy DAS and CRP level decreased significantly, p<0.001. DAS remission was achieved in 82.6% of pts. The incidence rate of AH – 14 (29.2%), dyslipidemia – 31 (64.5%), family history of early CVD – 5 (10.4%) mmol/l and from 3.4 [2.8; 3.8] to 3.3 [2.6; 3.6]

Conclusions: antirheumatic therapy of early PsA pts in accordance with “T2T” principles improves lipid profile but not HRVs parameters. Lower HRV is a risk factor for cardiovascular disease and mortality that demands the further studying its influence on the cardiovascular prognosis in PsA pts.
SAT0454 FINGER FLEXOR TENDON PULLEY COMPLEX INVOLVEMENT IN PSA: A HIGH RESOLUTION ULTRASONOGRAPHIC STUDY

L. Tinazzi1, A. Marchetta2, D. Chessa3, D. Mc Gonagle4, P. Macchioni5, 1UCO Reumatologia, Ospedale Sacro Cuore Don Calabria, Negrar (Verona); 2Ospedale Sacro Cuore Negrar (Verona); Negar Verona; 3Ospedale Paolo Dettori, Tempio Pausania (OT), Italy; 4Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; 5Ospedale S.Maria Nuova UOC Reumatologia, Reggio Emilia, Italy.

Background: Psoriatic Arthritis (PsA) is often associated with hand involvement including synovitis and tenosynovitis and dactylitis. At the micro-anatomical level PsA is strongly linked to disease localisation to entheses and other sites of high mechanical stressing. Recently high resolution MRI has shown prominent abnormalities at the mini-entheses of the flexor tendon pulleys, a site of high physical stressing during finger flexion.

Objectives: This study tested the hypothesis that sonographic abnormalities were common at the hand flexor tendon mini-entheses in PsA including the A1, A2 and A4 in patients without active hand arthritis or dactylitis at the moment of ultrasound (US) scanning.

Methods: Consecutive patients affected by psoriasis (PsO) (23 cases), PsA (17) and healthy controls (HC) (19) were collected. The demographic characteristics are shown in Table 1. The cases were matched for sex, age and BMI. We excluded PsA patients with active arthritis or dactylitis at the moment of US study, the majority being under therapy with conventional DMARDs. The 26-40 flexor tendon of the dominant hand were scanned with a high resolution linear probe (10-22 MHz) using an Esaote MyLab Twice machine. The sonographer was expert in muscolo skeletal ultrasound (MSKUS) and was blinded to the clinical details. The following changes were scored: tenosynovitis, A1, A2 and A4 pulley tendon thickness and pseudotendinosynovitis (pertendinous oedema). Pulleys were explored with transverse and longitudinal scan.

Results: The A1, A2 and A4 pulleys were significantly thicker in PsA compared to PsO and healthy controls measuring both longitudinal and transverse scan (Table 2 shows means±SD value of transverse measures). In PsA patients, A1, A2 and A4 pulleys thickness were above than the 95th percentile of HCs values respectively in 84%, 80% and 100% of cases. Considering HCs and PsA we found that having a A1 thickness over the 95th percentile of HCs shows a sensitivity of 82% and specificity of 100% of PsA. Using ROC curve analysis we found that the presence of one A1 thickness over the 95th percentile of HCs have a sensitivity of 82% and specificity of 100% for PsA. Pertendinous oedema evaluated scanning the palmar side of proximal and intermediate phalanx was common in PsA patients (6/17) and absent in PsO and HCs.

Conclusions: This study suggests that PsA cases as a much higher burden of abnormalities in the mini-entheses of the flexor tendons on the hand. With the involvement resolution and capabilities of MKUS these findings may be relevant to understand the involvement of flexor tendon in PsA especially in sites with high mechanical stressing. Measuring A1, A2 and A4 thickness could be useful in detecting PsA cases without clinical signs of synovitis or dactylitis.

SAT0455 IMPACT OF PSORIATIC ARTHRITIS IN THE WORKPLACE: RESULTS OF THE FRENCH SURVEY PSOPRO

P. Claudepierre1, L. Bonnet1, Y. Roquelane2, P. Levy1, R. Aubert1, H. Bachelez1, 1Rheumatology, CHU Henri Mondor Creteil, Creteil; 2Medicine and Occupational Health, CHU Angers, Angers; 3Economies, Université Paris-Dauphine, PSL Research University, LEDA [LEGOS]; 4Patient advocacy groups France Psoriasis; 5Dermatology, AP-HP Hôpital Saint-Louis, Sorbonne Paris Cité Université Paris Diderot, Paris, France.

Objectives: The PSOPRO (Psoriasis & PsORessionnal life) survey, run under the auspices of the patient advocacy groups France Psoriasis, was aimed at measuring in comparison to the general population, the impacts of psoriasis occurring alone (PsO) or concurring with psoriatic arthritis (PsO+PsA) on patients’ working life.

Methods: From 13/07/16 to 08/08/16, 714 PsO patients, 18 of whom were under system treatment (PsO-ST), and 84 patients PsO+PsA were surveyed using a questionnaire drawn up by a multi-disciplinary scientific committee and conducted via the Internet. In addition to medical and professional characteristics, patients provided their recent absenteeism and presenteeism data, using a WPAI-PSO standardized self-questionnaire, as well as information about the interactions between psoriasis and their working life. Using the Student, Chi-deux and Fischer tests, patients were compared with a sample of 604 working respondents representative of the French population and questioned about the impact of possible health problems on their working life.

Results: The socio-demographic characteristics of the control group were similar to those of the total patient population with psoriasis, although men were slightly over-represented in the latter group. The duration of disease and cutaneous and rheumatological localisations were in line with those usually found in the literature. The unemployment rate over the previous 5 years and number of days of medical leave over the previous 12 months was higher in the PsO+PsA group as compared to the control group (Table 1). In the subgroup reporting a flare-up at the time of the survey, the impact of the disease on absenteeism, presenteeism and productivity was significantly higher in PsO-ST and PsO+PsA patients (Figure 1). Despite this, PsO-ST and PsO+PsA patients reported greater attachment to their work than did those in the control group (Table 1).

Table 1. Impact of psoriasis and psoriatic arthritis on functioning in the workplace and attachment to work.

Control group PsO PsO-ST PsO+PsA

Unemployment over the past 5 years, % (n) 31 (187) 34 (243) 41 (53) 57 (42) p < 0.05 versus control group respondents. PsO: psoriasis; PsO-ST: psoriasis under systemic treatment; PsO+PsA: psoriasis and psoriatic arthritis.

Number of days of medical leave over past 12 months, n 11 6 6 17* p < 0.05 versus control group respondents. PsO: psoriasis; PsO-ST: psoriasis under systemic treatment; PsO+PsA: psoriasis and psoriatic arthritis.

Work considered more important than other aspects of life, % (n) 8 (45) 10 (62) 20* (28) 25* (17) p < 0.05 versus control group respondents. PsO: psoriasis; PsO-ST: psoriasis under systemic treatment; PsO+PsA: psoriasis and psoriatic arthritis.

Work considered less important than other aspects of life, % (n) 42 (236) 49* (301) 21* (15) 27* (18) p < 0.05 versus control group respondents.

Conclusions: In patients with PsO, placement under systemic treatment or the co-existence of PsA appears to be associated with greater impact on patients' working life, though they also reported higher attachment to their work. Close supervision and appropriate care in PsO patients developing PsA should limit these impacts.

SAT0456 THERAPY MODIFICATIONS AMONG PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH A BIOLOGIC IN THE UNITED STATES – DESCRIPTIVE ANALYSES FROM AN ADMINISTRATIVE CLAIMS DATABASE

J.A. Walsh1, O. Adejoro2, B. Chastek2, G. Chun3, J.B. Palmer3, 1University of Utah School of Medicine, Salt Lake City, UT; 2Optum, Eden Prairie, MN; 3Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States.

Background: Biologic therapy used for the treatment of active psoriatic arthritis (PsA) can sometimes be augmented by adding non-biologic medications and/or...
escalating the dose of the biologic therapy. Limited data exist on how these therapy modifications are used in patients with PsA receiving biologic treatment in real-world settings.

Objectives: To describe therapy modifications (adding non-biologic medications or dose escalation of the current biologic therapy) in patients with PsA receiving biological therapy in the United States.

Methods: This study used US administrative claims data from the Optum Research Database. Adults with PsA who newly initiated (no evidence of use in the 12 months prior) a biologic between January 1, 2013 and January 31, 2015, and who continuously enrolled in a commercial or Medicare Advantage health plan (with baseline period) and 15 months following the index date, were included. To reduce confounding by patients with an early switch/discontinuation, therapy modifications were identified only in those patients who persisted with their index biologic for ~90 days. Therapy modifications identified included initiation of add-on medications (disease-modifying antirheumatic drugs [DMARDs], nonsteroidal anti-inflammatory drugs [NSAIDs], opioids, corticosteroids, antidepressants, anxiolytics, sleeping aids and topical analgesics) after the first 90 days of persistence, and dose escalation of the index biologic. Dose escalation was defined as a patient receiving a dose >10% above the reference dose from the product package for >90 days.

Results: Of the 1,010 patients included on their index biologic for >90 days, 80.5% initiated a subcutaneous tumor necrosis factor inhibitor (TNF-SC; adalimumab, certolizumab pegol or golimumab) as their index biologic, 12.0% initiated an intravenous TNF (TNF-IV; infliximab) and 7.5% initiated ustekinumab. During the 12-month baseline period, patients had a mean (standard deviation) number of claims of 2.9 (4.3) for conventional synthetic DMARDs (csDMARDs), 2.6 (5.0) for opioids, 2.2 (3.1) for NSAIDs and 2.0 (2.9) for corticosteroids. Overall, 49.5% of patients received ≥1 additional medication during the period from 90 days after the index date to the end of persistence with the index biologic or immediate 12-month post-index period. The most commonly added medications were corticosteroids (22.0%), opioids (17.1%), NSAIDs (12.9%) and csDMARDs (5.3%) (Table 1). Overall, 9.6% of patients had a dose escalation of the index biologic (33.9% for TNF-IV, 6.4% for TNF-SC and 5.3% for ustekinumab) in the immediate 12-month post-index period.

Table 1: Add-on medications initiated after 90 days from the index date to the end of persistence or 12 months among patients with PsA

Conclusions: In this descriptive, administrative claims-based study, nearly one-half (45%) of patients with PsA receiving biologic therapy initiated an add-on medication, most of which were pain medications. Further research is needed to better understand the reasons for therapy modifications during biologic treatment and the impact of insufficient control of pain in patients with PsA in the United States.

Acknowledgements: This study was sponsored by Novartis Pharmaceuticals Corporation, East Hanover, NJ.

was also used. In order to confirm the specificity of the new genetic variation associated with PsA risk, we analyzed the association with purely cutaneous psoriasis (PsC, n=614) and rheumatoid arthritis (RA, n=1,191). We performed a pharmacogenetic analysis to investigate the new PsA-specific pathways as a source for drug discovery in PsA.

