Among 251 patients with follow up of at least 12 months, 95.2% received steroids along with II line immunosuppressant (mycophenolate in 63.7%). Tolcizumab was given induction or rescue therapy to 44 patients. Revascularisation procedures were performed in 71.7%. Complete (ITAS 2010 = 0, CRP <6mg/L, angioiwe not-progression) and partial response was achieved in 176 patients (70.1%) and 42 (16.7%) respectively within 6 months. During a median follow up of 42 (1Q: 24–81) months, 116 (46.2%) maintained complete response till their last follow up with cumulative relapse free survival of 83%, 70% and 55% at 1, 2 and 3 years respectively. A model including baseline CRP<6.1mg/L, type 4 disease and DEI.Tak <9 predicted sustained inactive disease with an AUC of 70.2 (63.3–77.2, p<0.001). Initial steroid dosage of 0.5mg/kg/day was similar to 1mg/kg/day in terms of response or relapse. Overall, there were only 15 (5.9%) patients who never responded to treatment. There were 2 fatalities. At the last visit, 176 (70.5%) had stable disease. Damage progression (delta TADS) was lower in patients with sustained inactive disease than the rest, p<0.001.

Conclusions: Medical management arrested disease activity, damage progression and mortality in our cohort. Low baseline CRP and DEI.Tak scores and type 4 disease independently predicted sustained inactive disease.

UNDERSTANDING THE HETEROGENEITY OF LARGE-VESSSEL VASCULITIDES

E. Tombetti1, A. Ambrosi2, C. Godi2, B. Arth1, A.A. Manfredi2, J. Mason1.

1Imperial College London and Imperial College NHS Trust, London, United Kingdom; 2San Raffaele Hospital and Vita-Salute University, Milan, Italy

Background: Adult large-vessel vasculitides (LVV) are rare conditions, currently classified as two different diseases, Takayasu arteritis (TA) and giant cell arteritis (GCA). Despite being biologically and pathophysiologically different, the two are scarce at best. Arterial involvement, despite being the central disease feature, has been poorly addressed by research. We have developed two novel, imaging-based scores (the arteritis stenosis score [ASS] and arteritis dilation score [ADS]). ASS and ADS define stenotic and aneurysmal disease in a
core-set of 17 arteries and respectively represent the sum of stenosis and dilation scores in individual arteries

Objectives: To use ASS, ADS and the stenosis and dilation scores of individual arteries to describe a cohort of LVV patients and identify heterogeneity between patients.

Methods: The ASS, ADS and individual artery scores have been derived from 110 LVV (81 TA, 29 GCA) patients. Model-based clustering optimising the Bayesian Information Criterion and principal component analysis were performed.

Results: Arterial involvement was shown to be differed in GCA and TA. TA has higher ASS than GCA (median, IQR: 20, 11–29 Vs 5, 0–11; p < 0.001) and lower ADS (0, 0–5 Vs 6, 0–13; p = 0.019). The scatterplot of ASS and ADS revealed incomplete overlap of arterial involvement in GCA and TA. No differences were seen in TA with disease onset before or after 40 yrs. Age at onset, ASS and ADS did not correlate in TA, suggesting stenotic and aneuryismal arterial remodelling are independent. In GCA, ASS and ADS were negatively correlated ($p = 0.041; p = 0.031$) and ADS correlated with age at onset ($p = 0.383; p = 0.040$), suggesting the existence of a biologic “switch” between arterial stenosis and dilation, regulated by age at onset.

We accounted for geographical distribution of lesions by evaluating the scores of individual arteries with correspondence analysis. Arterial involvement was symmetric with tripolar segregation: stenosis in the supra-aortic branches, stenosis in the aorto-abdominal district and arterial dilation (Fig 1A). When patients exhibited the first two components, three different clusters were recognized (Fig 1B), with different ASS, ADS and damage as assessed by the TA damage score ($p < 0.001$ for all tests). 27/29 (93%) of GCA patients were included in cluster 1. Of interest, density graphs showed (i) a different distribution of arterial involvement in GCA and TA (Fig 1C-D), and (ii) potential for identification of novel disease subsets (2 in GCA and 3 in TA). A comparable distribution was seen in TA with onset before or after 40 yrs (Fig 1E). Lastly, when patients with disease onset after 50 yrs (11 TA, 28 GCA) were studied, a trimodal distribution was observed, suggesting discrete phenotypes of arterial involvement exist, rather than a continuum (Fig 1F).

Conclusions: Arterial involvement differs in TA and GCA, although some overlap exists. Elderly TA is similar to juvenile TA, while a potential biologic “switch”, yet to be identified, regulating the final outcome of arterial remodelling and influenced by ageing, is present in GCA. Three main patterns of arterial involvement appear to exist. LVVs represent the composition of different discrete subsets rather than a phenotypic continuum.

THU0300 CENTRAL NERVOUS SYSTEM INVOLVEMENT IN GRANULOMATOSIS WITH POLYANGIITIS (WEGENER) IN A LARGE SERIES OF PATIENTS WITH ANCA-ASSOCIATED VASCULITIDES (AAV).REVAS STUDY-GEAS-SEMI

Background: GPA is a necrotizing systemic vasculitis that usually involves ENT, lungs and kidneys. Neurological manifestations appear in 25–50% of patients, usually involving peripheral nervous system. CNS involvement, has been reported in only 7–11% of cases

Objectives: to describe the clinical features and outcome of patients with GPA and CNS involvement in a large series of patients with AAV

Methods: multicenter retrospective-longitudinal study that encompassed patients diagnosed with AAV between Jan 1995 and Nov 2014 in 21 Centres from Spain (REVAS Study). Statistical analysis was performed using SPS vs20 package

Results: 455 patients (188 GPA, 167 MPA and 100 EGPA) were included. Mean age at diagnosis was 55.7±17.2y. ANCA were positive in 86.8% of cases (55.8% C-ANCA, 51% P-ANCA). Median time to diagnosis was 4 weeks (IQR 10). Median follow-up time was 80 months (IQR 105). Neurological involvement was documented in 156 (34.5%) patients, but only 33 (7.3%) presented CNS involvement at disease onset. From those patients, 20 (60.6%) had GPA. Mean age at diagnosis of patients with GPA and CNS involvement was 51.±16.7y. ANCA were positive in all cases (15 C-ANCA-PR3, 5 P-ANCA-MPO). Headache was the main neurological symptom (60%) followed by sensory (45%) and motor impairment (35%). MRI and/or ango-CT scan were performed in all cases. Cerebral ischaemic lesions were observed in 10 patients, and granulomatous lesions in 5, including pachymeningitis (n=6), spinal cord pachymeningitis (n=2) and isolated granulomatous lesions (n=1). Lumbar puncture was performed in 8 (40%) patients and revealed CSF abnormalities in 70. Diagnosis was confirmed by meningeal biopsy (n=2), ENT biopsies (n=5) and renal biopsy (n=2) in patients with CNS granulomatous lesions, and by renal, pulmonary or peripheral nerve biopsy in patients with CNS ischaemic lesions. Headache was predominant in patients with granulomatous lesions, while sensory and motor impairment were predominant in patients with ischaemic lesions. Mean BVAS at disease onset was 29.±9.7, significantly higher than in GPA total cohort (18.±9.2). Renal involvement was more common in patients with ischaemic lesions than in those with granulomatous lesions (80% vs. 40%, p<0.001), and ENT involvement in patients with granulomatous forms (70% vs. 50%, p<0.005). Most patients (70%) received oral CF for induction therapy. Two patients received rituximab. For maintenance therapy, 25% of patients received AZA, 20% MMF and the remaining CF. 70% of patients received TM-SX. During follow-up, 58.8% and 40% of patients developed bacterial and opportunistic infections, respectively. Infections were related to oral CF therapy (p<0.029). Long-term neurological sequelae were noted in patients with ischaemic lesions (40%) and spinal cord pachymeningitis (100%)

Conclusions: Patients with GPA and CNS involvement have more severe disease at presentation and more treatment-related side effects than patients without CNS involvement. Long-term neurological sequelae are more frequent in patients with ischaemic lesions and spinal cord pachymeningitis

SAFETY FOLLOWING INITIATION OF RITUXIMAB IN GRANULOMATOUS WITH POLYANGIITIS (GPA) OR MICROSCOPIC POLYANGIITIS (MPA): INTERIM ANALYSIS OF THE RITUXIMAB IN ANCA-ASSOCIATED VASCULITIS REGISTRY (RAVER)

J. Niles¹, N. Allen², J.A. Block³, C.L. Koening⁴, C.A. Langford⁵, A. Abril⁶, A.S. Lee⁷, P.A. Merkel⁸, L.E. Mertz⁹, P.A. Monach¹⁰, L.W. Moreland¹¹, P.H. Nachman¹², T. Peikert¹³, R.F. Spiera¹⁴, D. Brunetta¹⁵, ¹Massachusetts General Hospital, Boston, MA; ²Duke University Medical Center, Durham, NC; ³Rush University Medical Center, Chicago, IL; ⁴University of Utah, Salt Lake City, UT; ⁵Cleveland Clinic Foundation, Cleveland, OH; ⁶Mayo Clinic, Jacksonville, FL; ⁷University of Pennsylvania, Philadelphia, PA; ⁸Mayo Clinic, Rochester, MN; ⁹Boston Medical Center, Boston, MA; ¹⁰University of Pittsburgh School of Medicine, Pittsburgh, PA; ¹¹University of North Carolina, Chapel Hill, NC; ¹²Hospital for Special Surgery, New York, NY; ¹³Wallace Rheumatic Disease Research Center, Los Angeles, CA, United States; ¹⁴F. Hoffmann La Roche, Ltd., Basel, Switzerland; ¹⁵Genentech, Inc., South San Francisco, CA, United States; ¹⁶pm Statistical Consulting Services, Ltd., Ely, United Kingdom

Background: Therapy-related serious adverse events (SAEs) are important causes of morbidity in patients with GPA or MPA. Long-term safety data of rituximab in GPA/MPA are limited.

Objectives: To characterize safety events in an observational registry of patients with GPA/MPA initiating rituximab.

Methods: This interim analysis of RaVeR, an ongoing open-label real-world study of adult patients with GPA or MPA initiating rituximab (dose/frequency determined by investigator), was conducted when 50% of patient-years (PY) were collected (July 2015–October 2016). Safety events included serious infections (SI), infusion-related reactions (IRR), serious cardiac events, malignancies, and other serious events. Crude incidence rates (IR) and 95% CI were calculated. Trial registration number: NCT01613599

Results: 97 patients (202 PY) received rituximab, of whom 70% received rituximab retreatment. Median follow-up was 2.4 years. Overall, 91% of patients were ANCA-positive and 78% had GPA. 17 patients (17.5%) had a history of plasmapheresis or dialysis; 20 (20.6%) were receiving rituximab plus cyclophosphamide at baseline. 13 patients had 20 SIs (9.13/100 PYs [95% CI: 5.58–14.10]). 9 patients (9.3%) experienced 13 serious cardiovascular (CV) events (5.93/100 PYs [95% CI: 3.16–10.15]), 12 of which were reported as unrelated to rituximab. Of the 13 CV events, 9 were atrial arrhythmias and most patients had a history of renal or CV disease history. There were no serious IRRs or SAEs within 24 hours of rituximab infusion. There were 6 deaths (2.74/100 PYs [95% CI: 1.01–5.86]); causes of death included septic shock, intestinal lung disease, congestive heart failure, cardio-respiratory arrest and 2 deaths of unknown etiology. The severe disease flare rate was 5.94/100 PYs (95% CI: 3.16–10.15). Among patients who received rituximab retreatment, the IRs of SAEs (26.1/100 PYs) and SIs (7.29/100 PYs) were not increased compared with the overall cohort.

Conclusions: In this interim analysis of patients with GPA/MPA treated with rituximab, SAEs were not increased compared with comparable cohorts of patients with renal involvement. Safety events did not increase with rituximab retreatment. These results are consistent with the known safety profile of rituximab and provide preliminary long-term, practice-level safety data for rituximab in GPA/MPA.

HISTOLOGY FINDINGS IN GIANT CELL ARTERITIS (GCA) AND THEIR RELATIONSHIP WITH THE ULTRASOUND RESULTS: ANALYSIS OF DATA FROM THE TABUL STUDY (TEMPORAL ARTERY BIOPSY VS ULTRASOUND IN DIAGNOSIS OF GIANT CELL ARTERITIS)

C.B. Ponte¹,², S. Monti³, S. Singh⁴, A. Hutchings⁵, A. Diamantopoulos⁶, B. Dasgupta⁷, W.A. Schmidt⁸, R.A. Luqmani⁹. ¹Department of Rheumatology, Hospital de Santa Maria; ²Rheumatology Research Unit, University of Pavia; ³Interventional Imaging, Genomics and Translational Medicine, University of Oxford, Oxford; ⁴Department of Health Services Research and Policy, London School of Hygiene and Tropical Medicine, London, United Kingdom; ⁵Department of Rheumatology, Hospital of Southern Norway Trust, Kristiansand, Norway; ⁶Department of Rheumatology, Southend University Hospital; ⁷Saint Mary’s Hospital, Southend-on-Sea, United Kingdom; ⁸Department of Rheumatology, Immunology, and Rheumatic Diseases, Berlin-Buch, Berlin, Germany; ⁹Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

Background: Although temporal artery biopsy (TAB) has been the gold standard for diagnosis of GCA, ultrasound has superior sensitivity but lower specificity. Occasionally, histological evidence of inflammation is restricted to the vasa vasorum, which is difficult to assess with TABs, and both, which could limit the diagnostic sensitivity of ultrasound for GCA. Moreover, false positive ultrasound results have been described in patients with arteriosclerosis on histology.

Objectives: To compare histologic findings with ultrasound results from patients with suspected GCA included in the TABUL study (a multinational study to assess the relative performance of ultrasound and TAB for diagnosing GCA).

Methods: All patients with newly suspected GCA underwent an ultrasound of both temporal and axillary arteries, followed by a TAB, within 7 days of confirming glucocorticoid therapy. TAB pathological diagnoses were analysed and the different histological features were compared with the ultrasound results using Chi-square or Fisher exact tests.

Results: Results for TAB and ultrasound were available in 388 patients (69% with a final clinician’s diagnosis of GCA). An artery was definitely obtained in 363 (94%) TABs; the pathological diagnosis was GCA in 104 (29%) cases, arteriosclerosis in 35 (10%), normal in 203 (56%) and other conditions in 21 (6%). All TABs compatible with GCA also had a final clinician’s diagnosis of GCA (73% with positive ultrasound). Table 1 shows that ultrasound positivity occurred more frequently in patients where the media was the predominant site of inflammation compared with the ultrasound result was positive in 9 (26%) cases where TAB was consistent with arteriosclerosis, 8 (89%) of whom had a final clinician’s diagnosis of GCA. The ultrasound was positive in 64 (32%) cases where TAB was normal, 52 (81%) of whom had a final clinician’s diagnosis of GCA.

Conclusions: Amongst patients with suspected GCA, ultrasound is more likely to be positive when histological inflammation is predominantly present in the intima-media. No significant correlation between histologic findings and negative ultrasound results was found, but the small number of cases with predominant vasa vasorum infiltrates in our cohort limited this analysis. There was only one false positive ultrasound in patients with arteriosclerosis on TAB.

CLINICAL FEATURES AND PROGNOSIS OF ANCA-ASSOCIATED VASCULITIS WITH RENAL INVOLVEMENT AT DIAGNOSIS

Background: Kidneys are major organs targeted by antineutrophilic cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Clinical manifestations, laboratory data, and prognosis of AAV with renal involvement at diagnosis are not elucidated.

Disclosures of Interest: None declared

Objectives: We compared clinical features of AAV with renal involvement with patients without renal involvement.

Methods: We conducted an observational study of 104 patients with AAV (12 esophageal granulomatosis with polyangiitis, 23 granulomatosis with polyangiitis (GPA), 68 microscopic polyangiitis, 3 renal limited vasculitis) between in 2008 to 2016 in Nagasaki University Hospital. Using medical records, we analyzed the patients' baseline variables, laboratory data, clinical symptoms, and therapeutic outcomes after treatments including episodes of relapses, initiation of dialysis, and death. Renal involvement was defined as the state with estimated glomerular filtration rate > 60 mL/min/1.73 m² or microscopic hematuria (2+ or greater) which were not caused by renal diseases except for AAV.

Results: Sixty-nine patients had renal involvement. Patients with renal involvement had higher median age at diagnosis than patients without renal involvement group (75 years vs. 66 years, p < 0.001). Patients with renal involvement included fewer GPA patients compared to other AAV types. Patients with renal involvement had lower hemoglobin levels (10.3 g/dL vs. 12.3 g/dL) and lower platelet levels (23.7x10⁴/μL vs. 28.7x10⁴/μL), Patients with renal involvement had higher erythrocyte sedimentation rate (78 mm/h vs. 20 mm/h), MPO-ANCA titers (16 U/mL vs. 58 U/mL) and urine protein levels (0.81 g/gCr vs. 0.15 g/gCr). Patients with renal involvement had lower C3 levels, but CH50 and C4 levels did not differ between in two groups. There were no differences in treatments including doses of prednisolone and use of mycophenolate pulse and cyclophosphamide between in two groups. Multivariable regression analysis revealed that age at diagnosis is the most significant explanatory variable to renal involvement. Nineteen percent of patients with renal involvement had initiation of dialysis. Multivariable analysis demonstrated estimated glomerular filtration rate at diagnosis is the most significant explanatory variable to initiations of dialysis (p = 0.010). Receiver operating characteristic curve showed the cutoff level of estimated glomerular filtration rate 37mL/min/1.73 m² was predictive of mortality. Renal involvement was defined as the state with estimated glomerular filtration rate > 60 mL/min/1.73 m² or microscopic hematuria (2+ or greater) which were not caused by renal diseases except for AAV.

Conclusions: Our study confirms the high mortality rate among vasculitides patients and mainly among those requiring admission to ICU. SOFA score and pre-admission treatment with rituximab have been found to be predictive of mortality.

THU0305

EPIDEMOLOGY OF ANCA-ASSOCIATED VASCUITIS IN NORTHERN NORWAY

A.T. Nilsen 1, R.A. Watts 2, W. Koldingsnes 3
1Department of Rheumatology, University Hospital of North Norway, Tromsø, Norway; 2Norwich Medical School, University of East Anglia, Norwich, United Kingdom

Background: The ANCA-associated vasculitides (AAV) have increased in prevalence since the 1980s, with granulomatosis with polyangiitis (GPA) being most prevalent in Caucasian population in circumpolar areas. This was also shown in a study on GPA in northern Norway between 1984 and 1998, which further showed an increasing incidence [1].

Objectives: The present study aimed to investigate the subsequent 15-year period in the same region, now including all the AAVs.

Methods: The study area has 11 hospitals, no private specialist in rheumatology or nephrology, and an adult population of 371 928. We retrospectively searched all hospital databases, using ICD-10 codes potentially compatible with AAV. Patients diagnosed with AAV from 1999 through 2013 according to the European Medicines Agency (EMEA) algorithm, and for GPA also the subgroup fulfilling the American College of Rheumatology (ACR) 1990 criteria, were included. For prevalence data, patients residing in the area, but with AAV diagnosis prior to 1999, were included too.

Results: Using the EMEA algorithm, 90 incident cases were classified as GPA, 39 as microscopic polyangiitis (MPA) and 14 as eosinophilic granulomatosis with polyangiitis (EGPA). Within the GPA group, 78 patients also met the ACR criteria. The results for incidence and prevalence are given in Table 1:

<table>
<thead>
<tr>
<th></th>
<th>Annual incidence/million</th>
<th>Point prevalence at 31. Dec</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACR GPA</td>
<td>11.4</td>
<td>16.7</td>
</tr>
<tr>
<td>EMEA GPA</td>
<td>11.4</td>
<td>19.6</td>
</tr>
<tr>
<td>EMEA MPA</td>
<td>2.7</td>
<td>6.5</td>
</tr>
<tr>
<td>EMEA EGPA</td>
<td>2.7</td>
<td>2.7</td>
</tr>
<tr>
<td>All AAV</td>
<td>16.8</td>
<td>29.0</td>
</tr>
</tbody>
</table>

Conclusions: The GPA incidence and prevalence in this study are the highest reported. Though the incidence has stabilized, prevalence is still increasing, albeit at a decelerating rate (Graph 1). Moreover, the total AAV prevalence doubled in the last 10 years, exceeding previous estimates. Incidence of MPA and EGPA are both within the range found elsewhere. But the GPA incidence appears to be rising reminiscent of GPA before the turn of the century.

null
Methotrexate (MTX), in clinical practice. Other factors associated were also investigated.

Methods: An inception cohort of GCA was assessed in the outpatient clinic at Hospital Clínico San Carlos, including patients from the date of diagnosis (Jan-1991 until Sept-2013), and followed-up until Sept-2014. Main outcome: relapse. A subjective improvement, patient has again symptoms or signs of GCA with high ESR and the need to increase corticosteroids at least 10mg. The independent variable was exposure to MTX over time. Covariates: Sociodemographic, clinical, and treatment. Incidence rates of relapses (IR) per 100 patient-years with their 95% confidence intervals (CI) were estimated using survival techniques. Time of exposure comprised the period from diagnosis until last of follow-up, main outcome, exposure to MTX or the end of the study. MTX influence on IR was analyzed by multivariable Cox models.

Results: 168 patients were included (675 patient-years). 80% of them were females and mean age at diagnosis was 76.7±7 years. 85% of the patients were on MTX, with mean dose of 10 mg/week. 31% of patients had relapses with an IR of 12 [9.6–14.9]. The median number of relapses was 1 [1–2], with a median lag time of 1.6 [0.6–6.3] years. In the multivariate analysis, exposure to MTX had less risk of relapse than those who never on MTX (p<0.05). Other variables included in the final model were: visual alterations, constitutional symptoms or malaise at clinical presentation of GCA.

Conclusions: The use of MTX seems to decrease the risk of recurrences. We also found other factors influencing on flares.

THU0310 FREQUENCY OF RELAPSES AND TREATMENT DISCONTINUATION DURING LONG-TERM FOLLOW-UP OF PATIENTS WITH GIANT CELL ARTERITIS

C. Tsalapak, A. Lazarini, K. Antonatou, K. Thomas, K. Kladivianou, C. Koutsianas, D. Vassilopoulos, J. Doutopoulos. Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens School of Medicine, Hippokration General Hospital, Athens, Greece.

Background: There are limited data regarding the long term outcomes of patients with giant cell arteritis (GCA) in the modern therapeutic era.

Objectives: To evaluate relapse, treatment discontinuation and complication rates in GCA patients during long term follow-up. Methods: A retrospective systematic chart review of GCA patients who were followed in an Academic Rheumatology Unit between 2002 to 2016 was performed. Demographic, clinical, laboratory and treatment data were collected and analyzed.

Results: 53 GCA patients were included in the study. 62% (n=33) are women with a mean age at diagnosis of 73±6.8 years and median duration of symptoms of 1.3 months. 41 patients (77%) had biopsy proven GCA while in 5 patients, clinical diagnosis was made. The most common symptoms were headache (60%), fever (51%), scalp tenderness (45%), jaw claudication (39%), visual disturbances (23%), polymyalgia rheumatica symptoms (9%) and vision loss (6%). Regarding laboratory data at baseline, the mean Hb and CRP were 101±32 g/dl and 381.000±134.000, respectively. All patients were initially treated with tapering steroids. Among different variables, only male sex was associated with earlier treatment discontinuation.

Conclusions: This study focuses on follow-up GCA patients with a longer duration of disease with a significant number of patients (n=28, 53%) among these 67% were laboratory and 56% clinical. To evaluate relapse, treatment discontinuation and complication rates in GCA patients during long term follow-up.

THU0311 FECAL MICROBIOTA IN BEHÇET’S SYNDROME PATIENTS WITH MUCOCUTANEOUS AND UVEITIS INVOLVEMENT

D. Tecer1, F. Gogus1, A. Kaikano2, M. Erdogan2, S. Coban2, M. Hasanneisoğlu1, T. Karakan5,1. Department of Physical Medicine and Rehabilitation, Division of Rheumatology, 2Department of Medical Microbiology; 3School of Medicine phase 3 student; 4Department of Ophthalmology; 5Department of Gastroenterology, Gazii University, Faculty of Medicine, Ankara, Turkey.

Background: Inflammatory immunity has a major role in the pathogenesis of Behçet’s syndrome. The gut microbiome is a stable component of the immune system. It plays an important role in the formation of the immune system in the early life and in the continuation of immune homeostasis through the life. Dysbiosis, imbalance in the gut microbiota, can lead to many serious metabolic and inflammatory pathologies.

Objectives: We aimed to investigate the gut microbiota structure in Behçet’s syndrome patients with mucocutaneous and uveitis involvement only.

Methods: 6 patients with Behçet’s syndrome with uveitis, 12 patients with familial Mediterranean fever (FMF) and 9 patients with Crohn’s disease (CD) and 10 healthy controls were included. Patients, positive and healthy controls were excluded if they had one of the following combined diseases/situations: a) gastrointestinal surgical history (e.g. bariatric surgery, gastroctomy or colectomy), b) antibiotic or probiotics use in the last 3 months, c) specific dietary restriction, d) malignancy, e) additional autoimmune disease or inflammatory bowel disease.

Conclusions: Fecal microbiota of patients with Behçet’s syndrome and of positive control groups (FMF and CD) differed significantly from that of healthy controls. In a subgroup of patients with Behçet’s disease with uveitis and mucocutaneous involvement only, firmicutes species seem to be the dominant bacterial flora.

THU0312 PERFORMANCE CHARACTERISTICS AND PREDICTORS OF TEMPORAL ARTERY ULTRASOUND AND BIOPSY FOR THE DIAGNOSIS OF GIANT CELL ARTERITIS IN A REAL WORLD POPULATION: A PROSPECTIVE COHORT STUDY

R. Conway1, S. Di Bello1, L. O’Neill1, G.M. McCarthy2, C.C. Murphy3, D.J. Veale1, U. Fearon4, R.P. Killeen5, E.J. Heffernan5, E.S. Molloy1. 1Rheumatology, St Vincents University Hospital; 2Rheumatology, Mater Misericordiae University Hospital; 3Ophthalmology, Royal College of Surgeons in Ireland; 4Medical Rheumatology, Trinity College Dublin; 5Radiology, St Vincents University Hospital, Dublin, Ireland.

Background: The diagnosis of giant cell arteritis (GCA) remains a clinical one. Temporal artery (TA) ultrasound (US) has been proposed as a new diagnostic tool in GCA.

Objectives: To assess the performance characteristics of TA US and biopsy in routine clinical practice.

Methods: All patients presenting with suspected GCA to our institutions are recruited to a prospective registry. Patients who had both a TA US and biopsy performed at the time of presentation were included in the current study. US was performed by 2 radiologists. The performance characteristics of both tests were compared to physician diagnosis at six months following presentation. Predictive factors for positive US and biopsy were explored in univariate and multivariable logistic regression analyses.

Results: 132 patients were included, 123 (76%) with GCA. Mean (SD) duration of glucocorticoids was 6.6 days (19.4) at the time of TA US and 6.2 days (8.4) at the time of TA biopsy. US had a sensitivity of 52.8% (95% CI 43.7, 61.9) and specificity of 71.8% (95% CI 54.8, 84.5). There were 11 false positive US results; 5 with migraine, 2 other vasculitides, 2 local infections, 2 malignancies. Biopsy

THU0313 DISCONTINUATION DURING LONG-TERM FOLLOW-UP OF PATIENTS WITH GIANT CELL ARTERITIS

D.J. Veale1, U. Fearon4, R.P. Killeen5, E.J. Heffernan5, E.S. Molloy1. 1Rheumatology, St Vincents University Hospital; 2Rheumatology, Mater Misericordiae University Hospital; 3Ophthalmology, Royal College of Surgeons in Ireland; 4Medical Rheumatology, Trinity College Dublin; 5Radiology, St Vincents University Hospital, Dublin, Ireland.
had a sensitivity of 48.8% (95% CI 39.7, 57.9) and specificity of 97.4% (95% CI 84.9, 99.9). A hypothetical sequential strategy of US followed by biopsy in the case of negative US had a sensitivity of 78.9% (95% CI 70.1, 85.5) and specificity of 71.8% (95% CI 54.9, 84.5), equivalent to a simultaneous testing strategy. Time on glucocorticoids did not significantly impact the results of US or biopsy. The only factor independently predictive of a positive US was male sex (OR 5.53, 95% CI 2.72 to 11.22, p < 0.001). The only factor independently predictive of a positive biopsy was jaw claudication (OR 2.40, 95% CI 1.11, 5.21, p = 0.027).

</tbody>
</table>

Conclusions: TA US is a useful tool in the diagnosis of GCA; however false positive tests occur in 7% and thorough clinical assessment remains crucial. Prior glucocorticoid treatment has no clear impact on results.

THU0313 INFERIOR AND SUPERIOR VENA CAVA THROMBOSIS IN BEHÇET'S DISEASE. MOROCCAN EXPERIENCE

F.Z. Alauzi1, M. Moudariti2. 1Internal medicine; 212 rue la saone, Polo, University Hospital Ibn Rochd, Casablanca, Morocco

Background: Behçet's disease (BD) is a systemic disorder with a vascular tropism where the vessels might be affected. Venous thrombosis is the most common vascular complication. Among its locations, vena cava thrombosis (VCT) is rare but can be life-threatening.

Objectives: To quantify the frequency of VCT and analyse epidemiological, clinical and therapeutic modalities.

Methods: A retrospective study was conducted in the internal medicine department of the University Hospital IbnRochd of Casablanca, over a period of thirty-five years between 1980 and 2016.

Results: Among the 1618 cases of Behçet's disease, all diagnosed in our service and meeting the diagnosis criteria as defined by the international study group (ISG) for Behçet's disease, 52 patients who fulfilled the ACR criteria were included in the study.

Conclusions: Vena cava thrombosis in the context of Behçet's disease is a very serious pathology threatening the patient's vital and functional prognosis. Preventive measures, early diagnosis and effective treatment are the keys to a successful management of such complications' risks.

Disclosure of Interest: None declared

THU0314 RADIOLOGIC ACTIVITY IS THE MAJOR DETERMINANT FOR PHYSICIANS WHILE DECIDING ACTIVE DISEASE IN TAKAYASU ARTERITIS

G. Kenar1, P. Cetin2, H. Yarkan1, B. Zengin1, G. Can1, M. Birlik1, F. Onen1. 1Rheumatology, Dokuz Eylul University School of Medicine, Izmir; 2Rheumatology, Dumlupinar University, Kutahya, Turkey

Background: There are no valid follow-up parameters in the assessment of disease activity in Takayasu arteritis (TA).

Objectives: To investigate the impact of incorporation of vascular imaging into ITAS in the assessment of disease activity in TA.

Methods: 52 patients who fulfilled the ACR criteria were included in the study. PGA, Kerr et al.'s criteria and ITAS2010/ITAS-A scores were evaluated in all patients in serial visits. All the patients were followed using 3–6 monthly B-mode/Doppler ultrasonography (USG) and 6–12 monthly magnetic resonance angiography (MRA).

Radiological activity (Rad) was defined based on the presence of any of the 3 parameters including new vessel involvement by any technique (5 points), increase in vessel wall thickness on USG (3 points) and vessel wall edema on MRA (3 points). Then we incorporated these scores with ITAS-A to obtain a composite disease activity index (ITAS2010-A-Rad) (Table 1). Active disease was defined as ITAS-A-Rad >4 points.

Results: Total 410 visits of 52 TA patients (mean age 50.7 yrs, 92.3% mean follow-up duration 6.4±2.9 yrs) were evaluated. Radiological assessment was done in 359 visits (by USG in 271 and by MRA in 190). Patients were categorized as having active disease in 194 visits (47.4%) according to Physician’s global assessment of disease activity (PGA) and 72 visits (17.5%) according to Kerr et al. criteria. The agreement between them was fair (κ: 0.29). Radiological activity was determined in 105 out of 359 visits (29.2%). The total agreement between radiological activity and Kerr at al. criteria was 83% (κ=0.52). There were 43 visits with new vessel involvement by any radiologic technique; all visits included patients with active disease based on both PGA and Kerr et al. criteria (Table 2). The ITAS-A-Rad was significantly correlated with all the other activity parameters including ITAS2010, ITAS-A, and APRs.

There were 43 visits with new vessel involvement by any radiologic technique; all visits included patients with active disease based on both PGA and Kerr et al. criteria (Table 2). The ITAS-A-Rad was significantly correlated with all the other activity parameters including ITAS2010, ITAS-A, and APRs.

Conclusions: Vena cava thrombosis in the context of Behçet's disease is a very serious pathology threatening the patient's vital and functional prognosis. Preventive measures, early diagnosis and effective treatment are the keys to a successful management of such complications' risks.

1Nephrology Department, University of Athens, School of Medicine, Athens, Greece

Disclosure of Interest:
None declared

Background: Peripheral nerve involvement is relatively frequently encountered in patients with granulomatosis with polyangitis (GPA). Central nervous system (CNS) manifestations are reported to occur in about 10% of GPA patients.

Objectives: We aimed to estimate the prevalence of CNS involvement in Greek patients with GPA, describe the related clinical characteristics, and identify possible predicting factors for its occurrence. We also compared the clinical picture and long term outcomes of GPA patients with and without CNS involvement.

Methods: We retrospectively reviewed the medical charts of all patients with ANCA-associated and biopsy proven small vessel vasculitis (AAV), diagnosed in our hospital between 1995-2015, who had CNS involvement. Demographics, serological and clinical features, at the time of AAV diagnosis, of CNS involvement and during the follow-up time, were recorded. Comorbidities, associated treatments, and outcome indicators (including relapse rate and treatment-related adverse events), were performed between GPA patients with and without CNS involvement.

Results: 77 patients with GPA were identified in our AAV registry. Of these, nine (11.7%) developed CNS manifestations, either at clinical presentation (33.3%) or during the follow-up (66.7%). At the time of CNS involvement, all patients were characterized by increased acute phase reactants and all but one patients had vasculitic manifestations in several other organs/systems and increased titers of ANCA. CNS symptomatology included: sensor and/or sensorimotor symptoms (33.3%), seizures (33.3%) delirium and/or hearing loss (33.3%), hemiparesis (22.2%), diplopia (11.1%) and cerebellar symptoms (11.1%). Findings of MRI were: cerebral ischemic lesions (55.6%), focal dural thickening with enhancement (22.2%), orbital mass formation (11.1%) and mastoiditis causing facial nerve palsy bilaterally (11.1%). Patients with CNS involvement, compared to those without, at initial AAV disease, experienced vasculitic manifestations of the ENT system more frequently (77.8% versus 25.4%, p=0.004) and they had a lower overall disease activity, as assessed by the BVAS score, while during the course of the overall disease experienced lung vasculitis less frequently (44.6% vs 78.4%, p=0.02). Comparisons between GPA patients with and without CNS manifestations did not reveal any differences in long-term outcomes including relapse rate/100 person-months, (95% CI [1.812 (0.920–2.229) Vs 1.033 (0.757–1.378), respectively] p=0.171), survival (Mantel-Cox test, p=0.244) and treatment-related adverse events.

Conclusions: CNS involvement was recorded in 11.7% of our GPA patients, either during the initial phase or as a late disease sequela. ENT involvement and low BVAS score at disease onset were more common in GPA patients with CNS manifestations. Based on our results, CNS involvement did not affect the long term outcomes of GPA patients.

THU0315 | EPIDEMIOLOGY OF TAKAYASU ARTERITIS IN NORTHERN ITALY

G. Restucia
L. Boirati
P. Macchioni
M. Catanoso
P. Manuso
G. Salvanari
1Rheumatology, Arcispedale S Maria Nuova; 2Servizio interzzieladiale di epidemiologia, Azienda unita sanitaria locale, Reggio Emilia e Arcispedale S Maria Nuova, Reggio Emilia, Italy

Background: Takayasu arteritis (TA) is a large vessel vasculitis of unknown etiology, predominantly affecting the aorta and/or its major branches and occurring before the age of 40 years. TA has been described worldwide with an annual incidence in Europe ranging from 0.4 to 1.3 /1.000.000. Tak is more common in female. In the largest study from Japan, the female to male ratio was eight to one. In a recent Swedish epidemiologic study no male were identified. There are no epidemiologic studies regarding Takayasu arteritis in Italian population.

Objectives: To investigate the epidemiology of Takayasu arteritis in a Northern Italy area.

Methods: All patients with incident TA diagnosed between 1997 and 2015 living in the Reggio Emilia area were identified by capture and re-capture checking at computerized discharge diagnosis codes (ICD10) and at outpatients databases from rheumatology, internal medicine, surgery, pathology, imaging departments of Reggio Emilia Hospital and by examining the Reggio Emilia district database for rare diseases. The Reggio Emilia population is predominantly of Caucasian origin (92.5%) with a yearly increase in general population of 0.5% from 438.588 inhabitants in 1997 to 533.827 in 2015.

Results: There were 5 women satisfying ACR 1990 criteria for TA diagnosis during the 18 years study period. The overall age and sex-adjusted 18 years incidence per 100,000 persons aged <40 years was 2.2. (95% CI:0.71 to 5.09). The overall age-and sex-adjusted 20 years incidence per 100,000 women aged <40 years was 4.5. (95% CI:1.46 to 10.48). Median age at disease onset was 29 years and at diagnosis was 39 years. The prevalence of TA in the general population on December 31 2015 was 0.9 (95% CI: 0.31 to 2.19) while in female population aged <40 years was 4.4. (95% CI 1.47 to 10.54). All patients are still alive on December 31, 2015.

Conclusions: As observed in other epidemiological studies, Tak is a rare disease also in Northern Italy with a large prevalence of female.

Disclosure of Interest: None declared

THU0317 | CARDIOVASCULAR RISK FACTORS AND COMORBID DISEASES IN TAKAYASU ARTERITIS

H. Masyan
1Rheumatology, Arcispedale S Maria Nuova; 2Servizio interzzieladiale di epidemiologia, Azienda unita sanitaria locale, Reggio Emilia e Arcispedale S Maria Nuova, Reggio Emilia, Italy

Objectives: The medical charts of all patients with ANCA-associated and biopsy proven small vessel vasculitis (AAV), diagnosed in our hospital between 1995–2015, were retrospectively reviewed and GPA patients with CNS involvement were identified. Demographics, serological and clinical features, at the time of AAV diagnosis, of CNS involvement and during the follow-up time, were recorded. Comorbidities, associated treatments, and outcome indicators (including relapse rate and treatment-related adverse events), were performed between GPA patients with and without CNS involvement.

Methods: We studied 88 (77F/11M) consecutive TA patients and 71 (66F/5M) SLE patients between May and November 2016. In addition, age and gender matched, 96 (80F/16M) healthy controls were included. Study participants were interviewed with the help of a standardized questionnaire that assess the presence or absence of traditional atherosclerotic risk factors and several comorbid conditions according to the Charlson comorbidity index. Additionally, Framingham coronary heart disease risk score was calculated. In this study we looked at the frequency of traditional atherosclerotic risk factors and comorbidity conditions among patients with TA and suitable diseased and healthy controls.

Results: Smoking was more frequent among the healthy controls, whereas hypertension and family history of cardiovascular diseases were more common among TA patients. Patients with SLE were found to have less hyperlipidemia. The Framingham risk scores did not differ among the groups. Pericardial/pleural and renal diseases were more frequently observed in SLE patients, whereas cardiovascular diseases and chronic lung diseases were more common in TA patients. Inflammation bowel diseases were only observed in TA patients.

Conclusions: Traditional atherosclerotic risk factors are not increased in TA. Comorbidities in these patients are mainly due to the complications of vascular involvement. The frequency of inflammatory bowel diseases and inflammatory upper/lower back pain is substantially high and deserves further research. Moreover, the increased incidence of cardiovascular and rheumatic diseases among the first-degree relatives of TA patients suggest that genetic mechanisms may play role in TA.

CORONARY ARTERY DISEASE IN PATIENTS WITH BEHÇET’S DISEASE: A RETROSPECTIVE, SINGLE CENTER STUDY

H. Chen 1, Y. Zhang 2, W. Chen 3, J. Liu 1, L. Wang 1, F. Zhang 1, W. Zheng 1
1Rheumatology, Peking Union Medical College Hospital, Beijing, China; 2Oncology and Immunology, The fourth hospital of Hebei Medical University, Hebei; 3Cardiology, Peking Union Medical College Hospital, Beijing, China

Background: Behçet’s disease (BD) is a chronic inflammatory disease affecting various size of arteries and veins. Coronary artery disease (CAD), a life-threatening condition, is rarely reported in patients BD.

Objectives: To investigate the clinical characteristics of BD patients complicated with CAD, and to elucidate the potential risk factors of CAD in BD patients.

Methods: We retrospectively reviewed all the medical records of patients who were admitted to our institute from 2001 to 2016. CAD was defined as at least one coronary artery stenosis (≥50%) (or) occlusion of coronary arteries confirmed by angiography or contrast-enhanced computer tomography. BD patients with CAD and age- and gender-matched BD patients without CAD (at 1:3 ratio) were enrolled. Demographic, clinical and laboratory data were systemically collected, analyzed and compared between two groups.

Results: In total, 19 patients, including 17 male and 2 female, were complicated with CAD. The mean onset age of BD was 34 and the mean duration from the onset of BD to the diagnosis of CAD was 4.1 year. Angina pectoris (8/19) and acute myocardial infarction (8/19) were the most common CAD symptoms, arrhythmia was presented in one patient, and three patient remained asymptomatic. Coronary artery aneurysm, stenosis and occlusion were presented in 9, 13 and 3 patients, respectively. Smoking (7/19) was frequently observed, while hypertension (3/16), diabetes mellitus (2/19), obesity (1/19) and alcohol consumption (1/19) were rarely present. Additionally, seven arterial and two veins in BD patients with CAD presented with active BD disease symptoms and elevated inflammatory markers, which implicated aberrant vascular inflammation was the key mechanism of CAD in BD patients. CRP, but not traditional CAD risk factors, was the risk factor of CAD in BD patients.

MR ANGIOGRAPHY FOR EVALUATION OF VASCULAR INFLAMMATION IN ELDERLY PATIENTS WITH LARGE VESSEL VASCLITUSS

I. Smitienko 1, P. Novikov 2, E. Atyasova 1, 1Medical Center “Petroskii Vorota”; 2Sechenov First Moscow State Medical University, Moscow, Russian Federation

Objectives: The aim of the study was to evaluate the feasibility of MR angiography (MRA) for evaluation of vascular inflammation in elderly patients with large vessel vasculititss.