Results: LDA analysis identified a new association between rs3971712 gene and PsA (P<5e-08). In the GWAS pathway analysis, we identified and validated a total of 14 genetic pathways associated with PsA risk. From these, the glycosaminoglycan (GAG) metabolism pathway was also found to be significantly associated with PsA risk when directly contrasted to the PsC cohort as well as the RA cohort. At a functional level, we detected a significant differential expression of GAG metabolism pathway genes in blood samples from PsA patients compared to PsC patients. The pharmacogenetic analysis identified several FDA-approved drugs likely to modify the GAG pathway.

Conclusions: This study represents an important step towards the characterization of the genetic factors specific to PsA risk.

Background: Psoriasis arthritis is one of chronic, relapsing, inflammatory autoimmune disorders with skin lesions and joint damage. A therapeutic revolution of psoriatic arthritis (PsA) is still a considerable unmet need in the past decades. It has been well known that the imbalance of Th17 cells and regulatory T cells (Tregs) may be a pivotal cause of PsA. Correction of this dysfunction can be a potential therapy of PsA.

Objectives: In this study, we measured and compared both absolute numbers and proportions of CD4+CD17+ Th17 cells and CD4+CD25+Foxp3+ Treg cells in peripheral blood of PsA patients and healthy controls to explore the immunopathogenesis of PsA; on the other hand, the effects of low-dose recombinant human IL-2 (rIL-2) on Th17 and Treg cells were investigated in patients with PsA.

Methods: Both absolute numbers and proportions of Th17 and T cells in peripheral blood, defined as the CD4+CD17+Th17 cells and CD4+CD25+Foxp3+ Treg cells in peripheral blood of PsA patients and healthy controls to explore the immunopathogenesis of PsA; on the other hand, the effects of low-dose recombinant human IL-2 (rIL-2) on Th17 and Treg cells were investigated in patients with PsA.

Results: The absolute count of Th17 cells in patients with PsA was very significantly higher than that of healthy controls (P<0.01), but the proportions of Th17 cell were not seen difference between PsA and healthy controls (P>0.05). In contrast with treated-PsA patients, the absolute count of Th17 cells was significantly higher in untreated-PsA patients (P<0.05). After the course of rIL-2 treatment, there was a significant increase in the absolute count of Th17 cells (P<0.05), but no difference in the absolute count of Th17 cells, Th17/Treg was significantly lower and went back to normal.

Conclusions: The results suggest that, the proportion, but the decrease in the absolute count of Th17 cells, defined as the CD4+CD17+ populations, contributes to the pathogenesis of PsA. After the treatment of rIL-2, there was a more significant increase in the absolute count of Treg cells than that of Th17, and consequently the balance of Th17/Treg was restored to normal, leading to the development of new therapies.

Background: In recent years, research on the interleukin 1[IL-1 β]–regulating protein complex, called the inflammasome, has shown interesting associations with chronic, inflammatory diseases. E.g. for Rheumatoid Arthritis (RA) (1) and psoriasis (PsO) (2, 3) associations with genetic polymorphisms in genes related to the inflammasome has been discovered. So far, no studies investigating genetic polymorphisms in inflammasome genes in Psoriatic Arthritis (PsA) patients have been published.

Objectives: To examine whether polymorphisms in genes related to inflammasomes confer increased risk for psoriatic arthritis.

Methods: DNA from 771 PsA patients and 793 healthy controls from Sweden were analyzed for different single nucleotide polymorphisms (SNPs) in NLRP3 (rs39298419, rs17531135, rs4553135), CARD8 (rs2045211) and NLRP1 (rs8079304, rs878329).

Results: Significant associations with PsA were found between carriage of allele, C, of rs878329 in NLRP1 (Chi²=2.65, OR (95% CI): 1.25 (1.02–1.53), p=0.028). Genotype distribution was also significantly different between patients and controls and for rs878329 in NLRP1 there was a significant difference in allele frequency (G/C) between patients and controls (Chi²=2.58, OR (95% CI): 1.20 (1.03–1.36), p=0.016). No significant associations with PsA were found for the other SNPs analyzed.

In genotype analysis, a significant higher frequency of genotype GG in rs878329 in PsA was detected (32.9% vs 26.9%, Chi²=2.46, OR (95% CI): 1.34 (1.07–1.71), p=0.011), whilst no significant differences were detected for genotypes GC or CC. For rs4553135, a significantly higher frequency of genotype TG (43% vs 37%, OR (95% CI): 1.66, OR (95% CI): 1.01 (1.05–1.53), p=0.033) and significantly lower frequency of genotype TT (50.5% vs 56.1%, Chi²=2.44, OR (95% CI): 0.80 (0.63–0.98), p=0.028) was seen in PsA, no significant difference was detected for genotype GG.

Conclusions: Carriage of rs878329C in NLRP1 was less frequent in patients with PsA compared with controls indicating a protective effect, but when different genotypes were analysed the difference likely results from an increased risk of PsA with genotype GG. The results are in contrast with the study of Ekman et al, where an increased transmission of rs878329C to family members with PsA was seen (3), indicating that carriage of genotypes may be associated with increased risk for carriers of C, but in agreement with the study of Sui et al on patients with RA, where an association was detected for carriage of C (OR 0.82, p=0.02), with the risk genotype for RA being G (4). Thus, the genotype GG possibly confers risk of arthritic disease whilst the C-allele seems associated with skin disease.

Carriage of rs4553135G in NLRP3 was more frequent in PsA patients compared with controls indicating an increased risk of disease, but only genotype GT was significantly increased in PsA. In the current association analyses were compared between one SNP in NLRP3 and one SNP in NLRP1, indicating a possible involvement in pathogenesis of PsA disease.

Background: Selection of the correct target to guide treatment is crucial for effective disease management in patients with psoriatic arthritis (PsA).

Objectives: To evaluate the prognostic value of several low disease activity (LDA) targets in PsA and in patients with PsA and psoriasis to assist physicians choose a valid target that facilitates assessment in clinical practice.

Methods: This was a post-hoc analysis from the PRESTA1 clinical study. LDA targets analyzed were: Disease Activity in PsA (DAPSA) LDA ≤14 (tender joint count [TJC], swollen joint count [SJC]), patient global visual analog scale [Pt VAS], C-reactive protein [CRP], clinical (c)DAPSA LDA ≤13 (DAPSA without CRP); and minimal disease activity (MDA) measurement defined as 5/7 cut-offs (TJC ≤1, SJC ≤1, psoriasis activity and severity index [PASI] ≤1, Pt pain ≤15mm, Pt VAS ≤20mm, health assessment questionnaire ≤0.5, tender enthesal points ≤1). Additional MDA measurements were investigated where 5/7
Multiple facets of PsA were demonstrated to distinguish treatment effect, perform better in statistical terms than traditional joint-only indices\(^1\) and could be used as a treatment target in clinical trials in PsA.

**Methods:** Secukinumab provided sustained improvement in the signs and symptoms of PsA over 104 weeks (wks) in the FUTURE 2 study.\(^2\) Here, we report the ability of secukinumab to reach and sustain PASDAS based low disease activity (LDA) up to 104 wks in the FUTURE 2 study using a post-hoc exploratory analysis.

**Results:** PASDAS score (mean [SD]) at baseline was 5.9 (0.9), 6.0 (1.0) and 5.8 (1.0) in the secukinumab 300mg, 150mg and PBO groups. In the overall population at Wk 16, PASDAS LDA was achieved in 37/96 (38.5%) and 34/99 (34.3%) of pts, treated with secukinumab 300mg and 150mg, respectively; vs. 14/87 (16.1%) with PBO. A high proportion of pts treated with secukinumab 300 and 150mg achieved LDA (49/83 [59.0%] and 58/87 [64.4%], respectively) at Wk 104. The proportion of pts achieving PASDAS LDA and remaining in HDA at Wks 16 and 104 by anti-TNF use (naïve/inadequate response [IR]) and disease duration (≤2 years vs. >2 years since diagnosis) and reported using non-mutually exclusive categories at group level and as observed analysis. Secukinumab 75mg data are not reported as this was not considered an effective dose.\(^2\)

**Conclusions:** A higher proportion of secukinumab-treated pts at Wk 16 achieved PASDAS LDA than PBO, with LDA sustained at group level at Wk 104. Discriminatory effect of PASDAS was consistent with that previously reported in the GRACE project.\(^4\) A higher proportion of anti-TNF\(\alpha\)-naïve pts treated with secukinumab achieved and sustained PASDAS LDA than anti-TNF\(\alpha\)-IR pts whereas similar proportion of pts treated with secukinumab achieved PASDAS LDA irrespective of time since diagnosis (≥2 years vs. >2 years).

References:

Conclusions:

- FACIT-F was significantly greater with SEC vs. PBO at Wk 16 in both FUTURE 1 and 2 (P = 0.002; Table 1).
- Improvements were generally somewhat larger in TNF-naive pts than in TNF-IR pts.
- Correlation analyses did not identify any BL factors that consistently predicted a 20% reduction in CRP and the EULAR remission criteria.

Results:

- FACIT-F was 27.8–28.9 and 26.6–29.2 at BL across groups in FUTURE 1 and 2, respectively. Improvements in fatigue seen with all doses of SEC vs. PBO from Wks 4–24 were sustained through 156 wks in FUTURE 1 and 104 wks in FUTURE 2 in both the overall population and subgroups stratified by prior exposure to TNF (Table).
- The numerically higher responses with SEC vs. PBO from Wks 15 vs. 300 mg SC, respectively. At Wk 16, PBO pts with ≥20% reduction in tender/swollen joint count (non-responders) were re-randomized through 156 wks. Improvement in fatigue were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).
- Across both studies, approximately 68% of pts were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).
- Improvement in fatigue were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).
- Improvement in fatigue were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).
- Improvement in fatigue were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).
- Improvement in fatigue were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).

Background:

- Fatigue is a common symptom in patients with PsA and is negatively associated with HRQoL and social functioning. Secukinumab (SEC), a fully human anti-IL-17A mAb, rapidly improved signs and symptoms, physical functioning, HRQoL, and fatigue in TNF-naive and TNF-IR pts in PsA.

Objectives:

- To assess the long-term effects of SEC on fatigue in TNF inhibitor (TNF)-naive PsA pts and those with an inadequate response or intolerance to TNF inhibitor therapy (TNF-IR).

Methods:

- 606 and 397 pts were randomized to SEC or placebo (PBO) in FUTURE 1 (10 mg/kg IV followed by 150 or 75 mg SC) and FUTURE 2 (300 mg, 150 or 75 mg SC), respectively, at Wk 16, PBO pts with ≥20% reduction in tender/swollen joint count (non-responders) were re-randomized to SEC or placebo at Wk 15 to 5 mg/kg IV followed by 150 or 75 mg SC (FUTURE 1) and SEC or 300 mg SC (FUTURE 2); responders were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).
- Across both studies, approximately 68% of pts were TNF-naive and 32% were TNF-IR. Fatigue was assessed at baseline (BL) and Wks 4, 8, 12, 16, 24, 52, 104, and 156 (FUTURE 1 only) using FACIT-F (higher score = less fatigue). Fatigue response was defined by an increase in FACIT-F score of >4 from BL (corresponding to the MCID). Correlations between BL characteristics and improvements in fatigue were investigated using a logistical regression model. Only data with approved doses of SEC (300/150 mg) are shown.

Results:

- FACIT-F was 27.8–28.9 and 26.6–29.2 at BL across groups in FUTURE 1 and 2, respectively. Improvements in fatigue seen with all doses of SEC vs. PBO from Wks 4–24 were sustained through 156 wks in FUTURE 1 and 104 wks in FUTURE 2 in both the overall population and subgroups stratified by prior exposure to TNF (Table).
- The numerically higher responses with SEC vs. PBO from Wks 15 vs. 300 mg SC, respectively. At Wk 16, PBO pts with ≥20% reduction in tender/swollen joint count (non-responders) were re-randomized through 156 wks. Improvement in fatigue were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).
- Improvement in fatigue were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).
- Improvement in fatigue were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).
- Improvement in fatigue were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436).

Acknowledgments:

- Background: Recommendations on psoriatic arthritis (PsA) state that the target of treatment should be remission or inactive disease. Multiple potential targets have been developed and proposed, each with a different composition of clinical measurements.

Objectives:

- Our aim is to use an existing real life dataset of a large group of patients in a low disease activity state, to compare different targets and provide further evidence to choose a target.

Methods:

- This analysis uses data from a cross-sectional real life cohort of 250 PsA patients (EULAR16–2124). All patients were considered in an acceptable disease state according to the treating rheumatologist, defined by the fact that the rheumatologist did not consider to modify the current treatment. Remission/inactive disease targets were the DAPSA [TJC; SJCP; patient global visual analogue scale (Pt VAS); pain VAS; CRP] and clinical (c)DAPSA [(DAPSA minus CRP) remission] (<4), very low disease activity (VLD) [7/7 of TJC ≤1; SJCP ≤1; Pt pain ≤16; Pt VAS ≤20; HAQ ≤0.5; tender enthesal points ≤1], and PASDAS <1.9 or near remission (NR).

Results:

- 113 pts were in cDAPSA remission, 107 in DAPSA remission, 56 met VLD and 37 in PASDAS NR. There was a very high percentage exact agreement between DAPSA and cDAPSA (96%) reflecting the similarity of the two definitions. DAPSA/cDAPSA and VLDA show high correlation (Pearson 0.611 and 0.590 resp) but VLDA is more stringent in comparison with both DAPSA scores. The correlation between NR and DAPSA/cDAPSA/VLDA was lower, (Pearson 0.400, 0.403 and 0.412 resp). Again PASDAS NR was generally more stringent than DAPSA/cDAPSA remission but greater dissimilarities are seen between PASDAS NR and VLDA where 14 patients are in VLDA but not PASDAS NR and 29 are in PASDAS NR but not VLDA.

Discussion:

- Although presence of active joint disease was similar across the different measures, VLDA presents as a more stringent cutoff with less residual disease in PASI, TJC and less impact on DLOQ and HAQ. All targets had similar % of patients...
with a raised CRP. The DAPSA measures which do not include an enthesis measure show more patients with an active enthesis.

There was a limited consequence on QoL measures when residual disease activity was allowed in certain domains in these remission states. In those patients with active enthesis or skin disease, no differences were found on PROs on quality of life and functionality. The severity of active skin disease pooled–reported pooled PASI-2 (present in 20/110 pts achieving DAPSA) was reflected by an impact on DLQI (2.85 (SD2.9) vs. 1.23 (p=0.003). This effect was not seen when the cutoff of for PASI-1 was used.

Conclusions: This comparison of the different remission targets shows that VLA4 presented as the most stringent target. Inclusion of laboratory markers seems not to be a necessity although the exclusion of a skin domain might result in a significant understatement of skin disease in some patients despite an impact on their QoL.

SAT0465 AN INTEGRATED SAFETY DATA ANALYSIS ACROSS ALL PHASE II AND PHASE III CLINICAL PROGRAMS FOR USTEKINUMAB IN PSORIATIC ARTHRITIS, CROHN'S DISEASE, AND PSORIASIS

Objectives: Therapeutic decisions are based on efficacy, but clinicians need to consider medication safety in this process. Here, we report ustekinumab (UST) integrated safety data in patients (pts) with psoriatic arthritis (PsA), Crohn's disease (CD), and psoriasis (PsO). We also compare a subset of PsA pts with & without baseline methotrexate (MTX).

Methods: Integrated safety data from 3 PsA, 5 CD, & 4 PsO trials were analyzed. PsA studies included the Ph2 trial (CNTO743T10) & the 2 Ph3 trials (SUMMIT 1 & 2) with 222, 615 & 312 pts exposed to UST, respectively. The percentage of pts in the Ph3 study that received MTX was 20.5%. No concomitant DMARDs with the exception of MTX (approximately 50% of pts in each study) were permitted in the 2 Ph3 studies. In the 5 CD studies (Ph2/3Ph3), 1749 pts were exposed to UST. In the 3 Ph3 CD studies, pts received one dose of UST 130mg or ∼6mg/kg IV at induction (UNIT1-1 & UNIT1-2), then 8 weeks later, entered the maintenance phase (IM UNIT1) and received UST 90mg SC q8w or q12w for 44 weeks. The percentage of pts on background MTX in UNIT1-1 was 9.2% & in UNIT1-2, 4.8%. In the PsO studies (1Ph2/3Ph3), a total of 3117 pts received UST 45mg or 90mg SC; no concomitant DMARD therapy (including MTX) was permitted. The PsO studies were completed through 5-years of follow-up. All pts who received at least 1 dose of UST were included in this analysis. Safety events are reported in events per 100-pt years. 95% CI for events per 100 PY were estimated.

Results: Through 1 year of follow-up, a total of 1018 PsA pts were treated with UST, of which 465 were co-treated with MTX. Of the 1749 CD pts treated with UST, 193 received MTX. Discontinuation rates of UST due to adverse events (AEs) were comparable across disease states irrespective of MTX use (Table). AE rates (95% CIs for events/100 PY) were noted to be comparable in the UST vs PBO groups for all diseases pooled irrespective of MTX use (240.39, 432.45) vs PBO (534.50, 170.40). Serious adverse event rates (SAEs) were also comparable in the UST vs PBO groups for all diseases pooled–reported UST (14.25, 16.56) vs PBO (24.05, 32.18). Infections and Serious infections (SIs) had numerically lower event rates in UST vs. PBO groups for all diseases pooled–reported UST (122.16, 128.72) vs PBO (120.94, 138.27) and UST (2.10, 3.05) vs PBO (2.76, 6.00), respectively (Table). Major adverse cardiovascular events (MACE) did not appear to significantly differ in both PBO & UST pts in PsA, PsO and CD. Event rates of malignancy (excluding non-melanoma skin cancer) were comparable across all disease states. No deaths in Pts or CD were reported.

Conclusions: UST demonstrates a favorable safety profile in an integrated safety data analysis across the PsA, CD, & PsO phase 2 & 3 clinical trials. The use of UST in PsA appears to be safe & well-tolerated, with fewer event rates of SAEs & SIs noted vs PBO. Despite higher overall rates of SAEs & SIs observed in CD pts, the data do not suggest an influence of UST on either.

SAT0466 PREGNANCY IN WOMEN WITH PSORIATIC ARTHRITIS: PREGNANCY OUTCOMES AND CHANGES IN DISEASE ACTIVITY

M.E.B. Closw, G. McDaniel, A.M. Eudy. Rheumatology, Duke University Medical Center, Durham, United States

Background: Very little has been published about psoriatic arthritis (PsA) in pregnancy, and it remains unknown whether pregnancy outcomes are impacted by this disease or whether disease activity is changed by pregnancy or delivery.

Objectives: To discover the rate of pregnancy complications for women with psoriatic arthritis, and to determine whether psoriasis and the associated arthritis change during and following pregnancy.

Methods: A retrospective survey was completed by 40 women aged 20–50 years with psoriatic arthritis managed at a university center. Each survey collected information about infertility, pregnancy outcomes and complications, as well as patient-reported assessments of changes in both skin and joint disease activity at the onset of pregnancy, over the course of the pregnancy, and in the months following pregnancy. Simple statistics were used to compare outcomes before and after the diagnosis of PsA.

Results: The survey was completed by 40 women with PsA. The majority (93%) were white, non-Hispanic with a high level of education (40% completed college and another 30% either started or finished a graduate degree); 62.5% were married. The average age at the time of the study was 37.4 (SD 7.9) years and age at PsA diagnosis was 30.9 (8.4) years. Twenty-five women reported they had ever tried to become pregnant, and of those, 9 had been unable to become pregnant after 12 months of trying or had been diagnosed with infertility by a physician (36%). The reasons for infertility or inability to become pregnant included pelvic inflammatory syndrome (44%), problem with ovulation (11%), problem with uterus (11%), elevated prolactin (11%), infection in pelvic area (11%), and/or cervical problems (30%). Infertility was unexplained in 33%.

There were 70 pregnancies to 26 patients, with 37 pregnancies occurring after the diagnosis of PsA (see table). Pregnancy outcomes following PsA diagnosis were worse than those prior to PsA diagnosis, particularly the rate of pregnancy loss (32% compared to 12%; p=0.05) and preterm birth (48% compared to 21%; p=0.002). Only 24% of patients took psoriasis or arthritis medications during pregnancy. The most commonly used medications during pregnancy were TNF inhibitors (16%), corticosteroids (8%), and DMDARs (5%). The large majority of patients had minimal arthritis and psoriasis during pregnancy.

*Two twin pregnancies.*
Only 12% had moderate and 6% had severe arthritis. Similarly, only 10% had moderate and 7% had severe psoriasis. During and following pregnancy, about half of all patients reported no change in either joint or skin activity during and follow pregnancy, with fairly equal numbers reporting improved and worsened arthritis. On the other hand, 42% had improved psoriasis during pregnancy compared to 6% in whom arthritis worsened. There did not appear to be a significant postpartum flare.

**Conclusions:** Our analysis found that among women with PsA who have tried to become pregnant, 36% experienced infertility, primarily due to PCOS. Compared to pregnancies occurring before the diagnosis of PsA, pregnancies after PsA diagnosis had a lower frequency of live births and a higher frequency of preterm births. Overall, in this cohort of women with mostly mild disease during pregnancy, arthritis pain and psoriasis activity did not appear to substantially worsen during pregnancy.