Methods: 16 patients with established on PET with 18F-FDG large vessel vasculitits (14 female and 2 male, average age 66 years) were enrolled in our study. 14 patients had giant cell arteritis (just only 3 biopsy-proven cases), 2 patients with isolated aortitis of thorax aorta and 2 cases of PMR-associated arteritis. The average duration of any disease was 8 months. All patients underwent MRA with or without contrast enhancement of aorta and its branches at 1.5T Philips scanner (Avanto, Maastricht, The Netherlands). All patients had repeated MRA at 6 and 12 months. All images were studied by one specialist. We evaluated the role of mural oedema as a sign of activity of vasculitis. The results of MR-angiography were compared with clinical and laboratory data, ultrasound and PET/CT results.

Results: A total of 42 MRA were obtained in 16 patients. Significant mural oedema of thorax aorta or large arteries was shown by imaging in 20 of 42 cases (48.0%) and correlated with clinical and laboratory signs of vasculitits activity. Progressive arterial stenosis detected by ultrasound and increased uptake of 18F-FDG on PET, 12 patients with high degree of inflammation on MRA were steroid-naïve. In 22 cases (52%), MRA had showed mild or moderate oedema of the arteries’ wall. Low-moderate activity of vascular inflammation in our patients was associated with moderate or high of immunosuppressive therapy (mean ± SD). However, gradual reduction in the intensity of immunosuppression in 4 patients with mild mural oedema was associated with development of relapse of large vessel vasculitis. Notably, contrast enhancement did not improve significantly edema imaging.

Disclosures: Visualization of artery wall oedema by MRA may be a useful approach to detect persisting inflammation elderly patients with large vessel vasculitits.

Disclosure of Interest: None declared

THU0321 ALTERATIONS IN THE PERIPHERAL B CELL COMPARTMENT IN PATIENTS WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGITIS (CHURG-STRAUSS SYNDROME)

M. Rizzi, M. Engesser, R.E. Voll, A. Tollo, I. Janowska, N. Venhoff, J. Thiel, University of Freiburg, Department of Internal Medicine/Clinical Immunology, University Hospital Freiburg, Freiburg, Germany

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) belongs to the group of ANCA associated vasculitides. While the combination of asthmatic symptoms and vasculitits characterizes the disease clinically, eosinophilia and increased serum IgE concentrations are serologic hallmarks. The role of B lymphocytes in EGPA has not been defined so far, but therapeutic response to rituximab in EGPA points towards a role of B-cells in the pathogenesis of EGPA.

Objectives: To characterize the peripheral B cell compartment in patients with EGPA, to analyze the in vivo potential of B lymphocytes to class-switch to IgE, and to assess in vitro the differentiation of naïve B cells to IgE-secreting plasmablasts.

Methods: 25 laboratory works were included as ANCA-positive EGPA patients. PBMCs were stimulated with CD40L and IL-21 and IL-4 in enriched Iscoves’ medium with fluorescent-labeled monoclonal antibodies against: CD27, CD20, CD38, IgD, IgG, IgA, IgM, and peripheral CD19 B-cell count. B cell populations (naïve, marginal zone, class-switched B cells and plasmablasts) were analyzed by staining PBMCs with fluorescent-labeled monoclonal antibodies against: CD27, CD20, CD38, CD21, and BAF-F. For in vitro differentiation assays magnetically isolated B lymphocytes from EGPA patients and aged matched healthy controls were stimulated with CD40L and IL-21 and IL-4 in enriched Iscoves’ medium supplemented with 10% FCS, 1 μg/mL insulin, 2.5 μg/mL apo-transferrin, 1% nonessential amino acids, 2 mmol/L glutamine, and 1 μg/mL reduced glutathione. Starting the cultures with equal number of B cells, the absolute number of plasmablasts, and IgE class switched cells after 9 days was determined by counting the events in the CD20mphCD38mph and the IgG4CD19mph gate by flow cytometry. IgE secretion in the supernatant was measured by ELISA.

Results: 18 patients (8 females, median age 59 years) with EGPA diagnosed according to ACR and CHC-criteria were included into the study. 22% of patients were ANCA-positive. Immunosuppressive therapy was azathioprine in 11 patients, methotrexate in 3 patients, and leflunomide or mycophenolate in one patient each and two patients received no immunosuppressive treatment. 7 patients had a history of a prior cyclophosphamide therapy. Median lymphocyte count was
normal (1.2×10⁴/μl; normal range 1.1 to 3.2×10⁴/μl) but peripheral B cell numbers were markedly diminished (37/μl normal range: 100 – 500/μl). While the percentage of naïve B cells (53%) and marginal zone like cells (10.5%) were within normal range, the percentage of class-switched memory B cells was high (28.2%). To assess the in vitro class switch capacity to IgE the number of IgE class-switched cells was determined by counting the events in the IgA/D/IgE gate. The percentage of IgE-classed switched was 6.8% (range: 0.3%-34%) and not statistically different from healthy controls.

Conclusions: In the EGPA-patients we report we observed markedly diminished B-cells despite of normal lymphocyte counts. Within the B cell compartment, there was a shift toward late B cell maturation stages. In vitro B-cell development to IgE-classed switched was not increased in EGPA-patients pointing towards a non-B cell intrinsic mechanism.

DESCRIPTIVE STUDY OF ASIAN INDIAN PATIENTS WITH RHEUMATOID VASCLITIS IN RETROSPECTIVE: A SINGLE, TERTIARY CARE CENTRE EXPERIENCE

J. Mathew1, A. Ganapati1, R. Goel1, S. Pulikoti1, A.J. Mathew1, R. Janardhana1, M. Sowri2, D. Danda1, R. Rotar1, M. Ogric1, Ž. Šigoni1, S. Sodin-Šemrl1,2, S. ˇCuˇcnik1,3, M. Tomˇsiˇc1,4, A. Hoˇcevar1.

1Rheumatology, Private Practice, Ljubljana; 2Rheumatology; 3Biostatistics, Medical University of Primorska, Koper; 4Faculty of Pharmacy, University of Primorska, Koper, Slovenia

Background: Rheumatoid vasculitis (RV) is a severe extra-articular manifestation of rheumatoid arthritis (RA), with high morbidity and mortality reported in literature

Objectives: To describe the Asian Indian perspective on RV patients, their clinico-laboratory features and their outcome along with the factors affecting them

Methods: A retrospective review of cases with documented RV in our tertiary care centre was carried out. The visit during 1993-2014 was selected for those satisfying Scott & Bacon criteria for RV

Probable RV was defined as patients not satisfying Scott & Bacon criteria, but were managed like RV after exclusion of alternate diagnosis. Birmingham Vasculitis activity score (BVAS) version 3.0 was used for monitoring activity of RV

Results: 63 patients of RV were identified, with a study period prevalence of 0.7%, in our RA cohort. 33 (52.4%) patients were female. Mean age of patients was 50.7±11.5 years with median duration of RA being 6 years. Involvement of Peripheral Nerve System (PNS) was the commonest manifestation of RV in 52/63 (82.5%) patients followed by skin in 34/63 (53.9%) patients. Rheumatoid Nodule was seen in 14/ 63 (22.2%) patients. Percentage of current and ex-smokers combined,was same as rheumatoid nodule prevalence, 52 (82.5%) patients had biopsy evidence of vasculitis. 28/51 (55.8%) patients were started on mycophenolate, 13/51 (25.5%) patients on cyclophosphamide, 8/51 (15.7%) patients on azathioprine, 4/51 (7.8%) patients on Methotrexate as immunosuppressive (IS) agent along with mean dose of 46.0±23mg/kg/day) prednisolone. Additionally, Rituximab & IVIg were used in 2 patients each respectively. 3 months after initiation of immunosuppression 26/50 (52%) patients on follow-up were in remission and 39/47 (82.9%) patients attained remission at 6 months. Mean time to achieve remission was 151.1±86.3 days. All IS agents were equally effective in inducing remission at 3 and 6 months and showed statistically similar BVAS reduction at 3 and 6 months from baseline (t test & chi-square test). 7 (11.2%) patients were lost to follow up during 1993-2014 year cumulative follow up. Multiple regression analysis showed that at baseline presence of PNS involvement, eosinophilia, thrombocytosis, higher BVAS score and above of eye involvement and higher hemoglobin % at baseline were predictors for remission, at 3 months (p<0.05). 4/50 (8%) patients had relapse of vasculitic symptoms. 2 and 5 year survival rates were 96.2% and 83.9% respectively

Conclusions: Our cohort of Asian Indian RV was comparatively younger with lesser RA duration, less percentage of ever-smokers, lesser rheumatoid nodule prevalence, higher PNS involvement with better survival/mortality rates compared to published literature. All IS agents showed equal rates of BVAS remission & BVAS reduction at 3 and 6 months of treatment

References:
[1] Scott DG, Bacon PA. Intravenous cyclophosphamide plus methylprednisolone BVAS reduction at 3 and 6 months of treatment to published literature. All IS agents showed equal rates of BVAS remission & lesser RA duration, less percentage of ever-smokers, lesser rheumatoid nodule prevalence determined by counting the events in the IgA/D/IgE gate. The percentage of IgE-classed switched was 6.8% (range: 0.3%-34%) and not statistically different from healthy controls.

Conclusions: In the EGPA-patients we report we observed markedly diminished B-cells despite of normal lymphocyte counts. Within the B cell compartment, there was a shift toward late B cell maturation stages. In vitro B-cell development to IgE-classed switched was not increased in EGPA-patients pointing towards a non-B cell intrinsic mechanism.

NEUTROPHILS IN GIANT CELL ARTERITIS: MONITORING DISEASE PROGRESSION DURING THERAPY TAPERING

T. Kuret1, K. Lakota1,2, P. Žigon1, M. Ogric1, Ž. Rotar1, R. Ješe1, S. Sodin-Šemrl1,2, Ž. Čučnik1,3, M. Tomšič1,4, A. Hočevar1.

1Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana; 2FAMNIT, University of Primorska, Koper; 3Faculty of Pharmacy; 4Faculty of Medicine, University of Ljubljana, Slovenia

Background: Giant Cell Arteritis (GCA) represents a medical emergency due to risk of permanent vision loss and/or cerebrovascular insults. Polymyalgia rheumatic (PMR) frequently coexists with GCA1. No diagnostic or prognostic markers are yet known for GCA and predicting relapses during steroid therapy tapering is difficult. Biomarkers, such as serum amyloid A (SAA) and interleukin-6 (IL-6) provide added value for monitoring inflammation and a recent investigational study indicated the potential use of neutrophils and their surface markers in GCA pathogenesis2.

Objectives: To determine the percentage of neutrophils, T and B cells, and the mean fluorescence intensity (MFI) of L-selectin (CD62L) and Integrin αM (CD11b) on CD16+ neutrophils in peripheral blood of newly diagnosed, untreated GCA and PMR patients vs. healthy controls (time 0) and at GCA follow-up (7, 30 and 90 days after therapy)

Methods: Flow cytometry of stained, lysed and fixed whole blood was performed in 10 GCA patients (6 followed longitudinally), 7 PMR patients and 5 healthy controls (7-colour immunophenotyping kit, Miltenyi). Levels of SAA and IL-6 were measured in sera of GCA patients (n=6) using nephelometry and ELISA, respectively.

Results: Percentage of neutrophils was significantly higher at time 0 in GCA and PMR patients compared to healthy controls. Expression of both CD62L and CD11b on CD16+ neutrophils was also higher in GCA and PMR patients, as compared to healthy controls. Longitudinally, GCA patients showed an initial decrease in percentage of neutrophils, at day 7 in comparison with time 0, increasing on days 30 and 90, while both T (CD4+) and B cells exhibited a significant elevation in % at day 7, with a decline at days 30 and 90. The MFI of neutrophil CD62L steadily decreased from day 0 (85.80±45.45) to day 7 (71.99±29.93) and day 30 (57.61±42.17), while showing a substantial increase on day 90 (85.40±60.33), CD11b expression diminished initially and remained reduced on day 90. Levels of SAA and IL-6 declined sharply from day 0 to 7 (>10-fold drop) and day 30, with gradual elevation of both on day 90.

Conclusions: Neutrophil CD62L may represent a good surface marker for monitoring disease progression following glucocorticoid tapering. SAA and IL-6 exhibit a sharp decrease at early time points, increasing at day 90. In the future, a larger, longer study of neutrophils and their CD62L expression could support clinicians in their decision when and how to re-evaluate therapy in GCA patients

RELATIONSHIP OF THE INITIAL SYMPTOMS TO THE DIAGNOSIS DELAY AND POOR PROGNOSIS IN PATIENTS WITH TAKAYASU ARTERITIS

K. Matsumoto, Y. Kanoke, K. Isumi, K. Yamaoka, T. Takeuchi. Internal Medicine, Division of Rheumatology, Keio University School of Medicine, Tokyo, Japan

Background: Clinical courses of Takayasu arteritis are of great variety. Its non-specific initial symptoms can cause the delay in diagnosis and lead to poor prognosis. However, the symptoms of very early phase of Takayasu arteritis and their effects on diagnosis delay and prognosis are unclear.

Objective: To clarify the characteristics of initial symptoms of Takayasu arteritis, the delay in diagnosis, and its relationship with prognosis.

Methods: The consecutive patients with Takayasu arteritis with analysable information in our hospital were enrolled. Initial symptoms, laboratory findings before diagnosis, the duration from symptom onset to diagnosis, and prognosis were investigated. Initial symptoms were divided into 7 groups; cranial symptoms (dizziness, syncope, headache, neck pain, hemi-paralysis, and jaw claudication), visual symptoms (vision loss and visual field loss), extremities symptoms (claudication of extremities, coldness of limbs, bilateral difference in blood pressure, and limb numbness), cardiaco/aortic symptoms (dyspnea on exertion, palpitation, and chest compression), hypertension, general illness (fever, fatigue, body weight loss, and arthralgia), and abnormal medical examinations (heart murmur, bruit on any extremities, and abnormal chest X-ray). Poor outcome was defined as a cardiovascular surgery or death.

Results: A total of 98 patients were enrolled with the median observation period of 12.1 years (range, 1 month to 59 years). Eighty-seven (88.7%) patients had poor outcomes. The initial symptoms before diagnosis were cranial symptoms in 25.5%, visual symptoms in 5%, extremities symptoms in 26%, cardiaco/aortic symptoms in 7%, hypertension in 9%, general illness in 26%, and abnormal medical examinations (heart murmur, bruit on any extremities, and abnormal chest X-ray). The duration from symptom onset to diagnosis was 792, 52, 567, 752, 1318, 293 and 1014 days (p=0.10), respectively; the rate of poor outcome was 29.6 vs 38.9 years, p=0.026, and resulted in poor outcome more frequently than those with (42.6 vs 22.6%, p=0.058).

Conclusions: The initial symptoms of Takayasu arteritis before diagnosis varied widely, and majority of them were non-specific. Lacking inflammatory signs were related with delayed diagnosis and poor prognosis.

THU0326 ASSOCIATION BETWEEN THE TC-HDL RATIO AND DISEASE ACTIVITY IN PATIENTS WITH TAKAYASU ARTERITIS

L. Pan1, J. Du2, H. Liao 1.
1Rheumatology and Immunology; 2Beijing An Zhen Hospital, Capital Medical University, Beijing, China

Background: Accelerated atherosclerosis has become the main cause of morbidity in patients with autoimmune diseases such as RA and SLE [1]. The Cholesterol/High-density Lipoprotein Cholesterol (TC-HDL-C) ratio is a high discriminatory power index for coronary heart disease. A high TC-HDL-C ratio has been extensively used as a predictor of CVDs [2]. EU-Mark Task Force recommended that the TC-HDL-C ratio should be regarded as an important prognostic indicator for future cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) [3]. However, the relationship between the TC-HDL-C ratio and disease activity of Takayasu arteritis (TAK) is unclear.

Objectives: To investigate changes in the TC-HDL-C ratio and to evaluate the relationship between the TC-HDL-C ratio and disease activity of TAK.

Methods: A retrospective study of 103 patients with TAK and 73 healthy controls was performed. We compared the triglyceride (TG), TC, low-density lipoprotein cholesterol (LDL-C), HDL-C and TC-HDL-C ratio between patients and healthy controls, and we analyzed correlations between the lipid parameters and indexes

Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.4818
of TAK activity. A ROC curve was used to determine the predictive value of TC/HDL-C ratio in patients group.

Results: The TG level was higher in patients with TAK than in the controls (p=0.000). The TC, LDL-C, and HDL-C levels were significantly lower in patients with TAK than in the controls (p=0.000, p=0.000, and p=0.000, respectively). The HDL-C level was significantly higher in the active TAK group than in the inactive TAK group (p=0.005). The TC/HDL-C ratio was significantly increased in patients with disease activity (p=0.001), and it exhibited a positive relationship with the high-sensitivity C-reactive protein level (r=0.234, p=0.003) and Kerr score (r=0.219, p=0.031). In addition, the TC/HDL-C ratio of 3.698 was determined as a predictive cut-off value of TAK (sensitivity 61.0%, specificity 78.6%, area under the curve=0.743) (Figure 1).

Conclusions: For the first time, we showed that serum levels of TC, LDL-C, and HDL-C were significantly lower in patients with TAK, and the TC/HDL-C ratio has a positive relationship with the disease activity of TAK, suggesting that the TC/HDL-C ratio may be a potential indicator for monitoring the disease activity of patients with TAK.

THU0328 PRECURSORS OF SEVERE DAMAGE IN ANCA-ASSOCIATED VASCULITIS: DATA FROM A MONOCENTRIC INCIDENCE COHORT

M. Felicetti, R. Padovan, M. Cerchiaro, M. Zen, L. Punzi, F. Schiavon. Department of Medicine DIMED, Operative Unit of Rheumatology, University of Padova, Padova, Italy

Background: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) are multi-systemic diseases associated with anti-neutrophil cytoplasmatic antibodies (ANCA). Patients develop severe and irreversible damage, even in early stages of the disease, but data about prognostic factors are limited.

Objectives: To assess items and predictors of severe damage in a monocentric cohort of ANCA-associated vasculitis (AAV) patients, classified as GPA or MPA.

Methods: Clinical and serological data of patients, followed-up in a daily practice setting, were retrospectively revised. Severe damage, defined as a Vascular Damage Index (VDI) 3 5, was assessed after 12 months and at last examination (LE). The number of flare/year at LE was significantly higher in patients with disease activity (p=0.001), and it exhibited a positive relationship with the high-sensitivity C-reactive protein level (r=0.234, p=0.003) and Kerr score (r=0.219, p=0.031). In addition, the TC/HDL-C ratio of 3.698 was determined as a predictive cut-off value of TAK (sensitivity 61.0%, specificity 78.6%, area under the curve=0.743) (Figure 1).

Conclusions: For the first time, we showed that serum levels of TC, LDL-C, and HDL-C were significantly lower in patients with TAK, and the TC/HDL-C ratio has a positive relationship with the disease activity of TAK, suggesting that the TC/HDL-C ratio may be a potential indicator for monitoring the disease activity of patients with TAK.

A.A. Manfredi, G.A. Ramirez, V. Cantì, E. Tombetti, M. Baldini, E. Baldisera, P. Rovere-Querini, N. Maugeri, San Raffaele Scientific Institute, Milano, Italy

**Background:** Takayasu's arteritis (TA) is a rare large-vascular vasculitis characterized by the persistent involvement of the vessel walls. The role of innate immune cells in TA is poorly understood. Biomarkers to be used for assessment of TA activity and clinical outcome are missing. A trivial model of myeloperoxidase (MPO) distribution (simultaneous occurrence of neutrophils with complete depletion, reduced and normal content of the enzyme) is detectable in the very early phase of acute myocardial infarction and has been associated with a burst of neutrophil interaction with activated platelets.

**Objectives:** Here, we aimed at characterizing the phenotype of neutrophils and platelets in patients TA and correlating these biological findings with clinical data.

**Methods:** Neutrophil MPO expression has been studied in 93 subjects, including 20 age-matched controls and 73 patients with systemic vasculitis. Interestingly, 25 patients with chronic stable atherosclerosis (CSA), eight patients with giant cell arteritis (GCA), five patients with granulomatosis with polyangiitis (GPA), four patients with eosinophilic GPA (EGPA) and ten patients with polymyalgia rheumatica (PMR). Blood samples were collected and processed as described.

**Results:** High neutrophil MPO content, platelet P-selectin and High-Mobility Group I (HMGB1) in platelet microparticles (PDMP) release were assessed by flow cytometry.

**Conclusions:** Neutrophils and platelets are significantly activated in TA. Paroxysmal neutrophil activation, leading to complete MPO depletion, is a common feature and predict ischemic events and as such the clinical disease outcome.

**DOI:** 10.1136/annrheumdis-2017-eular.6068
led to the myocardial infarction, and death. Pathological manifestation of cardiac involvement in PAN included the left ventricular hypertrophy due to renovascular arterial hypertension in 26 cases (70.3%). In addition, interstitial myocarditis was observed in 4 cases (10.8%).

**Conclusions:** Our data suggest that cardiac involvement is common in polyarteritis nodosa (81.1%), and coronary vasculitis affecting medium and small-sized arteries with wide range of acute and chronic changes can be the life-threatening condition.

**Disclosure of Interest:** None declared

**EVALUATION OF SUBCLINICAL VASCULAR DAMAGE IN PATIENTS WITH POLYMYALGIA RHEUMATICA: A CROSS-SECTIONAL STUDY USING AN INTEGRATED, NON-INVASIVE APPROACH OF COLOR DOPPLER ULTRASOUND AND CARDIO-ANKLE VASCULAR INDEX (CAVI) MEASUREMENT OF ARTERIAL STIFFNESS**

P. Sessa1, J.M. Rutigliano 1, R. Scrovio 1, V. Silvestri1, F. Cicirello2, G. La Torre6, F. Conti4, F. Priori1, C. Alessandri1, V. Ricci1, M. Di Franco1, B. Gossetti2, G. Valesini1.1) Department of Internal Medicine and Medical Specialties; 2) P. Stefanini General and Specialist Surgery Department; 3) Department of Cardiovascular Science; 4) Department of Public Health and Infectious Diseases, University of Rome la Sapienza, Roma, Italy

**Background:** The association of chronic inflammatory rheumatic disorders with an increased risk of vascular disease, especially cardiovascular and cerebrovascular disease, is a consolidated matter, but data on polymyalgia rheumatica (PMR) are still inconsistent.

**Objectives:** The aim of our cross-sectional study was to investigate the presence of vascular damage in patients with PMR by analyzing subclinical vascular disease through validated, non-invasive cardiovascular damage markers.

**Methods:** We enrolled patients with PMR diagnosed according to the EULAR classification criteria and, as controls, patients with major cardiovascular risk factors (MVCVR) including hypertension, diabetes, hypercholesterolemia, cigarette smoking, and obesity. In all of them we performed color Doppler ultrasound to evaluate the common and peripheral main arteries, followed by ankle-brachial index (ABI) and carotid artery stenosis (APAD); we also assessed the ankle-brachial vascular index (CAVI) to measure arterial stiffness.

**Results:** Forty-eight patients with PMR and 56 with MVCVR were included. Demographic parameters were balanced between groups. A significant increase of IMT (1.03±0.23 vs 0.89±0.20; p=0.02), CAVI (8.59±1.23 vs 7.59±0.93; p=0.001) and APAD values (22.0±4.86 vs 19.1±4.65; p=0.03) was found in PMR patients with respect to MVCVR controls. No differences were reported with regards to the prevalence of carotid artery stenosis or ABI values between the two groups. No significant correlation between disease duration or duration of glucocorticoid treatment and IMT or CAVI values was found in PMR patients. Results of bivariate analysis showed a significant correlation between IMT and CAVI in both PMR and MVCVR patients (r²=0.845 and 0.556, respectively; p<0.001).

**Conclusions:** Our study adds new information on cardiovascular risk in PMR patients, showing an increase in subclinical cardiovascular lesions and paving the way for further studies to define the utility and modality of cardiovascular screening for primary prevention in these patients.

**ACETYLCHOLINESTERASE IS HIGHLY EXPRESSED IN THE INFLAMED VESSEL WALL OF PATIENTS WITH GIANT CELL ARTERITIS**

P. Therkildsen1, B.D. Nielsen1, K.K. Keller1, T. Steiniche2, L.C. Gormsen3, I.T. Hansen 1, E.-M. Hauge 1, 1Department of Rheumatology; 2Department of Nuclear Medicine and PET Centre, Aarhus University Hospital, Aarhus, Denmark

**Background:** The temporal artery biopsy (TAB) remains the gold standard in the diagnosis of giant cell arteritis (GCA) and is part of the ACR Classification criteria for GCA. However, TABs are false-negative in 10–60% of cases [1]. Cellular studies have shown that activated immune cells upregulate the acetylcholinesterase (ACHE) expression [2]. If ACHE is upregulated in the active GCA vessel wall, it may potentially improve the TAB as a diagnostic tool.

**Objectives:** To investigate the in-situ expression of acetylcholinesterase (ACHE) in the vessel wall of patients with biopsy-positive GCA and compare to non-GCA patients.

**Methods:** In this histological case-control study, TABs from a total of 24 TAB-positive GCA and 44 TAB-negative non-GCA patients (21 patients with a final diagnosis of PMR, 23 patients with other diagnosis) were retrospectively selected from TABs performed between January 2012 and December 2015. A total of 295 TABs were assed for inclusion. Only positive TABs showing clear tranvilral inflammation in the vessel wall were included. Patients treated with ~7 days of prednisolone prior to the TAB were excluded. Clinical data were obtained from electronic patient records to confirm or dismiss clinical diagnosis. TAB-HE-stains were reviewed by a pathologist with expertise in vasculitis. Immunohistochemical methods were used to determine the ACHE expression. The histological inflammation and ACHE

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.5074
expression were assessed and graded on 0–4 scale, blinded to histological and clinical data. Solitary AChE staining of the media was not included in the assessment.

Results: 24 positive and 44 negative TABs, with corresponding clinical positive and negative GCA diagnosis, were included in this study. We found that 10/24 positive TABs showed high AChE expression (grade 2) and 14/24 showed moderate AChE expression (grade 1). No AChE expression was observed outside the media in negative TABs from non-GCA patients (i.e. grade 0). The AChE expression was in 79% agreement with the degree of histological inflammation with a kappa value of 0.58. Prednisolone treatment for up to 7 days did not suppress the AChE expression. Neither the AChE expression, nor the histological inflammation showed correlation to any clinical or biochemical findings.

Conclusions: Our study shows that high to moderate AChE expression was observed in all 24 biopsies from TAB-positive GCA patients and that the AChE expression was in good agreement with the histological inflammation. No non-specific AChE expression was observed outside the media in any of the 44 TABs from TAB-negative non-GCA patients. This indicates that AChE could play a significant role in the inflammatory process in GCA and may be a potential biomarker in inflammatory diseases such as GCA.

References:
[2] Fujii, T., et al., Expression of acetylcholine in lymphocytes and modulation of specific AChE expression was observed outside the media in any of the 44 TABs from TAB-negative non-GCA patients. This indicates that AChE could play a significant role in the inflammatory process in GCA and may be a potential biomarker in inflammatory diseases such as GCA.

THU0337 CLASSIFICATION OF ANTINEUTROPHILIC CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS AND CLINICAL IMPACT AND OUTCOME

S. Deshayes 1, A. Aouba 1, K. Kathy2, D. Mariotte2, T. Lobbedez3, N. Martin Silva 1. 1Department of Internal Medicine; 2Department of Immunology; 3Department of Nephrology, CHU de Nantes, Nantes, France

Background: Antineutrophil cytoplasmic antibody (ANCA)–associated vasculitides (AAV) have overlapping manifestations. Classifications based on clinical criteria or ANCA specificity have emerged to individualize homogenized group of patients in terms of clinical forms and outcomes.

Objectives: The aim of our study was to retrospectively re-evaluate the clinical impact and outcome of our monocentric AAV patients' cohort, according to classifications based on clinical criteria and/or ANCA specificity.

Methods: A retrospective monocentric study carried out in Caen university hospital led to identify proteinase-3 (PR3) or myeloperoxidase (MPO)-ANCA AAV patients (via an ELISA technique), respectively from March 1997 to June 2016, and from September 2011 to June 2016. Patients with eosinophilic granulomatosis with polyangiitis were excluded. AAV were classified between granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA), and GPA vs MPA (p < 0.001) and GPA vs MPA (p < 0.005). As expected, ear-nose throat involvement were significantly higher in PR3-ANCA vs MPO-ANCA, and GPA vs MPA (p < 0.001). Survival was significantly higher in
anti-MPO GPA but relapse-free survival was lower, compared to anti-MPO MPA (p=0.038 and p=0.015, respectively). Without difference in treatments. Relapse-free survival was lower in GPA, compared to MPA (p<0.001). Among GPA patients, there was significantly more deaths in PR3 than MPO patients (p=0.02), but without significant difference between ANCA types for all other considered criteria, including survival (p=0.08).

Conclusions: The clinicopathological classification appeared as the strongest criteria for distinguishing homogeneous forms and prognosis of AAV. Besides their diagnostic value, ANCA may not exhibit further great interest, especially in GPA.

THU0338 CLINICAL PRESENTATION AND OUTCOMES OF EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS: ANCA-NEGATIVE VS ANCA-POSITIVE

E. Zagvozdkina, P. Novikov, S. Moiseev, Sеченov First Moscow State Medical University, Moscow, Russia, Moscow, Russian Federation

Objectives: The aim of the prospective study was to compare clinical presentation at diagnosis and long-term outcomes of eosinophilic granulomatosis with polyangiitis (Churg-Strauss) (EGPA) patients according to antineutrophil cytoplasmic antibody (ANCA) status.

Methods: EGPA was classified according to the Revised CHCC Nomenclature and ACR1990 criteria. Activity of vasculitis was evaluated using BVAS. A minor relapse was defined as an increase in at least one new or worse minor item and no major BVAS item. A major relapse was an increase in at least one major BVAS item.

Results: We followed 93 patients with EGPA for a mean±SD of 6.3±5.6 years. Their mean±SD age was 46.6±13.8 years, and 96.8% patients had a history of asthma. The most common EGPA manifestations at diagnosis included ENT manifestations (88.2%), fever (78.5%), peripheral neuropathy (73.1%), lung involvement (59.1%) and skin lesions (49.5%). Thirty seven of 93 patients (39.8%) were ANCA-positive. These patients had significantly more frequent myalgia and mononeuritis multiplex, than the ANCA-negative patients. The difference in occurrence of kidney disease between the two groups did not reach statistical significance. However, all three patients with rapidly progressive kidney failure were ANCA-positive. BVAS at diagnosis and VDI at the end of the follow-up were significantly higher for ANCA-positive patients. The follow up duration was 587.7 patient-years. The incidence of all vasculitis relapses was 14 per 100 patient-years and 3.7 per 100 patient-years, respectively. The 3- and 5-year relapse-free survival rate was 65.4% (95% CI 54.6–76.2) and 43.1% (95% CI 30.4–55.7), respectively. The frequency of vasculitis relapses was 2.1 per 100 patient-years in the ANCA-positive group versus 1.9 per 100 patient-years in the ANCA-negative group (P=0.4).

Conclusions: The characteristics of EGPA patients differ according to their ANCA status. Although clinical outcomes were similar in both groups, EGPA is characterized by relapsing course of disease. The minor vasculitis relapses predominated in the structure of relapses.

THU0339 FECAL CALPROTECTIN LEVELS AS AN INDICATOR OF ACTIVE DISEASE IN BEHÇET’S SYNDROME PATIENTS WITH GASTROINTESTINAL INVOLVEMENT: A CONTROLLED STUDY

S.N. Esatoğlu1, I. Hatemi2, Y. Ozguler1, G. Hatemi1, H. Uzum3, A.F. Celik2, H. Yazi1.
1Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology; 2Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Gastroenterology; 3Istanbul University, Cerrahpasa Medical School, Department of Biochemistry, Istanbul, Turkey.

Background: Elevated fecal calprotectin (FC) levels indicate activity in Crohn’s disease (CD) and ulcerative colitis and are used as non-invasive biomarkers in these diseases. Gastrointestinal involvement of Behçet’s syndrome (GIBS) shows clinical and endoscopic similarities to CD. A previous study suggested that FC may help to diagnose GIBS patients (1), but we are not aware of any studies addressing its role in identifying disease activity in such patients.

Objectives: To determine whether FC helps to distinguish active GIBS patients from those in remission.

Methods: We collected fecal and serum specimens before colonoscopy from 39 GIBS patients who agreed to participate (Table). Twenty-six patients were asymptomatic whereas 13 had abdominal pain and/or diarrhea. We also filled disease activity index for intestinal Behçet’s disease (DAIBD) and Crohn’s disease activity index (CDAI) in each patient. Active gastrointestinal (GI) involvement was defined as having ulcers on colonoscopy. We included 22 active and 25 inactive CD patients as controls. We used 150 μg/L as the cut-off for a positive FC level. None of the patients were receiving NSAIDs that could increase FC levels.

Results: Among the 39 GIBS patients, 14 had active ulcers on colonoscopy (8/13 symptomatic and 6/26 of asymptomatic). FC level was >150 μg/L in 12/14 active GIBS patients and in 6/25 patients in GI remission (OR: 19, 95% CI: 3 to 110). The median FC and CRP levels were higher among active GIBS patients whereas serum calprotectin levels were not different (Table). Among CD patients, 16/25 active patients and 3/22 patients in remission had a FC level >150 μg/L (OR: 11, 95% CI: 11 to 49). There was a high correlation between FC and CDAI scores (r=0.64, p<0.001) and a very high correlation between FC and DAIBD scores (r=0.71, p<0.001), while FC was not correlated with serum calprotectin and CRP levels. Among the 6 GIBS patients who had high FC levels despite being in remission for GI involvement, 2 had active mucocutaneous lesions, 1 had concomitant macrophage activation syndrome (MAS), 1 had polylymphocytosis with trisomy 8 and 2 were started high dose corticosteroids. Repeat FC levels could be obtained in 3 of these patients, after the resolution of MAS and mucocutaneous lesions, and were <150 in all 3.

Table 1. Demographic, clinical and laboratory features of active GIBS patients and in GIBS patients who are in remission.

</tr>
</tbody>
</table>

Conclusions: FC seems to be a useful non-invasive tool for identifying active GI involvement in GIBS patients. Whether the presence of other BS manifestations can cause false positive results in GIBS patients in remission remains to be studied. On the other hand, serum calprotectin levels do not seem to be useful in identifying active disease in GIBS patients.

ADRENAL INSUFFICIENCY DURING GLUCOCORTICOID TREATMENT IN PATIENTS WITH POLYMYALGIA REUMATICA OR GIANT CELL ARTERITIS

T. Laursen1, H. Locht1, B. Jensen1, S. Borresen2, U. Feldt-Rasmussen3, L. Hilsted1, E.M. Bartels4, *Center for Rheumatology and Spine Diseases, Rigshospitalet; 1Department of Endocrinology, Rigshospitalet; 1Department of Clinical Biochemistry, Rigshospitalet; 1The Parker Institute, Department of Rheumatology, Copenhagen, Denmark

Background: Adrenal insufficiency secondary to long-term systemic glucocorticoid treatment is a well-recognized problem. However, the extent and prevalence of this phenomenon has not been thoroughly explored.

Objectives: To investigate the prevalence of adrenal insufficiency in patients with polymyalgia reumatica (PMR) and giant cell arteritis (GCA) during treatment with low-dose methylprednisolone (10 mg/day) and to correlate the adrenal response to a 250 microgram Synachten® test.

Methods: Outpatients were examined when prednisolone doses were between 2.5 and 10 mg/day for >6 months. Adrenal function was evaluated after a 48-hour pause of prednisolone, using a 250 μg Synachten® (ACTH) test where plasma cortisol levels were measured at baseline and 30 minutes after Synachten injection. Adrenal insufficiency was defined as plasma cortisol <420 nmol/l after 30 minutes according to the validated Roche Elecsys®Cortisol II assay. Accumulated doses of prednisolone for the individual patients were calculated. A multiple regression analysis was used to test for an association between the plasma cortisol after 30 minutes and the accumulated dose of prednisolone.

Results: Forty-eight patients (35 women) completed the Synachten® test. Seven (14.6%) patients exhibited adrenal insufficiency. Median age was 74 years (Range: 52–99 years). Median accumulated dose was 3,402 mg (Range: 820–21,200 mg). Median plasma cortisol after 30 minutes was 562 nmol/l (Range: 92–989 nmol/l). In patients with adrenal insufficiency, median plasma cortisol was 122 nmol/l (Range: 56–275 nmol/l) at baseline and 207 (Range: 92–420 nmol/l) after 30 minutes. In patients without adrenal insufficiency, median plasma cortisol was 359 (Range: 97–1104 nmol/l) at baseline and 584 nmol/l (Range: 429–989 nmol/l) after 30 minutes. Accumulated doses of prednisolone did not differ in patients with and without adrenal insufficiency (p=0.49). Plasma cortisol after 30 minutes was not associated with accumulated dose of prednisolone (estimate: −0.01, 95% CI: −0.02 to 0.05, p=0.66) when adjusting for sex and age.

Conclusions: Iatrogenic adrenal insufficiency was prevalent among patients with PMR or GCA treated with low dose prednisolone. Adrenal function was not affected in AAV patients. Secondary aims were to correlate the FLT3 ligand serum concentrations with clinical and laboratory parameters. The elevation more likely reflects the therapeutic regimen and history than disease activity as we could show that patients with more intensive treatment including both CYC and AZA show higher FLT3 ligand serum levels when compared to patients with less intense therapy.

FLT3 LIGAND CONCENTRATIONS ARE ELEVATED IN ANCA-ASSOCIATED VASCULITIDES (AAV) AND ARE INFLUENCED BY IMMUNOSUPPRESSIVE THERAPY

N. Venhoff, T. Jothil, R.E. Voll, A.C. Venhoff, U. Salzer, Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Medical Faculty, University of Freiburg, Freiburg, Germany

Background: The cytokine Flt3 ligand is an important co-factor for early hematopoiesis by mainly driving the development of lymphoid and early B-cell precursors. In the periphery functions of Flt3 are more pleiotropic involving the regulation of differential T cells, dendritic cells as well as peripheral B-cells. Besides its well-known roles in hematological disorders and as an indicator of bone marrow (BM) output capacity, the possible involvement of Flt3 ligand in autoimmune disorders was only discovered recently.

Objectives: Our primary aim was to analyze if FLT3 ligand serum concentrations are influenced in AAV patients. Secondary aims were to correlate the FLT3 ligand serum concentrations with clinical and laboratory parameters. And, since FLT3 ligand concentrations are elevated in different states of bone marrow failure, we are affected in AAV patients. Secondary aims were to correlate the FLT3 ligand concentrations are elevated in different states of bone marrow failure, we

Methods: We performed a cross sectional study using a sandwich ELISA to determine FLT3 ligand concentrations in the serum of 98 well-characterized AAV patients (69 GPA, 20 MPA and 9 EGPA) and 144 healthy controls (HC). Statistical evaluation was done using Mann-Whitney or unpaired, two-tailed Student’s t-test. Results: In patients with AAV, FLT3 ligand concentrations were significantly elevated (207 pg/ml +/- 116.2 in AAV versus 142.5 pg/ml +/- 65.98 in HC; p<0.0001). Disease specific analysis revealed significantly elevated FLT3 ligand concentrations in GPA (217.6 pg/ml +/- 123; p<0.0001), but no significant differences for MPA and EGPA when compared to HC. FLT3 ligand concentrations did not correlate to serological or clinical markers of disease activity, however, overall disease activity was low in the studied cohort. To assess the influences of treatment regimen on FLT3 ligand concentrations, we focused our analysis on treatment histories of cyclophosphamide (CYC) and azathioprine (AZA) and grouped the patient cohort according to the cumulative CYC dose (< or >5g and/or duration of AZA therapy (< or >6 months). AZA and CYC naïve patients (n=10) showed FLT3 concentrations comparable to HC (121 pg/ml +/- 42.3), but in patients with low dose CYC and short term AZA therapy FLT3 concentrations were significantly higher (176.6 pg/ml +/- 51.6), both compared to treatment naïve patients and HC (p=0.0095 vs. AAZ/CYC naïve, p=0.0105 vs HC). Intensified treatment was associated with even further increased concentrations of FLT 3 ligand with highest concentrations found in patients treated with >5g CYC cumulative dose or AZA treatment for >6 months (263.4 pg/ml +/- 172.6; p=0.0024 vs. AAZ/CYC naïve, p<0.0001 vs HC).

Conclusions: FLT3 ligand concentrations are elevated in patients with AAV, especially in patients with GPA. The elevation more likely reflects the therapeutic regimen and history than disease activity as we could show that patients with more intensive treatment including both CYC and AZA show higher FLT3 ligand serum levels when compared to patients with less intense therapy.

UTILIZING “REAL LIFE” DATA IN ORDER TO EVALUATE THE ASSOCIATION BETWEEN GIANT CELL ARTERITIS AND AUTOIMMUNE THYROID DISEASE

Y. Yavne1, S. Tiosano2, A. Watad2, D. Comanescu3, Y. Shoenfield4, A.D. Cohen3,4, H. Amital5. 1Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv; 2Department of Medicine ‘B’, Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer; 3Chief Physician’s Office, Clalit Health Services, Tel Aviv; 4Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva; 5Department of Medicine ‘B’, Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Aviv, Israel

Background: In 1977, How et al.1 described the case of a simultaneous presentation of giant cell arteritis (GCA) and hypothyroidism. In the following decades, numerous studies have attempted to determine whether a significant association exists between GCA and autoimmune thyroid dysfunction, with conflicting results2–6.

Objectives: To evaluate whether a genuine association exists between GCA and autoimmune thyroid disease.

Methods: Utilizing the medical database of Clalit Health Services, we compared the proportion of autoimmune thyroid disease between patients with GCA and age- and gender-matched controls in a cross-sectional study. Univariate analysis was performed using Chi-square and student t-test and a multivariate analysis was performed using a logistic regression model.

Results: 5,663 GCA patients and 23,308 age- and gender-matched controls were
included in the study. The proportion of hypothyroidism amongst GCA patients was increased in comparison with controls (18.2% vs. 6.91%, respectively, \( p < 0.001 \)), as was hyperthyroidism (2.56% and 1.19% respectively, \( p < 0.001 \)). After controlling for confounders, GCA demonstrated a robust independent association with hypothyroidism on multivariate logistic regression (OR 2.097, 95% CI 1.187-4.188, Table 1). In contrast, when a similar model was performed in order to assess the nature of the association between GCA and hyperthyroidism, it was found to be non-significant, with an OR of 1.097.

Table 1. Multivariate logistic regression of covariates associated with hypothyroidism.

THU0343 | THE EFFECT OF ADAлиммабУМ ON CLINICAL MANIFESTATIONS AND PRO-INFLAMMATORY CYTOKINES MИЛІЄУ IN PATIENTS WITH BЕHЕТС’S DІЗІАС

Y. Braun-Moscovici, Y. Tavor, D. Markovits, K. Toledano, A. Rozin, M. A. Nahir, A. Balbir-Gurman. Rheumatology Department, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion, Haifa, Israel

Background: Behet’s disease is a multisystemic chronic relapsing inflammatory disease, classified among the vasculitides. The etiology of Behet’s disease is unknown. Several cytokines, among them TNF-\( \gamma \), are involved in the pathogenesis of the disease.

Objectives: We aimed to assess efficacy and safety of Adalimumab (ADA) in patients with active Behet’s arthritis not responding to one or more DMARDS and to assess the impact of treatment on the cytokine milieu.

Methods: Eligible patients (pts) with active Behet’s arthritis were enrolled in a 24 weeks single center prospective open-label study. Pts who relapsed within 12 weeks following ADA discontinuation could enter a 3 year extension study. The efficacy was assessed by 68 tender and 66 swollen joint count, patient visual analogue scale (VAS) for pain, physician overall disease activity VAS, health assessment questionnaire (HAQ), Behet’s Disease Current Activity Form (BDCAF), C reactive protein (CRP) and erythrocyte sedimentation rate (ESR). TNF-\( \gamma \), IL-1\( \beta \), IL-6, INF-\( \gamma \), IL-10 and IL-17A were evaluated at baseline, after 24 and 48 weeks of treatment, by ProcartaPlex Human High Sensitivity – Immunoassay kit. Trough ADA serum level and no antibodies improved after providing ADA weekly.

Results: Tender joints were increased in comparison with controls (18.2% vs. 6.91%, respectively, \( p < 0.001 \)). The disease relapsed in 9/10 pts, within 4–6 weeks following ADA interruption, 7 pts with low ADA trough levels and no antibodies improved after providing ADA weekly. The disease relapsed in 9/10 pts, within 4–6 weeks following ADA interruption, 7 pts enrolled into the extension study.

Conclusions: ADA treatment was well tolerated and achieved a significant improvement in arthritis and mucocutaneous manifestations and lowered IL-6 serum concentration in all study pts but only 40% reported significant pain reduction. A subset of pts with insufficient improvement in joint tenderness and generalized pain may require comprehensive pain management besides anti-inflammatory therapy.

THU0344 | A RHEUMATOLOGY LED PATHWAY FOR THE INITIAL MANAGEMENT OF GCA IMPROVES DIAGNOSTIC OUTCOMES COMPARED TO THE GENERALIST

Z. Farah, M. Gulati, M. Mathieu, H. Alam, S. Hamdulay. Rheumatology, Northwick Park Hospital, London, United Kingdom

Background: Giant Cell Arteritis (GCA) is a medical emergency requiring prompt and appropriate management to prevent complications. The British Society of Rheumatology (BSR) has set out guidelines on the appropriate management of suspected GCA targeting both primary and secondary-care physicians. Hospitals increasingly using care-pathways to facilitate appropriate initial management of GCA by non-rheumatologists. Evidence is limited, however, on the impact of such interventions on patient care.

Objectives: To evaluate the impact of designing a GCA care-pathway for non-rheumatologists (acute and general physicians) on patient care in terms of: (i) duration from referral to temporal artery biopsy (TAB) and rheumatology review; (ii) glucocorticoid therapy burden; and (iii) proportion of referrals with a final diagnosis of GCA.

Methods: We performed a retrospective study of all patients diagnosed with GCA between 3 periods: prior to introducing a GCA pathway (2007–2009), rheumatology led GCA pathway (2010–2012), and non-rheumatology led GCA pathway (2012–2016). We identified patients from a TAB database and collected general demographic data, initiation of glucocorticoid therapy, referral for TAB and rheumatology clinic, date of TAB and clinic review, biopsy findings, and final diagnosis.

Results: Table 1 summarises the main findings. After introducing the rheumatology-led pathway (2010–2012), rate of referrals for TAB per month declined to 0.78, the proportion of patients having a TAB within 14 days of referral reached 100%, and the proportion of patients with a positive biopsy increased to 30% suggesting appropriate use of the pathway and an improvement in care. However introducing a non-rheumatology led GCA pathway (2012–2016), led to increased referral numbers. The proportion of TAB within 14 days decreased, and the proportion with a positive biopsy declined (17%).

Table 1. A statistically significant improvement was observed in swollen joint count, physician VAS and BDCAF and in IL-6 levels, but not in tender joint count or HAQ. Resolution of oral and urogenital ulcers was achieved in all pts. Significant reduction of pain was reported by 40% of pts. No relapse of uveitis or other disease manifestations occurred during the study. The reduction in IL-6 levels correlated with the physician VAS and BDCAF but not with HAQ. No correlation was found between change in IL-10 level and VAS pain. The levels of INF-\( \gamma \), IL-17A, TNF-\( \alpha \) were undetectable in all pts. IL-1\( \beta \) was elevated in 1 patient only. ADA serum trough levels were in the therapeutic range in 7/10 pts. One patient developed high antidrug antibodies titer and ADA serum trough level of 0 with a concomitant increase in VAS pain and IL-6 concentration. Another patient with low ADA trough levels and no antibodies improved after providing ADA weekly. The disease relapsed in 9/10 pts, within 4–6 weeks following ADA interruption, 7 pts enrolled into the extension study.

The non-rheumatology led GCA pathway was associated with higher glucocorticoid burden. In this cohort, 23/35 (41.1%) patients who were found not to have GCA received more than 21 days of high dose steroids (40-60mg Prednisolone) whilst awaiting rheumatology review. 4 patients whose final diagnosis was not GCA received high dose steroids for more than 30 days (max 109 days).

Conclusions: 1. Availability of a rheumatology-led GCA pathway leads to improved care for patients with suspected GCA
2. Easy access for referral of patients with headache as assessed by the non-specialist can lead to over-use of the pathway and inappropriate referrals
3. Non-rheumatology-led GCA pathway can lead to a high glucocorticoid burden, especially in an elderly demographic with other comorbidities

Spondyloarthritis - treatment

THU0345

1Department of Rheumatology, Diakonhjemmet Hospital, Oslo; 2Department of Rheumatology, Drammen Hospital, Drammen; 3Department of Rheumatology, University Hospital of North Norway, Tromsø; 4Department of Rheumatology, St. Olavs Hospital, Trondheim; 5Reumatismesykehuset, Lillehammer; 6Department of Rheumatology, Forde Central Hospital, Forde, Norway

Background: Tumour necrosis factor inhibitors (TNFi) have revolutionized treatment of axial spondyloarthritis (axSpA). The five different available TNFi have not been compared directly, and whether effectiveness differs between agents is unknown. In Norway national authorities consider the different TNFi equivalent, and since 2009 the least expensive drug following an annual national tender has been the drug-of-choice in the publicly funded healthcare system. This has lead to variations across different years in drug use where choice of TNFi has been predominantly based on national price policy and not clinical characteristics.

Objectives: Comparing response to TNFi during the first year of treatment of axSpA in biologics-naïve patients over years with highly varying uptake of different TNFi.

Methods: We included the 981 biologics-naïve patients with axSpA from the NOR-DMARD register who started their first TNFi from 2009 through 2015. The preferred drugs in national recommendations were: 2009 adalimumab, 2010 golimumab, 2011 etanercept, 2012 etanercept, 2013 golimumab, 2014 certolizumab, 2015 certolizumab/biosimilar infliximab (CT-P13). We compared the estimated change in Ankylosing Spondylitis Disease Activity Score (ASDAS) between treatment years at 3, 6 and 12 months after treatment start using a mixed model with subject-specific random intercept, adjusting for baseline disease activity, age, sex and treatment centre.

Results: Demographics, drug uptake and baseline characteristics for each year 2009–2015 are listed in table 1. The preferred drug was started in 57–91% of patients. There was a trend towards lower ASDAS and disease duration over time. There were no differences in treatment effectiveness between the years, regardless of the substantial differences in type of TNFi used (figure).

Conclusions: Real-life data do not show differences in response to TNFi despite large annual variation in type of TNFi prescribed, indicating similar effectiveness of the available TNFi in patients with axSpA. This supports the practice of selecting drug based on cost and feasibility of use, as is the current practice in Norway. Further adoption of this principle can provide access to TNFi treatment to more patients, as it reduces costs and healthcare resources are limited.

CONCOMITANT FIBROMYALGIA IN AXIAL SPONDYLOARTHRITIS HAS A NEGATIVE IMPACT ON TNF ALPHA BLOCKERS TREATMENT EFFECT IN REAL LIFE

Background: Coexisting fibromyalgia (FM) in axial spondyloarthritis (axSpA) can represent therapeutic challenges, particularly when evaluating the treatment effect of biologics (i.e. TNF alpha blockers (TNFB)). Indeed, since FM patients often report high levels of pain and disability there is the risk of classifying such patients as refractory to TNFb (i.e. as not reaching a significant improvement in disease activity).

Objectives: To evaluate the impact of concomitant FM on the TNFb treatment effect in axSpA.

Methods: Design: Prospective observational national study with 2 visits 3 months apart (baseline and 12 weeks after TNFb initiation) (Predict-Spa study ClinicalTrials.gov: NCT03309088). Patients: axSpA patients (diagnosis according to treating rheumatologist) initiating a TNFb. Data collection: the FIRST questionnaire (Fibromyalgia Rapid Screen Test) which screens for FM, patients and disease characteristics and effectiveness measures (e.g. ASAS response components). Statistical analysis: FM positive screening was defined by a FIRST score ≥5/6; the primary efficacy outcome was the ASAS 40. Non-responder imputation and baseline observation carried forward imputation (for binary and continuous outcome variables, respectively) was performed. Impact of FM on the TNFb treatment effect was evaluated by multivariable logistic regression, with ASAS 40 as the dependent variable and FM as the independent variable; were also included in the model other factors previously reported in the literature as associated with treatment efficacy (i.e. X-ray and MRI sacroiliitis, abnormal CRP (<-3mg/L), HLA B-27, smoking status, previous TNFb exposure, age>40 and male gender).

Results: Among the 527 patients enrolled in the study, 508 patients were analysed. Mean age was 41.4 ± (11.6), 237 (46.7%) were women, with a 6.1±8.5 mean disease duration. Among them, 192 (37.8%) were screened as FM by the FIRST questionnaire. Overall efficacy of the TNFb was good (ASAS40, 201/508 (39.6%)) though 50 patients (9.8%) patients discontinued the TNFb before the follow-up visit and were considered as non-responders. Patients with FM presented less frequently an ASAS 40 response (87/192 (45.3%) vs 171/316 (54.1%), for the FM vs non-FM groups according to the FIRST definition. Presence of FM was independently associated with poorer ASAS40 response (adjusted odds ratio, OR = 0.5 [95% CI 0.3 – 0.8]) while X-ray sacroiliitis (1.8 [1.2 – 2.8]), abnormal CRP (1.6 [1.0 - 2.4]) and absence of previous exposure to TNFb (1.7 [1.1 – 2.6]) were found to be associated with an ASAS40 response.

Conclusions: This study 1) confirms the “conventional” predisposing factors of TNFb treatment response such as X-ray sacroiliitis, abnormal CRP and absence of previous exposure to TNFb; and 2) suggests that concomitant FM influences treatment response. FM deserves to be screened in axSpA, in particular in case of a decision to initiate a TNFb therapy.

**Methodology:** Children with a new diagnosis of early axSpA (≤ 18 yrs) were included if they fulfilled the ASAS criteria for axSpA, started a first TNFi after recruitment and had available BMI data as well as a baseline and follow-up visit at wk16.

**Results:** In comparison to normal weight and overweight patients, obese individuals were significantly older, had a longer symptom duration and higher BASFI and BASMI levels, while ASDAS levels were comparable between the 3 groups (Table 1). Data to calculate the ASAS40 response was available in 496 patients (7%). It was reached by 44%, 35% and 28% of patients with normal weight, overweight and obesity, respectively. (p=0.02; Table 2). A significantly lower odds ratio (OR) for achieving ASAS40 response was found in adjusted analyses in obese patients vs patients with normal BMI (OR 0.35, 95% confidence interval (CI) 0.11–0.73, p=0.01). Comparable results were found for the other outcomes assessed. The adjusted predicted ASAS40 OR in overweight vs normal weight patients was 0.69, 95 CI 0.38–1.24, p=0.22.

**Conclusions:** IV GLM 2mg/kg was efficacious in reducing the signs and symptoms of AS compared with PBO. GLM was well-tolerated through wk28; the safety profile was consistent with other anti-TNFs, including SC GLM.
However, anti-drug antibodies (ADA) may be responsible for decreased efficacy. Methotrexate reduces adalimumab immunogenicity in rheumatoid arthritis (1). **Objectives:** The aim of the study was to evaluate the effect of methotrexate on ADA detection in SpA patients receiving adalimumab. **Methods:** One hundred and ten SpA patients eligible for adalimumab 40 mg S/C every other Wednesday were randomized on a 1:1 ratio to receive MTX 10 mg S/C every week or 2 weeks prior (V0) adalimumab (MTX+), or adalimumab alone (MTX-). ADA detection and adalimumab concentration were assessed 4 weeks (V2), 8 weeks (V3), 12 weeks (V4) and 26 weeks (V5) after starting adalimumab (V1). The main outcome was the percentage of positive patients for ADA detection at V5 or last visit. **Results:** Patients’ characteristics (sex, previous TNF inhibitors, disease duration, HLA B27, BMI, BML) were comparable between the two groups. One hundred and seven patients were analyzed, 55 in the MTX+ group versus 52 in the MTX- group. ADA were detected at V5, in 39/107 (36.4%) patients; 13/52 (25%) in the MTX+ group versus 26/55 (47.3%) in the MTX- group (p=0.03). Adalimumab concentrations were statistically higher in the MTX+ group as compared with the MTX- group at V2, V3, V4 and V5 (Figure 1). There was no difference in terms of adverse events and efficacy between the two groups. **Conclusions:** MTX reduces immunogenicity and ameliorates pharmacokinetics of adalimumab in SpA patients. The clinical impact of this combination requires longer period studies. **References:**

**THU0351 ADALIMUMAB TAPERING WITH COMBINED METHOTREXATE CAN BE EFFECTIVE AS MAINTENANCE THERAPY IN SPA-RELATED UVEITIS**

**F. Liang**, J. Zhou, Y. Wang, H. Xu, L. Liang, X. Yang. Dept. of Rheumatology, 1St Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

**Background:** Anti-TNF agents have deeply improved the therapeutic efficacy of spondyloarthritides (SpA)-related uveitis [1]. Despite the benefits of anti-TNF drugs, patients need to stay on treatment for a long time. There has been a clear medical need to consider the long-term safety and increased drug costs. Unanswered question for physicians is whether TNF blockers can be reduced or even stopped in SpA-related uveitis, or how can it be reduced in patients have achieved remission or LDA. The current study aimed to investigate the effectiveness and safety of adalimumab tapering strategy in SpA-related uveitis.

**Objectives:** The aim of this study was to evaluate the effectiveness of tapering of adalimumab combined with MTX in patients with spondyloarthritides (SpA)-related uveitis.

**Methods:** We performed a retrospective analysis. SpA patients with uveitis admitted to a south China hospital were enrolled. Demographic information, clinical characteristics, laboratory findings, intraocular inflammation, visual acuity, and macular thickness were documented every 3 to 6 months. **Results:** In 32 cases of SpA-related uveitis who achieved clinical remission for at least 6 months after receiving a standard dose of adalimumab in combination of MTX, adalimumab was tapered and MTX was continued. Dosing interval of adalimumab was spaced by 30% every 3 months up to complete stop. Twenty-six cases without MTX were analyzed for comparison. No significant difference of demographic characteristics and BASDAI, CRP, ESR was found between the two groups at the baseline. During the first 12 months of adalimumab tapering, tapering of MTX and BASDAI remains stable in both groups. Recurrent uveitis was found in the group with combined MTX. In the group without combined MTX, 2 patients (2/6, 7.7%) presented increased anterior chamber inflammation and visual acuity. At the end of 24 months, mean BASDAI, CRP and ESR remained low in both groups. Two cases (2/32, 6.3%) in the group of combined MTX were documented increased BASDAI higher than 4, but no recurrent uveitis was observed. Altogether 5 cases (5/32, 15.6%) in the group of combined MTX had recurrent uveitis, in which 4 cases (4/5, 80%) initiated adalimumab tapering at 6 months’ remission. In comparison, 8 cases (8/26, 30.8%, p<0.001) in the group without combined MTX had recurrent uveitis, in which 6 cases initiated highly relevant for these patients with chronic NSAIDs use and increased CV risk (1).

**Objectives:** The objective of this study was to determine the relationship between NSAIDs use and the occurrence of CV events, including myocardial infarction (MI) and stroke, in patients with SpA.

**Results:** In this is an ancillary study of the observational, cross-sectional, multicenter, international ASAS-COMOSPA study. The inclusion criteria were: age >18 years and SpA diagnosis. In order to overcome prescription bias when comparing patients who ever received/did not receive NSAIDs, a propensity score (PS) to predict NSAIDs intake was calculated. Patients who had never received NSAIDs were matched to patients who ever received an NSAID according to the PS. In this matched population, the probability for a patient to present a CV event was estimated by logistic regression. Furthermore, in the global population of the study, factors associated with the occurrence of CV event were explored by logistic univariate analysis, here including the NSAIDs score (2) for the last three months, age and gender, and using the PS as an adjustment variable. **Results:** Of the 3984 patients enrolled in the study, data on CV event occurrence was available for 3961 patients. Among them, 3548 patients received NSAIDs (89.6%) and 376 had never received NSAIDs (10.4%). Patients who had never received NSAIDs had more often inflammatory bowel disease (9.9% vs 5.3%), and a less severe disease (% of bamboo patients: 2.0% vs 7.6%). Among the 756 matched patients, 29 (3.8%) patients reported a CV event (21 MI, 13 strokes and 5 MIs+stroke). The number of patients with CV event was not significantly different between the two groups, ever and never NSAIDs exposure respectively (16 (2.1%) vs 13 (1.7%), OR =1.86 [0.94–3.69]). No difference was observed between the two groups for MI and stroke compared separately (12 (1.6%) vs 9 (1.2%), OR =2.96 [0.41–21.03] and 8 (1.1%) vs 5 (0.7%), OR =0.926 [0.288–3.21] respectively). In the second model, where PS was used as a covariate, the occurrence of overall CV event was independent of age (OR =2.7 [2.3–3.2]) and male sex (OR =1.9 [1.2–3.0]), but not with the NSAIDs score (OR =1.0 [0.9–1.1]). **Conclusions:** The use of NSAIDs does not seem to be as associated with the occurrence of CV event in patients with SpA, however it cannot be excluded that the study is underpowered. Further prospective studies are needed to confirm these results.

**DOI:** 10.1136/annrheumdis-2017-eular.2665
adalimumab tapering at 6 months’ remission and 2 cases initiated adalimumab tapering at 9–12 months’ remission. No patients had recurrent uveitis at 12 months’ remission or longer in both groups. Adalimumab plus MTX were well tolerated in patients experiencing increases and decreases in structural lesion scores over 2 yrs.

Conclusions: Pts who received tofacitinib who had AS experienced clinically meaningful reductions in axial MRI inflammation. Pts achieving MIC for MRI inflammation had increased clinical response rates.

TOSTATINIB TREATMENT IS ASSOCIATED WITH ATTAINMENT OF THE MINIMALLY IMPORTANT REDUCTION IN AXIAL MRI INFLAMMATION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

W.P. Maksymowych 1, D. van der Heijde 2, X. Baraliakos 3, A. Deodhar 4, M. Brown 5, S.P. Sherlock 6, K.S. Kanik 7

1 University of Alberta, Edmonton, AB, Canada; 2Leiden University Medical Center, Leiden, Netherlands; 3RheumaZentrum Rutheger, Herne, Germany; 4Oregon Health & Science University, Portland, OR, United States; 5Queensland University of Technology, Brisbane, Australia; 6Pfizer Inc, Cambridge, MA; 7Pfizer Inc, Collegeville, PA

**Objectives:** To assess whether MIC in SIJ and spine can discriminate between tofacitinib and placebo (PBO) in patients with ankylosing spondylitis (AS) and if the clinical response is consistent with global change scores.

**Methods:** In this 16-week (wk) Phase 2, double-blind, dose-ranging study (NCT01786668), 207 adult pts meeting modified New York AS criteria were randomised 1:1:1 to PBO or tofacitinib 2, 5 or 10 mg twice daily (BID) for 12 wks. Clinical endpoints included in this post-hoc analysis were: Assessment of SpondyloArthritis International Society 20% improvement (ASAS20) and ASAS40, 40% improvement (ASAS40) response rates, AS disease activity score major improvement (ASDAS MI; change ≥ 5 from baseline), ASDAS inactive disease (ASDAS ID; < 1.3), Bath AS disease activity index (BASDAI), Bath AS functional index (BASFI) and back pain. Pts (%) achieving MIC in SIJ, spine and both SIJ and spine, in tofacitinib and PBO groups, were summarised based on observed data, and pooled tofacitinib (5 and 10 mg BID) vs PBO data were compared using Fisher’s exact test. Concordance between achieving MIC and Wk 12 clinical responses was assessed. Wk 12 clinical responses were compared between pts achieving MIC in SIJ and spine.

**Results:** MRI data for 164 pts were evaluated. Baseline demographics were generally well balanced between treatment groups and typical of AS populations. Tofacitinib 2, 5 and 10 mg BID improved mean (range) SPARC scores vs PBO (SIJ: -2.2 (-22.0, 10.5), -3.5 (-34.5, 11.0), -3.6 (-29.0, 0.5) vs 0.0, 0.0, 0.0; spine: -2.3 (-34.5, 20.5), -2.5 (-38.5, 8.0), -2.7 (-32.5, 7.5) vs -0.8 (-8.0, 14.0). Approximately 3 times more pts achieved MIC in SIJ or spine in the pooled tofacitinib group vs PBO (SIJ: 34.1% ≥ 11.8%, p < 0.05; spine: 38.6% ≥ 11.8%, p < 0.01). Achieving MIC in SIJ and spine correlated with clinical response. In pts of the pooled ASAS20, ASAS40 and ASDAS MI responses were more likely in pts achieving MIC in SIJ or spine (Table) vs not achieving MIC. Compared with not achieving MIC, pts on tofacitinib achieving MIC in SIJ had larger improvements in BASDAI, BASFI and back pain.

**Conclusions:** Pts who received tofacitinib who had AS experienced clinically meaningful reductions in axial MRI inflammation. Pts achieving MIC for MRI inflammation had increased clinical response rates.

**Background:** Demonstrating a structural effect of TNF inhibitors in axial SpA is not straightforward and the results are conflicting among the available studies. We aimed to evaluate the impact of ETN on imaging outcomes in a 2-year follow-up using the SpA MRI Scoring System (SSS). For each group, differences were calculated between percentages of patients experiencing increases and decreases in structural lesion scores over 2 yrs.

**Objectives:** To compare 2 yrs of structural lesion changes on T1W MRI in the sacroiliac joints (SIJ) of pts receiving etanercept (ETN) in a clinical trial to similar pts not receiving biologics in a cohort study.

**Methods:** Pts had recent onset non-radiographic (nr)-axSpA fulfilling ASAS criteria. Study group: pts receiving ETN 50 mg once weekly for 2 yrs in EMBARK (NCT01258738). Control group: pts in a longitudinal cohort study not receiving biologics for 2 yrs (DESIIR, NCT01648907). Outcome measure: change in structural lesions of erosion, backfill, fat metaplasia, and ankylosis. MRI images were read by 3 experienced readers unaware of image chronology and pt group, using the SpondyloArthritis Research Consortium of Canada SIJ Structural Score (SSS). For each group, differences were calculated between percentages of patients experiencing increases and decreases in structural lesion scores over 2 yrs.

**Results:** Pts had recent onset non-radiographic (nr)-axSpA fulfilling ASAS criteria. Study group: pts receiving ETN 50 mg once weekly for 2 yrs in EMBARK (NCT01258738). Control group: pts in a longitudinal cohort study not receiving biologics for 2 yrs (DESIIR, NCT01648907). Outcome measure: change in structural lesions of erosion, backfill, fat metaplasia, and ankylosis. MRI images were read by 3 experienced readers unaware of image chronology and pt group, using the SpondyloArthritis Research Consortium of Canada SIJ Structural Score (SSS). For each group, differences were calculated between percentages of patients experiencing increases and decreases in structural lesion scores over 2 yrs.

**Conclusion:** Pts achieving MIC, pts on tofacitinib achieving MIC in SIJ had larger improvements in BASDAI, BASFI and back pain.

DISEASE WORSENING AND SAFETY IN PATIENTS SWITCHING FROM ORIGINATOR INFlixIMAB TO BIOSIMILAR INFlixIMAB (CT-P13) IN THE RANDOMIZED NOR-SWITCH STUDY: EXPLORATIVE ANALYSIS IN SPA PATIENTS

G.L. Goll1, I.C. Olsen1, N. Bolstad2, K.K. Jørgensen3, M. Lorentzen4, C. Merk5, J. Jahnsen3, E.A. Haavardsholm1, T.K. Kvien1 on behalf of the NOR-SWITCH-STUDY: EXPLORATIVE ANALYSIS IN SPA PATIENTS

Background: The NOR-SWITCH study is a 52-week randomized, double-blind, non-inferiority, phase IV switch trial in patients with Crohn’s disease (CD), ulcerative colitis (UC), spondyloarthritis (SpA), rheumatoid arthritis (RA), psoriatic arthritis (PsA) and plaque psoriasis (Ps) on stable treatment with originator infliximab (Remicade®), INX, funded by the Norwegian government. Previously, primary analyses of the pooled indications have been published1.

Objectives: To investigate efficacy, safety and immunogenicity in SpA patients treated with continuous INX vs patients switched to CT-P13 (biosimilar infliximab, Remsima®) in the NOR-SWITCH study (explorative analyses).

Methods: Patients were randomized 1:1 to continued INX or switch to CT-P13. Serum drug levels were analysed by automated in-house assay. The primary endpoint was disease worsening according to disease-specific composite measures and/or consensus between investigator/patient. Exploratory subgroup analyses examined disease worsening and safety in SpA. The primary endpoint was analysed by logistic regression, adjusted for diagnosis and disease duration.

Results: Demographics, occurrence of disease worsening, change in disease measures and treatment-emergent adverse events (TEAE) were similar (Table), as were serum drug levels for INX and CT-P13 (Figure).

Conclusions: Explorative analyses in the NOR-SWITCH study showed similar efficacy, drug levels and safety in SpA patients switched to CT-P13 as those on continuous INX. The study was not powered to show non-inferiority within each diagnosis.

Objectives: To investigate changes in width of hyaline cartilage of hip joints in patients with AS under treatment with sulfasalazine and adalimumab during 12 month.

Methods: The 53 patients with AS (42 male, 9 female, average age is 37.6 years old, duration of disease is 14–152 month) were included into study. All patients were treated by NSAIDs and sulfasalazine (2 g per day) at least 3 month before study. In treatment of 27 patients (1st group) was added adalimumab (40 mg subcutaneously every 2 weeks), other 26 patients (2nd group) were left on previous treatment regime. Patients were observed during 12 months of treatment including measurements of pain visual analog scale (VAS) in hip movement, maximal distance between ankle, pelvic, X-ray and sonography of hip joints by 10–18 MHz probe. BASRI-Hips index was applied for radiographic estimation of structural damage of hip joints [3]. During sonography width of hip joint capsule and hyaline cartilage were measured. The Mann-Whitney-U test was used for comparison of changes in clinical and sonographic data between two groups of patients.

Results: After 12 month treatment period in patients of 1st group in comparison with patients of 2nd group more significant decrease of pain VAS during hip movement (on 27.3 [18.8; 32.5] mm vs 4.7 [0.5; 9.6] mm, p =<0.01), increase of maximal distance between ankle (on 124.3 [92.2;145.6] mm vs 3.5 [1.2; 6.5] mm, p =<0.05) and decrease of joint capsule width (on 2.4 [1.0; 3.6] mm vs 0.4 [0.1; 1.1] mm, p =<0.05) had been determined. In patients of 1st group width of hyaline cartilage had been increased on 0.15 [0.4; 0.22] mm, while in patients of 2nd group width of hyaline cartilage had been decreased on 0.8 [0.0; 1.4] mm (p =<0.05). These cartilage changes were accompanied by decrease of mean BASRI-Hips index on 1 point in 2nd group and absence of changes of BASRI-Hips index in 1st group. The correlation between changes in width of hip hyaline cartilage and pain VAS during movement in hip joints (∼r=0.52 [0.38; 0.61]) and maximal distance between ankle (∼r=0.47 [0.32; 0.60]) had been revealed.

Conclusions: Treatment with adalimumab leads to decrease of clinical and sonographic signs of coxitis and improvement of hyaline cartilage structure. The increase of width of hip hyaline cartilage correlates with clinical effect of treatment of coxitis in patients with AS. More prolonged observation is needed for analysis of correlation between changes in hyaline cartilage structure and radiographic progression of hip joints damage in AS.

to the application of the EMA recommendation (interaction p value=0.140). In the 59 pts not treated in accordance with the EMA recommendation, the treatment effect in the sub-groups of pts without (vs with) concomitant FM was 38% vs 40% respectively, p=0.891. In the 449 pts treated in accordance with the EMA recommendation, the treatment effect in the sub-groups of pts without (vs with) concomitant FM was 50% vs 46%, p=0.042.

Conclusions: This study suggests that 1/ French rheumatologists are applying the EMA recommendation in daily practice 2/ these recommendations result in a better outcome in terms of short term symptomatic treatment effect. In this study, concomitant FM was not more frequently observed in patients without (vs with) objective sign of structural damage on inflammation and the impact of a concomitant FM was not more pronounced (or even lower) in pts without (vs with) objective sign of structural damage or inflammation.

THU0358 ROSUVASTATIN IMPROVES NITRIC OXIDE AND ENDOTHELIAL FUNCTION AND SUPPRESSES INFLAMMATORY DISEASE ACTIVITY IN ANKYLOSING SPONDYLITIS

A. Syngle 1, N. Garg 2, P. Krishan 2. 1Cardio Rheuma, Healing Touch City Clinic, Chandigarh and Fortis Multi Speciality Hospital, Mohali, India, Chandigarh; 2Department of Pharmaceutical Sciences and Drug Research, Punjabi University, Patiala, India

Background: Nitric oxide (NO) regulates the synthesis of several inflammatory mediators, functions of inflammatory cells in the inflamed joint and plays a central role in the regulation of blood vessel tone 1. Therefore, NO inhibitors represent important therapeutic advancement in the management of inflammatory diseases. Rosuvastatin improves NO and endothelial dysfunction in patients with heart failure but its effect on NO has not yet been tested in Ankylosing Spondylitis (AS) patients.

Objectives: To investigate the effect of rosuvastatin on nitrite levels (NO surrogate) and its relationship with endothelial function and inflammatory measures in AS.

Methods: 40 consecutive patients (20 in Rosuvastatin (10 mg/day) and 20 in placebo arm) meeting the modified New York criteria for AS, with active disease despite treatment with conventional synthetic DMARDs were recruited. Serum nitrite estimation was carried out by Griess reaction. Flow-mediated dilatation (FMD) was assessed using AngioDefender. Inflammatory measures included BASDAI, BASFI, ESR and CRP. Pre-inflammatory cytokines (TNF-α, IL-6 and IL-1) were measured at baseline and after 24 weeks.

Results: After 24 weeks, significant improvement in serum nitrite was observed in rosuvastatin group (5.27±0.26 to 4.11±0.19, p<0.01) compared with placebo (5.47±0.26 to 5.36±0.23, p=0.33). At 24 weeks; FMD, TNF-α, and IL-6 improved significantly in rosuvastatin group compared with placebo. At 24 weeks, ESR, CRP, BASDAI and BASFI significantly improved in rosuvastatin group compared with placebo. After treatment with rosuvastatin, nitrite correlated inversely with FMD (r=-0.47, p=0.03) (Fig.1A) and positively with TNF-α (r=0.64, p=0.01) (Fig.1B), CRP (r=0.52, p=0.01) (Fig.1C) and LDL (r=0.54, p=0.01) (Fig.1D).

Conclusions: Rosuvastatin reduced serum nitrite concentration and improved endothelial dysfunction in AS patients. Rosuvastatin lowers the proinflammatory cytokines, especially IL-6 and TNF-α, which downregulates CRP production and thus the production of NO. Rosuvastatin also favorably improved the lipid levels in AS patients. Rosuvastatin exerts anti-inflammatory, immunomodulatory and vasculoprotective effect in ankylosing spondylitis through both cholesterol dependent and cholesterol independent pathways.

THU0359 SECUKINUMAB DEMONSTRATES CONSISTENT SAFETY OVER LONG-TERM EXPOSURE (UP TO 3 YEARS) IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: POOLED ANALYSIS OF THREE PHASE 3 TRIALS

A. Deodhar 1, X. Baraliakos 2, H. Marzo-Ortega 3, J. Sieper 4, M. Andersson 5, B. Porter 6, T. Fox 3, 1Oregon Health & Science University, Portland, United States; 2Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany; 3Nîhru lmbru, Lïhtåmrm, Uol, Leêds, United Kingdom; 4Charité-Universitätsmedizin Berlin, Berlin, Germany; 5Novartis Pharma AG, Basel, Switzerland; 6Novartis Pharmaceuticals Corp., East Hanover, United States

Background: Safety data for secukinumab in the treatment of ankylosing spondylitis (AS) have been reported from three Phase 3 studies: MEASURE 1 (NCT01358175)1, MEASURE 2 (NCT01649375)2 and MEASURE 3 (NCT02009816).2 Objectives: To report long-term (up to 3 years) pooled safety and tolerability data for secukinumab in AS (data cut-off: 25 June 2016).

Methods: Overall, 371, 219 and 226 patients with active AS were randomised in MEASURE 1, MEASURE 2 and MEASURE 3, respectively. Study design, efficacy and safety results of these studies have been published earlier.2 Secukinumab doses differed in the studies and included intravenous 10 mg/kg or subcutaneous (75–300mg) multi-dose loading, followed by subcutaneous (i.e., maintenance dosing (75, 150, or 300mg). Data collected up to the last patient performing the Wk 156 visit in MEASURE 1, the Wk 104 visit in MEASURE 2, and the Wk 52 visit in MEASURE 3 were pooled at the patient level. Exposure-adjusted incidence rates were calculated to account for differences in treatment exposure and analyses included all patients who received ≥1 dose of secukinumab 150 or 300mg.

Results: A total of 510 patients were included in the analysis (968.9 patient-years of exposure). The exposure-adjusted AE and SAE rates with secukinumab across the entire safety period were 159.2 and 5.4 per 100 patient-years, respectively. Nasopharyngitis, diaphoresis and headache were the most frequently reported AEs. The incidences of Candida infections, serious infections, inflammatory bowel disease, major adverse cardiac events, neutropenia and uveitis were low and consistent with previous reports over shorter exposure periods.2 (Table). No cases of suicidal ideation or depression were reported.

Improvments in sleep problems and pain in patients with active ankylosing spondylitis treated with intravenous golimumab: 28-week results of the phase III GO-ALIVE trial

A. Deodhar, J.D. Revillée, E.K. Chan, S. Peterson, N. Li, E. Hsiu, L. Kim, K.H. Lo, D.D. Harrison, C. Han, T. Fox, Shareholder of: Novartis, Employee of: Novartis, T. Fox

Objectives: To investigate the effect of intravenously administered (IV) Golimumab (per modified New York criteria) and BASDAI in patients with active Ankylosing Spondylitis (AS).

Methods: GO-ALIVE is a Phase 3, multicenter, randomized, double-blind, placebo-controlled trial. Pts (aged >18 years) had a diagnosis of definite AS (per modified New York criteria) and BASDAI >4, total back pain visual analogue scale (VAS) >40 mm, CRP >0.3 mg/dL. At baseline, 208 pts were randomized to IV golimumab 2mg/kg (N=105) at Wks 0, 4, and every 8 wks or placebo (N=103) at Wks 0, 4, and 12, with crossover to IV golimumab at Wk 16 and through Wk 52. Sleep problems were assessed using the Medical Outcomes Study Sleep Scale (MOS-SS). An increase in score also used to generate the composite Sleep Problems Index. An increase in score through Wk 52. Sleep problems were assessed using the Medical Outcomes Study Sleep Scale (MOS-SS). An increase in score also used to generate the composite Sleep Problems Index.

Results: Mean changes in MOS-SS Sleep Index and 6 subscales are presented through Wk 52. Sleep problems were assessed using the Medical Outcomes Study Sleep Scale (MOS-SS). An increase in score also used to generate the composite Sleep Problems Index. An increase in score also used to generate the composite Sleep Problems Index. An increase in score also used to generate the composite Sleep Problems Index. An increase in score also used to generate the composite Sleep Problems Index.

Conclusions: Adult pts with active AS treated with IV golimumab showed improvements in sleep problems, total back pain, and night back pain. Night back pain improvement was associated with improvement in sleep problems.

PRESCRIPTION PATTERNS OF BIOLOGICAL DISEASE MODIFYING DRUGS AND BIOSIMILARS IN ANKYLOSING SPONDYLITIS – A COLLABORATION BETWEEN BIOLOGICAL REGISTERS IN THE FIVE NORDIC COUNTRIES

Objectives: To explore the prescription patterns of old (TNF-inhibitors) and newer bDMARDs (secukinumab, ustekinumab) including bsDMARDs (SB4, CT-P13) over time in AS in the Nordic countries in order to illustrate the potential of a common Nordic collaboration.

Methods: Data regarding the numbers of AS patients (pts) (ICD10 code M45) who initiated bDMARD treatment (irrespective of treatment course number) during the period 2011–2016 were collected from the Nordic rheumatologic biological registries Sbgr (Sweden), Nor-DMARD (6 Norwegian treatment centres), DANBIO (Denmark), ROB-FIN (Finland, 2011–2015) and ICEBIO (Iceland).

Results: In total, 6,610 bDMARD treatment initiations were identified (Sweden 3654, Norway 1078, Denmark 782, Finland 789, Iceland 307). The prescription patterns of bDMARDs changed substantially over time. In 2016, the number of pts initiating a bsDMARDs exceeded those starting an originator bDMARD (figure). Few patients were treated with ustekinumab (Denmark <10 pts, Finland <10, Sweden 26) and secukinumab (Denmark <10 pts, Sweden 57).

Figure: The 5 Nordic countries, total number of AS patients initiating bDMARD per year

Conclusions: The use of bsDMARDs in AS is rapidly increasing. The use of drugs with new modes of action is still low, which illustrates the need for collaboration across countries to provide real life data with sufficient power for new innovative therapies in the future. The Nordic rheumatologic registries represent a unique resource for these efforts.
opportunity to study effectiveness and safety of bDMARDs, including bsDMARDs in AS.

**Table 1. Percentage of patients with events of uveitis on Randomized Controlled Trials**

**Methods:** To analyze evidence on efficacy of anti-TNF drugs approved for AS treatment in UV, IBD and dactylitis as associated with.

**Objective:** To analyze evidence on efficacy of anti-TNF drugs approved for AS treatment in UV, IBD and dactylitis associated with.

**Results:** Fifty studies were included (seventeen RCTs, six meta-analyses and twenty seven observational studies). From the RCT we extracted the results presented in Table 1 for uveitis and in Table 2 for IBD. None reported results for dactylitis. Of the meta-analyses included, only one presents results. These one shows that the incidence of uveitis is lower in patients taking etanercept than placebo (incidence of 8.6 and 19.3 per 100 patients per year, respectively; p value =0.03). In OS comparing different drugs, in one the risk of developing uveitis (UV), inflammatory bowel disease (IBD) and dactylitis is scarce.

**Background:** Treatment with biotechnological agents (infliximab, etanercept, adalimumab, golimumab and certolizumab pegol) in ankylosing spondylitis is effective. However, evidence regarding the potential efficacy of these anti-TNF drugs in the extra-articular manifestations of ankylosing spondylitis, namely in uveitis (UV), inflammatory bowel disease (IBD) and dactylitis is scarce.

**Objective:** To analyze evidence on efficacy of anti-TNF drugs approved for AS treatment in UV, IBD and dactylitis associated with.

**Methods:** A systematic literature review was performed using the PubMed and Cochrane Library databases. Randomized controlled trials (RCT), meta-analyses and observational studies (OS) reporting efficacy of anti-TNF agents in extra-articular manifestations of AS were included.