**ALL 10-YEAR CARDIOVASCULAR RISK SCORES ARE SIMILAR IN PATIENTS WITH PSORIATIC ARTHRITIS AND PSORIASIS**

**N. Ikumi**, F. Farkas 1, A. Szentpetery 2, B. Kirby 3, O. FitzGerald 4

1Rheumatology; 2Dermatology, St. Vincent’s University Hospital, Dublin, Ireland

**Background:** Psoriatic arthritis (PsA) and Psoriasis (PsO) are associated with higher cardiovascular (CV) risk with higher risk in patients with a severe disease phenotype. Long-term CV risk is evaluated using several methods for the general population.

**Objectives:** The aim of the study was to compare CV risk factors and 10-year CV risk scores between patients with PsA and PsO vs PsO only.

**Methods:** PsA patients fulfilling the CASPAR criteria and PsO with disease duration <10 years were enrolled consecutively from Rheumatology and Dermatology clinics. Fasting bloods were obtained for glucose, insulin and lipids, hypertension (HTN) and metabolic syndrome in PsA group, and completed questionnaires on health and quality of life. Four different CV risk scores were calculated: (1) Framingham Coronary risk score (FCS); (2) American College of Cardiology and American Heart Association (ACC/AHA) 10-year atherosclerotic cardiovascular disease (ASCVD) algorithm; (3) Systematic Coronary Risk Evaluation (SCORE) algorithm; and (4) QRISK2 (2016).

**Results:** 232 patients (100 PsA and 132 PsO) were recruited with mean age 52.4 ± 10.5 for PsA and 39.7 ± 14.4 for PsO. Mean disease duration for PsA was 17.9 ± 10 years. There were significantly more patients with hypertension (HTN) and metabolic syndrome in PsA group, and patients taking DMARDs and/or biologics treatment were also higher compared to PsO. Fasting glucose, insulin, lipids, BMI and waist/hip ratio did not show significant differences. The mean FCS, ASCVD, SCORE, and QRISK2 were significantly higher in PsA as compared to PsO, 4.7 ± 7.0% vs. 4.4 ± 8.2% P < 0.0001; 2.7 ± 1.6% vs. 1.1 ± 1.8%, P = 0.0002; 11.2 ± 9.9% vs. 5.2 ± 6.4%, P < 0.0001, respectively. However, after adjusting for age and sex, all CV risk scores were similar. Multiple regression analysis revealed that waist/hip ratio significantly correlated with all CV risk scores in both PsA and PsO patients.

**Conclusions:** While psoriatic arthritis is associated with higher CV risk, similar CV risk scores were calculated in both PsA and PsO patients.

**PRESENCE OF POOR PROGNOSTIC FACTORS MAY PREDICT RESPONSE TO ABATACEPT IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM A POST HOC ANALYSIS FROM A PHASE III STUDY**

**P. Mease 1, I. McInnes 2, V. Strand 3, O. FitzGerald 4, H. Ahmad 5, A. Johnsen 6, J. Papp 7**, 1Department of Medicine, Center and University of Washington, Seattle, United States; 2University of Glasgow, Glasgow, United Kingdom; 3Stanford University, Palo Alto, United States; 4St Vincent’s University Hospital and University College Dublin, Dublin, Ireland; 5Bristol-Myers Squibb, Princeton, United States

**Background:** Abatacept, a selective T-cell co-stimulation modulator, significantly increased ACR20 response and had an overall beneficial effect on musculoskeletal symptoms in patients (pts) with active psoriatic arthritis (PsA) in the Phase III Active pSoriaTic arthritis RAndomisedEd triAL (ASTRAEA, NCT01860976). Factors that may predict responses to abatacept were explored in this post hoc analysis.

**Objectives:** To evaluate the relationship between baseline characteristics and abatacept response in a post hoc analysis of ASTRAEA.

**Methods:** Pts were randomized (1:1) to SC abatacept 125 mg weekly or placebo for 24 weeks in this trial. Pts without ≥20% improvement in joint counts at Week 16 were switched to open-label abatacept (early escape). ACR20 response rate in pts stratified by baseline variables was investigated in a multivariate analysis and odds ratios (ORs) generated to identify differences in response. Using a cut-off of OR > 1.2, indications in which abatacept appeared to have a meaningful treatment benefit, baseline variables were further investigated in a univariate analysis and estimated differences calculated.

**Results:** Of 424 pts enrolled, 213 received abatacept and 211 placebo. In abatacept-treated pts, the multivariate model showed a difference in ACR20 response (OR 1.29, 95% CI 1.15–1.45) vs baseline CRP (< upper limit of normal (ULN) vs > ULN: OR 1.346 [95% CI 0.668, 2.712], DAS28 (CRP) (>5.1 vs ≤5.1: 1.489 [0.728, 2.836]), dactylitis (≤0 vs > 0: 1.372 [0.708, 2.659]), and median baseline erosions ≤3 vs > 3: 1.924 [1.032, 3.587]). In placebo-treated pts, the OR was 1.2 for CRP > ULN and >5.1. These factors, with their previously identified as indicating poor prognosis in PsA, were balanced between treatment arms at baseline. In the univariate model by poor prognostic factors, the differences in ACR20 response rates with abatacept treatment vs placebo in distinct subgroups were numerically greater in pts who were positive for these prognostic factors at baseline than in those who were not (Figure).

**Conclusions:** These findings identified subgroups of pts with PsA with certain baseline characteristics in whom abatacept is most likely to be effective. The predictive factors identified are aligned with poor prognostic factors in the EULAR and Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) guidelines, and may indicate pts with the highest unmet medical need.

**INTEGRATED EFFICACY ANALYSIS OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS**

1Department of Medicine, University of Queensland, St Lucia, Brisbane, Australia; 2Leeds Institute of Rheumatology and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; 3Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, United States; 4Probiot Medical Research and K Papp Clinical Research Inc, Waterloo, ON, Canada; 5Fundacion Ramon Dominguez, Hospital Clinico Universitario, Santiago de Compostela, Spain; 6Pfizer Inc, Groton, CT; 7Pfizer Inc, Collegeville, PA, United States

**Background:** Tofacitinib is an oral Janus kinase inhibitor under investigation for treatment of psoriatic arthritis (PsA).

**Objectives:** To assess the integrated efficacy of tofacitinib in patients with PsA treated in Phase III clinical trials.

**Methods:** Pts were included in this analysis if they were ≥18 years of age and had ≥10 swollen joints and ≥20 tender joints at baseline. Pts were treated with oral tofacitinib 5 or 10 mg twice daily for up to 1 year in the core studies and up to 2 years in the open-label extension studies. The analysis included all patients from the core studies (ASTRAEA, NCT01860976) and the open-label extension study (ASTRAERETRO, NCT02486831). The population included pts from Phase III studies regardless of discontinuation. Pts were included if they discontinued therapy due to non-response or adverse events, or if they completed at least 1 year of treatment.

**Results:** Of 3162 pts included in the analysis, 1349 (43%) were treated in core studies and 1813 (57%) were treated in the core studies plus 1 year of open-label extension. The majority of pts were female (75% in core studies vs 80% in core studies plus open-label extension). The mean age was 52 years, and most pts (81%) had PsA with active arthritis. The mean baseline CRP was 2.7 mg/L and the median disease duration was 10 years. At Week 16, 41% of all pts achieved ≥20% improvement in swollen joints and tender joints compared to baseline (ACR20). The overall ACR20 response rates were 24% in core studies and 30% in core studies plus open-label extension. Median change in DAS28 (CRP) decreased from 5.2 at baseline to 3.9 at Week 16. A 12-week change in median CRP was -0.33 mg/L from baseline to Week 16. A 12-week change in median ESR was -12 mm/h from baseline to Week 16. The mean change in HAQ-DI was -0.33 from baseline to Week 16.

**Conclusions:** Tofacitinib was associated with improvement in pts with PsA in Phase III trials. The results from this analysis support the use of tofacitinib in the treatment of pts with PsA.

**Disclosure of Interest:** [Disclosure statements]

DOI: 10.1136/annrheumdis-2017-eular.1641
Objectives: To determine efficacy based on pooled data from 2 pivotal Phase 3 studies of tofacitinib in patients (pts) with active PsA.

Methods: Data were pooled from 2 placebo (PBO)-controlled, double-blind, multicentre, global Phase 3 studies (OPAL Broaden [N=422; 12 months; NCT01877668]; OPAL Beyond [N=394; 6 months; NCT01882439]). Pts had active PsA and either inadequate response (IR) to <1 conventional synthetic disease-modifying antirheumatic drug (csDMARD) and were tumour necrosis factor inhibitor (TNFi)-naïve (OPAL Broaden), or had IR to disease-modifying antirheumatic drug (csDMARD) and were tumour necrosis factor inhibitor (TNFi)-naïve (OPAL Beyond). Pts were randomised to tofacitinib 5 mg twice daily (BID), 10 mg BID, adalimumab 40 mg subcutaneous injection once every 2 weeks (OPAL Broaden only) or PBO. In addition, to a single, stable background csDMARD. PBO pts advanced to tofacitinib 5 mg or 10 mg BID at Month (M)3. Endpoints included ACR20/50/70 response rates (≥20%, ≥50% and ≥70% improvement) compared with baseline (BL), HAI-2 (Health Assessment Questionnaire Disability Index), HAQ-DI (Health Assessment Questionnaire Disability Index) and enthesis absence, % DSS (Dactylitis Severity Score) and dactylitis absence and %ΔDLQI (Dermatology Life Quality Index). Pts who discontinued treatment were re-randomised for a 3-year extension phase. Efficacy results at Week (Wk) 156 are presented for those pts originally randomised to tofacitinib (n=308) and included ACR20/50/70 (≥20%, ≥50% and ≥70% improvement) vs PBO at M3 were observed for peripheral arthritis and physical function endpoints for tofacitinib 5 mg and 10 mg BID: ACR20, ACR50, ACR70, %ΔHAI-2 (least squares mean [LSM]), and %ΔHAQ-DI response (Table 1).

Results: For pooled data, pts were predominantly white (94.2%) and female (55.4%) with ≥5 peripheral swollen or tender joints (98.0%), enthesitis (LEI≥0; 67.5%), dactylitis (DSS≥0.525%), psoriatic skin body surface area ≥8% (67.7%) and CRP levels above the upper limit of normal (>2.87 mg/L; 62.5%) at BL. Mean age was 49.1 years and PsA duration was 8.0 years. Significant improvements in psoriasis, enthesis and dactylitis endpoints vs PBO were also observed for tofacitinib 5 mg and 10 mg BID at M3: PASI75 (%ΔDSS [LSM], dactylitis absence and %ΔDLQI (Dermatology Life Quality Index). Pts who discontinued treatment were re-randomised for a 3-year extension phase. Efficacy results at Week (Wk) 156 are presented for those pts originally randomised to tofacitinib (n=308) and included ACR20/50/70 (≥20%, ≥50% and ≥70% improvement) vs PBO at M3 were observed for peripheral arthritis and physical function endpoints for tofacitinib 5 mg and 10 mg BID: ACR20, ACR50, ACR70, %ΔHAI-2 (least squares mean [LSM]), and %ΔHAQ-DI response (Table 1).