**Results:** Results: Fifty studies were included (seventeen RCTs, six meta-analyses and twenty seven observational studies). IMMUNOGENICITY OF ANTI-TNF DRUGS AND CLINICAL RESPONSE IN PATIENTS WITH SPONDYLOARTHROPATHIES

D. Geiger 1, Y. Degboe 1, T. Baruncture 2, A. Cantagrel 1, A. Ruysen-Witrand 1, A. Constantin 1.
1 Rheumatology, Centre de Rhumatologie, CHU Purpan, Place du Dr Baylaz, Toulouse Cedex 9, 2 Rheumatology, Centre Hospitalier Universitaire de Bordeaux, Bordeaux, France

Background: Antidrug antibodies (ADAB) seem to be associated with a loss of response in immune-mediated inflammatory diseases (1) and in psoriatic arthritis (2). Objectives: To assess the effect of ADAB on clinical response in patients with spondyloarthritis (SpA) treated with anti-TNF drugs. Methods: We conducted a systematic literature review of controlled trials and observational studies looking at the effect of ADAB on response to anti-TNF drugs (Adalimumab (ADL), Certolizumab (CTZ), Etanercept (ETA), Golimumab (GOL) and Infliximab (INF)) in patients with axial or peripheral SpA. Databases analysed were PubMed, the Cochrane library, and ACR/EULAR meeting abstracts, until January 2017. A meta-analysis was performed using the inverse variance approach and statistical heterogeneity was assessed with the Cochran Q-test. Results: The study included 503 patients with axSpA treated with ADL (172[34.2%] women, mean age [±SD] 40.5 [±13.2] years, mean disease duration 9.7 [±14.7] years), receiving a total of 675 lines of treatment ([I-line n=503, II-line n=118, III-line n=54]) with a TNFα antagonist ([IFX, 173 infliximab [IFX], 173 adalimumab [ADL], 89 golimumab [GOL], 141 etanrect [ETNI]). At the time of TNFI introduction, 28.6% patients claimed at least one EAM (IBD 11.3%, uveitis 10.9%, and PsO 8.8%). The baseline presence of at least one EAM was associated with a more frequent prescription of an anti-TNF monoclonal antibody rather than etanercept (34.1% versus 21.9%, respectively, p=0.005). In detail, EAMs were found in 41.6, 39.9, 29.8, and 21.9% patients treated with GOL, ADA, IFX, or ETN, respectively. The prevalence of IBD was significantly higher (p=0.004) in patients treated with ADA (12.7%), IFX (14.3%), or GOL (11.2%) compared with ETN (4.9%). Uveitis was numerically more frequent in GOL (20.2%) and ADA (13.5%) rather than IFX (9.5%) and ETN (9.9%) groups. Finally, PsO was similarly high in patients treated with ADA (10.9%) and GOL (10.1%), and numerically lower in the ETN (7.1%) and IFX (5.9%) groups. Conclusions: In our cohort of axSpA patients treated with TNFis, EAMs were highly heterogeneous. The presence of extra-articular involvement has been carefully taken into account when a TNF was required to better control the disease. In particular, IBD and uveitis drove more frequently the choice toward an anti-TNF monoclonal antibody instead of the receptor. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.7379

GASTROINTESTINAL INFECTIONS IN PATIENTS WITH SPONDYLOARTHROPATHIES TREATED WITH ANTI-TNF DRUGS: RESULTS OF GISEA REGISTER

1Department of Rheumatology, Gaetano Pini Institute, 2Rheumatology Institute of Lucania (IRel) - Rheumatology Department of Matera; Potenza; 3UOC Reumatologia, Dipartimento di Medicina, AOUI, Verona; 4Department of Clinical Sciences and Community Health, Division of Rheumatology, University of Milan and Gaetano Pini Institute, Milan, Italy

Background: Extra-articular manifestations (EAMs), such as uveitis, inflammatory bowel diseases (IBD) and psoriasis (PsO), frequently complicate the disease course of patients with axial spondyloarthritis (axSpA), although prevalence data on this regard are still controversial. The occurrence of EAMs might also contribute to the decision of introducing a biologic therapy and even influence the choice between the available TNF inhibitors (TNFIs). Objectives: The aim of this study was to retrospectively evaluate the prevalence of IBD, uveitis, PsO, and IBD, uveitis and PsO in patients treated with TNFis, investigating how these influences the choice of treatment. Methods: Clinical data from axSpA patients treated with a TNFi between 2003 and May 2016 where obtained from a multicentre registry. Prevalence of EAMs (uveitis, IBD and PsO) was calculated at the time of TNFi prescription, evaluating the distribution according to drug subgroup. Results: The study included 503 patients with axSpA (172[34.2%] women, mean age [±SD] 40.5 [±13.2] years, mean disease duration 9.7 [±14.7] years), receiving a total of 675 lines of treatment ([I-line n=503, II-line n=118, III-line n=54]) with a TNFα antagonist ([IFX, 173 infliximab [IFX], 173 adalimumab [ADL], 89 golimumab [GOL], 141 etanrect [ETNI]). At the time of TNFI introduction, 28.6% patients claimed at least one EAM (IBD 11.3%, uveitis 10.9%, and PsO 8.8%). The baseline presence of at least one EAM was associated with a more frequent prescription of an anti-TNF monoclonal antibody rather than etanercept (34.1% versus 21.9%, respectively, p=0.005). In detail, EAMs were found in 41.6, 39.9, 29.8, and 21.9% patients treated with GOL, ADA, IFX, or ETN, respectively. The prevalence of IBD was significantly higher (p=0.004) in patients treated with ADA (12.7%), IFX (14.3%), or GOL (11.2%) compared with ETN (4.9%). Uveitis was numerically more frequent in GOL (20.2%) and ADA (13.5%) rather than IFX (9.5%) and ETN (9.9%) groups. Finally, PsO was similarly high in patients treated with ADA (10.9%) and GOL (10.1%), and numerically lower in the ETN (7.1%) and IFX (5.9%) groups. Conclusions: In our cohort of axSpA patients treated with TNFis, EAMs were highly heterogeneous. The presence of extra-articular involvement has been carefully taken into account when a TNF was required to better control the disease. In particular, IBD and uveitis drove more frequently the choice toward an anti-TNF monoclonal antibody instead of the receptor. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.5726

DO EXTRA-ARTICULAR MANIFESTATIONS AFFECT THE CHOICE OF BIOLOGIC THERAPY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS? A MULTICENTRE REAL-LIFE ANALYSIS

E.G. Favalli 1, S. D’Angelo 2, A. Carletto 3, A. Becciolini 1, F. Martinis 4, G. Tramontano 2, M.G. Raimondo 4, M. Biggioggero 4, A. Marchesoni 1.

Background: Extra-articular manifestations (EAMs), such as uveitis, inflammatory bowel diseases (IBD) and psoriasis (PsO), frequently complicate the disease course of patients with axial spondyloarthritis (axSpA), although prevalence data on this regard are still controversial. The occurrence of EAMs might also contribute to the decision of introducing a biologic therapy and even influence the choice between the available TNF inhibitors (TNFIs). Objectives: The aim of this study was to retrospectively evaluate the prevalence of IBD, uveitis, PsO, and IBD, uveitis and PsO in patients treated with TNFis, investigating how these influences the choice of treatment. Methods: Clinical data from axSpA patients treated with a TNFi between 2003 and May 2016 where obtained from a multicentre registry. Prevalence of EAMs (uveitis, IBD and PsO) was calculated at the time of TNFi prescription, evaluating the distribution according to drug subgroup. Results: The study included 503 patients with axSpA (172[34.2%] women, mean age [±SD] 40.5 [±13.2] years, mean disease duration 9.7 [±14.7] years), receiving a total of 675 lines of treatment ([I-line n=503, II-line n=118, III-line n=54]) with a TNFα antagonist ([IFX, 173 infliximab [IFX], 173 adalimumab [ADL], 89 golimumab [GOL], 141 etanrect [ETNI]). At the time of TNFI introduction, 28.6% patients claimed at least one EAM (IBD 11.3%, uveitis 10.9%, and PsO 8.8%). The baseline presence of at least one EAM was associated with a more frequent prescription of an anti-TNF monoclonal antibody rather than etanercept (34.1% versus 21.9%, respectively, p=0.005). In detail, EAMs were found in 41.6, 39.9, 29.8, and 21.9% patients treated with GOL, ADA, IFX, or ETN, respectively. The prevalence of IBD was significantly higher (p=0.004) in patients treated with ADA (12.7%), IFX (14.3%), or GOL (11.2%) compared with ETN (4.9%). Uveitis was numerically more frequent in GOL (20.2%) and ADA (13.5%) rather than IFX (9.5%) and ETN (9.9%) groups. Finally, PsO was similarly high in patients treated with ADA (10.9%) and GOL (10.1%), and numerically lower in the ETN (7.1%) and IFX (5.9%) groups. Conclusions: In our cohort of axSpA patients treated with TNFis, EAMs were highly heterogeneous. The presence of extra-articular involvement has been carefully taken into account when a TNF was required to better control the disease. In particular, IBD and uveitis drove more frequently the choice toward an anti-TNF monoclonal antibody instead of the receptor. Disclosure of Interest: None declared DOI: 10.1136/annrheumdis-2017-eular.5779
Furthermore, univariate models showed that age (p=0.738), disease duration (p=0.090), previous DMARDs (p=0.616), and HAO (p=0.674) and BASFI (scores p=0.850) were not statistically significant predictors of gastrointestinal infections.

Conclusions: The incidence rate of gastrointestinal infections in SpA patients treated with anti-TNF drugs is not increased. Being female and having comorbidities are predictive factors of gastrointestinal infections.

**THE INFLUENCES OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS ON SERUM VEGF AND BMP-2 LEVELS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

G. Gao, L. Lu, Z. Li, Y. Li. Rheumatology, the First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

Background: VEGF has been found abnormal in patients with SpA and related to disease activity [1, 2]. BMP-2 has a function of promoting the osteothesis formation, and may be involved in the integration process of AS spine [3, 4]. VEGF and BMP-2 interact with each other, participating in the formation of osteoblast [5]. COX-2 works together with the expressions of BMP2 and VEGF is an important factor of heterotopic ossification [6].

Objectives: To investigate the serum levels of VEGF and BMP-2 in axSpA treated with different anti-TNF drugs and their possible relationship with disease activity.

Methods: 120 patients with axSpA were randomized administered with imrecoxib or celecoxib respectively for 3 months. Serum VEGF and BMP-2 were detected. ESR, CRP, BASDAI, BASFI and SPARC were measured.

Results: A statistically significant change was found in ESR, BASDAI, patients global assessment of disease activity, Schober test and intermalleolar distance (r=0.628, 0.542, 0.238, 0.299, 0.353, 0.369, 0.373, 0.359, -0.274, P <0.05). And the BMP-2 levels were correlated with CRP and lumbar side flexion (r=0.213, -0.190, P <0.05). Serum VEGF levels were significantly increased in HLA-B27-positive patients than in HLA-B27-negative ones (P <0.05).

Conclusions: NSAIDs can not only improve symptoms and function, but also reduce saccroilitis possibly by affecting the levels of VEGF and BMP-2. Imrecoxib and celecoxib have the same efficacy. The response to treatment was correlated with the expression of HLA-B27.

Secukinumab 150mg provides sustained improvements in the signs and symptoms of active ankylosing spondylitis with high retention rate: 3-year results from Phase III trial, measure 2

Background: Secukinumab improved signs and symptoms of ankylosing spondylitis (AS) over 2 years in the MEASURE 2 study (NCT01649376).1,2

Objectives: To report the efficacy and safety of secukinumab over 3 years from the MEASURE 2 study.

Methods: 219 patients (pts) with active AS were randomised to subcutaneous secukinumab 150mg (72 pts), 75mg (73 pts) or placebo (PBO, 74 pts). At Week (Wk) 16, PBO treated pts were re-randomised 1:1 to secukinumab 150mg or 75mg, irrespective of clinical response. Pts initially randomised to secukinumab and those who switched from PBO to secukinumab at Wk 16 were included in the analysis (secukinumab 150mg, N=106 and secukinumab 75mg, N=105).

Outcome measures were ASAS20 and ASAS40 at Wk 156, ASAS-6/5/6, BASDAI, ASDAS CRP, ASDAS-CRP Inactive Disease, ASDAS-CRP partial remission, ASAS partial remission.

Results: 156 Wks (n=156) achieved ASAS 20, 18 (60%) ASAS 40, 12 (40%) of patients with marked ASAS 5/6 responses, and 72.4% (76/105) for 75mg. Higher discontinuation rates for 75mg were in part due to lack of efficacy or patient/guardian decision. Efficacy reported as observed. Safety analyses included all pts who received ≥1 dose of secukinumab.

Conclusions: Secukinumab 150mg provided sustained improvement in the signs & symptoms along with physical functions with >80% retention rate through 3 years in pts with AS. Safety profile remained favourable and was consistent with previous reports.1,2

Increased interleukin-17a concentration remains high in patients with ankylosing spondylitis treated with tumour necrosis alpha inhibitors within the year

I.Z. Gaydukova, A. Rebrov. Hospital Therapy, Saratov State Medical University, Saratov, Russian Federation

Background: Ankylosing spondylitis (AS) is associated with changes in the serum cytokines concentrations. During the treatment cytokines profile could change in different manner.

Objectives: The aim of the study was to evaluate the changes in concentration of interleukin-17A (IL-17A) in patients with AS, treated with tumour necrosis factor alpha inhibitors (anti-TNFα) during the year.

Methods: 30 patients with AS, fulfilled m. New-Y ork criteria, with BASDAI ≤4.0 and NSAIDs non-responders were involved in the study. Mean age of AS patients at baseline was 36.3±9.19 years (M ± SD), the duration of AS was 11.4±9.6 years, 22 (73.3%) of patients – male. 20 healthy volunteers were involved as controls (mean age 40.1±7.7 years, male - 12 (60%). All AS patients were treated during the year with Remicade (infliximab, MSD®) - 5 mg/kg at the recommended scheme. BASDAI, ASDAS CRP indices were calculated. C-RP, TNFα and IL-17A levels were measured before the treatment with anti-TNFα (baseline) and 52±2 weeks after the baseline. Number of patients achieved ASAS 20, ASAS 40 responses, and ASAS partial remission was evaluated. The statistics was performed with SPSS17.

Results: Baseline concentrations of TNFα and IL-17A in AS patients were higher than in healthy subjects (28.4±14.4 and 2.4±2.1, respectively, p <0.000). Significant reduction of AS activity, but not of IL-17A serum concentration was marked at week 52, Table 1. 24 (80%) achieved ASAS 20, 18 (60%) – ASAS 40, 12 (40%) of patients with...
AS achieved ASAS partial remission. IL-17A was lower in patients who achieved remission compared to those who achieved the remission.

**THU0372**  
**EFFECT OF TNFI VERSUS NSAID ON SPINAL RADIOGRAPHIC PROGRESSION OVER 4 YEARS IN EARLY ANKYLOSING SPONDYLITIS: RESULTS FROM TWO OBSERVATIONAL COHORTS IN SOUTH KOREA

J.W. Park1, M.J. Kim1, J.K. Park2, Y.J. Lee3, E.B. Lee1, Y.W. Song1, E.Y. Lee1
1Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul; 2Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Gyeonggi-do, Korea, Republic Of

**Background:** It is uncertain whether early suppression of inflammation by tumor necrosis factor inhibitor (TNFI) leads to a decreased radiographic progression in axial spondyloarthritis (axSpA).

**Objectives:** To compare the radiographic progression over 4 years in patients with early ankylosing spondylitis (AS) using TNFI versus nonsteroidal antiinflammatory drug (NSAID)

**Methods:** A total of 215 patients with early AS (symptom duration<10 years) were included based on the availability of radiographs at baseline and 2- and/or 4-years of follow up. Among them, 135 patients with TNFI were from SNUH-biologics cohort (TNFi group) and other 80 patients with NSAID were from control cohort in Seoul National University Bundang Hospital (NSAID group). Radiographic progression was assessed by two blinded readers using modified Stokes AS Spinal Score (mSASSS). Linear mixed model was applied to compare the radiographic progression between the two groups after adjustment for clinical factors. We also performed a sensitivity analysis after the propensity score matching in which age, smoking status, baseline CRP and baseline mSASSS were included as covariates.

**Results:** Patients in the TNFI group showed higher baseline BASDAI (6.7 vs. 3.1) and CRP (2.2 vs. 1.1mg/dL) as compared with those in the NSAID group. There were no differences between the two groups regarding age, gender, HLA-B27, smoking status and baseline radiographic damage. Overall, radiographic progression rate (95% CI) during the observation was 0.72 (0.57–0.87) unit/year. TNFI group showed significantly slower progression than NSAID group (β=0.33 unit/year, p<0.042). This result was consistent after adjusting for age, smoking status, baseline CRP and presence of baseline syndesmophytes (β=0.50 unit/year, p<0.001) (Table). In the subgroup analysis of patients without baseline syndesmophytes, TNFI group showed no radiographic progression over time whereas NSAID group did not (0.03 [-0.22–0.27] vs. 0.45 [0.20–0.71] unit/year). These results were not changed when the same analysis was performed in the post-matched population (78 TNFi group vs. 78 NSAID group).

**Conclusions:** In patients with early AS, TNFI led to a decreased radiographic progression as compared with NSAID treatment. This result suggests that early and durable suppression of inflammation using TNFI can have beneficial effect on the radiographic outcome of AS.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.3321

*Regression coefficient indicates the progression of mSASSS over one year. Gender, HLA-B27, baseline BASDAI and time-averaged NSAID index were not included because they did not show a significant (p<0.1) interaction with time in the univariate analysis.

**Conclusions:** In patients with early AS, TNFI led to a decreased radiographic progression as compared with NSAID treatment. This result suggests that early and durable suppression of inflammation using TNFI can have beneficial effect on the radiographic outcome of AS.

THU0373 USE OF CORTICOSTEROID HIP JOINT INJECTIONS IN Spondyloarthritis Patients under TNF Alpha Inhibitors

K. Maatallah 1, A. Ben Ouhiba 1, I. Mahmoud 2, S. Belghali 3, W. Hamdi 1, M. Khchir 1, R. Tekaya 2, L. Abdelmoula 2, 1Department of Rheumatology, M.T Kassab Institute; 2Department of Rheumatology, Charles Nicolle Hospital; 3Department of Rheumatology, Farhat Hached Hospital, Tunis, Tunisia

Background: The hip disease is a serious complication of spondyloarthritis (SpA), engaging the functional prognosis of patients. TNF alpha inhibitors are a breakthrough for the treatment of SpA and the management of this complication.

Objectives: To assess the efficacy of TNF alpha inhibitors on hip involvement in SpA by evaluating the use of intra-articular corticosteroid infiltrations.

Methods: Observational cohort study that included 94 SpA patients with hip disease (ASAS2009). Two groups were studied. Group 1 (G1): patients under anti-TNF alpha therapy and Group 2 (G2): TNF alpha inhibitors naïve patients. Clinical (BASDAI, BASFI, hip (pain/mobility), index of severity for osteoarthritis for the hip (ISH)), biological (CRP) data were assessed and the use of corticosteroid hip joint infiltration was compared. Evaluations were performed and compared between the 2 groups at baseline (T0), two years (T2) and Tn (greater than or equal to 3 years). The correlation study was made by Pearson test. A correlation was considered statistically significant if p < 0.05.

Results: Group 1 and 2 included 48 and 46 patients respectively. The socio demographic and clinical characteristics of the disease were comparable between the two groups. Significant and radiological assessment of the two groups of patients were comparable at T0. Group 1 had however a more active disease and a greater functional impairment. NSAIDs were prescribed in 40% of patients in G1 and 86% in G2 (p < 0.0001). DMARDs were prescribed in 20 patients in G1 and in 22 patients in G2 (p < 0.06). In G1 patients received infliximab, adalimumab and etanercept in 48%, 15% and 37% of cases respectively. Four patients of G1 and three of G2 patients received intra-articular corticosteroid infiltration in the year prior to the initial assessment (p = 0.7). Assessment at T2 showed a greater improvement in clinical and biological parameters of the disease in group 1 than in group 2 (p2-T0) significantly lower in group 1 for the BASDAI (p < 0.0001), the BASFI (p < 0.0001) and the ISH (p = 0.017). The number of painful hip was significantly lower in group 1 (p < 0.0001). The evaluation at Tn showed a sustained clinical and biological efficacy of TNF alpha inhibitors in Group 1. The use of corticosteroid injections was significantly higher in group 2. Table 1 summarizes the assessment of different parameters at T2 and Tn.

Conclusions: Hip involvement is a marker of severity of spondyloarthritis. Anti-TNF alpha treatment is effective on hip disease. It reduces the use of intra-articular injections of corticosteroids.

Disclosure of Interest: None declared

THU0374 LONG-TERM EFFECTS OF TNF-ALPHA INHIBITORS ON BONE MINERAL DENSITY AND THE INCIDENCE OF VERTEBRAL FRACTURES IN PATIENTS WITH ANKYLOSING SPONDYLITIS

K. Beek 1, M. van der Weijden 1, W. Leem 1, C. Van Denderen 2, M. Nurmohamed 1, I. van der Horst-Bruinsma 1, K. Beek 1Katholieke Universiteit, Leuven, Belgium; 2Quantacite, Hitchin; *Pfizer, Sandwich, United Kingdom; +Pfizer, SANV, Medical Department, Brussels, Belgium

Background: Ankylosing Spondylitis (AS) is not only characterized by pathological bone formation leading to ankylosis but also by bone loss which may lead to vertebral fractures (VFx). TNF-alpha inhibitors (TNFi) have proven to be effective in blocking the inflammation process. A few studies also showed an increase of bone mineral density (BMD) in AS patients treated with TNFi but the incidence of VFx after two years of treatment was increased.

Objectives: To evaluate the long-term effect of TNFi on BMD and the incidence of VFx in patients with AS.

Methods: Consecutive TNFi naive patients diagnosed with AS according to the Modified New York criteria were included. Patients were recruited from the VUMc and the Amsterdam outpatient clinic Reade and were treated with TNFi for 4 years. BMD at hip and lumbar spine (LS) were measured at baseline, after 2 and 4 years. T-scores were categorized as “normal BMD”, “osteopenia” and “osteoporosis”, based on the WHO osteoporosis criteria.3 The incidence of VFx was determined by two observers using the Genant method.6

Results: In total, 70 AS patients with complete datasets (67.1% male) were included. The mean age was 41.6 years and the disease duration (time since diagnosis) was 9.8 years. At baseline 42% of the patients had a decreased BMD of the hip and 34% of the spine, of whom 19 patients (27%) had both a decreased hip BMD as well as a decreased lumbar BMD. The BMD of spine and hip improved after 2 and 4 years of TNFi treatment (Table 1). In 7 patients (10%), 8 VFx were observed both at baseline and after 2 years. After 4 years of TNFi-treatment 11 VFx were observed in 9 patients.

Conclusions: After 4 years, 2 out of 9 patients with ≥1 VFx had a decreased BMD at hip and lumbar spine whereas the other 7 patients had a normal BMD. The majority of VFx was localized in the mid or lower thoracic spine.

Table 1. BMD measurement in spine and hip of 70 AS patients treated with TNFi

Abstract THU0374 – Table 1. Comparison of Clinical and biological variations between the 2groups at T2 and Tn

THU0375 CHARACTERISTICS ASSOCIATED WITH IMPROVEMENTS IN SPARCC SIJ AND ASDAS SCORES IN PATIENTS WITH NON-RADIODIGRAPHIC AXIAL SPONDYLOARTHRITIS TREATED WITH ETANERCEPT

K. de Vlam 1, A. Burden 2, M.A. Dilleen 3, C. Boone 4, K. Beek 1Katholieke Universiteit, Leuven, Belgium; 2Quantacite, Hitchin; *Pfizer, Sandwich, United Kingdom; +Pfizer, SANV, Medical Department, Brussels, Belgium

Background: The EMBARK trial of etanercept (ETN) (NCT01258738) has demonstrated the long-term efficacy of ETN in patients with non-radiographic axial spondyloarthritis (nr-axSpA) and shown correlations between decreased inflammation and clinical outcomes.2

Objectives: To determine which baseline (BL) characteristics are associated with clinical improvements after 48 weeks of treatment with ETN in patients with nr-axSpA.

Methods: This post hoc analysis was performed on data from patients with nr-axSpA enrolled in the 92-week open-label phase of the EMBARK trial. The primary analysis population was the EMBARK modified intent-to-treat (mITT) population (patients who had ≥1 dose of ETN, had ≥1 on-therapy evaluation, and met the Assessment in Ankylosing Spondylitis classification criteria for axSpA). Patients’ SpondyloArthritis Research Consortium of Canada (SPARCC) sacroiliac joint (SIJ) scores and Ankylosing Spondylitis Disease Activity Scores (ASDAS) were recorded, and patients were divided into 4 quadrants (Q1–4) based on the minimally important change (MIC) for each instrument (SPARCC SIJ change from Baseline above [≥2]; ASDAS cTB <1; 1). Patients in Q1 achieved MIC in SPARCC SIJ but did not achieve MIC in ASDAS. Q2 did not achieve MIC in SPARCC SIJ and did not achieve MIC in ASDAS. Q3 did not achieve MIC in SPARCC SIJ but achieved MIC in ASDAS. Q4 achieved MIC in SPARCC SIJ and achieved MIC in ASDAS. Missing data were imputed using last observation carried forward. P-values were obtained using the Chi-squared test (categorical variables) and the Kruskal-Wallis test (continuous variables) in order to compare BL characteristics across improvement status. Multivariable
multinominal logistic regression modelling was used to calculate which BL characteristics were associated with clinical improvements when adjusted for all other BL characteristics.

Results: At screening, male patients had significantly higher median SPARCC SIJ scores compared with female patients (4.83 [range 0.0–48.0] vs 1.5 [0.0–32.0], P < 0.0001). Male patients comprised 59.1% of 194 patients included in either SPARCC SIJ scores, ASDAS or both (Q1/3, Figure). There was a statistically significant difference in the number of male versus female patients who achieved MIC in both scores (Q4), compared with patients who achieved MIC in only one or neither (Q1–3, Figure) (P < 0.0001). However, multinominal logistic regression modelling showed that age (P=0.0358), BL ASDAS (P=0.0001), and screening SPARCC Spine (P=0.0358) and SPARCC SIJ (P=0.0001) scores, not gender, were significantly associated with achievement of MIC in both SPARCC SIJ and ASDAS at wk48 for the total population (after adjustment for the effects of other variables).

Figure: Numbers of Patients who Did or Did Not Achieve MIC in SPARCC SIJ Score (≥2.5 cU/mL) or ASDAS (≥1.1 cU/mL).

Conclusions: Although BL summaries showed a significant difference in gender across quadrants, the BL SPARCC SIJ score was strongly correlated with gender (male patients had more inflammation). When both were included in a multivariable model, gender was non-significant. Only age, BL ASDAS, and screening SPARCC SIJ and Spine scores were associated with MIC after 48 weeks of etanercept treatment.

THU0376 REAL-WORLD USE OF SECUKINUMAB WITH AND WITHOUT A LOADING REGIMEN AMONG PATIENTS WITH ANKYLING SPONDYLITIS IN THE UNITED STATES: PATIENT PROFILE AND DOSING

K. Oelke 1, G. Chun 2, Y. Li 3, X. Liu 3, Y. Park 3
1Rheumatic Disease Center, Glendale; 2Novartis Pharmaceuticals Corporation, East Hanover; 3KMK Consulting, Inc, Morristown, United States

Background: Secukinumab is a fully human anti-interleukin-17 monoclonal antibody for the treatment of patients with moderate to severe plaque psoriasis, psoriatic arthritis and ankylosing spondylitis (AS), and may be administered with or without a loading regimen of 150 mg at weeks 0, 1, 2, 3 and 4 followed by maintenance dosing every 4 weeks. The dosing pattern of secukinumab in a real-world setting of patients with AS has not been evaluated in clinical practice in the United States.

Methods: Retrospective data from the Symphony Health Solutions Lx commercial claims database were used to identify AS patients who had ≥1 secukinumab treatment between January 15, 2016 and June 30, 2016. Patients eligible for inclusion were ≥18 years of age who had the diagnosis of AS and ≥1 pharmacy or medical claim in the 12 months prior to their first secukinumab treatment (index date). Patient demographics and secukinumab dosage were examined at the index date. Clinical characteristics, comorbidities and treatment history in the 12 months prior to the index date were identified and presented by use versus no use of a loading regimen of secukinumab.

Results: A total of 152 patients who initiated secukinumab were included in this study; the mean (SD) age of included patients was 45.3 (11.1) years and 53.9% were female. Of the 152 patients, 119 patients (78.3%) received a loading regimen and 33 (21.7%) did not. Patient demographics, clinical characteristics and treatment history were not significantly different between the two cohorts (Table 1). The majority of patients (65.5%) with loading initiated secukinumab with the 150-mg dose, whereas the majority of patients (60.6%) without loading initiated with the 300-mg dose. More than half of the patients in each cohort received a biologic therapy during the 12-month baseline period (loading, 65.5%; no loading, 51.5%). Other prior treatments included oral corticosteroids (30.3% for both), conventional synthetic disease-modifying antirheumatic drugs (DMARDs) (loading, 31.9%; no loading, 21.2%) and targeted synthetic DMARDs (loading, 4.2%; no loading, 12.1%). The prevalence of comorbidities was similar between the two cohorts, with the most prevalent comorbidities being hypertension (19.1%), rheumatoid arthritis (19.1%) and other skin diseases (18.4%).

Table 1. Demographics, clinical characteristics and treatment history of patients with AS treated with secukinumab with or without a loading dose of 150 mg

</table>

Conclusions: In this retrospective, administrative claims-based study, the majority of patients with AS who received secukinumab treatment with a loading regimen. Although only the 150-mg dose of secukinumab is approved for the treatment of AS, almost 40% of patients received the 300-mg dose, indicating a need to better understand patient and treatment characteristics for secukinumab in patients with AS. The results of this study provide early insights into real-world use of secukinumab with and without a loading regimen in patients with AS in the United States.

THU0377 LOW DOSE IL-2 THERAPY CAN RECOVERY TH17/TREG CELL BALANCE IN PATIENTS WITH SPONDYLOARTHRITIS THROUGH INCREASING REGULATORY T CELLS NUMBERS

F. Jinnan 1, X. Dan 1, G. Qianqian 1, Q. Kaiil 1, G. Chong 1, L. Xiaodong 1
1Department of Rheumatology, The Second Hospital of Shanxi medical University, Taiyuan, China; 2Department of Pathology, Brigham and Women’s Hospital, Harvard Medical School, Boston, Boston, American Samoa

Background: The imbalance in the number of Th17 and Treg cells is suggested to be associated with the pathogenesis of SpA. Recent studies have shown that interleukin-23 (IL-23) and Th17 play a crucial role in the pathogenesis of SpA. However the status of CD4+CD25+Foxp3+T cells which exert immunoregulatory functions are remains to investigate.
Objectives: To explore the status of the immunologic balance between Th17 cells and Treg cells in patients with SPA, and to assess the effect of low dose IL-2 on the peripheral CD4+ T cells.

Methods: Two hundred and two patients, who met the Assessment of Spondyloarthritis International Society (ASAS) criteria were enrolled and given conventional therapy, including Nonsteroidal Anti-Inflammatory Drugs (NSAIDs), biological agents, Sulfasalazine, glucocorticoid. Eighty seven patients were not only given conventional therapy, but also injected subcutaneously low dose IL-2 (50 WIU/day for 5 days). Clinical and laboratory indicators were compared before and after IL-2 treatment. The CD4+ T cells in peripheral blood were measured by multicolor flow cytometry. A side effects were observed in the course of therapy.

Results: The absolute number and ratio of CD4+CD25+Foxp3+ regulatory T cells in peripheral blood of patients with SPA was significantly decreased compared with the healthy control group, (25.13 (18.76,37.37) vs. 33.06 (22.87,42.33), P<0.001); Th17/Treg (0.29 (0.18, 0.49) vs. 0.20 (0.15, 0.34), P=0.001). The absolute number of Treg cells increased more than 3-times (22.70 (14.47, 30.10) vs.67.87 (48.21, 105.82), p<0.001) after 5 days of low dose IL-2 treatment. Th17/Treg was significantly higher (0.32 (0.18, 0.57) vs. 0.20 (0.15, 0.34), P<0.001) before treatment compared with healthy controls.

Conclusions: The decrease of CD4+ CD25+ Foxp3+ T cells might play a key role in the pathogenesis of SPA. Low dose IL-2 therapy can restore and maintain the balance of Th17 and Treg cells by increasing Treg cells numbers specificity. The therapy is safe. More attention should be paid on the long term benefits of low-dose IL-2 therapy in the further research.

THU0378 IMPACT OF THE ADALIMUMAB PATIENT SUPPORT PROGRAM ON CLINICAL OUTCOMES IN ANKYLOSING SPONDYLITIS: RESULTS FROM THE COMpanIY STUDY

L. Bessette1, C. Thorne2, B. Millson3, K. Charland4, K. Donepudi5, T. Gaetano5, V. Remple4, M. Latour4, M-C. Laliberté4, 1Department of Medicine, Laval University, Quebec City, Canada; 2Southlake Regional Health Centre, Newmarket, Ontario; 3QuintilesIMS, Markham; 4AbbVie Corporation, St. Laurent, Canada

Background: Adalimumab (ADA) is a TNF-α inhibitor indicated for various inflammatory autoimmune diseases including ankylosing spondylitis (AS). Patients receiving ADA in Canada are eligible to enroll in the AbbVie Care patient support program (PSP) which provides them with personalized services including ongoing monitoring of disease state as determined by a Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score and received prior NSAID(s) at baseline (BL) were categorized by BL: (1) time since diagnosis (< 2 years), (2) age (< 35 years vs 35–45 years vs ≥ 45 years), and (3) number of prior NSAIDs (≤ 2 vs >2) and (4) at the time of the follow-up BASDAI assessment was compared in patients with received CCC and patients without CCC. Robust Poisson regression was used to estimate the adjusted relative risk (RR) of controlled disease. Analyses were adjusted for patient age group, sex, region, prior biologic use, days lapsed between last follow-up visits, and baseline disease control status category.

Results: A total of 249 patients met eligibility criteria and 123 (49%) of these had received CCC. Of the 249 patients, 184 (74%) had controlled disease (BASDAI ≤ 4) at the follow-up assessment, 98 (80%) in the CCC group and 86 (68%) in the no CCC group. In the multivariable regression analysis, there was an increased likelihood of achieving controlled disease in the CCC group relative to the group without CCC (RR = 1.23, 95% confidence interval: 1.06–1.42; p-value = 0.0055).

Conclusions: AS patients receiving tailored services through the ADL PSP in the form of care coach calls have an increased likelihood of achieving controlled disease within 6 to 18 months. These results may help refine interventions aiming at improving clinical outcomes in AS patients.

THU0379 IMPACT OF TIME SINCE DIAGNOSIS, AGE, AND NUMBER OF PRIOR NSAIDS ON ANKYLosing Spondylitis: EFFECTS OF ADALIMUMAB 52-WEEK CLINICAL RESPONSE TO ADALIMUMAB IN PATIENTS WITH ANKYLosing SPONDYLITIS

J. Sieper1, A. Deodhar2, M. Hojink3, Y. Zhang4, M. Dougdoss5, 1Charité Universitätsmedizin Berlin, Berlin, Germany; 2Oregon Health & Science University, Portland, United States; 3AbbVie, Ljubljana, Slovenia; 4AbbVie Inc., N Chicago, United States; 5René Descartes University and Hôpital Cochin, Paris, France

Objective: The objective of this analysis was to examine the impact of time since diagnosis, age, and number of prior NSAIDs as surrogates for disease duration on clinical outcomes in AS pts from ATLAS trial treated with ADA for 52 wks.

Methods: ATLAS3,4 was a phase 3 randomized double-blind placebo (PBO)-controlled trial evaluating the safety and efficacy of originator ADA in pts with active AS who failed NSAID therapy. In this post hoc analysis, pts who received at least one dose of ADA during the PBO-controlled period or open label extension and received prior NSAID(s) at baseline (BL) were categorized by BL: (1) time since diagnosis (< 2 years vs ≥ 2 years), (2) age (<35 years vs 35–45 years vs ≥45 years), and (3) number of prior NSAIDs (≤ 2 vs >2). The effect of time since diagnosis, age, and number of prior NSAIDs on AS outcome measures following 52 wks of ADA treatment was examined.

Results: At wk 52, 274 pts had received at least one dose of ADA and had at least one prior NSAID at BL. A majority of pts were ≥ 5 y since AS diagnosis (188 [68.6%]), <5 y of age (163 [59.5%]), HLA-B27+ [213 [77.7%]], and had <2 prior NSAIDs (158 [57.7%]). Pts with shorter time since diagnosis were generally younger (late thirties). Across all subcategories, ~70% of pts were male. The BL disease activity measures were numerically similar across most categories. Following 52 wks of ADA treatment, the proportions of pts achieving ASAS20 and ASAS40 responses were numerically higher and mean decreases in BASDAI and BASFI scores from BL larger in subcategories with shorter time since diagnosis, younger age, and fewer prior NSAIDs (Table). There were significant differences in ASAS40, BASDAI, and BASFI scores between time since diagnosis (<2 vs ≥ 2 and < 5 vs ≥ 5) and age (<35 vs ≥ 45) subcategories.

Conclusions: Following 52 wks of ADA treatment, shorter time since diagnosis and younger age were associated with greater clinical improvements and improvements in disease activity and functionality. Although younger age (<35 vs ≥ 45) had significant positive impact on the clinical outcomes similar to wk 12 results, shorter time since diagnosis (<2 vs ≥ 2 and < 5 vs ≥ 5) was also associated with better 52-wk clinical outcomes. These results suggest that early effective therapeutic intervention may improve long-term clinical outcomes in AS pts.

**Background:**
Published reports suggest that patients with Spondyloarthritis (SpA) in remission under treatment with TNFalpha inhibitors (TNFi) could obtain the best benefit at lower dose of the drug. **Objectives:**
To evaluate effectiveness of a strategy of dose reduction of TNFi in SpA patients in clinical remission and to explore baseline characteristics predictive of maintenance of the response. **Methods:**
Retrospective observational study, including patients with SpA meeting ASAS criteria treated with TNFi following a dose optimization protocol (lower doses or longer intervals than approved), from 2008 to 2015. Criteria for optimization was patients with BASDAI≤2 and/or C reactive protein level (CRP)<5 mg/L for at least 6 months. Patients who relapsed (BASDAI>2 and/or CRP>5 mg/L) returned to standard dose. Clinical/analytical parameters and drug’s survival time until relapse were recorded. SPSSv.17 software was used for contrast means. Survival Kaplan-Meyer curves was analysed. **Results:**
148 SpA patients treated with TNFi, 32/149 patients (21.5%) included in optimization protocol. 27 patients (84.3%) with increased interval between doses, remaining with reduced dosifiction. Table 1 shows baseline characteristics of patients on optimization group (means/SD or proportion). 18/32 patients (56.2%, C39.01–73.4) maintained clinical remission with optimized dose at 36.5 months (median). Table 2 shows activity parameters of both relapsed and maintained response patients. There were either baseline differences or at optimization time between patients who maintained remission and not, but relapsed patients showed higher CRP at optimization time, without statistically significant differences. 72.2% (13/18) of patients on sutained remission were on intermediate uveitis. Mean disease duration was 151±117.1 months (range 6–27), 9 patients are still on CZP treatment. Ten eyes showed improvement of visual acuity (41.7%), 10 remained stable and 2 worsened. During the follow-up no serious adverse events were reported. Four cases withdrew CZP treatment: 2 due to worsening of articular symptoms but without any uveitis events; 1 due to macular edema and 1 due to uveitis activity. One patient switched to infliximab, one to golimumab, and 2 required switch to tocilizumab. In all 13 patients except 2, CZP achieved a good control of SpA activity.

**Conclusions:**
CZP demonstrated effectiveness in patients with uveitis-associated to SpA refractory to previous TNFi treatment. **References:**

**RESULTS OF A REAL LIFE DOSE-REDUCTION STRATEGY**

**CERTOLIZUMAB PEGOL IS EFFECTIVE IN UVEITIS ASSOCIATED TO SPONDYLOARTHROPATHY REFRINGATORY TO OTHER TUMOUR NECROSIS FACTOR INHIBITORS**

**Background:**
Uveitis is one of the most common extra-articular manifestations of patients with spondyloarthritis (SpA). In severe cases, uveitis may require the use of biological therapy, primarily tumor necrosis factors inhibitors (TNFi), being infliximab the currently used infliximab and adalimumab. However, another TNFi such as certolizumab pegol (CZP), with indication for SpA patients, could be an effective option in cases of inefficacy or adverse events to other TNFi, as we have previously reported 1.

**Objectives:**
Our objective is to analyze the effectiveness and the safety profile of CZP in patients with refractory SpA-associated-uveitis.

**Methods:**
Observational, multicentric, retrospective study. We selected all patients with a diagnosis of SpA (including ankylosing spondylitis (AS), psoriatic arthropitis (PsA), non-radiographic axial SpA (nr-axSpA) and SpA associated to inflammatory bowel disease (IBD-SpA)) who had refractory uveitis (confirmed by an Ophthalmologist) as main extra-articular manifestation, and who received CZP for at least 6 months. Variables analyzed: age, sex, diagnosis, type of uveitis, duration since the first uveitis episode and number of eyes affected; previous treatment (NSAID, disease-modifying anti-rheumatic drugs (DMARDs), immunosuppressive or biological therapy); outcome, and time to follow-up.

**Results:**
Twenty-four eyes of 13 patients (10 men); age 49.5±11.7 (range 29–71 years) were included in the study. Diagnosis were: seven AS, four PsA, one nr-axSpA, and one IBD-SpA. Type of uveitis: 9 anterior, 3 panuveitis, and 1 intermediate uveitis. Mean disease duration was 151±117.1 months (range 5–420). 84.6% patients had previously received biological therapy (46.1% ≥2 biological agents). 61.5% received CZP in monotherapy and 5 patients received concomitant treatment: 4 methotrexate and 1 azathioprine. In all cases CZP was started due to inefficacy to previous treatment except for 2 cases whose primary reason was the occurrence of adverse events (one injection site reaction and one development of relapsing polychondritis). After a follow-up of 13.1±6.6 months (range 6–27), 9 patients are still on CZP treatment. Ten eyes showed improvement of visual acuity (41.7%), 10 remained stable and 2 worsened. During the follow-up no serious adverse events were reported. Four cases withdrew CZP treatment: 2 due to worsening of articular symptoms but without any uveitis events; 1 due to macular edema and 1 due to uveitis activity. One patient switch to infliximab, one to golimumab, and 2 required switch to tocilizumab. In all 13 patients except 2, CZP achieved a good control of SpA activity.

**Conclusions:**
CZP demonstrated effectiveness in patients with uveitis-associated to SpA refractory to previous TNFi treatment.

INCIDENCE OF UVEITIS IN NON-STEROIDAL

Acceptable treatment with etanercept compared with the other treatments.

Disclosure of Interest: None declared.

Disclosure of Interest: None declared.

Conclusions: This analysis confirms the slow rate of radiographic SIJ progression over 2 yrs in nr-axSpA. The observed data suggest a lower rate of progression with ETN than without a TNF inhibitor.

THU0384 THE EFFECT AND SAFETY OF YISAIPU (YISAIPU) IN THE TREATMENT OF PATIENTS WITH NONRADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN CHINA

M. Zhao1, G. Shi2, Y. Tao3, X. Wang4, S. Cao1, Z. Lin1, Z. Liao1, Q. Kong1, J. Gu1. 1Rheumatology department, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou; 2Rheumatology department, The First Affiliated Hospital of Xiamen University, Xiamen; 3Rheumatology department, The Second Affiliated Hospital of Guangzhou Medical University; 4Radiology department, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease, which includes AS and nr-axSpA. Anti-TNF-α agents, such as Yisaipu (Yisaipu) are frequently used in nr-axSpA patients in China, but the related data is limited.

Objectives: The aim of this research is to assess the efficacy and safety of Yisaipu in the treatment of patients with nr-axSpA in China.

Methods: The inclusion of study population consisted of 150 patients who met the ASAS criteria for axial SpA but not the modified New York radiographic criteria for AS, had a score of ≥4 on the BASDAI or a score of ≥2.1 on the ASDAS-CRP and had been treated unsuccessfully with ≥1 NSAIDs for 4-week. Patients were assigned to receive Yisaipu (made in China) 50 mg/week and contin-

Based on 2 of 3 readers assigning same category; otherwise considered no change. Some patients started with lowest possible score and could not improve. Δ, change. Percent pts with worsening – percent pts with improvement. 1One-way ANOVA. 2Adjusted for covariates listed in Methods. 3P=0.005.
primary efficacy end point was the improvement of ASDAS-CRP. Secondary end points included ASAS 20, ASAS 40, ASAS 5/6, ASAS partial remission and BASDAI. Safety was evaluated during scheduled visits.

**Results:** 123 patients with active nr-axSpA were enrolled between April 19, 2014, and July 10, 2015. The mean age of the 123 nr-axSpA patients was 25.3±5.9 years. The ASDAS-CRP and BASDAI decrease from 2.7±0.9 to 0.7±0.4, from 4.5±1.0 to 0.9±0.8, respectively between weeks 0 and 24. The patients achieved the ASDAS-CRP<2.1 was 96.7%. ASDAS-CRP major and important improvement were achieved by 41.4%, 79.8%, respectively at weeks 24. ASAS 20, ASAS 40, ASAS5/6 and ASAS partial remission were achieved by 75.0%, 54.8%, 65.4% and 35.2%, respectively at week 24. Yisaipu-treatment was associated with statistically significant improvements in all parameters, including BASFI, BASMI, PGH, PSA, EL, CRP concentrations. Most adverse events in the open-label phase were mild or moderate in severity.

**Conclusions:** Yisaipu was effective and well-tolerated during the 24-week study period and was associated with a significant improvement in the signs and symptoms of active nr-axSpA.

**Disclosure of Interest:** None declared

THU0387 THE CLINICAL IMPORTANCE OF THE THYROID NOODULES DURING TUMOR NECROSIS FACTOR-ALPHA INHIBITOR THERAPY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

R. Terlemez 1, K. Akgün 2, D. Palamar 2, H. Sari 1, 1 Physical medicine and rehabilitation, Şişli Hamidiye Etfal Research and Training Hospital; 2 Physical medicine and rehabilitation, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey.

Background: TNF is a pivotal regulator of inflammation and the cytokine system. Besides this, there is no doubt that TNF has a major role in cancer biology. TNF has a dual defensive and offensive role in carcinogenesis (1). TNF-blocking treatment has led to improvements in the management of inflammatory diseases. Even though their efficacy as anti-inflammatory drugs is well-proven, there are some concerns about the adverse effects of anti-TNF therapy (2). Basic research suggests that the evaluation of infections and malignancy as major adverse effects should be performed effectively (3). However, some studies conducted so far have dubious notions that anti-TNF therapy increases the risk of cancer (3,4). Objectives: Objective of the study was to determine the clinical importance of the thyroid nodules in patients with axial spondylarthropathy (axSpA) rests with the need to exclude thyroid malignancy. The aim of this study is to assess the risk of thyroid malignancy in axSpA patients receiving anti-TNF therapy.

Methods: From September 2015 until December 2015, 70 patients diagnosed with axSpA according to ASAS criteria, were included in the research. Forty of the patients had received anti-TNF therapy, and 30 of the patients were anti-TNF naive. A clinician from the Physical Medicine and Rehabilitation clinic performed ultrasonography on all patients to screen for thyroid nodule(s). If thyroid ultrasonography revealed an abnormal finding, the patient was referred to a radiologist.

Results: The mean (SD) age was 38±9.87 years; % 75.7 of the patients were male. None of the demographic differences between the groups were statistically significant. Fifteen of the forty patients that received anti-TNF therapy and eleven of the thirty anti-TNF naive patients had thyroid nodule(s). Four patients from the anti-TNF group underwent fine needle aspiration biopsy, and two of them were diagnosed with papillary thyroid carcinoma. None of the nodules in anti-TNF naive patients required biopsy. When compared to the normal population, the standardized incidence ratio (SIR) was found to be increased in both male (SIR: 2.03% 95 CI: 1.9 to 18) and female (SIR: 2.7% 95 CI: 2.6 to 24) cases.

Conclusions: We see a mild increase in thyroid malignancies in axSpA patients that received anti-TNF therapy. Consequently, the thyroid gland should also be taken into consideration while screening for malignancy before anti-TNF therapy.

THU0388 EFFICACY AND SAFETY OF ADALIMUMAB IN PATIENTS WITH NON-RADILOGIC AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE 28-WEEK OPEN-LABEL PERIOD OF THE ABILITY-3 STUDY

R. Landewé, 1, S. Sieper 2, R. Inman 3, A. L. Pangan 4, X. Wang 4, J. K. Anderson 4, 1University of Amsterdam, Amsterdam, Netherlands; 2Charité Universitätsmedizin Berlin, Berlin, Germany; 3Toronto Western Hospital, Toronto, Canada; 4AbbVie, North Chicago, United States.

Background: Adalimumab (ADA) significantly improved clinical response at wk 12 vs placebo in patients (pts) with non-radiographic axial spondyloarthritis (nr-axSpA) in the ABILITY-1 study. The subsequent, ongoing ABILITY-3 study is assessing continuation vs withdrawal of ADA in nr-axSpA pts who respond to ADA.

Objectives: Evaluate the efficacy and safety of ADA during the open-label lead-in period of ABILITY-3.

Methods: ABILITY-3 has a 28-wk lead-in open-label ADA (40 mg every other wk) period; pts who achieve sustained remission (Ankylosing Spondylitis Disease Activity Score inactive disease [ASDAS-ID] at wk 16, 20, 24 and 28) are randomized to double-blind placebo (withdrawal) or ADA (continuation) for 40 wks (longing). From wk 20–28, pts who did not achieve ASDAS-ID were discontinued. Adult pts with nr-axSpA (fulfilling Assessment of SpondyloArthritis International Society [ASAS] criteria but not modified New York criteria) with objective evidence of inflammation in the sacroiliac joints or spine on MRI or elevated hs-CRP at screening; active disease at baseline (defined by ASDAS ≥ 2.1; BASDAI ≥ 4, and total back pain score ≥ 4); and inadequate response to ≥ 2 NSAIDs were eligible.

Results: Of 673 pts enrolled, 51% were women and mean BASDAI was 7.0±1.4 (Table). At wk 28, 305 (45%) pts were randomized (ASDAS-ID: 33% at wk 12, 44% sustained at wk 28; nonresponder imputation) and 368 (55%) pts achieved sustained remission (not achieving sustained remission, n=300 [45%]; other reasons, n=68 [10%]). In observed analysis, 59%, 35%, and 22% of pts achieved ASAS40, ASDAS-ID, and ASAS partial remission, respectively, at wk 12, similar to wk 12 data from ABILITY-1 pts with objective inflammation at baseline. The proportions of pts achieving ASAS20, ASAS40, ASDAS-ID, ASDAS CII, and ASDAS M1 increased, and mean BASDAI and back pain scores decreased over time (observed analysis; Figure). Adverse events (AEs) were reported by 468 pts (70%), most commonly nasopharyngitis (n=121 [18%]), upper respiratory tract infection (n=81 [12%]), and headache (n=56 [8%]); serious AEs occurred in 19 (3%) pts.

Conclusions: Baseline disease activity was higher in ABILITY-3 pts than reported in prior trials. After 28 wks of open-label ADA therapy, disease activity improved and sustained remission was achieved in 44% of pts. Efficacy and safety in this nr-axSpA population were consistent with findings from ABILITY-1.
IS THERE ANY ROLE OF IMMUNOGENICITY ON THE RESIDUAL RESPONSE TO THE ANTI-TUMOR NECROSIS FACTOR ALPHA THERAPY IN PATIENTS WITH ANKYLOSING SPONDYLITIS: THE FIRST RESULTS OF A PROSPECTIVE COHORT STUDY

1 Rheumatology, Kadir Celbi University Faculty of Medicine, Izmir; 2 Rheumatology, Gulhane Military Hospital, Ankara; 3 Rheumatology, Adnan Menderes University Faculty of Medicine, Aydin; 4 Rheumatology, Hacettepe University Faculty of Medicine, Ankara; 5 Rheumatology, Ege University Faculty of Medicine, Izmir; 6 Rheumatology, Kocaeli Military Hospital, Kocaeli; 7 Rheumatology, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul; 8 Rheumatology, Kocaeli University Faculty of Medicine, Kocaeli; 9 Biochemistry, Ankara Yildirim Beyazit University Faculty of Medicine, Ankara; 10 Rheumatology, Gaziantep University Faculty of Medicine, Gaziantep, Turkey

Background: Although anti-tumour necrosis factor agents (anti-TNFs) are very effective in most patients with ankylosing spondylitis (AS) significant proportion of patients quit the treatment due to non-response or adverse events. The development of anti-drug antibodies (ADAs) and low serum drug levels might have a mechanistic role in loss of efficacy of or the development of adverse events in patients treated with anti-TNFs. There is limited data regarding the immunogenicity of anti-TNFs in patients with AS.

Objectives: Therefore the aim of this study was to evaluate the relationship between the formation of ADAs, serum through drug levels and clinical response to anti-TNFs in patients with AS.

Methods: In total 350 AS patients with a new anti-TNF agent prescription in the last two weeks period were planned to include this multi-center prospective observational cohort study. Herein we are presenting the data of first 102 patients who had >3 months follow-up. Clinical data and serum samples were collected at baseline and at every three months of treatment. Serum drug levels and ADAs were measured by ELISA in one center to avoid inter-assay variability.

Results: 102 biologic naïve AS patients (75 [74%] male, mean ±SD age; 37.2±10.7 years) who started anti-TNF agents (14 infliximab [13.7%], 27 adalimumab [26.5%], 33 etanercept [32.4%] and 28 golimumab [27.5%]) were included in the present analysis. In comparison to baseline values BASDAI, ASDAS- CRP and CRP values were significantly decreased in third months of follow-up (P <0.001) (table). At 12 weeks of follow-up 9 patients (9%; 2 on infliximab and 7 adalimumab) had ADAs and 20 (20%; 10 on adalimumab, 4 infliximab, 4 golimumab and 2 etanercept) had no detectable drug levels. The presence of ADAs were significantly correlated with serum drug levels (P <0.001). Up to 12 months of follow-up none of patients treated etanercept developed ADAs. Third month BASDAI and ASDAS-CRP values were significantly higher in patients with ADAs (BASDAI values were 5.2±1.4 vs 3.0±1.8; P <0.001 and ASDAS-CRP values were 3.1±1.0 vs 1.9±1.1; P <0.001) (figure) and patients with no detectable drug levels BASDAI values were 4.1±1.8 vs 2.9±1.8; P=0.012 and ASDAS-CRP values were 2.7±1.3 vs 1.9±1.0; P=0.015).

Conclusions: ADAs against anti-TNF agents might develop as early as 12 weeks of treatment. Our results confirm that ADA development may hinder the anticipated response to anti-TNF agents in patients with AS.

THU0389 | EFFECT OF REHABILITATION ON THE CHEST EXPANSION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

S.D. Jandric1, Department for FRM, Faculty of Medicine, University of Banjaluka, Banja Luka, Republic of Srpska, Bosnia and Herzegovina

Background: Ankylosing spondylitis (AS) is a form of chronic inflammatory arthritis that leads to pain, stiffness, progressive spinal deformity, and spinal fusion, limitation of the spine, rib cage motion and severe functional impairment. Pulmonary function is altered in AS owing mainly to the limited chest expansion.

Objectives: The purpose of this study was to investigate the effect of rehabilitation on the limited chest expansion measured by respiratory index and relationship between duration of the rehabilitation and age, disease onset, disease duration and respiratory index in patients with AS during physical treatment and rehabilitation.

Methods: The study was designed as a retrospective study that included 47 consecutive AS patients (33 male and 14 female), average age of 52.5±11.58 years that were hospitalized and treated in rehabilitation center. Average duration of the rehabilitation was 17.7±5.92 days. Respiratory index was measured for all AS patients at the beginning and at the end of rehabilitation with a centimeter ribbon. Student’s t-test and Pearson’s test of correlation were used for statistically analysis.

Results: Average disease duration was 13.35±8.74 years, disease onset was at 39.64±12.87 years. Respiratory index was 1.98±1.34 cm at beginning of rehabilitation and 3.01±1.75 cm at the end of rehabilitation. The difference was statistically significant (t=8.025, p <0.001). Pearson’s test of correlation was shown statistically significant correlation between value of respiratory index at beginning and at the end of rehabilitation (r=0.872, p <0.001). Duration of the rehabilitation (hospital days) statistically significant correlate with value of respiratory index at beginning rehabilitation (r=−0.289, p <0.05), but not with age, disease duration and disease onset (p >0.05).

Conclusions: The physical therapy and rehabilitation has led to the improvement the respiratory index in patients with AS, which confirms its effectiveness. The value of respiratory index at beginning rehabilitation is associated with duration of the rehabilitation. Significant limitation in respiratory index indicates longer hospital stay. These results could be having importance in planning of rehabilitation of patients with AS.

THU0391 | FEMALE GENDER IS ASSOCIATED WITH A POORER RESPONSE TO TNF INHIBITORS IN ANKYLOSING SPONDYLITIS

T. Rusman1, M.T. Nurmohamed, J.C. van Denderen, I. Visman, I.E. van der Horst-Bruinisma, Amsterdam Rheumatology immunology Center (Departments of Rheumatology VU University Medical Center & Reade, Amsterdam, Netherlands

Background: Limited data are available on the influence of gender and lifestyle factors, such as smoking, alcohol consumption and Body Mass Index (BMI) on disease activity and response to TNF inhibitors in ankylosing spondylitis (AS).

Objectives: This study aimed to determine whether these factors influence age at diagnosis, disease activity and response to TNF inhibitors.

Methods: In a prospective study, clinical data (age, gender, C-reactive protein, Ankylosing Spondylitis Disease Activity Score (BASDAI), Bath Ankylosing Spondylitis Disease Activity Score (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and Bath Ankylosing Spondylitis Metrology Index (BASMI), smoking, alcohol consumption and BMI) were collected in AS patients from an observational cohort, who started or switched treatment with TNFI. Data were collected at baseline and after 6, 12 and 24 months. Independent t-tests and linear regression analyses were performed to assess the influence of gender and lifestyle factors on age at diagnosis and disease activity.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.2669
Results: In total, 312 consecutive AS patients, 34% female, were included with a mean follow-up of 18.9 months. Most patients (72%) 55% showed significant improvement after start of TNFi of whom 86 patients (28%) had a clinically important (ASDAS decrease -1.1) and 86 (26.9%) a major clinical improvement (ASDAS decrease -2.2). BMI was significantly correlated with age at diagnosis (p=0.016; 95% CI: 0.07(-0.65)); an increase of BMI with three points delayed the AS diagnosis with one year. At baseline, smoking and gender were not correlated with the ASDAS, but BASDAI and BASMI were both inversely related to BMI. Male gender was significantly associated with a higher chance at clinical response (improvement of the BASDAI with 50% or a 2 point decrease) to TNFi (p=0.041). At one year follow-up the clinical improvement of males versus females was respectively 62% vs. 43% and at two year follow-up 59% vs. 46%. Males also showed a significantly higher ASDAS improvement after one year of follow-up compared to females (p=0.015).

Conclusions: Significantly less females had a clinical response compared to males after one and two years of TNFi treatment. A higher BMI not only prolonged the time to AS diagnosis up to one year, but also negatively influenced the BASDAI and BASMI scores. Female gender and high body weight should be taken into consideration when the efficacy of TNFi is assessed, by stratifying for these factors in the analysis.

THU0039

DO WE REALLY NEED DMARDS ADDITION TO ANKYLOSING SPONDYLITIS PATIENTS TREATED WITH TUMOR NECROSIS FACTOR ALPHA INHIBITORS?

T. Reitblit 1, O. Cohen 2, D. Aharoni 2, E. Hadriani 3, G. Reifman 1, T. Braun-Moscovici 1, A. Balbir-Gurman 3, D. Department of Rheumatology; 1Laboratory Service, Barzilai MC, Ashkelon; 2B. Shine Rheumatology Unit, Rambam Health Care Campus and Rappaport Faculty of Medicine, Technion, Haifa, Israel

Background: The management of systemic inflammatory diseases, such as Rheumatoid arthritis (RA) and Ankylosing spondylitis (AS) has been revolutionized with the introduction of tumor necrosis factor alpha inhibitors (TNF-I). Significant reduction in disease activity and achievement of remission resulted in halting of joint damage and improved quality of life. Unfortunately, approximately 15–30% of patients fail to reach desirable improvement or lose drug effectiveness with time. It may be explained by immunogenicity and production of human anti chimeric antibodies (HACA). Presence of HACA against TNF-I have been associated with low levels of the drug and lose of therapeutic response. The prevalence of HACA in RA is estimated between 20–40%, and in AS between 25–64%. The difference in the pathogenesis of RA and AS as well as diverse approach in using disease modifying anti-rheumatic drugs (DMARDs) may influence HACA production and TNF-I levels in these conditions.

Objectives: To compare the incidence of HACA and infliximab, Etanercept, Adalimumab levels in patients with RA and AS with respect to concomitant DMARDs.

Methods: Patients with RA and AS data treated with TNF-I for at least 3 months in whom tests for HACA and infliximab, Etanercept, Adalimumab levels were available were extracted from patients’ files. Data included: demographics, concomitant treatment, and disease activity scores (BASDAI for AS and DAS-28 for RA). Serum for assessment of drugs level (ELISA) and HACA (ADAb;Promonitor, Bridging, ELISA) was obtained before the next drug administration. Univariate comparison was done using Student t test for the continuous variables and Chi square test for the categorical variables (P <0.05 was considered significant).

Results: Data on 53 patients with AS (mean age 47.9±11.9 years, 41.5%, 5% female) and 29 patients with RA (mean age 54.8±6.1 years, 75, 9% female) were available: 22 RA patients were treated with Methotrexate and 7 with other DMARDs; no one AS patient was treated with concomitant DMARDs. High level of HACA was found in 22.6% AS patients and in 34.5% RA patients (p=0.05); 86.8% patients with AS reached therapeutic level of drug compared to 69% RA patients (p=0.027). Drugs levels were similar in AS and RA patients (Table). Low

THU0392

SECUKINUMAB PROVIDES SUSTAINED REDUCTION IN FATIGUE IN PATIENTS WITH ANKYLOSING SPONDYLITIS THROUGH 3 YEARS: LONG-TERM RESULTS OF TWO RANDOMISED DOUBLE-BLIND PLACEBO-CONTROLLED PHASE 3 STUDIES

T.K. Kvien 1, A. Deodhar 2, L. Gossec 3, P.G. Conaghan 4, V. Strand 5, M. Østergaard 6, N. Williams 7, B. Porter 6, K. Gandhi 7, S. Jug 8,
1Diakonhjemmet Hospital, Oslo, Norway; 2Oregon Health & Science University, Portland, Oregon, United States; 3UPMC University Paris 06, Paris, France; 4University of Leeds, Leeds, United Kingdom; 5Stanford University School of Medicine, Palo Alto, CA, United States; 6Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark; 7RTI Health Solutions, Durham, NC; 8Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States

Background: In patients (pts) with ankylosing spondylitis (AS), fatigue is a common symptom affecting health-related quality of life (HRQoL) and social functioning. Secukinumab (SEC), a fully human anti-IL-17A mAb, rapidly improved signs and symptoms, physical functioning, and HRQoL in pts with AS.1,2

Objectives: To assess the long-term effects of SEC on fatigue in TNF inhibitor (TNF-I) naïve and TNF inhibitor inadequate responder/intolerant (TNF-IR) AS pts in MEASURE 1 and MEASURE 2.

Methods: 371 and 219 pts were randomized to SEC or placebo (PBO) in MEASURE 1 (10 mg/kg IV followed by 150 or 75 mg SC) and MEASURE 2 (150 or 75 mg SC), respectively. At Week (Wk) 16, non-responder PBO pts were re-randomized to SEC 150 or 75 mg SC (in MEASURE 1) or SEC 300 mg SC (in MEASURE 2). PBO pts achieving ASAS20 response at Wk 16 were switched to SEC at Wk 24. Fatigue was measured at baseline (BL) and Wks 4, 8, 12, 16, 24, 52, 104 and 156 using FACIT-F, which assesses fatigue in the previous 7 days using 13 questions graded on a 0–4 scale (higher scores=less fatigue). An increase from BL in FACIT-F score of ≥4 points (based on MCID) was used to define “response”. Approximately 69% of pts were TNF- naive and 31% were TNF-IR across both trials. Analyses were based on the full analysis set and subgroups stratified by prior TNF therapy. Correlations between BL characteristics and improvements in fatigue were investigated using a logistical regression model. Only data from the approved dose (SEC 150 mg) are presented.

Results: FACIT-F was 24.5–25.6 and 22.6–24.3 at BL across groups in MEASURE 1 and 2, respectively. Improvements in FACIT-F with SEC at Wk 16 were sustained through Wk 156 in MEASURE 1 and Wk 104 in MEASURE 2 (Table). Rapid and sustained fatigue response were also seen in subgroups stratified by prior TNF use. In the overall population, LS mean changes (+SEM) from BL in FACIT-F scores were significantly greater with SEC vs PBO at Wk 16 in both MEASURE 1 (7.60±0.99 vs 3.34±1.05, P=0.002) and MEASURE 2 (8.10±1.09 vs 3.27±1.09, P=0.018); reductions in fatigue were sustained throughout the entire follow up in both trials (MEASURE 1 Wk 156: 9.81±0.95; MEASURE 2 Wk 104: 9.27±1.13). Similar results were reported in both TNF- naïve and TNF-IR pts. Correlational analyses based on pooled data from both trials did not identify any BL factors that
consistently predicted improvement in fatigue activity at Wks 16, 52, and 104. A one-unit increase in BL BASDAI score (i.e. worsening) was a significant factor for achieving FACIT-F response at Wk 104 (P<0.02).

Conclusions: SEC provided sustained improvements in fatigue for up to 156 wks in both TNF-naive and TNF-IR pts with AS. Fatigue response was generally highest for TNF-naive pts.

Disclosure of Interest: M. Eberhardt Employee of: Novartis, Consultant for: AbbVie, BMS, Boehringer Ingelheim, Celgene, Eli Lilly and Company, Lilly, Pfizer, Roche, AbbVie, BMS, Biogen, Boehringer-Ingelheim, Celgene, Chugai, Eli Lilly, Eire, Genentech/Roche, GSK, Janssen, Lilly, Merck, Novartis, Pfizer, Sanofi, USV.

Background: The 2016 AASAS guidelines recommend the use of a 50% improvement in BASDAI score (BASDAI 50) as a threshold for discontinuing biologics. However, this will result in suboptimal management of disease in a substantial proportion of pts. 

Objectives: To evaluate the impact of switching to BASDAI 28 (BASDAI 28) from BASDAI 50 in pts with AS and to assess the impact on treatment satisfaction, comorbidities, and drug-related treatment costs.

Methods: 2000 patients with AS were enrolled in a phase IV, non-interventional, real-life, observational study across 14 countries. A total of 2400 patients were assessed for eligibility, and 2000 were included, with a baseline mean BASDAI score of 5.0 (±2.2). AS patients enrolled in this trial had a high disease activity and comorbidities in patients with active PsA or AS in daily practice treated with secukinumab in Germany.

Results: Patients were reassessed at 0, 3, 6, 12, and 24 months. The proportion of pts with an elevated CRP was highest in gr.2 at BL. Proportion males n (%) 117 (68.0%), 21 (65.6%), 27 (73.0%), 27 (73.0%), 28 (69.0%). Mean age ± SD (range) 52.8 (3.3–660.0), 18.3±17.8 (1.0–60.6), 19.7±52.7 (0.3–660.0), 11.8 (±2.6).

Conclusions: The baseline characteristics of the population are comparable with those in previous studies. Secukinumab was well tolerated, and the efficacy of secukinumab in this real-world setting is consistent with the results of previous randomized, controlled, clinical trials.

**Background:**

bDMARDs (TNF or IL-17 inhibitors) have been shown to be efficacious in patients with axial spondyloarthritis (axSpA). However, approximately 30–50% of patients who receive a first bDMARD do not respond well. Current practice in these patients is switching to another bDMARD but the scientific evidence for this attitude is sparse.

**Objectives:**

To evaluate the efficacy of switching bDMARDs in patients with axSpA.

**Methods:**

A systematic literature review until February 2016 was performed using Medline, EMBASE and Cochrane databases. Furthermore, abstracts from the previous EULAR and ACR meetings were reviewed. The research question was formulated according to the PICO(s) method: Population (axSpA patients); Intervention (bDMARD); Outcome (clinical response); and Setting (longitudinal studies with follow-up ≤12 weeks of follow up including data from ≥50 patients).

Data was extracted using a form developed for this specific purpose. The quality of the studies was assessed based on CEBM Oxford. Clinical response in patients who switched to a second bDMARD was determined and compared with the one achieved after receiving the first bDMARD (a TNF) in all cases. Results are shown as median (range) and relative frequencies (%).

**Results:**

In total, 7 studies out of 1506 retrieved citations were included. All studies included patients with ankylosing spondylitis (AS). The study design was prospective observational (n=3), retrospective observational (n=2), open-label trial (n=1) and post-hoc analysis from two RCTs (n=1). The level of evidence for all the studies was 4. In these studies, a total of 4678 patients received a first bDMARD and 1198 patients switched to a second bDMARD (a TNF in all cases except in 51 patients that switched to secukinumab). Baseline characteristics of patients included in the studies were:

- 41 (38–44) years old, 67% (64–74) males, 78% (74–89) HLA-B27+ and BASDAI before switching 6.1±1.5.
- Mean change from baseline\(^4\) −3.3±2.4 (0.017) −3.1±0.2 −2.9±0.2

**Conclusions:**

In patients with AS who do not respond to a first TNF, switching to another bDMARD (either a TNF or secukinumab) is efficacious in a considerable number of patients (30–50%). However, the clinical response after receiving a second bDMARD is logical in those in pts with active AS over ≥3 yrs. Secukinumab was well tolerated with a favorable safety profile consistent with that reported previously.

THU0398 SECUKINUMAB SUSTAINS INDIVIDUAL CLINICAL RESPONSES OVER TIME IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS: 2-YEAR RESULTS FROM A PHASE 3 TRIAL, MEASURE 2

X. Baraliakos 1, M. Schift 2, K. Pavelka 1, A. Widmer 1, D. Porter 1, C. Gailezz 1 on behalf of the MEASURE 2 study group. 1Ruhr-University Bochum, Herne, Germany; 2University of Colorado, Denver, United States; 3Charles University, Prague, Czech Republic; 4Novartis Pharma AG, Basel, Switzerland; 5Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: The assessment of achieving, maintaining or improving clinical response to biologics in ankylosing spondylitis (AS) is a part of treat-to-target recommendations aimed at optimising treatment goals.1

Methods: This is a post-hoc analysis of AS pts originally randomised to secukinumab 150mg (approved dose) who completed the 16wk-double blind treatment period, followed by long-term uncontrolled treatment. Shift analyses on ASAS response between Wks 2 and 16 and Wks 16 and 52 or 104 were performed on subgroups of secukinumab 150mg treated pts categorised by their highest ASAS criteria response at the earlier time point (ASAS non-responder [ASAS NR], ASAS20 responder, ASAS40 responder) and evaluating whether this response was improved, sustained, or worsened at the later time point, based on observed analysis.

Results: Overall, 65, 61 and 59 pts treated with secukinumab 150mg had available data to determine ASAS responses for shift analyses from Wk 2 to 16 and Wk 16 to 52 or 104, respectively. At baseline, mean age was 41.9±12.5 years, mean time since diagnosis was 7.0±8.2 years and mean Bath Ankylosing Spondylitis Disease Activity Index score was 6.1±11.5. Approximately half of the ASAS NR pts at Wk 2 or 16 subsequently developed an ASAS 20 or 40 response at the later time point of Wk 16 or 52, respectively. A total of 79% pts improved their response from ASAS20 to ASAS40 at Wk 16 (Wk 2 to 16) and another 44% pts improved their response from ASAS20 to ASAS40 at Wk 16 from Wk 16 to 52. A majority (84%) of ASAS40 responders at Wk 2 or 16 maintained this response at Wk 16 or 52, respectively. Similar trends were observed in responses from Wk 16 to 104 (Figure).

Conclusions: In this post-hoc pt-level analysis, the majority of secukinumab 150mg treated pts maintained or improved their ASAS responses over time, consistent with the sustainability of group-level ASAS responses reported previously.2 In particular, the majority of pts who achieved either an ASAS20 or ASAS40 response at Wk 2 or 16 maintained or improved their response at Wks 16, 52 or 104, respectively.

THU0399 TAPERING THERAPY OF TNF-INHIBITOR FOR MRI CHANGES IN SPONDYLOARTHRITIS

Y. Song, Y. Cui, X. Zhang, H. Zeng, Y. Zeng. Guangdong General Hospital, Guangzhou, China

Background: TNF-inhibitors could significantly improve disease activity of SpA patients, however, there is still no answer to the effect of prolonged the interval of TNF-inhibitors on MRI changes.

Objectives: The aim of the study was to investigate whether prolonged the interval of TNF-inhibitor injection could maintain SpA at low disease activity and improve imaging changes of sacroiliac joint.

Methods: A total of 98 SpA patients were included and 67 of them received TNF-i with or without conventional DMARDs. TNF-i included Etanercept, Infliximab and Adalimumab. The full dosage treatment was defined as patients received Etanercept 50 mg per week, Infliximab 4 mg/kg at 0, 2, 6 week and Adalimumab 40 mg every two weeks. The dose of Etanercept was gradually reduced to 50 mg every two weeks, 50 mg every three weeks and then 50 mg per month. The infusion of Infliximab was reduced to every 8 weeks, every 12 weeks and then every 16 weeks. The interval of Adalimumab injection was changed from 3 weeks to 4 weeks and then to two months. After full dose treatment in the first 3 months, patients who administrated TNF-i were evaluated every 3–6 months. According to laboratory tests including ESR, CRP and IgA levels, BASDAI, BASFI, ASDAS results and sacroiliac joint SPARCC scores, the interval of TNF-i treatment was gradually prolonged. Fat metaplasia, bone erosion, sclerosis and ankylosis changes on MRI were compared between baseline, 4–6 months and 1–2 years.

Results: After 3 months of treatment, inflammatory indexes, BASDI, BASFI, ASDAS results and sacroiliac joint SPARCC scores, the interval of TNF-i treatment was gradually prolonged. Fat metaplasia, bone erosion, sclerosis and ankylosis changes on MRI were compared between baseline, 4–6 months and 1–2 years.

Conclusions: In this study, we have demonstrated that increasing the interval of TNF-inhibitors was associated with the maintenance of disease activity and MRI changes in SpA patients. Further research is needed to evaluate if this observation can be confirmed in additional studies.

P<0.05, **P<0.01.
group. The SPARCC scores in TNF-i group also decreased significantly (Figure 1, P<0.01). There was no significant progression in fat metaplasia, bone erosions, sclerosis and ankylosis during the follow-up period (P<0.05). Even though the inflammatory indexes and clinical evaluation of non-TNF-i group did not improved remarkably, SPARCC score were significantly reduced at 4–6 months and 1–2 years follow up at baseline (P<0.05).

Conclusions: TNF-i could reduce clinical and imaging inflammatory degree. Prolonged the interval of TNF-i treatment could maintain low disease activity and improve bone marrow edema, whereas fat metaplasia, bone erosion, sclerosis and ankylosis were not exacerbated.

**THU0400**  RISK FACTORS OF SAGITTAL TRANSLATION AFTER PEDICLE SUBTRACTION OSTEOTOMY ON ANKYLOSING SPONDYLITIS

Y.-S. Park 1, J. Kim, J.-S. Park. Department of Orthopaedic Surgery, Hanyang University Guri Hospital, Guri city, Korea, Republic Of

Background: Few studies on sagittal translation and its risk factors after pedicle subtraction osteotomy (PSO) in ankylosing spondylitis (AS) patients have been conducted. There is also no study on overall evaluation of radiologic parameters as the candidate of its risk factor.

Objectives: The aim of this study was to report the cases of sagittal translation which developed after PSO in AS patients with kyphotic deformity and to analyze its risk factors.

Methods: The subjects of this study were 53 AS patients (58 cases) who underwent PSO to correct their kyphotic deformity between March 2006 and August 2016. The 53 subjects consisted of 45 males and 8 females. Their mean age was 39.3 ±12.7 years (range: 23–67). After osteotomy, the patient was examined for the presence of sagittal translation in the correction site through intraoperative radiograph. The low modified Stoke AS spine score (mSASSS) was measured before the surgery. The vertebral parameters such as lumbar lordosis angle, thoracic kyphotic angle, and sagittal vertical axis, and the pelvic parameters such as pelvic incidence, pelvic tilt, and sacral slope were also measured before and after the surgery.

The subjects were grouped according to the presence and absence of sagittal translation, and their radiologic parameters were compared. In addition, the correlation between sagittal translation and each parameter was analyzed. Complications that developed during and after the surgery were also analyzed.

Results: Sagittal translation developed in 18 subjects (34%) or 19 cases (35%) (p<0.001). The mean lumbar lordosis angle and the mean sagittal vertical axis of both the sagittal translation (ST) group and the non-sagittal translation (Non-ST) group were successfully corrected (p=0.000, respectively). A significant difference in preoperative mean sacral slope was observed between the groups (p=0.045). The ST group showed a significantly higher mSASSS (48±12.07) than the Non-ST group (36±18.62) (p<0.002). In the multivariate regression analysis, sagittal translation was positively correlated with mSASSS (odds ratio 1.34, P=0.002) and the preoperative sacral slope (odds ratio 1.46, P=0.0009), and negatively correlated with the difference between preoperative and postoperative thoracic kyphotic angle (odds ratio 0.68, P=0.01). Both groups showed no finding of permanent neurologic complication after the surgery.

Conclusions: The incidence of sagittal translation after pedicle subtraction osteotomy was closely related with the severity of ankylosis in AS patients. Therefore, when pedicle subtraction osteotomy is performed for AS patients with severe ankylosis and high sacral slope, it is required that surgeon considers sagittal translation which could induce neurologic complication.

**THU0402** ULTRASONOGRAPHY AND DUAL-ENERGY CT (DECT) DO NOT PROVIDE THE SAME QUANTIFICATION OF URATE DEPOSITION IN GOUT: RESULTS FROM A CROSS-SECTIONAL STUDY

1Rheumatology; 2Description; Hôpital Saint Philibert, LOMME, France; 3Cross-Sectional Study; Hospital; Paris, France; 4Radiology, Hospital Saint Philibert, LOMME, France

Background: Gout is due to monosodium urate (MSU) deposition in joints and soft tissues. Ultrasonography (US) and dual-energy CT (DECT) have been shown to be effective in identifying MSU deposits. Both techniques can examine topi size. DECT is effective to identify soft-tissue MSU deposits and US can show joint deposition with the double contour (DC) sign. It is unknown if these two techniques provide the same quantification of the extent of urate deposition on a given joint.

Objectives: The main objective of this study is to compare the tophus size measured by US and by DECT. The secondary objective is to evaluate the correlation between the prevalence of the US DC sign and the global volume of urate deposits measured by DECT.

Methods: This prospective cross-sectional study included patients fulfilling the 2015 ACR/EULAR criteria for gout. Patients underwent US and DECT examinations of their knees and feet. The largest US tophi was selected as the index tophus. US examination of the DC sign was performed on the femoro-patellar joints, talo-crural joints and 1st metatarsophalangeal joints. Total volume of urate deposits of knees and feet was measured by DECT. The primary endpoint was the intra-class correlation coefficient (ICC) of the volume of the index tophus measured by US and DECT [CI 95%].

Results: A total of 64 patients were included in the study, of which 35 patients presented with at least one US tophus. Patients were in average 64.2 ± 13.9 years old. 84.4% were male, had an average ACR/EULAR score of 13 ± 6.25, and disease duration was 12 ± 14.7 years. Overall, 44 patients (88.8%) were currently taking urate lowering therapy and 22 patients (34.4%) had clinical tophi. Out of the 35 US selected largest tophi, 6 tophi were not seen in DECT. Of the tophi identified with both techniques, 10 were localized in the feet and 8 in the knees. The ICC of the tophus volume assessment by US and DECT was 0.45 [0.12–0.69]. The average volume of the largest US tophi was 2.7 ± 6.5 cm³ and 1.5 ± 3.3 cm³ when measured by DECT. If the index tophus was localized in the knee, the ICC was 0.36 [0.0–0.82] and was 0.68 [0.37–0.86] if the tophus was in the
the foot. The Spearman correlation coefficient between the DECT urate volume and the number of joints with a positive DC sign was 0.15.

**Conclusions:** US and DECT do not provide the same assessment of tophus size. The correlation is improved when considering tophi localized in the feet. The number of joints with positive DC sign does not correlate to the volume of tophus deposition in the soft tissues measured by DECT.

**THU0403**

URATE-LOWERING TREATMENT AND RISK OF INCIDENT UROLITHIASIS IN PEOPLE WITH GOUT: A NESTED CASE-CONTROL STUDY

C.-F. Ku, J.-S. Chen. Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China

**Background:** A higher risk of uric lithiasis has been reported in gout patients. However, whether urate-lowering treatments, including both xanthine oxidase inhibitors and uricosuric agents, are beneficial to reduce the risk or uric lithiasis in gout patients has not been examined.

**Objectives:** To investigate the independent associations between urate-lowering treatment (ULT) and the risk of uricolithiasis in incident gout patients.

**Methods:** We conducted a nested case-control study based on the Taiwan National Health Insurance Research Database (NHIRD), which was used to identify 473,858 newly diagnosed gout patients from the period from January 1, 2000 through December 31, 2004. All these patients were followed until December 31, 2013. We considered patients who first diagnose uricolithiasis after the date of entry cohort (gout onset) as cases and the diagnostic date was defined as index date. Each case was matched up to five eligible controls whose follow-up period included the case’s index date by sex, birth of year and gout diagnosis year. And the index date of case was assigned to the matched controls. Odds ratios (ORs) and 95% confidence interval (CI) of uricolithiasis associated with cumulative defined daily dose (cDDD) of xanthine oxidase inhibitor and uricosuric agents were modeled using multivariable logistic regression.

**Results:** Gout patients with incident uricolithiasis (n=32,654) occurring after the initial diagnosis of gout aged 20–79 were age- and sex-matched 1:5 to 163,270 gout patients without uricolithiasis. After adjusting for age, sex, urbanization status, income, occupation, and pertinent drugs and comorbidities, the OR of uric lithiasis associated with use of ULT among gout patients were 1.04 (95% CI 1.00 to 1.07) for those with 28–90 cDDD, 0.95 (95% confidence interval 0.91–0.99) for 91–365 cDDD and 0.77 (95% confidence interval 0.73–0.82) for >365 cDDD, compared with those with a cDDD <28. The OR (95% CI) for uricolithiasis associated with xanthine oxidase inhibitor use was 0.94 (0.89–0.99) for 28–90 cDDD, 0.90 (0.84–0.97) for 91–365 cDDD and 0.73 (0.63–0.83) for >365 cDDD. For uricosuric agents, the OR (95% CI) for uricolithiasis among those with 28–91, 91–365 and <365 cDDD were 1.04 (1.01, 1.08), 0.94 (0.90–0.98) and 0.78 (0.73–0.84), respectively.

**Conclusions:** Higher ULT consumption was associated with a lower risk of uric lithiasis. Xanthine oxidase inhibitors associated with reduced uricolithiasis risk consistently across the range of consumption studied but for uricosuric agents inadequate cumulative dose results in a higher risk despite the risk reduced gradually with a higher cumulative dose.

SELF-REPORTED SEVERITY OF GOUT IN A PRIMARY CARE SETTING AND ASSOCIATED FACTORS – RESULTS FROM A GOUT SURVEY IN PRIMARY CARE

**Background:** Patients with gout are usually seen in primary care. There are numerous reports regarding severity of gout in cohort studies and patients seen in more specialized care, less is known about the spectrum of severity of the disease in primary care.

**Objectives:** To describe the pattern of self-reported disease severity of gout and predictors thereof in a primary care setting.

**Methods:** All patients above 18 with an ICD10-diagnosis of gout at a health care visit in primary care (Jan 2015 through Aug 2016) were identified from primary care (Jan 2015 through Aug 2016) were identified from primary care. All patients above 18 with an ICD10-diagnosis of gout at a health care visit in primary care (Jan 2015 through Aug 2016) were identified from primary care. All patients above 18 with an ICD10-diagnosis of gout at a health care visit in primary care (Jan 2015 through Aug 2016) were identified from primary care. All patients above 18 with an ICD10-diagnosis of gout at a health care visit in primary care (Jan 2015 through Aug 2016) were identified from primary care.

**Results:** Over 40% of patients with gout in a primary care setting rated their disease as moderate or severe. The validity of the patients rating was supported by other covariates reflecting disease severity. The observations that women and those with hyperlipidemia reported a more severe disease needs to be further explored.

KILLING TWO BIRDS WITH ONE STONE? THE DASH DIET AND THE RISK OF GOUT: 26-YEAR FOLLOW-UP OF A PROSPECTIVE COHORT

S.K. Rai1, T.T. Fung2,3, N. Lu4, S.F. Keller1, G.C. Curhan4,5, H.K. Choi1,4,5

1Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital; 2Department of Nutrition, Harvard T.H. Chan School of Public Health; 3Department of Nutrition, Simmons College; 4Channing Division of Network Medicine, Department of Medicine; 5Renal Division, Department of Medicine, Brigham and Women’s Hospital, Boston, United States

**Background:** The Dietary Approaches to Stop Hypertension (DASH) diet, which reduces blood pressure and is recommended in cardiovascular disease (CVD) (1,2), has also been found to lower serum uric acid (SUA) levels, particularly among those with hyperuricemia (3). Thus, the DASH diet may be particularly useful in gout care by reducing both SUA and CVD risk, especially among patients with hypertension which affects 74% of gout patients (4), thereby “killing two birds with one stone”. However, corresponding data for the risk of gout are not available. In contrast, a Western dietary pattern may increase the risk of gout.

**Objectives:** To prospectively examine the relation between the DASH and Western dietary patterns and the risk of gout among men.

**Methods:** Using the Health Professionals Follow-Up Study, we prospectively examined the relation between the DASH and Western diets and incident gout in 44,444 male participants with no history of gout at baseline. Using validated food frequency questionnaires, each participant was assigned a DASH score (higher intake of fruits, vegetables, nuts, legumes, low-fat dairy products, and whole grains, and low intake of sodium, sweetened beverages, and red and processed meats) and a Western pattern score (reflecting higher intake of red and processed meats, French fries, refined grains, sweets, and desserts). We identified incident cases of gout meeting the preliminary ACR survey criteria for gout, adjusting for potential confounders including age, total energy intake, body mass index (BMI), diuretic use, history of hypertension, history of renal failure, and intake of alcohol and coffee. We conducted stratified analyses to evaluate whether the association between the DASH and Western patterns scores and the risk of gout differed by other variables, including BMI, alcohol use, and hypertension status.