Conclusions: In a pooled analysis of csDMARD-IR/TFN naïve and TNF-IR pts, tofacitinib 5 mg and 10 mg BID were superior to PBO at M3 across four PsA disease domains: peripheral arthritis, psoriasis, enthesis and dactylitis.
TRENDS IN CLINICAL CHARACTERISTICS ASSOCIATED WITH ACHIEVEMENT OF MINIMAL DISEASE ACTIVITY IN RESPONSE TO BIOLOGIC THERAPY IN PSORIATIC ARTHRITIS – ANALYSES FROM THE CORRONA PSORIATIC ARTHRITIS/SPODYLOARTHITIS (PSA/SPA) REGISTRY

P.J. Mease 1, C. Karki 2, M. Liu 2, A. Kavanagh 3, C.T. Ritchlin 4, D.H. Hulsey 5, R. Pandurengan 1, J.B. Palmer 2, J.D. Greenberg 1, 2, 3, 4, 5, 6, 7

Objectives: To retrospectively report the MDA and patient-reported outcomes (PROs) over time (baseline vs first follow-up [FU] visit vs second FU visit) which may contribute to achievement of MDA in responders versus non-responders to biologic treatment.

Methods: This analysis included all patients with PsA in the Corrona registry aged ≥18 years between March 2013 and March 2016 who received biologics (biologic initiation) at enrollment (baseline) and had ≥2 FU visits (at ≥6-month intervals, mean [SD] 2nd FU visit: 15.7 [3.7] months). Responders were defined as patients who achieved MDA at the second FU visit and remained on their index biologic.

Results: Of 148 patients who met the inclusion criteria (mean [SD] age, 54.7 [11.0] years; mean [SD] disease duration, 11.8 [10.1] years), 34 patients (23%) were responders (i.e., patients who had ≥2 MDA assessments/infestations, candida infections, Crohn’s disease, and malignant/unspecified tumors was 1.7 (27), 1.2 (17), 0.1 (2), and 0.9 (14) per 100 pt-yrs, respectively. Conclusions: Secukinumab provided sustained improvements in signs/symptoms and HAQ among clinical domains of active PsA in pts who completed ≥3 yrs of therapy. Secukinumab was well tolerated with a favorable safety profile consistent with that previously reported.1

SAT0471

TRENDS IN CLINICAL CHARACTERISTICS ASSOCIATED WITH ACHIEVEMENT OF MINIMAL DISEASE ACTIVITY IN RESPONSE TO BIOLOGIC THERAPY IN PSORIATIC ARTHRITIS – ANALYSES FROM THE CORRONA PSORIATIC ARTHRITIS/SPODYLOARTHITIS (PSA/SPA) REGISTRY

P.J. Mease 1, C. Karki 2, M. Liu 2, A. Kavanagh 3, C.T. Ritchlin 4, D.H. Hulsey 5, R. Pandurengan 1, J.B. Palmer 2, J.D. Greenberg 1, 2, 3, 4, 5, 6, 7

Objectives: To retrospectively report the MDA and patient-reported outcomes (PROs) over time (baseline vs first follow-up [FU] visit vs second FU visit) which may contribute to achievement of MDA in responders versus non-responders to biologic treatment.

Methods: This analysis included all patients with PsA in the Corrona registry aged ≥18 years between March 2013 and March 2016 who received biologics (biologic initiation) at enrollment (baseline) and had ≥2 FU visits (at ≥6-month intervals, mean [SD] 2nd FU visit: 15.7 [3.7] months). Responders were defined as patients who achieved MDA at the second FU visit and remained on their index biologic.

Results: Of 148 patients who met the inclusion criteria (mean [SD] age, 54.7 [11.0] years; mean [SD] disease duration, 11.8 [10.1] years), 34 patients (23%) were responders (i.e., patients who had ≥2 MDA assessments). The core components of MDA in these patients are shown in Table 1. Among responders, there were significant improvements in clinical characteristics and PROs such as mean TJC (3.4 vs 2.1 vs 0.6; P < 0.04), SJC (3.2 vs 2.0 vs 0.6; P < 0.01), percentage of affected BSA (6.2% vs 2.4% vs 1.4%; P = 0.03), patient pain (34.7 vs 26.1 vs 21.9; P = 0.007) and HAQ scores (0.6 vs 0.4 vs 0.3; P = 0.04); however, there were no significant changes over time for patient global assessment or entheseal counts (P = 0.05). Non-responders failed to have a significant improvement from baseline to the first and second FU visits in TJC, SJC, entheseal points, pain, patient global assessment and percentage of affected BSA (all P ≥ 0.05).

Conclusions: Only 23% of patients achieved MDA on their index biologic at the second FU visit and were considered responders. Over time, responders showed significant improvements in TJC and SJC and percentage of affected BSA, patient pain and HAQ scores; these most likely contributed to achievement of MDA response. A treat-to-target approach may be considered given the low number of patients in MDA.

SAT0474 | VERY LOW DISEASE ACTIVITY AND IMPACT OF DISEASE IN A SPANISH POPULATION WITH PSORIATIC ARTHRITIS

R. Queiroz, J.D. Cañete, C. Montilla, M.A. Abad, S. Gómez, A. Cabeza.

Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain

Background: The target of treatment in psoriatic arthritis (PsA) should be remission or inactive disease. A potential definition that would fit with the Treat-to-Target Recommendations would be MDA meeting all 7 criteria, proposed as a definition of very low disease activity (VLDA) in PsA. Patient reported outcomes (PROs), such as those provided by the novel PsAID questionnaire 2, are also important to evaluate healthcare interventions and to reflect the impact of PsA on patients’ lives.

Objectives: The aims of the present study were to evaluate the prevalence of VLDA in patients with PsA and how much residual active disease is still present, so as to determine whether PsAID could be an additional useful tool to assess PsA interventions in clinical practice.

Methods: This was a post-hoc analysis of data from a cross-sectional observational and multicenter study (MAAPS), aimed at evaluating the prevalence of MDA in a Spanish population with PsA, to describe their characteristics and to evaluate the association between MDA and the impact of the disease as assessed by the PsAID questionnaire in routine clinical practice. The original study included adult patients of both genders diagnosed with PsA according to CASPAR criteria with at least one year of evolution time of disease and on treatment with biological or conventional synthetic disease modifying anti-rheumatic drugs (cDMARD). Patients were considered in VLDA when they met all the MDA criteria:1: tender joint count <1, swollen joint count <1, PASI score ≤0.5, HAQ ≤0.5, tender entheseal points <1, patient global disease activity VAS score ≤1, and PDI ≤1.

The original study included adult patients’ lives.

Results: 227 patients were included, 133 (58.6%) in MDA state and 58 (25.6%) in VLDA state. VLDA patients suffered from a mild impact of the disease according to PsAID: the majority (82.5%) had a PsAID score <4 and a mean total score (SD) of 2.1 (2.6) IC95% [1.55–2.64], while 66.7% of MDA patients had a PsAID score <4 and a mean total score (SD) of 3.3 (3.1) IC95% [2.82–3.87]. Disability, as measured by HAQ was greater in MDA patients (mean SD (0.3) 0.5 IC95% [0.21–0.43]) than in those who reached VLDA state (mean SD (0.2) 0.3 IC95% [0.11–0.25]).

Conclusions: 26% of Spanish PsA patients achieve VLDA state in routine clinical practice. PsA patients who reached this state also had a very low impact of disease according to PsAID. VLDA state could represent a situation of clinical remission of PsA.

RECENT ONSET PSORIATIC ARTHRITIS: BASELINE DATA FROM THE REAPSER STUDY

Rheumatology, Hospital Universitario Central de Asturias (Coordinating Center), Oviedo, Spain

Background: The natural history of psoriatic arthritis (PsA) is very little known and the information regarding prospective cohorts is very scarce worldwide, including our country. REAPSER (Spanish Rheumatology Society Registry of Psoriatic Arthritis) is the first registry of Spanish patients with recent onset PsA.

Objectives: To describe the baseline characteristics of patients included in the REAPSER cohort.

Methods: Observational, multicentric study (34 centers), with consecutive inclusion. We included adults of both sexes 18 years of age or older with PsA that met CASPAR criteria, and duration of less than two years since the appearance of symptoms attributed to PsA. Annual follow-up visits will be carried out for 5 years. Measurements: socio-demographic data; employment status and impact of the disease; family history of PsA and other inflammatory diseases; comorbidities and treatment; lifestyle; use of health services; clinical status at the time of diagnosis of PsA; anthropometric data; clinical evaluation of PsA manifestations; radiographic evaluation; analytical determinations; treatment of PsA. The study has been approved by the ethical committees of the participating centers.

Results: Two hundred and fifteen consecutive patients were included, mean age 49.8±13.9 years.

SAT0475

FROM THE REAPSER STUDY

Rheumatology, Hospital Universitario Central de Asturias (Coordinating Center), Oviedo, Spain

Background: The purpose of this study is to compare and evaluate the demographic, clinical and laboratory features of elderly-onset psoriatic arthritis (EOPsA) and young-onset (YOPsA) patients.

Methods: One hundred and eighty patients diagnosed with PsA according to CASPAR criteria and followed-up in single center were included in this study. The patients with initial symptoms started after age 65 were accepted as EOPsA. Demographic, clinical, and laboratory data and the medications which the patients received were recorded and retrospectively evaluated.

Results: Nineteen (10.5%) of 180 patients were diagnosed as EOPsA, and 161 (89.5%) patients were evaluated as YOPsA. Mean patient age was 42.1±5 years for YOPsA group and 68.3±8.9 years for elderly onset group. Mean duration of disease was 5.6 years for early onset group and 1.3 years for elderly onset group (p=0.001). Fourteen (73.3%) of 19 EOPsA patients were female and 5 were male. Higher rates of fatigue, pain scores, comorbid diseases and acute phase reactants were detected in EOPsA patients comparing to YOPsA (p=0.000, p=0.000, p=0.001 and p=0.001 respectively). YOPsA patients have more dactilitis, nail involvement, elevated PASI scores, and smoking habits when compared with EOPsA patients (p=0.019, p=0.03, p=0.005, p=0.004 respectively). In terms of the treatment options chosen, there was no significant difference in the use of non-steroidal anti-inflammatory drugs (NSAIDs), corticosteroids (CS), methotrexate (MTX), and sulfasalazine (SS), but there was a more frequent use of anti-tumor necrosis factor-alpha in YOPsA group.

Conclusions: Herein we showed that YOPsA and EOPsA patients may have different demographic, clinical, and laboratory features. EOPsA patients are characterized with higher rates of fatigue, pain scores, comorbid diseases, and acute phase reactants and less dactilitis, nail involvement and anti-TNF-alpha usage.