**Results:** During 26 years of follow-up, we documented 1,731 confirmed cases of incident gout. A higher DASH score was associated with a lower risk for gout (multivariable relative risk [RR] for extreme quintiles, 0.68 [95% confidence interval, 0.57 to 0.80]; P for trend <.001) (Table 1). In contrast, a higher Western pattern score was associated with an increased risk for gout (multivariable RR for extreme quintiles, 1.42 [95% confidence interval, 1.16 to 1.74]; P for trend <.005) (Table 1). These associations persisted regardless of BMI, alcohol use, and hypertension status, and there was no significant interaction between these variables (all P for interaction >.17).

*The response rate was 54%. Response rates were significantly lower in women overall and in men under the age of 50. Covariates that were significantly associated with more severe self-reported severity of gout in the bivariate logistic regression models (Table 1) were: female sex, hyperlipidemia, higher number of previous attacks, attack during last month, HAQ. In the multivariate analysis objective measures of gout severity such as more than ten previous attacks and attack during last month were strongly associated with the patients grading of severity, in addition to presence of hyperuricemia (Table 1).

**Conclusions:** Over 40% of patients with gout in a primary care setting rated their disease as moderate or severe. The validity of the patients rating was supported by other covariates reflecting disease severity. The observations that women and those with hyperlipidemia reported a more severe disease needs to be further explored.
Conclusions: The DASH dietary pattern is associated with a lower risk of gout, suggesting that its urate-lowering effect among hyperuricemic individuals translates to a lower risk of gout. Conversely, the Western dietary pattern is associated with a higher risk of gout. The DASH diet may provide an attractive preventive dietary approach for the risk of gout, particularly given the high level of cardiovascular comorbidities among this patient population.

THU0406 SERUM URIC ACID LOWERING TREATMENT APPEARS UNNECESSARY DURING HEMODIALYSIS

M. Andrés 1,2, R. Soriano 1, E. Oliveira 3, C. Trigo 3, M.D. Arenas 4, E. Pascual 2,5
1 Departamento de Medicina Clínica, Universidad Miguel Hernández; 2 Sección de Reumatología; 3 Servicio de Análisis Clínicos, Hospital General Universitario de Alicante; 4 Unidad de Nefrología, Hospital Vithas Perpetuo Socorro; 5 Emeritus Professor, Universidad Miguel Hernández, Alicante, Spain.

Background: Gout patients often suffer from renal disease, some ultimately developing end-stage renal disease (ESRD) and requiring hemodialysis (HD) replacement therapy. Though some reports suggested that tophi disappear after HD, urate-lowering agents are frequently continued, often based on persistent high SUA levels before HD. Also, the impact of SUA levels in the survival of patients on hemodialysis (HD) is under discussion.

Objectives: To assess the SUA reduction achieved under HD and analyze the kinetics of SUA in a week of intermittent HD.

Methods: SUA levels were determined before and after HD sessions in consecutive 96 patients with end-stage renal disease (ESRD), and compared through paired samples. Student’s t test. Variables related to HD were analyzed whether associated with SUA reductions >80% using Student’s t test or ANOVA. Also, a kinetics study on selected 10 patients with hyperuricemia (SUA before HD) <6.8 mg/dL throughout intermittent HD sessions in a week period was performed; differences in SUA levels were analyzed by repeated measures ANOVA.

Results: Patients were mean aged 66.5 years (SD±13.8), 62 males (64.6%). Mean time on HD replacement was 7.1 years (±7.2). Before starting HD, 43.0% had hyperuricemia and 21.6% reported gout. Sixteen (16.4%) continued on urate-lowering agents after HD. Mean SUA levels before and after HD session was 5.2mg/dL (±1.0) and 1.0mg/dL (±2.4), respectively. Mean SUA reduction following HD was 80.2% (95% CI 78.4–82.0); 51 patients (56.7%) showed SUA reduction ≥80%. HD-related variables Kt/V<1.3 (p=0.006) and blood efflux <400mL/min (p=0.004) significantly associated with achieving SUA reduction >80%. Figure shows the SUA kinetics study: SUA significantly reduced all over the period and persisted below hyperuricemia threshold (p=0.015).

Conclusions: Under HD replacement therapy SUA levels effectively reduced and persisted below saturation point, suggesting that urate-lowering therapy appears unnecessary for patients with gout and ESRD.

Disclosure of Interest: None declared.

THU0407 HIGH GOUT CLASSIFICATION SCORE IS ASSOCIATED WITH ULTRASOUND FINDINGS IN PATIENTS WITH CRYSTAL-PROVEN GOUT

Rheumatolog, Diakonhjemmet Hospital, Oslo, Norway.

Background: The recent ACR/EULAR classification (1) classify gout in patients with at least 8 out of maximum 23 points, but presence of monosodium urate crystals in a symptomatic joint/tophus alone is sufficient for gout classification without need for further scoring. It is not known how in crystal-proven patients with increased serum urate (sUA) the whole range of classification points distribute.

Objectives: To determine the distribution along the spectrum of ACR/EULAR criteria in crystal-proven patients with insufficiently treated sUA levels, and if disease factors in gout are associated with high classification scores.

Methods: Baseline data from a prospective observational study were used from patients with crystal-proven gout who presented after a recent gout flare. Included patients had at baseline insufficiently treated sUA level (>360 μmol/L [>6 mg/dl]). Demographic, clinical data and sUA levels were collected from September 2015 to December 2016 in one rheumatology department. Ultrasound of joints was assessed with one total score for double contour sign, tophus, and aggregates in several joints and tendons/entheses. The score for ACR/EULAR criteria for gout was calculated.

Results: 89 patients were included, with baseline mean (SD) age 56.0 (14.8) years, 92% males, 88% Caucasians, disease duration 7.9 (7.3) years, presence of palpable tophi 19%, ultrasound score 19.9 (13.8), serum urate 486 (90) μmol/L, creatinine 78 (18) mg/dl, creatinine clearance 78 (18) ml/min, ESR 14 (14) mmh, body mass index 29.4 (4.9) kg/m², comorbidity score [SCQ] 3.5 (3.2), and physical function [HAQ] 0.3 (0.5). All patients satisfied clearly the scoring arm of the classification criteria with a median (range) 19 (11 – 23) of 23 possible points (Figure 1). Patients with a median and higher score above the median (>19 points) vs. lower score reported more gout flares during the last 12 months (p=0.001), had longer disease duration (9.2 vs. 6.2 yrs, p=0.05), and a higher ultrasound score (23.9 vs. 14.9, p=0.001). The groups with high and low scores were similar for age, gender, ethnicity, level of education, BMI, physical function, comorbidity score, sUA level and kidney function.

THU0408 GOUT IS AN IMPORTANT PREDICTOR OF WORK DISABILITY IN BOTH MEN AND WOMEN

V. Sigurdardottir 1,2, P. Drivelegka 1, A. Svárd 2, L.T. Jacobsson 1, M. Dehlin 1, M. Ingvarsdottir 1, A. Skarphede 1, P. Drivelegka 1, A. Svárd 2, L.T. Jacobsson 1, M. Dehlin 1, V. Sigurdardottir 1,2.
1 Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Gothenburg; 2 Centre for Clinical Research Dalarna, Falun, Sweden.

Background: Gout is the most common form of inflammatory arthritis with a prevalence of 1.5% in our area in the age group 50–59 years (1). Gout has a
substantial association with several comorbidities. Studies on the impact of gout on work disability on a population level are scarce.

**Objectives:** The primary objective of the study was to investigate if gout was a predictor of work absenteeism exceeding 90 days in a calendar year, controlling for comorbidities and socioeconomic status in men and women separately. Another aim of the study was to explore if urate lowering therapy (ULT) attenuated the risk of work disability for gout cases.

**Methods:** Gout cases were defined in the population based health care database (VEGA) of the Western Swedish Health Care Region (WSHCR) by having a first diagnosis of gout in the years 2003–2009 by ICD-10 codes (M10 and M14.0) in VEGA. Cases were included if their age at the time of diagnosis of gout was ≥82 years. Five controls for each case, matched for age, sex and place of residence were chosen from the census register by Statistics Sweden. Individuals with any work disability in the year before the index year were excluded from analysis. Data on predefined comorbidities registered previous to the index year was collected from VEGA by ICD-10 codes. Data on prescribed medications was collected from the national prescription database. Data on educational level, income and number of days per calendar year with sick-leave and disability pension was provided by Statistics Sweden. Conditional logistic regression taking into account the 1-to-5 matched design of the study was performed in individuals without work disability in the year before the index date for the outcome of ≥25% (≥90 days) work disability in the year after the index year. Possible predictors of work disability for gout cases were analyzed using logistic regression.

**Results:** 3068 incident gout cases (females N=1,654 (18%) of working age without prior work disability were matched to 15,077 population controls. After matching, 3258 controls with prior work disability were excluded leaving 11,819 controls for analysis. Of the women with gout, 69 (12.5%) became ≥25% work disabled in the year after the index-year as opposed to 117 (6.1%) of the female controls, p<0.0001. 163 men with gout (6.6%) became ≥25% disabled vs. 377 (3.8%) of male controls, p<0.0001. After adjusting for comorbidities and educational level gout increased the risk of work disability to a similar extent for men (OR 1.4, 95% CI 1.2–1.8) and women (OR 1.9, 95% CI 1.4–2.6). Cardiovacular and renal comorbidity as well as alcoholism, female sex and low educational level (less than 12 years) were important predictors of work disability in gout patients whereas receiving ULT during the time period being studied did not attenuate the risk (OR 0.8, 95% CI 0.5–1.1).

**Conclusions:** Gout is a significant independent predictor of work disability in both men and women. ULT did not attenuate the risk of work disability early after diagnosis for gout cases in this study, possibly explained by under-prescribing and sub-optimal dosage as previously shown in our region (1).

**THU0409 NOT JUST A SWOLLEN BIG TOE: INCREASING ALL-CAUSE HOSPITALIZATIONS IN PATIENTS WITH GOUT IN THE UNITED STATES: 1993–2014**

G. Singh 1, A. Mithal 2, A. Mithal 3

**Background:** Gout is a disorder of uric acid metabolism and often presents as acute severe joint pain. However, several recent studies have highlighted systemic complications of associated hyperuricemia in patients with gout, including possible increased risk of renal and cardiovascular comorbidities.

**Objectives:** To study all-cause hospitalizations in patients with gout in the United States (US) from 1993 to 2014.

**Methods:** The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. We examined all inpatient hospitalizations in NIS from 1993 to 2014 with a primary or secondary diagnosis of gout, and compared them to total all-cause US hospitalizations during the same period. US population estimates and projections for the resident US population were obtained from the US Census Bureau.

**Results:** There were 789.8 million all-cause hospitalizations in 6.4 billion person-years of observation from 1993 to 2014 (123.4 hospitalizations per 1,000 person-years). During this time-period, 9,741,598 hospitalizations occurred in patients with gout (152.2 per 100,000 person-years). All-cause US hospitalizations increased from 33.7 million in 1993 to 35.4 million in 2014, an increase of 4.8% over 22 years (Figure, dotted blue line). All-cause hospitalizations in gout patients have increased from 167,441 in 1993 (64.2 per 100,000 person-year) to 854,475 in 2014 (267.9 per 100,000 person-years, a dramatic increase of over 410% (p<0.0001, Figure solid red line). In 2014, hospitalizations in gout patients accounted for over 4.6 million hospital days at a total national cost of over US $42.6 billion.

**Conclusions:** All-cause hospitalizations in patients with gout in the US have significantly increased by 410% in the last 22 years, almost hundred-fold of the 4.8% increase in US population all-cause hospitalization rate in the same time period. This calls for an increase need for identification and management of serious co-morbid conditions in patients with gout.

**THU0410 GOUT AND THE RISK OF INCIDENT ERECTILE DYSFUNCTION: A BODY MASS INDEX-MATCHED POPULATION-BASED STUDY**

N. Schlesinger 1, N. Lu 2, H.K. Choi 3, 1Medicine, Rutgers/ Robert Wood Johnson Medical School, New Brunswick; 2Medicine, Harvard Medical School, Boston, United States

**Background:** Gout is the most common inflammatory arthritis. Erectile dysfunction is common in the general population; however, evidence regarding erectile dysfunction among gout patients is limited.

**Objectives:** Our purpose was to study whether there was an increased risk of erectile dysfunction among gout patients, as compared with the general population.

**Methods:** We conducted a cohort study using The Health Improvement Network, a large electronic medical record database in the United Kingdom. Up to five individuals without gout were matched to each case of incident gout by age, enrolment time, and body mass index. Multivariate Hazard Ratios for erectile dysfunction were calculated after adjusting for smoking, alcohol consumption, comorbidities and medication use.

**Results:** We identified 2290 new cases of erectile dysfunction among 38,438 patients with gout (mean age 63.6 years) and 8447 cases among 154,332 individuals in the comparison cohort over a 5-year median follow up (11.9 vs. 10.5 per 1000 person-years, respectively). Univariate (age, entry time and body mass index-matched) and multivariate Hazard Ratios for erectile dysfunction among patients with gout were 1.13 (95% CI, 1.08 to 1.19) and 1.15 (95% CI, 1.09 to 1.21), respectively. In our sensitivity analysis, restricting gout cases to those receiving anti-gout treatment (n=31,227) the magnitude of relative risk was stronger than the primary analysis; (multivariate Hazard Ratios =1.29; 95% CI, 1.22 to 1.37).

**Conclusions:** This population-based study suggests an increased risk of erectile dysfunction among gout patients, supporting a possible role for hyperuricemia and inflammation as independent risk factors for erectile dysfunction.

TREATMENT WITH NERIDRONATE IN CHILDREN AND ADULTS WITH OSTEONECROSIS IMPERFECTA: DATA FROM OMERACT, NOT CONTROLLED, THREE-YEAR ITALIAN STUDY

A. Fassio, L. Idalazzi, O. Viapiana, C. Benini, E. Vantaggiato, A. Giolli, M. Rossini, D. Gatti. Rheumatology, Ospedale S. Giovanni Battista, Turin, Italy

Background: Osteonecrosis Imperfecta (OI) is a rare generalized connective tissue disease. Its main features are skeletal fragility and substantial growth delay. Patients with tophaceous gout, improves significantly with allopurinol.

Objectives: To assess the long-term efficacy and safety of the treatment in young adults.

Methods: A cohort of patients with gout (ARA/ACR-EULAR) from the GRESGO cohort; this analysis includes the patients with ≥1 clinical node(s) considered as tophi in the baseline visit. Tophi size had r=0.93 among the 3 evaluations (ITst, ITSc, ITScr) and r=0.3 with ITh. Inter- and intraobserver variability was 0.8 and 0.9 respectively; there was significant improvement (p<0.001) in ITS, sUA, painful, swollen, limited to motion joints, HAQ, EROQOL, VAS pain, VAS health (patient and physician) also improved significantly.

Conclusions: in patients younger than 20 years, while, in patients older than 20 years, BMD significantly increased from baseline only at month 18, 30 and 36 respectively. The mean ultralradial BMC significantly increased from baseline to any time point in patients younger than 20 years, while there were no substantial or statistically significant differences from baseline to any time point in patients aged older than 20 years. The mean of fractures observed in the 3 years of treatment was significantly lower than that observed in the 3 years before the start of treatment in both groups (table 1).

Most of AE were symptoms of an acute phase reaction, which was reported in 47.3% of patients younger than 20 years and in 22.8% of those older than 20 years. Serious adverse events (SAEs) were reported in 19 patients (34.5%) younger than 20 years and in 26 patients (22.8%) aged older than 20 years. None of the reported SAEs in both groups was considered as treatment-related.

Table 1. Results of number of fractures per patient during treatment in the two patient populations

THU0414 INCIDENCE AND PREDICTORS FOR NEPHROLITHIASIS IN GOUT PATIENTS AND THE GENERAL POPULATION

A.J. Landgren1, L. Jacobsson1, U. Lindström1, T.Z. Sandström1, E. Fjellstedt2, P. Drivelégka1, V. Sigurdardottir1, L. Björkman 1, M. Dehlin 1.

A well-known complication of gout is an increased risk for nephrolithiasis (NL). The incidence rate of NL in the general population varies in different studies between 85 and 170/100 000 person-years, with a peak incidence in the ages 40–49 years. Several medications used in gout patients could affect the risk for NL, including allopurinol, losartan, thiazide- and loop-diuretics. Effect of these medications on risk of NL in gout patients, and the general population, has only scarcely been studied.

Objectives: In this cohort study we investigated: 1) overall incidence of NL in gout and general population (GP) controls 2) risk for first time NL in gout patients vs general population (GP) controls, and 3) predictors for first time NL in both groups separately.

Methods: Gout patients were identified from the regional health care database in western Sweden (VEGA), containing ICD10-codes for all regional Healthcare visits from 2000. Matched (birthyear, sex, county) GP controls were selected from the population register. National registers and VEGA were used to retrieve information on comorbidities, socioeconomic factors and current medications at start of follow-up. The study population had to be above 19 years of age, without NL prior to start of follow-up, and living in the Western Swedish Health Care Region (WSHCR). Follow-up began 2006–01–01, or at the first gout-diagnosis if this occurred later, and ended at death, emigration or 2012–12–31, whichever occurred first. Incidence rates (IR) per 1000 person-years and hazard ratios (HR) were calculated. Possible predictors for NL were based on risk factors presented in the literature.

Results: 29,968 gout patients and 138,678 matched GP controls were included. In gout patients there were 678 NL-events (IR: 6.2 per 1000 ppyrs at risk (95% CI: 5.7–6.6)) and in GP controls 2125 (IR 3.9 per 1000 ppyrs at risk (95% CI 3.7–4.0)). Risk for NL was increased in gout (HR=1.49, 95% CI: 1.35–1.64), and was higher in men compared to women (p<0.0001) in all age groups for gout cases and controls. All comorbidities and medications were more frequent in cases compared to controls (p<0.0001) at start of follow-up. Risk-factors for NL such as kidney disease (KD), obesity, diabetes were 2–4 times more common in gout patients compared to GP controls. Predictor point estimates for NL were similar as kidney disease (KD), obesity, diabetes were 2–4 times more common in gout cases compared to GP controls. In patients with gout, male sex, diabetes mellitus (DM), obesity predicted NL, whereas use of loop diuretics was protective. Overall, the most commonly used CVD drugs did not increase the risk for NL in patients with gout.

THU0415 A STRUCTURED MONITORING PROGRAM FOR DRUG ALLERGY IN PATIENTS NEWLY INITIATED ON ALLOPURINOL

B.Y. Thong1, K.-Y. Gan2, B.-H. Ang3, 1Rheumatology, Allergy and Immunology; 2Pharmacy, Tan Tock Seng Hospital, Singapore, Singapore

Background: Allopurinol allergy (drug eruption, severe cutaneous adverse reactions [SCAR] and drug induced hypersensitivity syndrome [DIHS]) develops during the first 2–12 weeks after initiation. SCAR risk factors include Chinese ethnicity, HLA-B*5801 positivity and chronic kidney disease. HLA-B*5801 testing to prevent SCAR has not been shown to be cost-effective in Singapore.

Objectives: To retrospectively study whether a structured monitoring program (SMP) can lead to early diagnosis of allopurinol allergy and prevent development of SCAR/DIHS.

Methods: SMP patients (cases) managed by rheumatologists were compared with controls managed by non-rheumatologists during the study period 1 Jan 2015 to 30 Jun 2016. Cases upon initiation of allopurinol had baseline full blood count (FBC), serum creatinine (Cr), alanine aminotransferase (ALT) and aspartate aminotransferase (AST) measured. If drug eruptions/abnormal laboratory tests developed during monitoring, allopurinol was stopped. The electronic dispensing system and computerized medical records were used for collection of patient demographics, indication for allopurinol use, initiation dose, monitoring intervals, laboratory results and clinical features of drug allergy. This was compared with the control group without an SMP. Chi square tests were used to compare differences in proportions and Mann-Whitney U test for differences in medians. P value ≤0.05 was considered statistically significant.

Results: There were 61 cases and 30 controls with comparable age (p=0.81), ethnicity (~80% Chinese) (p=0.63) and estimated glomerular filtration rate, eGFR (p=0.72). There were significantly more cases with tophaceous gout (41% vs 10%, p=0.003), while more controls tumour lysis syndrome prophylaxis (30% vs 0%, p=0.001). Median (interquartile range, IQR) starting dose of 50 (50) mg was lower among cases versus controls of 100 (200) mg (p<0.001); all cases had baseline and follow-up laboratory tests compared to controls (p<0.001). Cases were followed up at a median (IQR) of 2 (1.1) weeks after initiation then 5 (2.0) weeks after the first visit, whereas controls were reviewed 8 (8.9) weeks after initiation, then 11 (4.6) weeks after the first visit. Two patients in the SMP group with normal eGFR developed maculopapular eruption (MPE), 1 elevated ALT/AST, and 1 both MPE and elevated ALT/AST within the first 14 days of initiation. One control with lymphoma and baseline eGFR 31 ml/min/1.73m² developed DiHS (fever, MPE, elevated ALT/AST less than twice upper limit of normal) 43 days after initiation for tumour lysis prophylaxis. This occurred while on 2-weekly monitoring of FBC, ALT, AST. There were no cases of SCAR in both groups.
Conclusions: SMP facilitates early diagnosis of allopurinol allergy/DiHS which occurred during the first 2–6 weeks after initiation. Whether early cessation of allopurinol prevents development of SCAR, and reduces the need for HLA-B*5801 testing will require a larger prospective study.

THU0416
RAPID TOPHUS RESOLUTION IN CHRONIC REFRACTORY GOUT PATIENTS TREATED WITH PEGLOTICASE

B. Mandell, 1 A. Yeo, 2 P. Lipsky, 3 1Department of Medicine, Cleveland Clinic, Cleveland, OH; 2Horizon Pharma, Lake Forest, IL; 3AMPEL BioSolutions, LLC, Charlottesville, VA, United States

Background: It has been suggested that the velocity of resolution of tophi in persons with chronic tophaceous gout is related to the serum urate levels. However, few studies have measured serum urate less than 4.0 mg/dL or in nonresponders. Pegloticase is a recombinant uricase conjugated to polyethylene glycol approved in the US for treatment of patients with chronic refractory gout. It profoundly decreases serum uric acid in responders to <1 mg/dL. The results from the pegloticase clinical trials provided the opportunity to determine the impact of persistent and markedly low levels of serum urate on the velocity of tophus resolution.

Objectives: To assess the velocity of tophus resolution in subjects treated with pegloticase for chronic refractory gout.

Methods: This analysis used results from two randomized controlled trials (RCTs) of 6 months duration. 2,3 For tophus measurements, serial standardized digital photographs were analyzed by a blinded reader using computer-assisted quantitative measurement software. Subjects were defined as responders and nonresponders based on maintenance of a serum urate <8 mg/dL during intensive monitoring periods after 3 and 6 months of treatment.

Results: During the 6 months of the RCTs, a total of 952 tophus measurements were analyzed in 87 subjects, including 341 in 30 responders; 361 in 36 nonresponders receiving pegloticase infusions; and 250 in 21 subjects receiving placebo infusions. Mean serum urate levels in these subjects were 10.1, 0.3 and 0.3 mg/dL at baseline, 3 months and 6 months in responders; 10.7, 8.9 and 9.6 mg/dL in nonresponders; and 10.2, 9.8 and 9.7 mg/dL in placebo treated patients, respectively. At baseline, the mean tophus area in responders was 581.6 ± 742.7 mm² (mean ± SD; n=90 toph); in nonresponders it was 676.5 ± 1416.6 mm² (n=93 toph); and in placebo treated subjects it was 672.9 ± 1039.5 mm² (n=68 toph). By regression analysis, the velocity of tophus resolution over the 6 months of treatment was 50.1 mm²/month in responders; 14.0 mm²/month in placebo-treated patients (responders vs placebo treated subjects, p=0.001). In responders, the mean time to total tophus resolution was estimated to be 347 days (11.5 months, with a range of 5.6–36.4 months). During the 6 month treatment period, the area under the curve (AUC) of multiple serum urate measurements in responders was 6,067.9 ± 6,781.6 mg/dL hr compared with 34,647.4 ± 8,586.7 for placebo treated patients, and a correlation coefficient of 0.59 ± 0.58 between the two groups (p=0.01).

Conclusions: Pegloticase treatment causes a rapid resolution of tophi in responders as predicted from the profound and persistent serum urate lowering associated with this therapy.

PERIPHERAL NEUROPATHY IN PATIENTS WITH GOUT: ALTERATIONS BEYOND LOCAL DAMAGE

C.O. Lopez Lopez, 1 E. Corzo Dominguez, 1 M.D.L.L. Montes-Castillo, 1 H. Llanas 2, E. Alvarez Hernandez 2, 1 Pellez Ballestas 2, R. Burgos Vargas 2, J. Vazquez-Mellado 2 1Rehabilitation; 2Rheumatology, Hospital General de Mexico, Mexico city, Mexico

Background: Peripheral neuropathies (PN), are peripheral nervous system disorders associated to several causes. According to distribution are classified as: Local (mononeuropathy [MNPI]) or Systemic (Multiple mononeuropathy [MNP]). and polyneuropathy (PNP)). PN in gout has been scarcely described. Previous reports only consider MNP of median nerve at the wrist and MNPI of the ulnar nerve at the elbow, due to tophus compression.

Objectives: To describe the frequency and characteristics of PN in patients with gout and its association to gout related variables, co-morbidity and treatment.

Methods: Consecutive patients in GRESGAH, a cohort of 450 gout (ARA/ACG/ACR-EULAR) patients seen for the first time at Rheumatology department and treated according to published guidelines for gout. Variables included: demographic, clinical, biochemical data, HAO and 3 questionnaires for PN (DN4, LANSS and MNSI) previously translated and validated in our country. We perform urate Conduction Studies (NCS) following AAME guidelines (Include:Sensory action potential [sural, ulnar and median nerves], Compound muscle action potential [peroneal, tibial, median and ulnar nerves] and late F-wave [tibial and ulnar nerves]). This protocol was approved by the local IRB and the patients signed an informed consent. Statistical analysis: Student’s t-test, Mann–Whitney U test and X2.

Results: We included 162 gout patients, 98% males, 72% tophaceous gout, 48% severe tophaceous gout (STG), mean age 49±12 years, 14±10 years of disease duration, educational level 8±4 years, BMI 27.9±4.6kg/m². According to questionnaires: 56% DNA, 45% MNSI and 36% LANSS could be classified as PN. Sixty five percent had abnormal NCS: MNP: 52%, most of them (58%) neuropraxis. PNP 35% and 13% MNPI in them, axonal damage was reported in 88%. MNPI localization: Median nerve/carpal tunnel (89%); peroneal nerve/ibidia halluces (14%); ulnar nerve/medial elbow (1%). In responders vs placebo treated patients (p=0.001). In responders, there was a significant correlation between serum uric acid and responders as predicted from the profound and persistent serum urate lowering associated with this therapy.

Conclusions: PN is common among gout patients, PN could be diagnosed by questionnaires (particularly DN4) and NCS in 65%. L-PN (median nerve most of them) and S-PN (STG) 35% of the patients were nonresponders vs placebo treated subjects (p=0.001). In responders, the mean time to total tophus resolution was estimated to be 347 days (11.5 months, with a range of 5.6–36.4 months). During the 6 month treatment period, the area under the curve (AUC) of multiple serum urate measurements in responders was 6,067.9 ± 6,781.6 mg/dL hr compared with 34,647.4 ± 8,586.7 and 42,451.1 ± 6,396.1 mg/dL hr in nonresponders and placebo treated subjects, respectively (p=0.001). In responders, there was a significant correlation between the velocity of tophus resolution and serum urate AUC (p=0.009).

THU0418
A PROOF-OF-CONCEPT STUDY: TREATING TO THE TARGET WITH URATE LOWERING THERAPY IN REAL-WORLD GOUT PATIENTS

C.A. Janssen, 1 T.L. Jansen, 2 M.A. Oude Voshaar, 3 H.E. Vonkeman, 3 M.A. van de Laar 1 1Arthritis Center Twente, Department of Psychology, Health and Technology, University of Twente, Enschede; 2Department of Rheumatology, Viecu Mecical Center, Venlo, Netherlands

Background: Gouty arthritis is a common, potentially disabling and increasingly prevalent disease [1]. Last year, the European League Against Rheumatism (EULAR) task force gave gout the updated 2006 recommendations for the management of gout [2,3]. The guideline stresses the application of a targeted approach when initiating urate lowering therapy (ULT) in gout patients for reaching the recommended urate target (sUA) target values. However, data on clinical outcomes of real-world gout patients treated according to this approach are limited.

Objectives: To examine the clinical outcomes achieved in two patient cohorts in which differing targeted ULT treatment approaches were employed, both aiming to reach the EULAR recommended sUA targets.

Methods: We conducted a retrospective chart review study. Gout patients were included that had been treated at the rheumatology departments of two clinical centers in the Netherlands, applying different targeted ULT treatment approaches. Patients in cohort A followed an approach combining two modes of action once allopurinol monotherapy failed to reach the predefined target, whereas patients in cohort B were treated with sequential monotherapy following allopurinol
monotherapy failure. Outcome parameters were defined to reflect the EULAR recommendations concerning ULT [3].

**Results:** A total of 177 patients were included in the study; 99 in cohort A and 78 in cohort B. The majority (N=146, 82.5%) of the included patients from both cohorts were able to meet the predefined sUA target of <360 μmol/L. In addition, more than half (54.10%) of the patients reached the stringent sUA target of <300 μmol/L. The proportion of patients reaching sUA targets did not differ significantly (p=0.51) between the cohorts, with 80.8% (n=80) of the patients in cohort A reaching the primary sUA target, compared to 85.7% (n=66) in cohort B (Figure 1). In total, patients following treatment with first-line allopurinol, second-line monotherapy options or second-line combination therapy, 102/124 (82.3%), 25/31 (80.6%) and 19/21 (90.5%) respectively, reached the primary sUA target.

**Conclusions:** This chart review provides a proof-of-concept of the treat-to-target approach in gout patients when a targeted approach with ULT is applied. Further pragmatic randomized studies to investigate differences between specific treatment regimes in gout patients, together with costs, safety and patient-reported outcome measures are needed.

**IMPROVED SURVIVAL OF POST-MYOCARDIAL INFARCTION PATIENTS TREATED WITH ZOFENOPRIL COMBINED WITH XANTHINE OXIDASE INHIBITORS AS COMPARED TO PLACEBO OR OTHER ACE-I**

C. Bentivenga 1, E.R. Cosentino 1, F. Ventura 1, G. Magi 1, I. Ricci lamino 1, S. Bacchelli 1, E. Ambrosion 1, D. Degli Esposti 1, N. Malavolta 1, S. Corvaglia 1, G. Vukatana 1, C. Berghi 1,2 on behalf of SMILE. 1Cardiac-Thoracic-Vascular Department, Azienda Ospedaliera Universitaria Sant'Oroli-Malpighi; 2Cardiac-Thoracic-Vascular Department, University of Bologna, Bologna, Italy

**Background:** Oxidative stress is increased in hyperuricemic patients with acute myocardial infarction (AMI). In these patients, use of sulhydrylACE-inhibitors (ACEIs), such as zofenopril or captopril, and xanthine oxidase inhibitors (XOIs), may potentially result in an enhanced antioxidant effect and improved survival. However, the benefit of such combination in post-myocardial infarction has never been verified.

**Objectives:** To test the usefulness of the combination therapy Zofenopril + XOI in improving survival free from MACE in post-AMI patients.

**Methods:** We re-analyzed the data of the four SMILE (Survival of Myocardial Infarction Long-term Evaluation) studies by grouping patients according to the type of ACEIs and the use of XOIs. 165 (31.4%) of the 525 patients were treated with XOIs (79 under zofenopril and 86 under placebo, lisinopril or ramipril), whereas 360 were not (192 zofenopril and 168 placebo or other ACEIs). In these four groups, we separately estimated the 1-year combined risk of major cardiovascular events (MACE, death or hospitalization for cardiovascular causes).

**Results:** MACE occurred in 10.1% of patients receiving zofenopril + XOIs, in 18.6% receiving placebo or other ACEIs + XOIs, in 13.5% receiving zofenopril without XOIs and in 22.0% receiving placebo or other ACEIs, but no XOIs (p=0.034 across groups). Rate of survival free from MACE was significantly larger in patients treated with zofenopril and XOIs than with other ACEIs with no XOIs (hazard ratio: 2.29 (1.06, 4.91), p=0.034). A non-significant trend for superiority of zofenopril + XOIs combination was observed vs. zofenopril alone [1.19 (0.54, 2.64), p=0.669] or vs. placebo or other ACEIs combined with XOIs [1.82 (0.78, 4.26), p=0.169].

**RISK OF TOTAL HIP AND KNEE REPLACEMENT IN GOUT PATIENTS PRIOR TO AND FOLLOWING DIAGNOSIS: A NATIONAL POPULATION STUDY IN TAIWAN**

C.-F. Kuo 1, J.-S. Chen, K.-H. Yu, S.-F. Luo. Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China

**Background:** Total joint replacement (TJR) is a major surgical procedure aiming to replace damaged natural joints with artificial prosthesis to restore function and alleviate pain. Total knee replacement (TKR) and total hip replacement (THR) are major surgical procedures aiming to replace damaged natural joints with artificial prosthesis to restore function and alleviate pain. TJR has been associated with increased risks of cardiovascular disease and death, particularly in men with a history of diabetes mellitus, renal failure, and gout. Whether gout associates with an increased risk of TJR independent of these primary risk factors is controversial, despite tophaceous or chronic deforming gouty arthritis may lead to joint destruction and subsequent TJR.

**Objectives:** We carried out a case control study using the National Health Insurance (NHI) database with full coverage of the general population of Taiwan to investigate the burden of TJR in gout patients at diagnosis compared to matched controls. We further followed incident gout patients and their matched controls after diagnosis to compare their subsequent risk for TJR.

**Methods:** The Taiwan National Health Insurance database was used to identify 74,729 new diagnosis gout patients in 2005. These were matched 1:1 to 74,729 controls by birth year and sex with people who did not have gout diagnosis or urate-lowering treatment prescription. Odds ratios (ORs) of total hip or knee replacement (THR or TJR) at diagnosis and hazards ratios (HRs) after diagnosis were estimated adjusted for gender, age at diagnosis, comorbidities, co-medications, place of residence, income and occupation.

**Results:** Gout was associated with adjusted ORs (95% CI) of 0.87 (0.54 to 1.40), 1.01 (0.57 to 1.79), 0.93 (0.64 to 1.35) for the THR, TKR and TJR at diagnosis, respectively. The incidence rate of THR or TKR in the patients with gout was 1.60 and 1.76 (per 1,000 person-years) which was higher than matched controls (0.99 and 0.98, respectively). Gout was also associated with an adjusted HR (95% CI) of 1.41 (1.19 to 1.68), 1.37 (1.16 to 1.61) and 1.37 (1.22 to 1.56) for developing THR, TKR and TJR.

**Conclusions:** Compared to matched controls people with gout did not have an increased risk of TJR at diagnosis but the risk increased substantially after diagnosis. Whether adequate urate-lowering treatment reduces the risk requires further study.

**FEMALE PRIMARY GOUT HAD ITS UNIQUE ULTRASOUND FEATURES**

D.F. Lin 1, X. Guo 1, J. Cao 1, Y. Wu 1, J. Gu 1. 1Rheumatology department; Ultrasound department, the 3rd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

**Background:** Primary gout is a metabolic disease occurred in male and post-menopause female in most cases. Though the ultrasound features of gout had been discovered for several years, no reports illuminated whether there would be difference presentations between different genders in the joints.

**Objectives:** We employed ultrasound instead of dual-energy CT to explore more refined pathological manifestation of primary gout in different genders.

**Methods:** All cases were confirmed as gout fulfilling 1997 ACR classification criteria. All cases excluded secondary gout induced by drug, tumor, hypertension, diabetes mellitus, renal failure. Ultrasound was performed during chronic stage of gout but not at acute attack. The process was done by 2 observers blinded to
SEL-212: ENHANCED SERUM URIC ACID CONTROL IN HYPERURICEMIC PATIENTS THROUGH SELECTIVE MITIGATION OF ANTI-DRUG ANTIBODIES AGAINST PEGASITASE

E. Sands1, A. Kivitz2, L. Johnston1, T.K. Kishimoto1, J. M. Sverzut2, F. Lioté1,3, T. Bardin1,3, H.-K. Ea1,3, M. Petraitis1, I. Apanaviciene1, D. Virviciute2.

Objectives: To assess the initial safety and impact on sUA levels and ADA formation of SEL-212, which is designed to be the first non-immunogenic uricase therapy for refractory gout.

Methods: Cohorts of hyperuricemic (sUA ≥ 6 mg/dL) patients consented to a single dose of 0.4 mg/kg pegasitase alone, SVG-R alone (0.03–0.5 mg/kg), or 0.4 mg/kg pegasitase co-administered with SVG-R (0.03–0.3 mg/kg, SEL-212). A total of 124 patients were included in this analysis. Patients were dosed at baseline and at days 1, 14, 21, and 30 days after dosing.

Results: Sixty-three patients were enrolled with a median age of 49.4 years. Mean baseline sUA was 7.4±1.3 mg/dL. Patients dosed with pegasitase alone showed an immediate drop in sUA, which returned to baseline levels by 14–21 days after dosing. Patients treated with SVG-R alone showed no meaningful change in sUA. A 0.5 mg/kg dose of SVG-R showed no detectable ADA at day 30, and all 10 subjects showed a decrease in ADA titers by day 100. Patients treated with SVG-R alone showed no meaningful change in sUA.

Conclusion: SEL-212 was generally well tolerated at effective dose levels. One SAE (grade 2 rash) was observed in the lowest of the three effective dose levels (0.1 mg/kg SVG-R). A second SAE was determined by the investigator to be not related to study drug. All SAEs fully resolved. No SAEs were observed with SEL-212 at the higher effective dose levels (0.15 or 0.3 mg/kg). The maximum tolerated dose was defined as 0.3 mg/kg.

a trained musculoskeletal radiologist. For each DECT, clinical and biochemical characteristics of each patient were collected retrospectively.

**Results:** 22 patients (men 77%), mean age 62.5 years and mean BMI 28.4 kg/m² were included. Mean gout duration was 108 ±114.4 months, mean of last available serum uric acid level was 520 ±193 μmol/L, and 15 patients had at least one clinical tophus. Mean estimated glomerular filtration rate (MDRD formula) was 47.27 ±1 m²/1.73 m². One patient was on hemodialysis and one had received kidney transplant.

A total of 39 DECT has been performed: 28 of peripheral joints and 11 of the spine (9 lumbar, 1 sacroiliac and 1 cervical). Spinal DECT were done in 10 patients to explore recurrent inflammatory pain (n=3 lumbar, 1 cervical and 1 buttock) or mechanical back pain (n=2 lumbar). 4 spinal DECT were performed in asymptomatic patients with extended peripheral tophi. Spinal MSU crystal deposits were disclosed by DECT in 83% (5/6) and 25% (1/4) of symptomatic and asymptomatic patients, respectively. In all painful patients, MSU crystal deposition was considered as a likely explanation of spinal symptoms. Spinal MSU crystal deposits was identified in apophyseal joints (n=5), cervical intervertebral disc (n=1) and yellow or interspinous ligaments (n=4). All involved apophyseal joints were eroded (figure 1). No vertebral bone erosion was observed. Categorification of spinal tophus was observed in 4 patients. DECT identified peripheral deposits in 15/18 (83.3%) patients. In peripheral DECT, bone erosions were observed in 71.4% and joint effusion in 32.1% of DECT positive peripheral joints. MSU crystal deposits were observed in tendons, cartilages or synovial membranes in 82.1% of positive DECT joints and in soft tissues in 64.3% of positive patients. MSU crystal deposits were calcified in 7 cases.

**Conclusions:** MSU crystal deposits at the spine are present in 60% of patients in this retrospective DECT study. DECT can represent a performing imaging procedure for their detection in symptomatic patients. Further studies are needed to assess the clinical utility of DECT of the spine in gout.

**THU0426 THE FIRST METATARSOPHALANGEAL JOINT (MTP1) IS NOT THE MAIN LOCALIZATION OF GOUT AT DIAGNOSIS IN SUB-SAHARAN AFRICA**

F. Kemta Lekpa, M.S. Doualla, H. Namme Luma, Service de Médecine Interne, Douala General Hospital, Douala, Cameroon

**Background:** Numerous data in sub-Saharan Africa suggest that MTP1 is not the hallmark of gout (1–5).

**Objectives:** We carried out this study with the aim to determine the joint most involved at the time of diagnosis of gout in Cameroon.

**Methods:** We performed a cross-sectional study in all outpatients seen at the Rheumatology unit of the Douala General Hospital, Cameroon, between 2004 and 2014. We included patients with diagnosis of gout according to ACR criteria 1997.

The main characteristics of gout at diagnosis were collected, particularly the joints involved. A p <0.05 was significant.

**Results:** At the end of this study, 511 patients (415 men and 96 women) with the diagnosis of gout were included. The mean age was 55.9±10.8 years. Joint pain (n=508, 99.4%) was the leading reason for consultation at the time of diagnosis. The knees (n=390, 62.6%), ankles (n=187, 39.0%), and MTP1 (n=128, 26.7%) were the most affected joints. Table 1 presents the frequency of the joints affected, comparing our results with those of the other African series. There was no difference between MTP1 and others joints location (particularly knees and ankles) according to age, sex, place of residence, duration of disease, uric acid level, and associated comorbidities (p >0.05).

**Conclusions:** MTP1 is not the joint most involved at the time of diagnosis of gout in sub-Saharan Africa. Diagnosis of gout should be considered before any inflammatory knee and ankle pain in patients from sub-Saharan Africa. Genetic studies would provide a better understanding of this feature.

**THU0426 LONG-TERM ADHERENCE TO URATE-LOWERING THERAPY IN GOUT: DO NOT BLAME THE PATIENTS**

F. Perez-Ruiz, I. Uriñagüena, S.P. Chinchilla, Rheumatology Division, Hospital Universitario Cruces and Biocrucices Health Research Institute, Baracaldo, Spain

**Background:** adherence to urate-lowering treatment (ULT) in patients with gout is reported to be lower than 50% in the first year, below 20% at 2-year, and worse than in other chronic conditions such as hypertension, diabetes, or hyperlipidemia.

**Objectives:** to evaluate adherence to ULT both overall and during follow-up, to compare it to the adherence to medications for associated comorbidities, and to explore potential causes for non-adherence to ULT.

**Methods:** transversal study of a nested cohort of patients in a gout clinic in the hospital setting who were scheduled for a follow-up visit during 6 consecutive months in 2016. General data of patients, along with variables related to gout and to comorbidity conditions are systematically retrieved at first visit; prescribed ULT doses, adherence, and serum urate levels were obtained during the follow-up visits. Adherence was retrieved as medication possession rate (MPR) according to pharmacy offices from government electronic databases (including ~98% of the general population). Also, MPRs of drugs prescribed for hypertension, diabetes (only oral), and hyperlipidemia were obtained; if more than one drug prescribed for any of the previous, the best adherence per comorbidity treatment was entered.

Good adherence was considered as MPR> 80 percent of that prescribed, target serum urate (sUA) as <0.36 mmol/L. Patients are educated at first visit and encouraged to be adherent from baseline through follow-up visits.

**Results:** data were available from 209 patients who were scheduled for a follow-up visit during the observation period; 14 (6.7%) patients did not attend the visit. This sample was formed by 90% male, only 55% had received ULT previous to first visit, median age was 65 years at follow-up visit, 47% could be an opportunity for further improvement.

Good adherence was considered as MPR> 80 percent of that prescribed, target serum urate (sUA) as <0.36 mmol/L. Patients are educated at first visit and encouraged to be adherent from baseline through follow-up visits.

**Conclusions:** adherence to ULT measured as MPRs in a cohort of educated comorbidity. Therefore, we cannot blame poor adherence on the patients anymore. Targeting absenteeism could be an opportunity for further improvement.

AMBIENT AIR POLLUTION AND RISK OF ACUTE GOUT FLARES: A TIME-SERIES STUDY

H.J. Ryu1, M.R. Seo 1, H.J. Choi 1, J. Cho 2, H.J. Baek 1, 1 Rheumatology, 2 Occupational and Environmental Medicine, Gachon University Gil Medical Center, Incheon, Korea, Republic Of

Background: Air pollution is caused by substances that consist of solid particles, liquid droplets, or gases including carbon monoxide (CO), nitrate (NO), sulfur dioxide (SO2), ozone (O3), lead, toxic product from tobacco smoke and particulate matter (PM). Inhaled air pollutants can induce oxidative stress and this can contribute to trigger or exacerbate systemic inflammation and autoimmunity. The relations of air pollution with rheumatic diseases have been reported, especially in rheumatoid arthritis, systemic lupus erythematosus, systemic sclerosis and juvenile idiopathic arthritis. Gout is an inflammatory disease caused by deposition of monosodium urate (MSU) crystals. Acute gout flare is initiated with activation of the NLRP3 inflammasome and release of IL-1β by MSU crystals. PM <10μm in diameter (PM10) exposure has been reported to activate NLRP3 inflammasome in airway epithelial cells. The influence of air pollutants including PM10 to acute gout flares has not yet been known.

Objectives: To investigate the association between air pollution and acute gout flares

Methods: We obtained data from the National Health Insurance Database between 2007 and 2015 in Incheon, Republic of Korea by Health Insurance Review and Assessment (HIRA) service. The HIRA data included age, gender, national health insurance type, diagnosis code based on the International Classification of Diseases version 10 (ICD–10), visit date, procedure code, and prescription code. We studied the subjects of age ≥19 years who visited emergency department (ED) due to acute gout flare between 2008 and 2015. An acute gout flare was defined as an ED visit due to gout (ICD-10, M10) with any prescription of non-steroidal anti-inflammatory drugs (NSAIDs), acetaminophen, or colchicine. Comorbidities and prescription history were collected. The data of ambient PM10, O3, NOx, CO, and SO2 levels were obtained from the Ministry of Environment data sources. We performed time-series study. The group means with Poisson regression distribution were used to investigate the association between single air pollutant level and acute gout flares. To examine the delayed effect of air pollutant exposure before the ED visit day on acute gout flare, we established cumulative lag models (averaging levels of consecutive days).

Results: The total number of ED visits for acute gout flare from 2008 to 2015 in Incheon was 139,665, including 48.8% of 40–59 year-old men. The ED visits for acute gout attack were most likely to occur in summer (29.1%). Among the ED cases of acute gout flares, 11.0% had a prescription history of allopurinol or flurbiprofen as an ED visit due to gout (ICD-10, M10) with any prescription of non-steroidal anti-inflammatory drugs (NSAIDs), acetylsalicylic acid, or colchicine. The prevalence of allopurinol and flurbiprofen prescription was higher in the summer. 20% of the ED cases of acute gout flares had multiple comorbidities. Acute gout flares showed more significant association with O3 in the cases with hypertension and use of NSAIDs, colchicine, or statins. PM10 was more significantly associated with acute gout flares in the cases with congestive heart failure.

Conclusions: Ambient air pollution can induce acute gout flares and its influence on acute gout flares may increase according to the comorbidities or medications.

FGF23 IN FIBROUS DYSPLASIA

H. Floere 1, S. Mandelikova 1, X. Fillela 1, A. Monegal 1, N. Guahabens 1, P. Peris 1, 1Rheumatology Department, 2Clinical Biochemistry Department, Hospital Clinic, Barcelona, Spain

Background: Fibrous dysplasia of bone (FD) is an uncommon skeletal disorder, caused by missense mutations of the GNAS1 gene and is characterized by the development of fibro-osseous lesions that replace normal bone. FD can present with a broad spectrum of clinical manifestations, including the development of hypophosphatemic osteomalacia which is due to the production of the phosphaturic hormone fibroblast growth factor 23 (FGF-23) by the dysplastic bone tissue. Nevertheless, the prevalence of this clinical complication is not well known.

Objectives: To analyse the serum levels of FGF-23 in patients with FD and determine their relationship with the extension and activity of the disease, as well as with serum phosphate levels.

Methods: Twelve patients (7F:5M) with FD with a mean age of 50.67±16.4 years (24–79) were included. The clinical reports of the patients were reviewed, with special attention to the extension and activity of the disease, number and location of the affected bones, clinical complications and treatments received. Serum FGF-23 values were recorded in all subjects (determined by Immunotopsics, CA, USA [measuring FGF23 C- terminal], normal value <100 RU/ml), as well as serum phosphate and calcium values, bone turnover markers and their evolution with treatment.

Results: Serum levels of FGF-23 were increased (>130 RU/ml) in 6/12 patients (50%). In patients with and without high FGF-23 levels the number of affected bones (2.2±2 vs. 1.9±1, respectively) and the skeletal locations of FD were similar as was the age in both groups of patients (48.2±14 vs. 53.2±19 years). In addition, FD disease activity and extension were similar in the two groups as were the bone turnover marker values (FAO, PINP and CTx). Strikingly, differences between serum phosphate values were not observed between the two groups (FGF-23 >130: 3.9±0.9 mg/dl vs. FGF-23 <130: 3.5±0.6 mg/dl). Indeed, none of the patients with high FGF-23 levels had low serum phosphate values. Following bisphosphonate (zoledronate) treatment, there were no significant changes in FGF-23 values by "subsequently, an increase of 123% was found in one patient receiving denosumab, although hypophosphatemia was not associated.

Conclusions: Patients with FD frequently present elevated FGF-23 values with no effects on serum phosphate levels, thereby suggesting the presence of an alteration in processing this protein in the dysplastic bone tissue in this disease. The role of denosumab treatment in FD and its repercussion on FGF-23 levels need further study.

PHARMACOKINETICS, PHARMACODYNAMICS, AND COMPARATIVE EFFECTIVENESS OF ALLOPURINOL VERSUS VERINURAD (RDEA3170) AND FEBUXOSTAT IN HEALTHY ADULT MALE SUBJECTS

J.T. VanderLugt 1, M. Gillen 2, X. Yang 3, J. Hall 2, J. Jasper Clinical Research & Development, Kalamazoo, MI; 2AstraZeneca, Gaithersburg, MD; 3Ardea Biosciences, Inc., San Diego, CA, United States

Background: Verinurad (RDEA3170) is a novel selective uric acid reabsorption inhibitor in clinical development for the treatment of gout and asymptomatic hyperuricemia.

Objectives: This Phase 1, single-blind, multiple dose, drug-drug interaction (DDI) study evaluated the pharmacokinetics (PK), pharmacodynamics, and tolerability of verinurad in combination with febuxostat (FBX) in healthy male volunteers.

Methods: Subjects were randomized to receive once-daily doses of FBX or verinurad or verinurad alone for 7 days, FBX + verinurad or FBX + placebo on days 8–14, and the alternative single agent (FBX or verinurad or placebo) on days 15–21. Subjects received either the combination of verinurad 10 mg + FBX 40 mg or verinurad 2.5 mg + FBX 80 mg. Serial plasma/serum and urine samples were drawn at predetermined time points on Days 7, 14 and 21, and assayed for verinurad, FBX, and uric acid. Baseline samples were drawn on Day –1. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).

Results: Of 23 randomized subjects, 20 completed the study. FBX 40 mg had no apparent effect on the plasma Cmax and AUC for verinurad 10 mg, whereas FBX 80 mg increased the plasma Cmax and AUC for verinurad 2.5 mg by 25% and 33%, respectively. Verinurad had no effect on FBX PK. Renal clearance of verinurad was unchanged by FBX.

The mean maximal reduction in serum uric acid (sUA) was 76% with verinurad 10 mg + FBX 40 mg compared with verinurad 10 mg (56%) or FBX 40 mg (49%) alone (Figure 1A) and was 67% with verinurad 2.5 mg + FBX 80 mg compared with verinurad 2.5 mg (38%) or FBX 80 mg (57%) alone (Figure 1B). Consistent with the mechanism of action (MOA) of verinurad, 24-hr fractional excretion of uric acid (FEUA) increased (2.5 mg: 7.6%; 10 mg: 12.8%) vs baseline (6.5% and 6.0%, respectively). Renal clearance of uric acid (CLUR) increased similarly (2.5 mg: 9.0 mL/min; 10 mg: 12.3 mL/min) vs baseline (8.3 and 7.3 mL/min, respectively).

The increases were maintained for 24 hours with verinurad 10 mg + FBX 40 mg (40%) vs baseline (6.4% and 6.5%; CLUR: 4.91 and 4.96 mL/min, respectively). The alternative single agent (verinurad 10 mg or ALLO 300 mg) on Days 8–14, the alternative single agent (verinurad 10 mg or ALLO 300 mg) on Days 15–21. Colchicine 0.6 mg was taken once daily from day –14. Serial plasma/serum and urine samples were drawn at predetermined time points on Days 7, 14 and 21 and assayed for verinurad, FBX, oxypurinol (OXY), colchicine, and colchicine acid. Baseline samples were drawn on Day –1. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).

Conclusions: No DDI was found with the verinurad 10 mg + FBX 40 mg combination and only a modest one with verinurad 2.5 mg + FBX 80 mg. Both combinations were safe and well tolerated and resulted in greater reduction of sUA than either verinurad or FBX alone. These results support the continued development of this novel approach for the treatment of gout and hyperuricemia.

THU0431 COMPARATIVE EFFECTIVENESS OF ALLOPURINOL VERSUS FEBUXOSTAT FOR PREVENTING INCIDENT RENAL DISEASE IN OLDER ADULTS: AN ANALYSIS OF MEDICARE CLAIMS DATA

J. Singh, J. Cleveland. University of Alabama at Birmingham, Birmingham, United States

Background: Large scale randomized studies are underway to assess whether compared to placebo, each XO-inhibitor, allopurinol or febuxostat, can prevent renal function loss. This evidence is needed and will confirm their nephroprotective potential. However, neither study will answer a key question: Does the renal protective effect of allopurinol differ from that of febuxostat?

Objectives: To assess the comparative effectiveness of allopurinol vs. febuxostat for preventing incident renal disease in elderly.

Methods: In a retrospective study using Medicare claims data, we included patients newly treated with allopurinol or febuxostat (baseline period of 183 days without either medication). We used 1:5 propensity-matched Cox regression analyses to compare the hazard ratio (HR) of incident renal disease with allopurinol use and allopurinol dose vs. febuxostat (reference category).

Sensitivity analyses included multivariable-adjusted regression models.

Results: There were 31,465 new allopurinol or febuxostat treatment episodes in 26,443 patients; 8,570 ended in incident renal disease. Crude rates of incident renal disease per 100,000 person-days were 53 with allopurinol vs. 93 with febuxostat. Crude rates of incident renal disease per 100,000 person-days were lower with higher daily doses: allopurinol < 200 mg, 200–299 mg and >300 mg/day with 65, 48 and 43; and febuxostat 40 mg and 80 mg/day with 93 and 89, respectively.

In propensity-matched analyses, compared to febuxostat use, allopurinol use was associated with lower HR of incident renal disease, 0.61 (95% confidence interval: CI: 0.49, 0.77). Compared to febuxostat 40 mg/day, allopurinol doses <200, 200–299 and >300 mg/day were associated with lower HR of incident renal disease, 0.75 (95% CI: 0.65, 0.86), 0.61 (95% CI: 0.52, 0.73) and 0.48 (95% CI: 0.41, 0.55), respectively. Sensitivity analyses using multivariable-adjusted regression confirmed these findings.

Conclusions: Allopurinol was more effective than febuxostat in preventing incident renal disease in elderly patients. Future studies need to examine the mechanism of this renal benefit of allopurinol.

THU0432 PHARMACOKINETICS, PHARMACODYNAMICS, AND TOLERABILITY OF COMBINATION MULTIPLE DOSE ADMINISTRATION OF VERINURAD (RDEA3170) AND ALLOPURINOL IN ADULT MALE SUBJECTS WITH GOUT

J. Hall 1, M. Gillen 2, X. Yang 3, S. Liu 3, S. Walker 3, V. Clauson 1, M. Kankam 3, 1Ardea Biosciences, Inc., San Diego, CA; 2AstraZeneca, Gaithersburg, MD; 3Vince and Associates Clinical Research, Inc., Overland Park, KS, United States

Background: Verinurad (RDEA3170) is a novel selective uric acid reabsorption inhibitor in clinical development for the treatment of hyperuricemia and gout.

Objectives: This Phase 1, single-blind, multiple dose, drug-drug interaction study evaluated the pharmacokinetics (PK), pharmacodynamics (PD), pharmacokinetic interactions and tolerability of verinurad in combination with allopurinol (ALLO) in adult male subjects with gout.

Methods: Adult males with gout, aged 18–75 years, with serum uric acid (sUA) ≥8 mg/dL were randomized to receive once-daily oral doses of ALLO 300 mg or verinurad 10 mg alone for 7 days, ALLO 300 mg + verinurad 10 mg on Days 8–14, and the alternative single agent (verinurad 10 mg or ALLO 300 mg) on Days 15–21. Colchicine 0.6 mg was taken once daily from day –14. Serial plasma/serum and urine samples were drawn at predetermined time points on Days 7, 14 and 21 and assayed for verinurad, ALLO, oxypurinol (OXY), colchicine, and colchicine acid. Baseline samples were drawn on Day –1. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).

Results: Subjects (N=12) were mostly white (58.3%) with mean (SD) age of 51 (10) years. Following multiple doses, ALLO had no effect on Cmax and AUC of verinurad. ALLO Cmax was increased 33% but AUC was unaltered by verinurad. The Cmax and AUC for OXY, the active metabolite of ALLO, were reduced 32% and 38%, respectively, by verinurad. Colchicine plasma exposures were unaltered by verinurad. ALLO had no effect on urinary excretion of verinurad, whereas urinary excretion of OXY increased 19% by verinurad. The mean maximal decrease in sUA was 65% with verinurad + ALLO compared with verinurad (51%) or ALLO (43%) alone (Figure). Consistent with the mechanism of action (MOA) of verinurad, 24-hr fractional excretion of uric acid (FEUA) and clearance of uric acid (CLUR) were increased in the absence (9.2% and 11.5 mL/min, respectively) of ALLO (20% and 11.5 mL/min, respectively) versus baseline (4.5% and 5.7 mL/min) or ALLO alone (3.7% and 5.0 mL/min). Consistent with its MOA, ALLO decreased the amount of uric acid excreted in 24-hr urine (363 mg) compared with baseline (683 mg), verinurad alone (739 mg) or verinurad + ALLO (522 mg) but had no effect on FEUA or CLUR. No
serious AEs, discontinuations due to AEs, or clinically significant laboratory or ECG abnormalities were noted.

Conclusions: Although a modest drug–drug interaction was found between verinurad and ALLO, the combination was safe and well tolerated at the studied doses and resulted in greater reduction of sUA than either alone. These results support the evaluation of verinurad + ALLO as an alternative once-daily treatment option for hyperuricemia and gout.

THU0434 PHARMACODYNAMIC EFFECTS AND SAFETY OF VERINURAD (RDEA3170) IN COMBINATION WITH FEBUXOSTAT VERSUS FEBUXOSTAT ALONE IN ADULTS WITH GOUT: A PHASE 2A, OPEN-LABEL STUDY

R. Fleischmann1, P. Winkle2, J. Hall3, S. Valdez4, S. Liu5, X. Yan3, L. Hicks3, M. Hernandez-Illas6, 1University of Texas, Southwestern Medical Center, Metropolex Clinical Research Center, Dallas, TX; 2Anaheim Clinical Trials, Anaheim, CA; 3Ardea Biosciences, Inc., San Diego, CA; 44QPS MRA (Miami Clinical Research), Miami, FL, United States

Background: Verinurad (RDEA3170) is a high-affinity, selective URAT1 inhibitor in development for the treatment of gout and asymptomatic hyperuricemia.

Objectives: This Phase 2a, randomized, open-label, multicenter study investigated the multiple-dose pharmacodynamics (PD), pharmacokinetics (PK), and safety of oral verinurad in combination with febuxostat versus febuxostat alone in adults with gout (NCT02246673).

Methods: Patients aged ≥18 and ≤75 years with gout and serum uric acid (sUA) ≥8 mg/dL were randomized to 1 of 5 cohorts to receive febuxostat (40 mg and 80 mg) alone and in combination with verinurad (dose range 2.5 mg to 20 mg; 4 treatment periods per cohort, each treatment period 7 days). Medications were administered once daily ~30 min after breakfast. Colchicine 0.6 mg for gout flare prophylaxis was initiated at approximately Day -14 (start of urate-lowering therapy [ULT] washout) or Day -7 if not on ULT. Serial blood and urine samples were measured at preset intervals on Days -1, 7, 14, 21, and 28 for PD and PK endpoints. Safety assessments included adverse events (AEs) and laboratory, electrocardiograms, and vital sign parameters.

Results: Sixty-four patients were randomized (n=12–14 per cohort). Serum PD data pooled across cohorts demonstrated maximal % decrease in sUA from baseline (Emax) at 8–12 h after dosing. Addition of verinurad to febuxostat decreased sUA in dose-dependent manner (Figure 1). Greater sUA reductions were observed for dose combinations of verinurad ≥5 mg with febuxostat 40 mg versus febuxostat 80 mg alone. The rate of urinary uric acid excretion was reduced by febuxostat alone, but comparable to baseline levels with verinurad combined with febuxostat. Verinurad plasma exposures increased with verinurad dose and were comparable for febuxostat 40 mg and 80 mg doses. No drug-drug interaction on verinurad and febuxostat plasma PK parameters was observed. Verinurad at doses from 2.5 mg to 20 mg was well tolerated, with no serious AEs, withdrawals due to AEs, or renal-related events. The most frequent treatment-emergent AE possibly related to study medication was pain in extremity, in 2 patients receiving verinurad. Laboratory values and vital signs showed no clinically meaningful changes. There were no cases of serum creatinine elevation ≥1.5x baseline.

Conclusions: Verinurad coadministered with febuxostat dose-dependently decreased sUA while maintaining urinary uric acid levels comparable to baseline. All dose combinations of verinurad and febuxostat in this study were generally well tolerated with no serious AEs or renal-related events during combination treatment.

THU0435 PHARMACODYNAMICS, PHARMACOKINETICS, AND SAFETY OF VERINURAD (RDEA3170) IN COMBINATION WITH FEBUXOSTAT VERSUS FEBUXOSTAT ALONE AND VERINURAD ALONE IN JAPANESE ADULTS WITH GOUT OR ASYMPTOMATIC HYPERURICEMIA: A PHASE 2A, OPEN-LABEL STUDY

M. Shiramoto1, S. Liu2, Z. Shen1, J. Hall2, 1SOUSSIKAI PS Clinic, Fukuoka, Japan; 2Ardea Biosciences, Inc., San Diego, CA, United States

Background: Verinurad (RDEA3170) is a high-affinity URAT1 inhibitor in development for the treatment of gout and asymptomatic hyperuricemia.
RESULTS: Seventy-two patients with gout (n=37) or hyperuricemia (n=35) were randomized in this study. Addition of verinurad (2.5 mg to 10 mg) to febuxostat (10 mg, 20 mg, or 40 mg) decreased SUA in dose-dependent manner (Figure). Verinurad coadministered with febuxostat increased the amount of uric acid recovered in urine (Aeur), compared with baseline and the same dose of febuxostat administered alone, yet comparable with benzbromarone. Plasma CrmA and AUC exposures of verinurad and febuxostat exhibited dose proportional increases within the investigated dose range. No clear PK drug-drug interaction of verinurad and febuxostat with each other was observed. Verinurad at doses from 2.5 mg to 15 mg was well tolerated, with no serious AEs or withdrawals due to AEs. One treatment-emergent AE (diarrhea) was considered possibly related to both verinurad and febuxostat. Laboratory values and vital signs indicated no clinically meaningful changes.

CONCLUSIONS: Verinurad coadministered with febuxostat dose-dependently decreased SUA while maintaining Aeur comparable to benzbromarone. All dose combinations of verinurad and febuxostat in this study were generally well tolerated.

THU0437 IMPACT OF DIURETICS ON THE URATE LOWERING THERAPY IN PATIENTS WITH GOUT: ANALYSIS OF AN INCEPTION COHORT

L. Ranieri1, C. Contero2, M. Andrés1,2,1, Sección de Reumatología, Hospital General Universitario de Alicante, 2Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain

Background: Use of diuretics is a common bystander in patients with gout, and it has been reported to impact response to allopurinol [1,2] and likely lead to treatment failure and refractoriness. However, after the introduction of new urate-lowering therapies (ULT) and treat-to-target strategies, whether this inconvenient effect of diuretics persists has not received critical attention to date.

Objectives: To analyze the impact of the diuretic therapy on the response to ULT in patients with gout.

Methods: Retrospective analysis of an inception cohort in patients with crystal-proven gout (Jan2014-Nov2016). Patients were classified according to the use of diuretics (loop and/or thiazide) at baseline. The primary outcome variables were the reduction of serum uric acid (SUA) levels and the achievement of different objectives of SUA (6, 5, and 4mg/dL); as secondary outcome variable the maximum dose of ULT was registered, as well as other clinical, analytical, and ULT-related data. A comparative analysis was performed according to the use of diuretics, using Student’s t and chi-2 tests. Also, the analysis was stratified according to the ULT used.

Results: The inception cohort included 225 patients with an average age of 66 years (SD 14.1), being 98.2% of them men. The median duration of gout inclusion was 4 years (p25–75 1–10) and 21.3% presented tophi. At baseline, the median (p25–75) SUA and estimated glomerular filtration rate were 8.2 mg/dL (7.2–9.2) and 75.9 mL/min (27.2–88.3), respectively. A total of 98 patients

Table 2. Multivariate analysis of the predictive values for septic arthritis in patients with acute gout attack and those with septic arthritis*
Lack of Predictive Value of the NIAID/FAAN Criteria to Identify Subjects with Evidence of Immune Activation and Post-Hoc Designation of Pegloticase-Treated Subjects as Meeting NIAID/FAAN Anaphylaxis Criteria

J.-J. Liang, A. Kavanaugh, A. Yeo, P. Lipsky

Background: The NIAID/FAAN criteria have been widely applied to identify anaphylaxis despite having only modest specificity.1

Objectives: To evaluate the predictive value of the NIAID/FAAN criteria to identify evidence of immune activation in subjects with chronic refractory gout treated with pegloticase in randomized clinical trials (RCTs) who experienced infusion reactions (IRs), by assessing the capacity of biochemical testing for immunologic activation to confirm the likelihood of anaphylaxis.

Methods: During the RCTs supporting the approval of pegloticase for treatment of chronic refractory gout, subjects remained on therapy despite becoming nonresponders, which reflected the development of anti-drug antibodies (ADA); ~60% of subjects continued to receive pegloticase despite elevated ADA titers and many had IRs. In subjects receiving pegloticase every 2 weeks (q2w), 22/85 (26.5%) had a total of 43 IRs and 34/84 (40.5%) receiving pegloticase every 4 weeks (q4w) had a total of 70 IRs. 21/22 (95.5%) and 29/34 (85.3%) subjects with IRs in the q2w and q4w groups, respectively, were nonresponders. The 113 total IRs were categorized post hoc as to whether they met NIAID/FAAN criteria for anaphylaxis. Six IRs in 6 subjects met criteria, 53 IRs in 33 subjects had only one feature and were designated as “hypersensitivity”, and 54 IRs in 29 subjects had no features and were designated “other”. The clinical courses of these IRs and whether they were associated with elevated tryptase levels as a measure of mast cell degranulation or complement consumption as a measure of immune complex formation were assessed.

Results: Of all 852 infusions in subjects receiving q2w pegloticase, 43 (5.0%) were associated with IRs as were 70 of 830 infusions (9.5%) in subjects receiving q4w pegloticase. Of the 70 IRs associated with q4w administration, 3 (4.3%) met the criteria for anaphylaxis, 31 (44.3%) for hypersensitivity and 36 (51.4%) were other. The respective values for subjects receiving pegloticase q2w were 3/43 (7.0%), 22/43 (51.1%), and 18/43 (41.9%). A total of 14 IRs (12.4%) were associated with elevated tryptase and 31 (27.4%) with decreased complement CH50 levels. Immunologic abnormalities were not significantly different in the 3 groups, with 16.7%, 17.0%, and 7.4% of anaphylaxis, hypersensitivity and other IRs, respectively, having increased tryptase; and 0%, 30.2%, and 27.8%, respectively, having decreased complement. No subjects were classified as experiencing anaphylaxis by investigators, none required hospitalization, and 82 of the 113 IRs were attributed to pegloticase.

Conclusions: Post-hoc designation of pegloticase-treated subjects as meeting NIAID/FAAN criteria for anaphylaxis was not associated with a higher frequency of biochemical evidence of immune activation or a more severe clinical course. In pegloticase-treated subjects, the NIAID/FAAN anaphylaxis criteria did not identify subjects with IRs associated with elevated tryptase and decreased complement CH50 levels.

| sUA: serum uric acid; BMI: body mass index; DM: diabetic mellitus; eGFR: estimated glomerular filtration rate; CH50: chronic kidney disease.

Conclusions: Early-onset gout exhibited higher sUA and was associated with obesity but not with hypertension, diabetic mellitus and renal insufficiency. Longer disease duration and lower BMI were associated with tophi in the early-onset gout patients.

More Obesity and Higher Serum Uric Acid in Early-Onset Gout Patients in South China

Background: Gout incidence increases in a linear fashion with age until 70 years. It was reported that there was a trend of earlier onset gout. Few studies about clinical features of early-onset gout in China are reported.

Objectives: To investigate the characteristics of early-onset gout in south China.

Methods: We conducted a matched cohort study using a population based administrative health database that includes all outpatient visits, hospital admissions, vital statistics, and dispensed medications for all residents in British Columbia, Canada. Gout cases were defined using one ICD-9/10 code (274/M10) from a
physician or hospital visit. To ensure incident gout, we required that all cases have ≥10 years of prior registration without a gout diagnosis. Gout cases were matched 1:1 with controls on age, sex, and cohort entry time. Prior VTE events were excluded after matching. VTE was defined using ICD-9/ICD-10 codes plus use of oral anti-coagulant. We calculated incidence rate ratios (IRR) and age, sex, and entry time matched multivariable hazard ratios (HRs) for the risk of VTE. Sensitivity analyses were conducted to assess for unmeasured confounders (e.g., obesity).

**Results:** Among 105,307 individuals with newly diagnosed gout (61% male, mean age of 55 yrs), we observed 1,212 VTE events (mean follow-up time of 5.3 yrs). The fully adjusted HR was 1.27 (95% CI, 1.18–1.39) (Table 1). Our results remained significant in the sensitivity analyses (OR of 2.0 between gout and unmeasured confounder and a 50% prevalence for obesity). There were 437 incident VTE events within 3 yrs prior to the gout diagnosis. Compared to controls, during the 3rd, 2nd, and 1st yrs before gout diagnosis, the fully adjusted HRs for VTE in patients with imminent gout were 1.51, 1.58, and 1.73. The corresponding HRs in the 1st, 2nd, 3rd, 4th, and 5th yrs after gout diagnosis were 1.54, 1.39, 1.37, and 1.32, respectively.

*Adjusted for Charlson comorbidity index, cancer, alcoholism, hypertension, seizures, trauma, healthcare utilization, NSAIDS, HRT, glucocorticoids and fractures, surgery within 1 year before entry cohort.*

**Conclusions:** Patients with gout have an increased risk of VTE. The risk increases gradually before gout diagnosis, peaks in the year prior to gout diagnosis, and then progressively declines. Our findings suggest that hyperuricemia or gout associated inflammation may be a contributing factor for VTE.

HYPERURICEMIA IS ASSOCIATED WITH INCREASED INTEGRATED SAFETY OF LESINURAD, A NOVEL URIC ACID REABSORPTION INHIBITOR FOR THE TREATMENT OF GOUT

M.A. Becker1, R.T. Keenan2, P.P. Khanna3, K. Bos4, J. Li5, J. Hu6, W.B. White6. 1University of Chicago, Chicago; 2Duke University School of Medicine, Durham; 3University of Michigan, Ann Arbor; 4AstraZeneca Pharmaceuticals, Wilmington; 5Formerly Ardea Biosciences, Inc, San Diego; 6University of Connecticut School of Medicine, Farmington, United States

Background: Lesinurad is a selective uric acid reabsorption inhibitor recently approved at 200 mg daily in combination with a xanthine oxidase inhibitor (XOI) for the treatment of hyperuricemia associated with gout in patients who have not achieved target serum uric acid on an XOI (allopurinol or febuxostat) alone.

Objectives: To investigate the safety profile of lesinurad (LESU), we integrated safety data based on: (1) 3 large, pivotal, placebo-controlled, 12-month phase III (core) trials evaluating LESU 200 mg and LESU 400 mg in combination with an XOI, and (2) 2 extension studies, in which LESU-treated patients continued to receive LESU + XOI at the same dose and initially placebo-treated patients were randomized to receive LESU 200 mg or LESU 400 mg in addition to the XOI provided in the preceding core trial.

Methods: Safety data were pooled from the 3 core studies and 2 12-month extension studies using descriptive statistics for patients receiving ≥1 dose of study medication. To adjust for varying treatment durations, treatment-emergent adverse events (TEAEs) are expressed as exposure-adjusted incidence rates (number of subjects with events per 100 person-years [PY]).

Results: In the core studies, adverse event rates were comparable for XOI alone and LESU 200 mg + XOI groups for any TEAEs, serious TEAEs, and TEAEs leading to discontinuation (Table 1). Adverse event rates were higher with LESU 400 mg + XOI. Major adverse cardiovascular event (MACE) rates, which included cardiovascular death, myocardial infarction, or stroke, in the core studies were 0.71 (95% CI 0.15, 2.08), 0.96 (0.26, 2.47), and 1.94 (0.84, 3.82) per 100 PY for XOI alone and LESU 200 mg + XOI groups, respectively.

THU0443 HYPERURICEMIA IS ASSOCIATED WITH INCREASED CORONARY ARTERY CALCIFICATION IN MEN BUT NOT WOMEN

M.I. Dehlin1, P. Drivelakga1, V. Sigurðardottir1, O. Angénäs2, L.T. Jacobsson1, H. Forsblad d’Elia1,3. 1Dept of rheumatology and inflammation research, Institution of medicine, Sahlgrenska Academy, University of Gothenburg; 2Department of Cardiology, Sahlgrenska University Hospital, Gothenburg; 3Departments of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden

Background: Hyperuricemia is closely associated to cardiovascular disease although it has not been definitively established whether it is a marker or a causative agent. Serum uric acid (sUa) is strongly linked to the metabolic syndrome, hypertension (HT), dyslipidemia (DL) and higher BMI and higher CRP (hsCRP). CACs, reflecting calcification of coronary arteries, was determined (using computed tomography) in a Swedish cohort of 30 000 men and women aged between 50 and 64 years. A comprehensive pilot study in 1111 individuals was completed in 2012. In this pilot study we have examined the relation between CACs and sUa

Methods: In the SCAPIS pilot study we identified 1106 (552 males) individuals who were screened for traditional CVDRFs such as HT, DL, diabetes mellitus (DM), smoking, physical activity (PA), educational level (EDU), BMI, high sensitive CRP (hsCRP). CACs, reflecting calcification of coronary arteries, was determined according to Agatston. We measured sUa and related quartiles to CACs with multiple logistic regression analyses adjusting for traditional CVDRFs. CAC was defined positive if ≥1.

3Departments of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden

Objectives: Examine the association between sUa and CAC in men and women separately.

Methods: In the SCAPIS pilot study we identified 1106 (552 males) individuals who were screened for traditional CVDRFs such as HT, DL, diabetes mellitus (DM), smoking, physical activity (PA), educational level (EDU), BMI, high sensitive CRP (hsCRP). CACs, reflecting calcification of coronary arteries, was determined according to Agatston. We measured sUa and related quartiles to CACs with multiple logistic regression analyses adjusting for traditional CVDRFs. CAC was defined positive if ≥1.

Results: Age, BMI, smoking status, hsCRP, HT and DL showed no differences between sex while presence of CAC and diabetes was twice as common in men (Table 1). The three upper quartiles of sUa, (≥306 μmol/L), all significantly (p<0.05) predicted presence of CACs in men even adjusting for HT, DL, DM, smoking, PA, EDU, BMI, hsCRP and age in multivariate logistic regression, but not in women (Table 2).

Conclusions: Higher levels of sUa is associated with presence of CACs in men but not in women. This may merely reflect the earlier onset of atherosclerosis in men or possibly suggest biological differences in the effect of sUa on calcification of coronary arteries between sexes.

alone, LESU 200 mg + XOI, and LESU 400 mg + XOI, respectively. Renal-related TEAE rates in the core studies were 5.6, 7.3, and 15.4 per 100 PY, respectively. Longer exposure in the core + extension studies did not result in increases in any TEAEs, serious TEAEs, or TEAEs leading to discontinuation (Table 2). MACE rates were low in the core + extension studies, at 1.05 (95% CI 0.50, 1.39) and 1.48 (0.81–2.48) in the LESU 200 mg + XOI and LESU 400 mg + XOI groups, respectively. Renal events in the core + extension studies were lower in the LESU 200 mg + XOI than LESU 400 mg + XOI group at 8.6 and 14.6, respectively.

Conclusions: Lesinurad at the approved dose of 200 mg once daily demonstrated a consistent, acceptable safety profile. There were no new safety concerns in the core + extension studies.

Acknowledgements: This study was funded by Ardea Biosciences/AstraZeneca. None declared.

Methods: The Skåne Healthcare Register includes information on all health care visits with given ICD10-coded diagnoses for all citizens in the region (total population 1.3 million). SHR was searched for all adult (≥18 years) residents in Skåne region in year 2014, who between 1980 and 2014 had received at least one diagnosis of non-gout crystal arthropathy (ICD-10 code M11.0-M11.9) by any physician. The crude point prevalence at December 31st 2014 and the cumulative incidence in the calendar year 2014 were calculated. In addition, we examined the 2014 age- sex- standardized point prevalence and cumulative incidence of non-gout crystal arthropathy according to occupation (white collar blue collar with high or low skilled occupations), income (low/middle/high) and level of education (primary school/high school/university).

Results: The crude 2014 point prevalence and 2014 cumulative incidence of non-gout crystal arthropathy were 0.23% (0.22% - 0.24%) and 21.5 (18.6–24.3) cases per 100 000 persons at risk, respectively. Compared to women, men had numerically but not significantly higher prevalence (0.26% vs 0.20%) and incidence (24.6 vs 18.5 per 100 000 persons). This pattern remained regardless of age. The mean (SD) age of a person with prevalent non-gout crystal arthropathy was 71.5 (14.4) years. Both prevalence and incidence increased with increasing age and were highest in individuals ≥85 years (prevalence 1.4%), but decreased with years of education. Persons with middle income and blue collar high skilled occupation (e.g. skilled agricultural, forestry and fishery workers and craft and related trades workers) had the highest point prevalence and incidence of non-gout crystal arthropathy (figure).

Conclusions: Although considerably less prevalent than gout in southern Sweden non-gout crystal arthropathy affects about 0.2% of the adult population, i.e. a similar prevalence as for psoriatic arthritis in the same region. The prevalence increases with age and is highest among individuals aged 85 years or higher. There is a socioeconomic gradient with more affected individuals among people with lower level of education, middle income, and more manual work.

CO-MORBID GOUT IS ASSOCIATED WITH INCREASED CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH TYPE 2 DIABETES, BUT NOT CARDIOVASCULAR EVENTS OR MORTALITY

M. Milan1, S.K. Patel2, B. Wai1, P.M. Srivastava1, R.R.C. Buchanan1,1,2, L.M. Burrell1,2, 1Department of Medicine, Austin Health; 2Department of Medicine, University of Melbourne, Melbourne, Australia

Background: Gout is an inflammatory arthropathy characterised by elevated serum uric acid levels. In Australia, gout has a prevalence of 1.7 - 4%. This increased to 10% in a community based Australian patients with type 2 diabetes, although elevated serum uric acid did not predict cardiovascular (CV) or all-cause mortality. To date, the long-term outcomes of patients with diabetes and comorbid gout being followed up in the hospital out-patient setting have not been studied.

Objectives: To compare cardiovascular risk factors and long-term outcomes and mortality in patients with type 2 diabetes according to the presence or absence of gout.

Methods: 1,405 patients with type 2 diabetes were prospectively recruited from the outpatient setting at Austin Hospital. Baseline cardiovascular risk factors and comorbidities were identified. Patients were classified as having gout if they gave a history of gout or were taking medication for the treatment of gout. For statistical analysis, patients with diabetes (Group 1) were compared to those with diabetes and gout (Group 2).

Cardiovascular events and long-term CV mortality were assessed over a 10 year period.

Results: There were 1,329 patients with diabetes (Group 1, 95%) and 76 with diabetes and gout (Group 2, 5%). Patients with gout were older (68±11 vs. 64±12y, p<0.004), more likely to be male (80% vs. 59%, p=0.201). Results

- Serum uric acid levels in both groups. Comparison of results from baseline and after 6 months

- PGA (P=0.009), TJC and SJC (P=0.003), and SF-36 Bodily Pain (P<0.0001) for patients without clinically apparent tophat at baseline indicated significant improvements in serum UA (P<0.0001), flares (P<0.0001), PGA (P<0.0001), TJC and SJC (both P<0.0001), HAQ-DI (P<0.0001), and SF-36 Bodily Pain (P<0.0001).

Conclusions: These results indicate that chronic refractory gout patients may present with or without clinically apparent tophi. Tophaceous patients are distinguished by more tender and swollen joints, greater disability, and greater arthritis severity, but otherwise are similar to nontophaceous patients. Both groups had significant clinical benefit over 6 months of treatment with pegloticase.

EVIDENCE BASED DEVELOPMENT OF CRITERIA FOR COMPLETE RESPONSE IN PATIENTS WITH CHRONIC REFRACTORY GOUT

N. Schlesinger1, P. Khanna2, A. Yeo3, P. Lipsky4, 1Department of Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; 2Rheumatology, University of Michigan, Ann Arbor; 3Horizon Pharma, Lake Forest, IL; 4AMP/ELP BioSolutions, LLC, Charlottesville, VA, United States

Background: Preliminary criteria for remission in gout patients have recently been proposed. These include serum urate, acute flares, tophus, pain and patient global assessment. These preliminary criteria were based on consensus exercises and have not yet been tested in a large clinical trial database of chronic gout patients. Because of the availability of clinical results from subjects with chronic refractory gout treated with pegloticase (8 mg every 2 weeks), a mammalian recombinant uricase conjugated to polyethylene glycol that is approved in the US for treatment of adult patients with chronic gout refractory to oral urate lowering therapy, the utility of these proposed criteria could be assessed.

Objectives: To test the utility of the preliminary criteria to discern a complete response (CR) in subjects with chronic refractory gout treated with pegloticase (8 mg every 2 weeks).

Methods: Data from two randomized clinical trials (RCT) evaluating the impact of pegloticase therapy in subjects with chronic refractory gout were examined. Of this group of subjects, 42% had persistently lowered serum urate and 58% did not meet the urate-lowering endpoint of this RCT. Initially, individual patient data was reviewed to establish the frequency with which subjects, who were responders to pegloticase, met the proposed remission criteria. Mixed modeling was therefore employed on data from these subjects to determine the components of the model that best correlated with time of maximum benefit.

Results: Of 34 pegloticase responders, 25 (73.5%) met the published criteria of remission. However, pain assessment was often an outlier; data obtained by visual analogue scale and Medical Outcomes Study Short Form-36 questionnaire often differed. Mixed modeling was therefore employed on data from the subjects meeting criteria for remission to determine the components that best correlated with time to maximum benefit.

Other clinical outcome measures assessed in the clinical trial were also analyzed. Besides serum urate levels, the mixed model also included components of response that best correlated with time of maximum benefit included assessment of tophus (analyzed photographically), number of swollen joints, number of tender joints and patient global assessment. Using these criteria, 25 of the responders (73.5%) and 29.4% of the entire pegloticase-treated population met criteria for a CR. The median time to reach a CR was 252 days (range: 126-896 days). Of interest, when a decrease in serum urate was omitted, 6 (12.2%) of the pegloticase nonresponders also met criteria for a CR. Patients receiving placebo did not achieve the composite outcome measure considered as CR.

Conclusions: These results have defined criteria for achieving CR in individuals with chronic refractory gout treated with pegloticase and suggest that most individuals who persistently lowered their serum urate levels while on pegloticase reached criteria for CR in a median of 8.4 months. This composite CR definition can serve as an evidence-based target aiding the design and endpoints of future clinical trials.