SAT0476

DEMOGRAPHIC, CLINICAL, AND LABORATORY CHARACTERISTICS OF ELDERLY ONSET PSORIATIC ARTHRITIS

S. Kobak1, M. Orman2, 1Rheumatology, Istanbul University Faculty of Medicine, LIV Hospital, Istanbul; 2Statistics, Ege University Faculty of Medicine, Izmir, Turkey

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disease characterized with axial and peripheral joints involvement. It is rarely affects patients older than 65 years old.

Objectives: The purpose of this study is to compare and evaluate the demographic, clinical and laboratory features of elderly-onset psoriatic arthritis (EOPsA) and young-onset (YOPsA) patients.

Methods: One hundred and eighty patients diagnosed with PsA according to CASPAR criteria and followed-up in single center were included in this study. The patients with initial symptoms started after age 65 were accepted as EOPsA. Demographic, clinical, and laboratory data and the medications which the patients received were recorded and retrospectively evaluated.

Results: Nineteen (10.5%) of 180 patients were diagnosed as EOPsA, and 161 (89.5%) patients were evaluated as YOPsA. Mean patient age was 42.1±5 years for YOPsA group and 68.3±8.9 years for elderly onset group. Mean duration of disease was 5.6 years for early onset group and 1.3 years for elderly onset group (p=0.001). Fourteen (73.3%) of 19 EOPsA patients were female and 5 were male. Higher rates of fatigue, pain scores, comorbid diseases and acute phase reactants were detected in EOPsA patients comparing to YOPsA (p=0.000, p=0.000, p=0.001 and p=0.001 respectively). YOPsA patients have more dactilitis, nail involvement, elevated PASI scores, and smoking habits when compared with EOPsA patients (p=0.019, p=0.03, p=0.005, p=0.004 respectively). In terms of the treatment options chosen, there was no significant difference in the use of non-steroidal anti-inflammatory drugs (NSAIDs), corticosteroids (CS), methotrexate (MTX), and sulfasalazine (SS), but there was a more frequent use of anti-tumor necrosis factor-alpha in YOPsA group.

Conclusions: Herein we showed that YOPsA and EOPsA patients may have different demographic, clinical, and laboratory features. EOPsA patients are characterized with higher rates of fatigue, pain scores, comorbid diseases, and acute phase reactants and less dactilitis, nail involvement and anti-TNF-alpha usage.

SAT0477

THE COMPARISON OF ULTRASOUND SYNOVITIS AND ENTHESITIS FINDINGS AND CLINICAL FINDINGS IN PATIENTS WITH PSORIATIC ARTHRITIS AND SKIN PSORIASIS

T. Okang1, K. Inui1, Y. Sugioka2, K. Mamoto 1, H. Yoshimura1, T. Koike1,2,3, H. Nakamura1, 1Department of Orthopedic surgery; 2Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine, Osaka, 1Search Institute for Bone and Arthritis Disease (SINBAD), Health Foundation for Health and Welfare, Wakayama, Japan

Background: Conventionally, the assessment of affected joint count in patients with psoriatic arthritis (PsA) was relied for the detection of swelling and tenderness in the joints and enthesis by clinical physical assessment. To date, the modern imaging tool such as ultrasonography (US) can detect inflammation in the joint and enthesis more sensitively than clinical assessment.

Objectives: The aim of this study was to research the prevalence of US synovitis and enthesitis findings in patients with PsA and psoriasis (PsO) comparing with clinical assessment.

Methods: Total 101 patients, 54 patients with PsA and 46 patients with PsO, were consecutively included. HI VISION Ascendus (HitachiAloka Medical, Tokyo, Japan) was used with a 18-MHz linear array transducer. US examination was performed in MCP,PIP, DIP and wrist joints in both hand. Grayscale (GS) and power Doppler (PD) US were scored on a 0–3 semiquantitative scale for each joint. Moreover, the US assessment of enthesitis was performed. Lateral epicondyle, ilioitops enthesis, the proximal and distal anterior superior iliac spine, Achilles tendon and fascia plantaris tendon enthesion was scanned in both GS and PD assessment. Abnormal findings of enthesis was defined structure thickness, bursitis eosiion, calcification and power Doppler signal.

Results: US synovitis was found in 81.5% (n=44) and 60.9% (n=28) by GS, and 45.7% (n=21) by PD assessment, respectively in patients with PsA and PsO. Active synovitis (GS grade ≥ 2 and/or PD grade ≥ 1) was found in 37.8% (n=21) and 21.7% (n=12) in patients with PsA and PsO, respectively. Active enthesitis was detected in 25.4% (n=13) and 17.4% (n=9) in patients with PsA and PsO, respectively.
68.5% (n=37) in PsA and 45.7% (n=21) in PsO. US synovitis was more frequently found than clinical assessment. The most common sites of inflammatory synovitis were the wrist. US enthesisopathy was found in 87.0% (n=47) in patients with PsA and 56.5% (n=26) in patients with PsO. US enthesis was also more frequently found than clinical assessment. The most common sites of enthesisopathy were the enthesis in lateral epicondyle, quadriceps and Achilles tendon.

**Conclusions:** Our results showed that US was able to detect a high prevalence of inflammatory synovitis in peripheral joints and enthesis in patients with PsA. Moreover, subclinical inflammatory findings were also found in patients with PsO by US. US examination is useful to detect the inflammatory condition in patients with PsA and PsO than clinical examination.

**SAT0478** Rapid3 Questionnaire has high discriminating ability in minimal disease activity attainment in patients with early psoriatic arthritis treated according to tight control strategy in daily clinical practice (results of one-year open-label REMARCA study)

**Background:** RAPID3 is an instrument based on patient’s report outcomes (PROs) for the assessment of remission and disease activity in rheumatoid arthritis. The advantages of this questionnaire in treat-to-target (T2T) strategy in early psoriatic arthritis (EPA) have not been studied properly.

**Objectives:** To study discriminating ability of RAPID3 in minimal disease activity (MDA) attainment in patients with EPA treated during one year according to tight control strategy.

**Methods:** 61 (M/F–29/32) patients (pts) with active EPA, according to CASPAR criteria, mean age 37±10.6 years, PsA duration 11±3±10.2 months, psoriasis duration 75±8.9 months were included. All pts signed a consent form for participation in the open-label REMARCA study. At baseline and after 1 year (yr.) of therapy all pts underwent evaluation of PsA activity by TJC78, Swollen Joint Count (SJCT76), physician’s global disease activity (PtGDA), VAS, CRP, PGA (mg/l) and by PROs - patient global assessment PGA VAS, Health Assessment Questionnaire (HAQ), and RAPID3. The dose of Methotrexate (MTX) subcutaneous (s/c) was escalated by 5 mg every 2 weeks from 10 mg/wk up to 20–25 mg/wk. If pts did not achieve MDA after 6–9 months of MTX mono-therapy, combination therapy (CoT) of MTX+Adalimumab (ADA) was started in a standard regime; CoT was continued up to 1 yr. The proportion of pts who achieved MDA was calculated. MsSD, Me [Q25,75], %. Spearman rank correlation R, W-test, U-test, ROC-curve analysis were performed. All p<0.05 were considered to indicate statistical significance.

**Results:** By 1 yr. of therapy 36 out of 61 pts (59%) and 25 out of 61 pts (41%) were treated with MTX and with MTX+ADA accordingly. Significant improvements in PsA activity and PROs from baseline up to 1 yr. were observed: DAS 3.93 [3.20–4.58] vs 1.36 [0.82–2.25] (p<0.001), PGA 56 [48–69] vs 17 [10–21] (p<0.001), HAQ 0.81 [0.50–1] vs 0.36 [0.20–0.63] (p<0.001). Among those pts DAS 28 = 2.6 (p<0.05) was the optimal cut off point. RAPID3 based on PROs is a simple instrument for evaluating PsA activity. RAPID3 has shown high discriminating ability in MDA attainment in EPA pts treated according to tight-control strategy, and could be useful in daily clinical practice.

**SAT0479** Increased carotid intima-media thickness can discriminate significant coronary artery stenosis by coronary CT angiography in patients with psoriatic arthritis

T.H. Cheng1, Q. Zhang2, E.K.M. Li1, L.T. Wong2, A.P.W. Lee1, C.C. Szeto1, L.S. Tam1

1Department of Medicine and Therapeutics, the Chinese University of Hong Kong; 2Department of Diagnostic and Interventional Radiology, The Prince of Wales Hospital, Hong Kong, Hong Kong

**Background:** PsA patients have increased morbidity & mortality due to cardiovascular disease (CVD). However, their CV risk was underestimated by various CV risk score1. Subclinical carotid atherosclerosis may be considered as surrogate bulb & proximal ICA bilaterally. Significant coronary artery stenosis was defined as stenosis of the lumen >50%.

**Objectives:** To assess the relationship between carotid artery disease by ultrasound (US) and CAD by coronary computed tomography angiography (CCTA) and identify US parameters predictive of significant CAD

**Methods:** 91 subjects (56 males; age: 56±11 years; disease duration 9.4±9.2 years) underwent CCTA & carotid US (interval between two exams: 2–7 months) were recruited. Carotid intima-media thickness (cIMT) & the presence of plaque were determined by high resolution US in the distal CCA, bulb & proximal ICA bilaterally. Significant coronary artery stenosis was defined as stenosis of the lumen >50%.

**Results:** Carotid plaque was present in 33 (36%) patients & coronary plaque was present in 55 (60%) patients while 9 (10%) patients had significant coronary artery stenosis. 36 (40%) patients had non-zero calcium score (CAC>0) group. The mean cIMT was significantly higher in CAC>0 group compared to CAC=0 group (0.70±0.11mm vs 0.64±0.11mm, p=0.031). There was a trend suggesting the max cIMT increases with increasing CAC score, while the presence of carotid plaque increased significantly with rising calcium score (Table1). The mean cIMT increased significantly with number of coronary vessels harboring plaque, while there was a trend suggesting the max cIMT and the prevalence of carotid plaque may increase in patients with rising number of coronary vessels harboring plaques. The mean & max cIMT were significantly higher in SS+ group than SS- group [mean cIMT: 0.76±0.07mm vs 0.65±0.12mm, p=0.011; max cIMT: 0.93±0.14mm vs 0.80±0.16mm, p=0.020 (Table1)]. The prevalence of carotid plaque was similar between SS+ & SS- group [29 (35.4%) vs 4 (4.4%), p=0.421]. Using multivariate logistic regression, mean & max cIMT were independent explanatory variable of significant coronary stenosis after adjusting age, gender, disease duration & damaged joint count. The OR of significant coronary stenosis of every 0.1mm increase in mean & max cIMT were 1.07 (95% CI: 1.00–1.15, p=0.042) and 1.06 (95% CI: 1.00–1.11, p=0.036). Mean cIMT of 0.66mm was the optimal cut off.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.3010

Note: less compared to pts that did not achieve MDA-2.5 [1.3–5.3] and 8.1 [6.0–15.1] accordingly (U-test, p<0.001). According to the results of ROC-curve analysis RAPID3 score had a high discriminating ability for the presence of MDA - AUC 0.888 [0.808–0.969] (Fig. 1).

**Conclusions:** RAPID3 based on PROs is a simple instrument for evaluating PsA activity. RAPID3 has shown high discriminating ability in MDA attainment in PsA pts treated according to tight-control strategy, and could be useful in daily clinical practice.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.3010

---

**Figure 1.** ROC-curve analysis: association of RAPID-3 values and presence of MDA.
for discriminating patients with significant coronary stenosis (sensitivity: 100%; specificity: 44%). ROC analyses demonstrated that mean cIMT (AUC=0.801, p=0.003) has higher power than Framingham CVD risk score (FRS) (AUC=0.756, p=0.012).

Conclusions: Increased cIMT is associated with the presence & severity of coronary disease & obstructive coronary disease on CCTA in PsA patients. cIMT measurement can discriminate PsA patients with significant coronary stenosis better than FRS. PsA patients with moderate CVD risk should have carotid US for better CV risk stratification.

SAT0480

COMPARATIVE EFFECTIVENESS OF SECUKINUMAB AND THERAPEUTIC OPTIONS WITH DISCRETE MODES OF ACTION ARE NOW AVAILABLE FOR PSORIATIC ARTHRITIS (PsA). CLINICAL TRIAL DATA

Background: The therapeutic options with discrete modes of action are now available for psoriatic arthritis (PsA). Clinicians require evidence to guide decision-making.

Methods: Placebo arms were also matched; placebo-adjusted comparisons were possible only until week 16 because patients could receive active treatment from this point onwards. Logistic regression was used to determine weights for age, sex, race, body weight, methotrexate use, presence of psoriasis (<3% body surface area), mean PASI score, dactylitis, enthesitis, mean HAQ-DI score and physical NAFLD therapy. Recalculated outcomes from F1 and F2 (SEC, ESS=91; INF, ESS=59) were compared with data from IMPACT 2 (INF, n=100; placebo, n=100). Pairwise comparisons using odds ratios (ORs [95% CIs]) were performed for ACR 20, 50 and 70 responses at nearest-equivalent time points across trials: weeks 6/8, 14/16, 24 and 54/52. Mean changes from baseline in SF-36 Physical and Mental Component Summary (MCS) scores were also compared.

Results: There was no evidence of differences in ACR 20, 50 and 70 responses between SEC and INF at weeks 6/8, 14/16 (both placebo-adjusted) and 24 (non-placebo-adjusted). At week 54/52, ACR 20 and 50 responses were higher with SEC than INF (OR [95% CI]: 4.05 [1.98–8.30], p<0.001 and 1.90 [1.05–3.44], p=0.034, respectively). Improvements in SF-36 MCS scores were greater with SEC (ES=0.34, p=0.065) compared with INF (ES=0.01, p=0.034). A sensitivity analysis that added PsA duration, swollen joint count and CRP levels to the matching parameters yielded similar results.

Conclusions: In this MAIC, SEC showed evidence of superiority for symptomatic improvement (non-placebo-adjusted ACR 20 and 50) over INF for active PsA at 1 year. This was accompanied by greater improvements in SF-36 MCS scores. At earlier time points, there was no evidence of differences in ACR responses between SEC and INF.

SAT0481

THE RELATIONSHIP BETWEEN THE PATIENT ACCEPTABLE SYMPTOM STATE (PASS) AND DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS (PsA)

J.Z. Fei1, A. Perruccio2, Y. Ye1, D.D. Gladman1, V. Chandran1, 2Rheumatology; 2Orthopaedics, Toronto Western Hospital, University of Toronto, Toronto, Canada

Background: PASS is the highest level of symptoms beyond which patients consider themselves well. Psoriatic Arthritis Disease Activity Score (PASDAS) is a recently developed composite disease activity measure that summarizes a patient’s disease in a single 0–10 score.

Objectives: In this study, we aimed to identify the PASDAS cut-off points for PASS, and to examine the agreement between PASS and the PASDAS thresholds for low (<3.2), moderate (3.2–5.4), and high disease activity (>5.4).

Methods: Patients were prospectively recruited from the University of Toronto PsA clinic. A standard protocol including physician assessment and patient-reported outcomes was used to record variables required to calculate PASDAS. In addition, each patient was asked to “think about all the ways your PsA has affected you during the last 48 hours. If you were to remain in the next few months as you were during the last 48 hours, would this be acceptable to you?” to assess PASS. For analysis, the PASDAS threshold for PASS was identified with the ROC analysis to maximize specificity and sensitivity. Furthermore, the agreement between PASS and low, moderate, and high PASDAS disease activity cut-offs were evaluated.

Results: 169 patients [61% male, mean age 56.1, mean disease duration 16.9 years, mean (SD) PASDAS 3.25 (1.1)] were recruited. The PASDAS threshold for the patient acceptable symptoms state (PASS=) was identified to be 3.84 (AUC = 0.88, sensitivity 0.82, specificity 0.94) using ROC curve analysis. 91% of patients with low disease activity (PASDAS <3.2) considered their symptoms state acceptable (PASS+), and 100% of the patients with high disease activity (PASDAS >5.4) considered their symptom state as unacceptable (PASS–). Furthermore, the mean (SD) PASDAS was 4.5 (1.0) in the PASS- group and 2.6 (1.1) in the PASS+ group.

Conclusions: The PASDAS threshold for patient acceptable symptoms state is 3.84, which is within the moderate disease activity range. Thus with a PASDAS of 3.84 or lower, PsA patients consider their symptom state acceptable for the next few months. This cut-off should be considered for shared decision making regarding treatments in PsA patients.

SUBCLINICAL ENTHESOPATHY IN PSORIATIC PATIENTS AND ITS RELATION TO OTHER DISEASE PARAMETERS: AN ULTRASOUND STUDY

W. Gouda 1, M. Ismail 2, M. Doma 2, 1Rheumatology, Aswan University, Aswan; 2Rheumatology, Al-Azhar University, Assuit, Egypt

Background: Psoriasis is a chronic immune-mediated inflammatory skin disease characterized by reddish, thick patches covered with marked silvery scaling [1]. In about 70% of the patients, psoriasis is present many years before the onset of psoriatic arthritis [2]. The early recognition and therapeutic intervention especially with the new biologic treatments is critical to prevent the destructive and debilitating changes of psoriatic arthritis [3]. Enthesitis is inflammation at the attachment of tendons and ligaments to the bones, has been suggested as being the unifying feature of psoriatic arthritis, and the disease can be considered an enthesitis associated disorder rather than primary synovitic arthropathy [4].

Objectives: We aimed to correlate the subclinical enthesitises in patients with psoriasis detected by means of power Doppler (PD) ultrasonography (US) with other disease parameters. Methods: 50 persons with a definite diagnosis of psoriasis with no clinical evidence of arthritis or enthesitis were selected. All patients completed clinical assessment included Psoriasis severity (PASI) score, body mass index (BMI), PDUS evaluation of Achilles, quadriceps, patellar entheses and planter aponeurosis. US findings were scored according to the Glasgow Ultrasound Enthesitis Scoring System (GUESS).

Results: In 18 of 50 of patients (36%) PDUS found signs indicative of enthesopathy. The Achilles entheses had the highest number of PDUS signs of enthesopathy (33.3%), followed by distal patellar enthesis (22.2%), proximal patellar enthesis (16.7%), quadriceps enthesis (16.7%), and plantar aponeurosis enthesitis (11.1%) with variable enthesial morphostructural abnormalities. The GUESS score was directly correlated with age (p = 0.012), disease duration (p = 0.044), PASI (p = 0.035), BMI (p = 0.011), hyperuricemia (p = 0.011).

|                   | Normal 62 (12%) |
|                   | Abnormal (arthritis) 38 (36%) |

Conclusions: In addition to the importance of PDUS as a complimentary tool in examination of entheses in psoriatic patients, the presence of high PASI score in those with the increased BMI and hyperuricemia in addition to long disease duration could be considered as predictive parameters for the presence of psoriatic enthesitis.

Osteoarthritis

OSTEOARTHRITIS (OA) AND SOCIO-ECONOMIC STATUS (SES) PREDICTS THE ONSET OF COMORBIDITIES LINKED TO FREQUENT HEALTHCARE CONSULTATION

R. Hayward 1, K. Kaur 2, R. Wilkie 1, 1Research Institute for Primary Care & Health Sciences; 2Medical Student, Keele University, Keele, United Kingdom

Background: OA is the most common joint condition, the fourth leading cause of disability globally and the fastest increasing major health condition. In older adults, OA frequently coexists with other morbidities, but the temporal nature is unclear. There is abundant evidence that markers of low SES are associated with poor outcomes among people with musculoskeletal conditions, however the mechanism linking comorbidity may vary with SES.

Objectives: To examine if OA predicted the onset of comorbidities that are the reason for frequent consultation to primary care, and if this association was moderated by SES.

Methods: Cohort study combining questionnaire data at two time points (2005, 2008) in the North Staffordshire Osteoarthritis Project, and medical record data from 2000 to 2005 (n=3910). OA was defined by consultation to primary care for OA between 2000 and 2005, and the indication of moderate to extreme pain interference in the questionnaire (2005). Logistic regression examined the association between OA and the onset of seven comorbidities (anxiety, depression, widespread pain (WP), insomnia, cognitive impairment, neurosis, stress between 2005 and 2008) and restricted social participation, first unadjusted and then adjusting for putative confounders (comorbidity, socio-demographic and lifestyle factors). Moderation of the association between OA and new onset comorbidity by change in income, education and area-level deprivation was examined by including interaction terms in regression and stratified analyses. Results were reported as odds ratios with a 95% Confidence Interval (OR; 95% CI).

Results: Mean age was 63, 55% were female, and 942 (24%) had OA. In the unadjusted analysis, OA was significantly associated with new onset of seven comorbidities (p<0.05). After adjusting for confounders, OA was associated with the onset of WP (2.49; 1.96–3.17) and insomnia (1.58; 1.14–2.19). There was a significant non-multiplicative interaction between OA and income and new onset cognitive impairment (P=0.047); new onset of cognitive impairment in those with OA whose income remains adequate 29.1% of 38.1% in those with OA whose income remains inadequate), and between OA and education and new onset WP (P=0.012; new onset in those with OA and secondary education only was 37.4% of 50% in those with OA and had more than a secondary education).

Conclusions: OA was more likely to develop new physical and psychological comorbidities that lead to more frequent consultation to primary care than those without OA. Whilst confounders explained some of these associations, OA consultants may benefit from more proactive strategies to prevent further morbidity. Despite no significant multiplicative interactions, there were differences in the prevalence of new onset of morbidity in those with OA when stratified by SES. Onset of cognitive impairment was associated with inadequate income but WP was associated with those with higher education suggesting a “worried well” population seen both in other health surveys and in screening. OA and baseline morbidities were higher with lower SES and further exploration across the life-course will help to establish the role of SES on the natural history OA.

LOW MAGNESIUM INTAKE IS ASSOCIATED WITH INCREASED PAIN IN SUBJECTS WITH RADIOGRAPHIC KNEE OSTEOARTHRITIS: DATA FROM THE OSTEOARTHRITIS INITIATIVE

A. Shmagel 1, N. Onizuka 2, T. Vo 2, L. Langsetmo 3, K. Ensrud 3, A. Foley 1, P. Valen 1,6. 1Rheumatology, University of Minnesota; 2Medicine, VA Medical Center; 3Nephrology/Medicine, University of Minnesota; 4Medicine/Rheumatology, VA Medical Center, Minneapolis, United States

Background: Osteoarthritis pain appears to be caused, at least in part, by alterations in peripheral and/or central nociceptive pathways.[1] As magnesium is a known mediator of nociception, we hypothesized that low magnesium intake may be associated with increased pain in radiographic knee OA.

Objectives: To evaluate whether magnesium intake is associated with knee pain in radiographic knee osteoarthritis.

Methods: We investigated the associations between knee pain and magnesium intake from food and supplements in 2549 participants with prevalent radiographic knee OA (Kellgren-Lawrence score ≥2) in the Osteoarthritis Initiative cohort.[2] WOMAC pain scores in the affected knee were reported annually with total follow up period of 48 months. Magnesium intake was assessed at baseline by food frequency questionnaire and dietary supplement questionnaire, and expressed in gender-specific calorie-adjusted quintiles. Analyses used generalized linear mixed effects models with repeated measures.

Results: Among participants with baseline radiographic knee OA the mean total magnesium intake was 310 mg/day (SD 133) for men, and 288 mg/day (SD...
for women, with 68% of men and 44% of women below the estimated average requirement (EAR). The mean WOMAC pain score at 0, 12, 24, 36, and 48 months of follow up was 3.5 (SD 3.8), median score 2 (IQR 0; 6). After adjustment for age, gender, BMI, caloric intake, physical activity, smoking status, alcohol use, renal insufficiency, and the use of analgesics, subjects in the lowest quintile of magnesium intake (Q1) had, on average, 1 point higher WOMAC knee pain scores than subjects in the highest quintile (Q5): Q1 1.00 (0.61–1.39), Q2 0.69 (0.32–1.06), Q3 0.25 (-0.12–0.62), Q4 0.25 (-0.14–0.64); p<0.0001.

Conclusions: In a cohort of adults with prevalent radiographic knee osteoarthritis, magnesium intake overall was below recommended. Low magnesium intake as baseline was associated with increased pain in the affected knee over 48 months of follow up. These findings may be of growing importance as the average dietary magnesium intake for humans is declining.[3]

Conclusions: This is the first study to show gene expression alterations in uncultured CD271+ MSCs from OA patients. A notable increase in OPG is suggestive of MSCs’ bias towards inhibition of bone resorption in late hip OA and further incriminates the RANKL/OPG pathway, specifically in MSCs, in OA pathophysiology. Further studies are needed to define the role of native MSCs in lesion associated OA disease progression and to evaluate these as a possible target for treatment.

SAT0486 CATASTROPHIZING IN OSTEOARTHRITIS OF THE KNEE: DOES THE LEQUESNE SCORE TAKE IT IN COUNT? A PROSPECTIVE STUDY

J. Lecorney, M. Chouk, X. Guillot, C. Prati, D. Wendling, F. Verhoeven, Rheumatologie, CHRU de Besançon, Besançon, France

Background: knee osteoarthritis is a frequent matter of consultation in both general practice and rheumatology. Pain is the main symptom leading to a consultation. This painful experience can be influenced by various factors such as the anxiodepressive state or catastrophizing. Catastrophizing is known to be associated with lower analgesia results in total knee arthroplasty (1).

Objectives: The aim of this study is to evaluate the correlation between the functional status (assessed by the Lequesne score) and the catastrophizing (assessed by the Sullivan score) in patient with osteoarthritis of the knee.

Methods: We included patients consulting for knee osteoarthritis, meeting the OARSI criteria (2), one of the three general practitioners participating in the study or a rheumatologist at University Hospital. We excluded those with surgical indication. For each patient we registered the epidemiological data, the radiographic stage as well as the scores of Lequesne and Sullivan questionnaires. The correlation between the different scores were assessed with a Spearman test.

Results: A total of 100 patients were included, 50 consulting a general practitioner and 50 consulting a rheumatologist, between November 2015 and April 2016. Among these 100 patients, there were mainly women (57%) with a mean age of 64.8±1.77 years old. The mean radiographic stage was 2.66±0.11 on the Kellgren and Lawrence scale. The Mean Sullivan score was 12.96±1.18 and the mean Lequesne score was 10.46±0.47. There was a close correlation (r=0.3, p=0.006) between the Lequesne score and the radiographic scale. There was no correlation between the Sullivan score and the radiographic scale. However, the correlation between the Sullivan and the Lequesne scores was modest (r=0.47, p=0.001) (Figure 1). Thus, the Lequesne score is correlated with the radiographic scale and the Sullivan score. When we compare the two populations, it appeared that the people consulting a rheumatologist are majority of women (72%) and younger (62.58±1.8 VS 67.18±1.38 years, p<0.05) and with a shorter duration of symptoms (6.02±1.12 VS 7.95±1.5 Years, p<0.001). In terms of radiographic and functional impairment, the two populations were similar (Kellgren score of 2.59±0.15 VS 2.7±0.158 and Lequesne score of 11.13±0.67 VS 9.78±0.66, p<0.05) but there was a clear difference for the Sullivan score (16.8±1.67 VS 21±1.4, p<0.001).

Conclusions: Our study is the first to highlight a correlation between the Sullivan and the Lequesne scores in patient consulting for osteoarthritis of the knee. Moreover, unlike the Sullivan, score the Lequesne score is correlated with the radiographic scale. The strength of this study is the inclusion of both patients consulting the general practitioner and those consulting the rheumatologist to avoid a recruitment bias. Indeed, patients consulting the rheumatologist had a catastrophizing score more important for the same functional and radiological impairment than those consulting the general practitioner. Thus, our population is representative of the global population suffering from osteoarthritis of the knee in terms of age, sex-ratio, BMI. The Lequesne score is a global score correlated with structural damage and with psychological factors like catastrophizing.

SAT0485 INCREASED EXPRESSION OF OSTEOPROTEGERIN IN CD271+ MULTIPOTENTIAL STROMAL CELLS FROM FEMORAL HEADS OF PATIENTS WITH HIP OSTEOARTHRITIS

D.C. Ilas 1, S.M. Churchman 1, J. Aderinto 2, P.V. Giannoudis 1, D. McDonnagle 1, E. Jones 1, 1Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; 2Department of Orthopaedics, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Osteoarthritis is a disease of the whole joint, but subchondral bone marrow lesions (BMLs) closely correlate with disease progression [1]. We have previously shown that in OA femoral heads, subchondral bone multipotential stromal cells (MSCs) were 5-fold more abundant in MRI determined BML areas where they also showed reduced mineralisation capacity and altered RANKL expression compared to non-BML areas [2]. This offered novel insight into MSC involvement in the bone remodeling process in OA.

Objectives: The current study investigated a multi-lineage gene expression profile of native CD271+ MSCs from OA femoral heads focusing on osteogenesis and bone remodeling related genes compared to CD271+ MSCs from healthy trabecular bone.

Methods: Femoral heads were obtained from 17 OA patients undergoing total hip arthroplasty. Control samples included healthy iliac crest bone from 12 patients undergoing autograft harvesting for bone reconstruction and healthy femoral neck bone from 2 patients, extracted following core decompression surgery for avascular necrosis of the femoral head. CD271+ MSCs were extracted by enzymatic digestion and purified by FACS, as previously described [3, 4]. MSC cultures were generated by standard methods [4]. Quantitative real-time PCR was performed using TaqMan assays for 12 transcripts and gene expression was normalised to HPRT1.

Results: Sorted CD271+ cells from both groups displayed gene expression profiles indicative of their steady-state osteogenic, adipogenic, bone remodeling and stromal-support functions (Table 1). Three out of 11 transcripts showed significant increases in OA: alkaline phosphatase, melanoma cell adhesion molecule and osteoprotegerin (OPG) (p<0.05, Mann Whitney test). The proportion of CD271+ cells related to total live cells was more variable but on average 2-fold higher in OA (medians of 2.3 and 5.2%, respectively, not significant). Consistent with previous findings [4, 5], gene expression levels for the majority of transcripts were altered following MSC culture expansion (3 up-regulated and 8 down-regulated).

Conclusions: This is the first study to show gene expression alterations in uncultured CD271+ MSCs from OA patients. A notable increase in OPG is suggestive of MSCs’ bias towards inhibition of bone resorption in late hip OA and further incriminates the RANKL/OPG pathway, specifically in MSCs, in OA pathophysiology. Further studies are needed to define the role of native MSCs in lesion associated OA disease progression and to evaluate these as a possible target for treatment.

A RANDOMIZED, BLINDED, COMPARATOR-CONTROLLED TRIAL INVESTIGATING A 4-WEEK COURSE OF LYRICA IN SUBJECTS WITH KNEE OSTEOARTHRITIS WHO EXHIBIT NEUROPATHIC PAIN, COMPARED WITH A 4-WEEK COURSE OF PARACETAMOL

A. Wright1, P. Moss1, H.A. Benson2, R. Will3, P. Chowallour4, 1School of Physiotherapy and Exercise Science, 2School of Pharmacy, Curtin University; 3School of Medicine and Pharmacology, University of Western Australia; 4Department of Rheumatology, Royal Perth Hospital, Perth, Australia

Background: Knee osteoarthritis (OA) has been considered the archetypal model of inflammatory or nociceptive pain [1] but it is apparent that people with knee OA may present with different pain phenotypes including some with features of neuropathic pain [2,3].

Objectives: The aim of the present study was to select people with knee OA who exhibited features of neuropathic pain based on elevated cold pain thresholds (>15°C) and elevated PainDETECT scores (>13) and to determine if pregabalin would be more effective in reducing pain and improving function in this cohort than paracetamol.

Methods: The study used a double-blind, randomized, comparator-controlled design in participants with knee OA to compare the effectiveness of a standard dose of paracetamol (1000mg tid) with a titrated dose of pregabalin (Lyrica) taken daily over 28 days. A cohort of 90 participants with moderate to severe painful knee OA (Pain rating >4/10) who demonstrated features of neuropathic pain were included. Participants were selected from an initial cohort of 271 OA sufferers recruited from the Perth community based on screening of CPT and PainDETECT. Included participants were randomly assigned to receive either a four week course of pregabalin titrated to a maximum dose of 300mg or a four week course of paracetamol (4A,000mg).