CHARACTERIZATION OF PATIENTS WITH CHRONIC REFRACTORY GOUT WHO DO AND DO NOT HAVE CLINICALLY APPARENT TOPHI: RESPONSE TO PEGLOTICASE

N.L. Edwards1, J. Singh2, O. Troum3, A. Yeo4, P. Lipsky5. 1Department of Medicine, University of Florida, Gainesville, FL; 2University of Alabama at Birmingham, Birmingham, AL; 3Keck School of Medicine, University of Southern California, Los Angeles, CA; 4Horizon Pharma, Lake Forest, IL; 5AMP/ELP BioSolutions, LLC, Charlottesville, VA, United States

Background: The term “chronic refractory gout” defines a subset of chronic gout patients who are either intolerant of or unresponsive to standard uric acid (UA) lowering therapy (ULT). Subjects (N=85) meeting this definition were enrolled in a study of pegloticase (8 mg every 2 weeks [q2w], the approved dose), a mammalian recombinant uricase conjugated to polyethylene glycol that is approved for the treatment of chronic gout refractory to conventional oral ULT. Of this group of subjects, 73% had clinically apparent tophi, whereas 27% did not.

Objectives: To determine the clinical characteristics and response to pegloticase therapy in patients with chronic refractory gout with and without clinically apparent tophi.

Methods: This analysis used results from two pivotal randomized controlled trials to assess the clinical characteristics and the efficacy of pegloticase (8 mg q2w) in patients with chronic refractory gout with or without tophi at baseline. The results for serum urate (UA), flares, Patient Global Assessment (PGA), tender and swollen joints (TJC and SJC), BMI, body pain, Health Assessment Questionnaire-Disability Index (HAQ-DI), and the Arthritis-Specific Health Index (ASHI) and Bodily Pain from the Medical Outcomes Study Short Form 36 item (SF-36) were determined for each group.

Results: The analysis included patients with chronic refractory gout. 62 with tophi at baseline and 23 with no clinically apparent tophi. Differences in baseline characteristics between the two groups were similar at baseline, with the only significant differences in mean values between tophaceous and nontophaceous gout groups as follows: TJC, 14.2 vs. 5.00 (P<0.01); SJC, 10.9 vs 3.4 (P<0.003); ASHI, 50.4 vs 64.7 (P<0.003); and HAQ-DI, 1.3 vs 0.6, respectively (P<0.001). Other measures of disease impact and comorbidities were not significantly different between groups. Treatment with pegloticase 8 mg q2w resulted in significant and comparable reductions in serum UA in both groups. Comparison of results from baseline and after 6 months of treatment for patients with tophi at baseline indicated significant reductions in serum UA (P<0.0001), flares (P<0.0001), PGA (P<0.0001), TJC and SJC (both P<0.0001), HAQ-DI (P<0.0001), and SF-36 Bodily Pain (P<0.0001). Results for patients without clinically apparent tophi at baseline indicated significant improvements in serum UA (P<0.0001), flares (P<0.004), PGA (P<0.009), TJC (P<0.01), SJC (P<0.003), SF-36 Bodily Pain (P=0.03), and ASHI (P<0.001).

Conclusions: These results indicate that chronic refractory gout patients may present with or without clinically apparent tophi. Tophaceous patients are distinguished by more tender and swollen joints, greater disability, and greater arthritis severity, but otherwise are similar to nontophaceous patients. Both groups had significant clinical benefit over 6 months of treatment with pegloticase.

Scientific Abstracts
Thursday, 15 June 2017 377
Background: Gout is associated with significant burden and risk of readmission. Little is known about readmissions among Gout patients on a national level in the United States.

Objectives: The aim of this study was to describe unplanned hospital readmission rates among adult gout patients and assess predictors of readmission.

Methods: We analyzed the 2013 National Readmission Database (NRD) to quantify readmission rates among Gout patients. The NRD includes weighted discharge data from 21 geographically diverse states accounting for 49.3% of the U.S. population. It includes approximately 14 million un-weighted discharges nationwide. NRD data is from patients with non-Medicare payers (Medicaid, private, self-pay, or other). Gout hospitalizations were identified using the International Classification of Diseases, ninth Revisions, Clinical Modification (ICD-9-CM) diagnosis code 274.0x. All hospitalizations for patients age ≥18 were included. In efforts to exclude routine readmissions, we excluded those admissions related to pregnancy, those for chemotherapy, admissions where the patient was readmitted the same day as they were discharged, who had deaths during the same index hospitalization and hospitalizations for less than 24 hours, and those with missing discharge. We utilized Chi-square tests, t tests and Wilcoxon rank-sum tests as appropriate. Survey logistic regression was used to assess the relationship between potential predictors for readmissions and the odds of at least one 30-day unplanned readmission. This analysis was chosen given the NRD data, which involves nested, weighted observations that are inherently stratified in clusters to produce national estimates.

Results: A total of 10708 index hospitalizations which had Gout as the primary diagnosis were included in the analysis. Among those with a primary Gout diagnosis, there were 1215 30-days readmissions (11.3%). 14.33% percent of patients with Gout as the primary diagnosis on index hospitalization were readmitted within 30 days. Significant predictors of readmission included CHF, CKD, AF, APR-DRG severity level 3 or 4 (OR 1.51, 95% CI, 1.01–2.38 and OR 2.10, 95% CI, 1.06–4.58), discharge to specialized care (OR 1.47, 95% CI, 1.07–2.02), discharge to home health care (OR 1.35, 95% CI, 1.03–1.77), and discharge against medical advice (OR 3.85, 95% CI, 1.50–9.91), were significantly associated with 30-days readmission after adjusting for demographics, comorbidities, hospital characteristics, payer type, and the APR-DRG severity scale (Figure 1B).

Conclusions: In a national readmissions database, 11.3% of patients admitted with a primary diagnosis of Gout were readmitted within 30 days. Significant predictors of readmission included CHF, CKD, AF, APR-DRG severity level 3 or 4 and any discharge other than routine.

THUO451 A METHOD FOR COUNTING CALCIUM PYROPHOSPHATE CRYSTALS IN THE SYNOVIAL FLUID

P. Montagna, R. Brizzolara, S. Soldano, M. Cutolo, M.A. Cimmino. Department of Internal Medicine, University of Genova, Genova, Italy

Background: Identification of calcium pyrophosphate dihydrate (CPP) crystals in the synovial fluid (SF) from inflamed joints provides a definitive diagnosis of CPP deposition disease (CPPD) (1). CPP crystals may also be found in non-inflamed joints, allowing symptomatic periods (2). SF analysis and CPP crystals count could be used to evaluate disease activity during follow-up. It is more difficult than the count of monosodium urate (MSU) crystals, already tested in a previous work (3), for CPP crystals show different shapes, are often mixed and non-birefringent.

Objectives: To study an objective method for counting CPP crystals in the SF.

Methods: The SFs aspirated from the knees of 15 consecutive patients (8 men) affected by CPPD diagnosed according to the EULAR definition were analysed. Cytological evaluation included SF leukocyte and differential count. For crystal detection, a small drop of fresh SF was placed on a glass slide and examined by compensated polarized microscopy (400x). To facilitate crystal count, the slide was divided into 4 equal parts drawing a cross with a pencil. The count was performed by continuous viewing and for each field both the number of birefringent and non-birefringent crystals was noted. Two observers evaluated separately 6 SFs and repeated the count after 24 hours. SFs were divided into 4 groups: SFs with <50, from 50 to 400, from 401 to 1200, and >1200 crystals.

Results: Mean time needed for the count was 60 minutes. Inter-reader agreement was 0.68 (0.47–0.88) for CPP crystals, 0.68 (0.50–0.85) for the birefringent ones and 0.62 (0.38–0.81) for the non-birefringent ones. Intra-reader agreement was 0.48 (0.17–0.78) for the first examiner and 0.30 (0.14–0.74) for the second. In 7 patient the SF was aspirated from an inflamed knee. Crystal number did not correlate with the presence of knee inflammation (r=0.41; p<0.19), the SF volume (r=0.43; p=0.2) and the number of leukocytes (r=0.36; p=0.2). The % of PMN (r=0.25; p=0.37), and the presence of intracellular crystals (r=0.31, p=0.02) were significantly different from those of non-birefringent. Actively inflamed joints had a higher SF volume [11 ml (10–20 ml) vs. 2 ml (1–10 ml), p=0.03] and a higher percentage of PMN [72% (9–94%) vs. 12% (6–88%), p=0.02]. SF with intracellular crystals showed also a higher percentage of PMN (57% vs. 34–39%, and 3–46% vs. 0.006).

Conclusions: Our preliminary results indicate that CPP crystal count is less reliable and more time-consuming that that of MSU crystals. Non-birefringent crystals show lower inter-reader agreement than birefringent ones.

THUO452 IMMEDIATE AND LONG TERM EFFICACY OF ANAKIRNA IN ACUTE FLARES DUE TO HYDROXYAPATITE CALCIFICATIONS: A REAL-LIFE EXPERIENCE OF 13 CASES

P. Zufferey, R. Valcov, A. So. DAL, CHUV, Lausanne, Switzerland

Background: Calcifications composed of hydroxyapatite (HA) crystals can induce acute and severe pain accompanied by signs of acute inflammation. In a previous pilot study, we have shown that anakirina was effective in acute flare of calcific periarthritis of the shoulder in the short term

Objectives: The goal of this retrospective observational study was to confirm these results in a larger series of patients, extending the observation to other localizations and to report on the long-term follow-up.

Methods: All consecutive patients with an acute flare due to HA deposition and treated with anakirina between March 2011 and November 2016 were included. Pain was defined as symptoms of acute pain at rest present for ≥10 days. None of the patients had corticosteroid therapy in the last 2 weeks, none had responded to at least 48 hours of high doses of NSAIDs or other rheumatologic diseases explaining the symptoms. Clinical evaluation consisted of patient assessment of pain by VAS (10mm scale) at days 0, 1, 3, 21 and joint mobility. CRP and ESR measurements, ultrasound and x-ray examinations were performed before the
Heart and Carotid Changes in Fifty-Three Gout Patients Treated with Xanthine Oxidase Inhibitors: A Follow-Up Study

R.N. Gancheva 1,2, A. Kundraziev 1,2, M. Ivanova 1,2, T. Kundraziev 2,3, Z. Kolarov 1,2, 1Medical Faculty; 2Medical University; 3Faculty of Public Health, Sofia, Bulgaria

Background: Gout connects to cardiovascular (CV) morbidity and higher risk of death due to CV events. A few ultrasound studies assess the way in which heart and vessels change over time in gout patients (pts). It is still unclear whether treatment with allopurinol or febuxostat reduces to some extent target organ damage.

Objectives: We aimed to establish heart and vessels alterations developing over time in gout pts and to find out whether treatment with allopurinol or febuxostat is associated with a change in these structures.

Methods: A total of 53 gout pts were examined and divided into two groups: 31 gouty arthropathy without tophi, 24 males and 7 females aged 55.8±12.3 years and 22 gouty tophi, 20 males and 2 females aged 59±9 years. Pts underwent multimodal ultrasound examination at study entry and one year and six months thereafter. Anacor Laboratories Inc, Alachua, FL; Advanced Imaging Biometrics, Inc, 6.1x baseline were higher with LESU+XOI than XOI

Results: Treatment with allopurinol or febuxostat reduces to some extent target organ damage.

Conclusions: Improvement of pain, physical impairments and disabilities for the study group certifies the efficacy of the rehabilitation program including physical exercise in patients with hip arthropathy for aseptic necrosis of the femoral head and motivates the continuation of the study on a longer period of time and on a larger number of patients. Rehabilitation program must begin right after patients undergo surgery for hip replacement.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.5130
LESU+XOI treatment in the core-extension studies did not show an increase from core studies in EAIRs for any renal-related or kidney stone adverse event category (Table 2).

Conclusions: Lesinurad at the approved dose of 200 mg once daily combined with XOI demonstrated comparable rate of adverse events to XOI alone. There was no clinically relevant increase in these adverse events with the extension of treatment beyond 1 year.

THU0457 LESS THAN HALF OF PATIENTS TREATED WITH HIGH-DOSE ALLOPURINOL REACH SUA TARGET

R. Morlock1, D.C. Taylor2, S. Baumgartner3, 1 YourCareChoice, Ann Arbor; 2Ironwood Pharmaceuticals, Inc., Cambridge; 3dB Consulting, Spokane, United States

Background: Although allopurinol is FDA approved for up to 800 mg per day and EMEA authorized for up to 900 mg per day, most patients receive 300 mg per day or less.

Objectives: To describe physician, patient, and treatment characteristics in gout patients treated with allopurinol and to assess the proportion of patients reaching serum uric acid (sUA) target by allopurinol dose.

Methods: Patient data from a quantitative survey of physicians were utilized and results confirmed through chart review. Initial and current dose of allopurinol, presence of co-morbid conditions, sUA lab results, physician specialty, and patient characteristics were assessed. Data on number of patients achieving target sUA<6mg/dL were also collected. Descriptive characteristics are presented as proportions or means and standard deviations (SD). Multivariate and descriptive statistics are used to describe patients with sUA<6 mg/dL.

Results: A total of 251 rheumatologists and 250 primary care physicians were interviewed. Of 2505 patients with gout, 1437 (57%) were treated with allopurinol. Use of high-dose allopurinol significantly differed by country with less than 6.5% of patients in France, Germany, and Spain given >300mg, whereas 10.2%, 19.5%, and 33.6% of patients in Italy, the US, and the UK, respectively, received a daily dose >300mg (p<0.01). Over 12 months the percentage of patients achieving sUA<6.0 mg/dL differed across the 6 countries. Looking across all countries, only 43.8% and 44.7% of patients achieved sUA<6.0mg/dL with 301–599mg and >600mg of allopurinol QD, respectively. A multivariable-adjusted model found patients with tophi (OR 3.42; p<0.01), co-existing alcoholism (OR 1.73; p<0.05), COPD (OR 2.01; p<0.05), smoking cessation treatment (3.49; p<0.05), and from the UK (OR 3.98; p<0.01) were more likely to be using >600mg of allopurinol. Regardless of allopurinol dose, the co-variates UK vs. other countries (OR 3.51; p<0.01), time on therapy >24 months (OR 1.39; p<0.01), and chart-documented co-existing hypertension (OR 1.36; p<0.05) were predictive of achieving sUA<6 mg/dL. Whereas physician sub-speciality (general practitioners vs. rheumatologists [OR 0.56; p<0.01]), having tophi (OR 0.72; p<0.05), and chart-documented co-existing alcoholism (OR 0.67; p<0.05), hyperlipidemia (OR 0.74; p<0.05), and kidney stones (OR 0.49; p<0.05) were found to be associated with not achieving sUA<6 mg/dL. After adjusting for confounding factors, over a 12-month period, there was no difference in achieving sUA<6 mg/dL for those treated with high- vs. low-dose allopurinol.

Conclusions: Allopurinol is approved for up to 800mg in the US and 900mg in the EU but the majority of patients are treated with <300mg per day. Less than 50% of patients achieve sUA<6mg/dL at any dose of allopurinol. These data suggest a need for consideration of new treatment options on top of allopurinol for uncontrolled gout patients.

DOI: 10.1136/annrheumdis-2017-eular.6234
Results: Treatment of SITK01 through SITK03 and SITT01 at concentration (250 mg/mL) decreased the cell viability. The PO-stimulated kidney epithelial cells with SITK01 through SITK03 treatment increased GLUT9 by 2.5 folds and decreased OAT3 by 1.5 folds (versus controls; p=0.012, and p=0.017, respectively). In PO-treated mice, uric acid levels were increased through GLUT9 and OAT3 transporters. The results indicated that SITK01, SITK02, and SITK03 showed the potential on uricosuric effects in a dual modulation of apical/basolateral sides of kidney epithelial tubular membranes.

Conclusions: The present findings demonstrated that three commercial herbal products showed potentials to reduce hyperuricemia-induced condition by changing protein expression levels in a transporter-uptake assay. The OAT3 and GLUT9 could be further investigated as the uricosuric group-targets on the apical sides at kidney epithelial tubular membranes.

THU0460 BARRIERS TO GOUT CARE: A SYSTEMATIC REVIEW AND THEMATIC SYNTHESIS OF 120 PROVIDERS AND 480 GOUT PATIENTS FROM QUALITATIVE STUDIES

S.K. Rai, H.K. Choi, S. Choi, A. Townsend, M.A. De Vera, 1,2, 3, 'Arthritis Research Canada, Vancouver, Canada; 2 Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital, Boston, United States; 3 Faculty of Medicine, University of British Columbia, Vancouver, Canada; 4 Exeter Medical School, University of Exeter, United Kingdom; 5 Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, Canada

Background: Despite gout’s well-known pathogenesis and the availability of effective urate-lowering therapy (ULT), management remains poor. However, limited research has sought to improve care among this patient population. An in-depth understanding of provider and patient perspectives on barriers to the delivery of optimal gout care is critical to informing the development of evidence-based interventions to effectively improve disease management and patient outcomes.

Objectives: To systematically review and thematically synthesize qualitative studies to date reporting provider and patient barriers to gout management.

Methods: We conducted a mapped search of MEDLINE, EMBASE, Cumulative Index to Nursing and Allied Health Literature, and Social Sciences Citation Index databases and selected qualitative studies reporting provider and patient perspectives on gout management. Thematic synthesis was used to combine the source studies and identify key themes across studies. Two authors independently read and annotated the data and after discussion agreed on an initial coding framework. Concepts were organized into descriptive themes, and the relationships between these descriptive themes were further explored to develop higher-order analytical themes.

Results: Our search strategy retrieved 2,750 articles after the removal of duplicates. After full-text review, 20 studies spanning several geographic settings worldwide (i.e., the US, the UK, New Zealand, Australia, and the Netherlands) met all inclusion criteria and were included in our systematic review. Of these, 16 studies reported gout patient perspectives (n=480 patients), while only 7 studies reported provider perspectives (n=120 providers, including general practitioners, rheumatologists and other specialists, and allied health professionals). Thematic synthesis identified three predominant interlocking analytical themes among providers: (a) knowledge gaps and management approaches, (b) perceptions and beliefs about gout patients, and (c) system barriers to optimal gout care (Table 1). We further identified four predominant themes among gout patients: (a) limited gout knowledge (e.g., the “curable” nature of gout), (b) attitudes toward taking medication, (c) interactions with healthcare providers, and (d) practical barriers to chronic medication use (Table 1).

<td>Humphrey et al.</td>
</tr>
</tbody>
</table>

Conclusions: Our thematic synthesis identified several barriers to gout care, particularly knowledge gaps among both providers and patients as well as strategies to reduce system barriers and support regular medication use are urgently needed to improve gout care.

THU0461 ACCURACY OF HUMASENS-PLUS POINT-OF-CARE URIC ACID METER USING CAPILLARY BLOOD OBTAINED BY FINGERTIP PUNCTURE

Background: A key factor in the success of gout management is the long-term lowering of uricemia below predetermined targets (300 or 360 μmol/l). Monitoring of uricemia in gout patients is therefore important, and is presently done in the clinical practice by capillary samples obtained by fingertip puncture. An uric acid (UA) meter allowing rapid testing by the health care professionals and self-measurement by the patient should improve management of gout.

Objectives: This study aimed to assess the reliability of immediate UA measurement in capillary blood obtained from fingertip puncture using the HumaSens®plus point-of-care meter (meter) compared with that of a standard laboratory assay (lab).

Methods: Capillary UA levels were measured from 236 consenting diabetic patients using the commercially available HumaSens®plus UA meter (European Commission marked and approved for EU market use). Each patient also had a plasma UA measurement in the biochemistry laboratory using an uricase laboratory assay (lab).

Results: Forty capillary samples were read LO by the meter: 11 were confirmed by lab to be below 180 μmol/l and 3 were above (189, 206 and 216 μmol/l). Two capillary samples were read HI and were measured at 303 and 313 μmol/l by lab. In the remaining 222 samples with meter and lab values, ICC was 0.90 [0.87–0.92] and Bland-Altman curve showed acceptable agreement over all the tested values. Best meter threshold for detection of hyperuricemia by the HumaSens®plus meter was 330 μmol/l (sensitivity 0.89, specificity 0.89, area under the ROC curve 0.95). Based on regression, plasma uric ise of 360 μmol/l corresponded to 343 μmol/l. Among the biological parameters tested, only hematocrit impacted capillary uric acid measurements, however negligibly.

No medication appeared to significantly affect test results. Plasma uric acid measurements were better correlated to LC-MS measurements (r=0.98 [0.96–0.99]) than capillary measurements (r=0.84 [0.75–0.90]).

Conclusions: The HumaSens®plus point-of-care meter was reasonably comparable to those of the laboratory assay. It is easy to use and may be useful in clinic and in epidemiologic studies.

THU0462 MORTALITY IN PATIENTS WITH GOUT: A SYSTEMATIC REVIEW

S. Mitchell1, H. Liedgens2, E. Johannes3, Decision Resources Group, Bicester, United Kingdom; 4Head Health Economics and Outcomes Research Market Access, SBEU Europe; 5Head Market Access Europe, Grünenthal Gmbh, Aachen, Germany

Background: Gout is a chronic, progressive, inflammatory disease characterised by elevated serum uric acid (sUA) levels (1). In Europe the prevalence of gout ranges from 0.9–2.5%, and is increasing (2). Published data indicate that gout is an independent risk factor for both all-cause and cardiovascular (CV)-related mortality (3, 4).

Objectives: To conduct a systematic review to identify studies reporting the association between gout and mortality (all-cause and CV-related).

Methods: Relevant publications were identified by interrogating electronic databases; Medline & MEDLINE In-Process, EMBASE and the Cochrane Library (accessed 3 May 2016). Eligibility criteria included adult patients with a definitive diagnosis of acute/chronic gout (self-reported/physician diagnosed), with no restriction on publication date, study design or geography.

Results: Nineteen studies met the pre-defined inclusion criteria and were reviewed. The studies were conducted in: the US (n=8); Taiwan (n=5); Canada (n=3); Australia (n=1); Singapore (n=1); and the UK (n=1). In addition to patients having a diagnosis of acute/chronic gout, 6 of the 19 studies were conducted in the following patient subgroups: renal transplant (n=1); chronic kidney disease (n=2); patients with a recent acute myocardial infarction (n=2); and patients with heart failure (n=1). There were several consistent finding across the 19 studies: (i) gout was associated with an increase in both all-cause mortality (reported hazard ratios [HR] ranges from 1.13 to 2.37) and CV-related mortality (reported HR ranged from 1.10 to 3.88) compared with patients without gout; (ii) the increased risk in all-cause mortality was primarily driven by an increase in CV-related mortality; (iii) the increased mortality risk was higher in females than males. One study reported that the presence of tophi was independently associated with a higher risk of all-cause mortality. Notably one study reported that patients who received urate-lowering therapy (ULT) had a statistically significant lower all-cause mortality and CV-related mortality risk relative to patients who do not receive ULT.

Conclusions: This systematic review confirms that gout is associated with an increased risk of all-cause and CV-related mortality; this was consistently reported across the eligible studies. The findings highlight the risk associated with gout and emphasise the need for appropriate treatment of this curable disease.

THU0463 EPIDEMIOLOGY OF GOUT AND HYPERURICEMIA IN NEW CALEDONIA

T. Bardin1, E. Magnat1, P. Clerson2, P. Richette2, B. Rouchon2, 1Rheumatology, Hôpital Lariboisière, Paris, France; 2Agence Sanitaire et Sociale, Nouméa, New Caledonia; 3Solids Clinical Studies, Roubaix; 4Rheumatology, Hôpital Lariboisière, Paris, France.

Background: New Caledonia is a Pacific island of 270,000 inhabitants with mixed ethnicities, including Melanesians (39.1%) and Polynesians (10.2%) and people from European ancestry (27.2%).

Objectives: To determine the prevalence of gout and hyperuricemia in the various ethnicities and to characterize associated factors.

Methods: A 3-degree random sample of the population aged 18 to 60 years old was reconstituted according to the 2014 New Caledonia census. Face-to-face interviews were performed by trained nurses who used a predefined questionnaire along with planned physical measurements. All participants underwent capillary measurement of creatinine level (StatSensor) and all men and only women older...

THU0465 CALCIUM PYROPHOSPHATE DEPOSITION DISEASE AND OSTEOARTHRITIS: TWO FACES OF THE SAME MEDAL? AN ULTRASONOGRAPHIC AND MICROSCOPY STUDY

V. Piccioni 1, A. Scarnu 1, A. Adinolfi 1, C.A. Scirè 2, B. Friedlan 1, L. Punzi 2, G. Filippu 1, 3, University of Siena, Siena; 2University of Padua, Padua; 3University of Ferrara, Ferrara, Italy

Background: Calcium pyrophosphate deposition disease (CPPD) and Osteoarthritis (OA) are frequently associated and CPPD with OA is recognized as a clinical entity [1]. However, there are differences in pathogenetic, microscopic and clinical aspects between the two diseases which are not clear and how CPPD and OA could affect each other is still a matter of debate.

Objectives: To assess the differences between CPPD and OA in terms of anatomic alterations of the knee joint and to compare males with females of the same age.

Methods: consecutive patients reaching the outpatient clinic for the presence of knee pain and with any amount of joint effusion were eligible for the study. Patients with diagnosis or suspicion of chronic inflammatory rheumatic conditions and those with severe intermittent bilateral knee pain were excluded. All enrolled patients were classified into two groups on the basis of the knee assessment: joint effusion (JE), synovial hyperthropy (SH), synovial power Doppler (PD), femoro-tibial osteoarthritis (TOA) and others which included CPPD and OA.

Results: 49 patients (28 women), mean age 70.29 yo (SD±10.93) were enrolled in the study; 23 subjects presented OA and 26 CPPD (23.07% acute arthritis, 77.6% CPPD with OA). At US, a statistically significant difference between CPPD and OA was found only for the grade of effusion, being more abundant in patients with OA. On the contrary, no differences were found regarding SH, PD, TOA, SH+PD+TOA. The analysis showed that CPPD patients presented a higher volume of SF, a higher total WBC count with a higher polymorphonuclear (PMN) cells percentage and lower monocytes percentage than patients with OA. Further, both total cell count and PMN percentage were positively correlated with the number of crystals in the SF. On the other hand, no statistically significant differences were found in the content of mononuclear cells and their concentrations between the two groups.

Conclusions: According to these results, patients with CPPD and OA present some distinct features, mainly regarding the characteristics of the SF, compared to patients with OA alone. These differences may reflect different underlying pathogenetic pathways for the two diseases. Surprisingly, the concentration of mononuclear cells in the two populations was similar.

Further studies are necessary in order to better understand the link between CPPD and OA and the role of ions concentration in the SF for the formation of crystals.

THU0467 SAFETY AND EFFICACY OF FEBUXOSTAT IN ADVANCED CKD PATIENTS WITH HYPERURICEMIA

V. Y. Chi, E. S. Park, S. S. Ahn, K. Y. Lee, S. J. Byun, J. Y. Pyo, S. M. Jung, S. W. Lee, Y. B. Park, J. I. Song, Internal medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

Background: In chronic kidney disease (CKD) patients, hyperuricemia is a common finding and might be one of modifiable risk factors for renal progression. However, dosing adjustments and increased risk of serious side effects of uric acid lowering agents in patients with reduced renal function lead to undercorrection of hyperuricemia, especially in patients with advanced CKD. Febuxostat is highly
effective and well-tolerated to treat hyperuricemia in CKD patients. Although several evidences demonstrated the usefulness of febuxostat in hyperuricemic CKD patients, clinical studies aimed at the CKD patients with inappropriately controlled hyperuricemia by allopurinol have been relatively lacking. 

Objectives: The study objective is to evaluate the safety and efficacy of febuxostat in patients, who have severe renal impairment and did not meet with the target uric acid levels using allopurinol.

Methods: Data were collected from 168 patients who had CKD with more than stage 3b and changed from allopurinol to febuxostat due to uncontrolled hyperuricemia between 2005 and 2014 at Yonsei University Medical Center. Uric acid and creatinine were analyzed at baseline and during the first 6 and 12 months after conversion of febuxostat. Estimated glomerular filtration rate was calculated using the formula of MDRD equation. The patients were defined as a well-controlled state when the uric acid values of the study subjects reached 3mg/dL at baseline (5.2±2.1 mg/dL at 6-month and 4.9±2.2 mg/dL at 12-month, p<0.001, respectively). Subjects reached to the target of uric acid levels less than 6mg/dL at 6- and 12-months after treatment of febuxostat [122 (72.6%) patients at 6-month and 133 (79.2%) patients]. The creatinine levels at baseline and 6-month were comparable (3.4±2.5 vs. 3.5±2.6 mg/dL at baseline and 6-month, p=0.61), meanwhile, the creatinine levels were significantly increased after 12-month compared to those at baseline (3.6±2.14 mg/dL, p<0.01). Abnormality of liver function test was observed in only one patient during the follow up period. None of the patients did not discontinue drug due to adverse events.

Conclusions: Present study demonstrated that substantial hyperuricemic CKD patients treated with febuxostat were achieved the target of uric acid levels without adverse events. Febuxostat is an effective and safe uric acid lowering drug in allopurinol-intolerant patients with advanced CKD.

THU0469
COMPARATIVE EFFECTIVENESS OF TAI CHI VERSUS AEROBIC EXERCISE FOR FIBROMYALGIA: A RANDOMIZED CONTROLLED TRIAL

C. Wang¹, C. Smid², R. Fielding³, W. Harvey¹, K. Reid³, L. Price¹, J. Driban¹, R. Kalish¹, R. Rones⁴, T. McAlindon¹. ¹Tufts Medical Center, Boston; ²Brown University School of Public Health, Providence; ³Tufts University; ⁴Center for Mind-Body Therapies, Boston, United States

Background: Fibromyalgia is a complex disorder with strong psychological and pain components. Tai Chi is an integrated mind-body approach that enhances both physical and mental health and has great potential to treat fibromyalgia.

Objectives: We aimed to investigate whether Tai Chi is more effective with longer lasting effects than aerobic exercise.

Methods: We conducted a 52-week, single-blind, randomized controlled trial of Tai Chi vs. aerobic exercise for fibromyalgia (ACR 1990 and 2010 diagnostic criteria). Participants were randomized to 1 of 4 Tai Chi interventions: 12 or 24 weeks of Tai Chi once or twice per week, or aerobic exercise held twice per week for 24 weeks. The primary endpoint was change in the Revised Fibromyalgia Impact Questionnaire (FQoR) score at 24 weeks. Secondary endpoints included change in patient’s global assessment, the Hospital Anxiety and Depression scale (HADS), Sleep Quality Index (PSQI), arthritis self-efficacy scale (ASES-8), and quality of life. The comparative efficacy of the five groups was determined using longitudinal models based on the intent-to-treat principal.

Results: The mean age of subjects was 52 years (SD 12), mean years of body pain of 9 years (SD 8), 92% were women, and 61% were white. Treatment groups did not differ in baseline outcome expectations. The average of all 4 Tai Chi groups, compared to aerobic exercise, showed significant improvements in FIQR scores, patient’s global, anxiety, and self-efficacy. All other outcomes favored Tai Chi over aerobic exercise (Table 1). The Tai Chi treatment with the same dosage as the aerobic group demonstrated an even larger effect for FIQR and for most other outcomes. The benefit of Tai Chi was consistent across instructors.

Conclusions: Tai Chi is more effective than aerobic exercise and can be considered as an important therapeutic option for patients with fibromyalgia.

WORK AND PROFESSIONAL RECOGNITION IN
FIBROMYALGIA PATIENTS – A NATIONAL FRENCH WEB
BASED SURVEY ON SICK LEAVE IN 1870 FIBROMYALGIA
FEMALE PATIENTS

F. Laroche 1 , D. Azoulay 1 , J. Guérin 1 , J. Coste 2 , S. Perrot 3 . 1 Pain Department,
Hospital University Saint Antoine; 2 Biostatistics, Hospital University Hotel Dieu;
3
Pain Department, Hospital University Cochin, Paris, France
Background: Fibromyalgia (FM) induces work limitations with an increase of
number of days of sick leave 3 to 4 fold higher (1, 2).
Objectives: Our objectives were to analyze work status, to determine risk factors
for sick leave and to compare women working to women in sick leave during the
past 12 months in a female population with FM.
Methods: 1870 female workers suffering from FM were selected from a large
internet-based national survey of 4516 responders (Fibromyalgie-SOS Association
website in France in 2014). Women having a FIRST score ≥5/6 were included.
Results: 1870 patients participated to the survey: 955 with full time job, 149
with part time job (related to FM status) and 766 on sick leave (7% 1–3 months,
27.3% 3–12 months and 62% >12 months). Fibromyalgia Impact questionnaire
(FIQ) score was slightly lower in the 1104 patients currently working compared to
the 766 on sick leave (56 versus 58.7), but not clinically different. 64,5% of the
population have been on sick leave during the last 12 months (average duration:
37 mean days for full time job and 122 among those with part time job).
Women being in sick leave were older (p<0,0001), single (p=0,0321), had less
ﬁnancial income (p<0,0001), used more antidepressants (p=0,0085) and more
anti epileptics (p=0,0102). Recognition of FM by occupational physicians or social
security doctors were lower among the workers (p<0.0001).
In the 1104 currently working, more than 33% have never been visiting
their occupational physician and 44,2% rarely. They reported no support from
these doctors (p=0,0011) particularly those having not being on sick leave.
Independent criteria of sick leave were transportation time (p=0.0131), work
difﬁculties (p=0.0031), hinders career progress (p=0.0196), sedentary occupation
and repetitive work (p=0.0195).
Conclusions: These data on a large ﬁbromyalgia population shows that clinical
status and also professional factors may inﬂuence work ability and sick leave.
The work factors include work difﬁculties, transportation time, sedentary and
repetitive occupation. These results should be taken into account by the work
professionals in order to facilitate work capacity in FM patients.

THU0471

THE EFFECTS OF TAPPING THERAPY ON PAIN, SYMPTOM
SEVERITY, DYSFUNCTIONS IN DAILY LIFE, DEPRESSION,
AND QUALITY OF LIFE IN PATIENTS WITH FIBROMYALGIA:
A RANDOMIZED CONTROLLED TRIAL

H.J. Suh 1 , S.T. Choi 2 , J.-S. Song 2 , S.H. Shin 3 . 1 Seoul National University
Hospital; 2 Internal Medicine, CHUng-Ang University College of Medicine; 3 Kyung
Hee University Nursing Science, Seoul, Korea, Republic Of
Background: Fibromyalgia is a disorder characterized by chronic widespread
musculoskeletal pain, often accompanied by fatigue, cognitive disturbance,
psychiatric symptoms, and multiple somatic symptoms. Various pharmacological
and non-pharmacological therapies have been tried in the management of
ﬁbromyalgia. However, unfortunately, management remains a challenge.
Objectives: Taping therapy has been shown to be effective for pain relief in
various musculoskeletal diseases. However, there was no trial for the patients with
ﬁbromyalgia. In this study, we evaluated the effects of taping therapy in patients
with ﬁbromyalgia.
Methods: This study is a randomized controlled trial with 60 ﬁbromyalgia patients.
All patients were satisﬁed with the 2010 American College of Rheumatology
diagnostic criteria for ﬁbromyalgia. Participants were randomized to the Kinesio
taping group (n=30) and to the non-elastic paper taping group (n=30) for the
control. Taping experiment was performed for three weeks (twice a week)
through the one-to-one meeting. Pain, symptom severity, dysfunctions in daily
life, depression, and quality of life (QoL) were assessed with the widespread pain
index (WPI), severity score (SS), ﬁbromyalgia impact questionnaire (FIQ), Beck
depression inventory (BDI), and the EQ-5D INDEX and EQ-5D VAS, respectively.
Results: The mean ages of taping group and the control group were 54.3±12.0
years and 53.2±12.7 years, respectively, and female patients were 25/30 (83.3%)
and 27/30 (90.0%) in both groups, respectively, and there were no differences
between two groups in the medication use such as anti-depressants and muscle
relaxants. Patients showed signiﬁcant improvements after Kinesio taping therapy
in pain (10.50±3.98 vs. 5.70±2.73, p<0.001), symptom severity (7.93±2.24 vs.

Thursday, 15 June 2017

385

5.27±1.98, p <0.001), dysfunction in daily life (65.03±18.75 vs. 43.25±18.87,
p<0.001), depression (18.17±8.55 vs. 13.00±6.75, p<0.001) and QoL (EQ5D INDEX, 9.10±1.54 vs. 7.67±1.40, p<0.001; EQ-5D VAS, 38.33±24.65 vs.
56.67±27.93, p <0.001), respectively. In the control group, however, the signiﬁcant
improvement was detected only in pain (10.53±3.87 vs. 9.27±3.57, p=0.012).
The changes before and after treatment in the Kinesio taping group revealed
signiﬁcant differences from those in the control group: pain (p<0.001), symptom
severity (p<0.001), dysfunction in daily life (p<0.001), depression (p=0.001) and
QoL (p<0.001 and p<0.001), respectively. There was no serious adverse event.
Conclusions: This study shows that Kinesio taping therapy has effects on pain,
symptom severity, dysfunctions in daily life, depression, and quality of life in the
patient with ﬁbromyalgia. Taping therapy could be a useful non-pharmacological
management modality for the ﬁbromyalgia patient.

THU0472

FAST3 (FIBROMYALGIA ASSESSMENT SCREENING TEST):
A COMPOSITE INDEX BASED ON MDHAQ PROVIDES CLUES
TO THE PRESENCE OF SECONDARY FIBROMYALGIA IN
PATIENTS WITH A PRIMARY DIAGNOSIS OF RHEUMATOID
ARTHRITIS AT HIGHER LEVELS THAN IDENTIFIED IN THE
MEDICAL RECORD: A CROSS SECTIONAL STUDY FROM
ROUTINE CARE

I. Castrejon 1 , K. Gibson 2 , J.A. Block 1 , T. Pincus 1 . 1 Rheumatology, Rush
University Medical Center, Chicago, United States; 2 Rheumatology, Liverpool
Hospital, Sydney, Australia
Background: Secondary ﬁbromyalgia (FM) is reported in 17% of RA patients1 ,
but may be under-recognized in patients with classical RA ﬁndings. A FAST3
(ﬁbromyalgia assessment screening test) index based on 3 MDHAQ (Multidimensional Health Assessment Questionnaire) scores gives similar results to ACR
ﬁbromyalgia criteria based on a widespread pain questionnaire,2 to assist in
recognizing patients with secondary FM3 .
Objectives: To study patients with a primary diagnosis of RA seen in routine care
for the proportion identiﬁed as having secondary FM according to a physician
diagnosis in the medical record versus a FAST3 Index of MDHAQ scores.
Methods: All patients complete an MDHAQ/RAPID3 at all visits in the waiting
area in routine care. The MDHAQ includes 0–10 scores for physical function,
pain, and patient global estimate, compiled into RAPID3, as well as a 0–48
RADAI self-report score of painful joints, and 0–60 symptom checklist. FAST3
has been developed previously as the 0–3 sum of 1 point each for 3 MDHAQ
scores: pain VAS ≥6, RADAI ≥16, and symptom checklist ≥16.3 FAST scores
of ≥2/3 had >80% agreement with ACR FM criteria based on a widespread
pain questionnaire2 to identify secondary FM.3 A random visit for each patient
with a primary diagnosis of RA with complete data was studied. The number
with a diagnosis of secondary FM in the medical record was compared to
the number with FAST3 scores of 0, 1, 2, 3, and with each of the 3 FAST3
components. Receiver-operating characteristic (ROC) curves were generated to
estimate sensitivity and speciﬁcity for each cut-point of the FAST3 score, using a
diagnosis of secondary FM by the physician as the external criterion.
Results: 287 patients with RA were studied, of whom 10 (3.3%) had a diagnosis
of secondary FM by the physician in the medical record and 61 (22%) had FAST3
scores of 2 or 3 (Table), including 6 of 10 identiﬁed as having FM in the medical
record. Overall, FAST3 was 0 in 161 RA patients (56%), 1 in 59 (20.6%), 2 in
46 (16%), and 3 in 21 (7.3%) (Table). Overall, 55 additional RA patients were
identiﬁed by FAST3 versus the medical record as having possible secondary FM.
The ROC area was 0.73 (95% CI, 0.57–0.89) (data not shown).

Conclusions: The same MDHAQ used to score RAPID3 may also provide a
FAST3 score as a screening tool for secondary FM in RA (and other) patients
(including primary FM). Secondary FM may be under-diagnosed by clinicians in
routine care. Further validation of FAST3 in other settings is needed.

THU0473
POLYSYMPTOMATIC DISTRESS SCALE, WIDE SPREAD PAIN INDEX, AND SYMPTOM SEVERITY SCALES, AND THEIR CORRELATES IN 169 PATIENTS WITH FIBROMYALGIA SYNDROME

K. Yaseen1, S. Kaouk2, D. Bork3, W.S. Wilke3, C. Gota3, 1 Internal Medicine, Cleveland Clinic; 2Rheumatology, John Carroll University; 3Rheumatology, Cleveland Clinic, Cleveland, United States

Background: The polysymptomatic distress scale (PSD) is considered a measure of FM severity and ranges from 0 to 31. It is calculated by adding the two components of the American College of Rheumatology (ACR) 2010 fibromyalgia (FM) criteria, widespread pain index (WPI) and symptoms severity scale (SS).

Objectives: To assess the strength of the pelvic floor and urinary loss in women with FM.

Methods: All consecutive FM patients who met the ACR 2010 criteria completed the following questionnaires: PSD and its subsets, WPI and SS.

Results: Of 169 patients, 85.7% were women, mean age 42.3 (13.3), BMI 29.3 (7.1), PHQ-9 13.7 (5.2), GAD-7 10.2 (9.1), HAQ-DI 6 (2.9), PDI 6 (2.1), WPI 14.3 (2.7), SS 10 (1.6). In univariate analysis PSD correlated significantly (p<0.01) with PHQ-9 (0.576), PDI (0.422), and GAD-7 (0.356). Widespread pain index correlated significantly with PHQ-9 (0.313), GAD-7 (0.239), HAQ-DI (0.259), and PDI (0.296). Symptom severity scale correlated significantly with PHQ-9 (0.496), GAD-7 (0.337), HAQ-DI (0.275), PDI (0.340). A linear regression analysis model, which included PHQ-9, GAD-7, PDI and HAQ-DI predicted 26% of PSD variance, p<0.001, and only PDI remained significantly correlated with PSD. A similar model predicted 0.348 of SS variance, (p<0.0001), and only PHQ-9 remained significantly correlated with SS. This model did not significantly predict WPI variability.

Conclusions: Depression, anxiety, pain disability and functional disability predict a small variance of fibromyalgia severity measured by PSD. In regression analysis, pain disability measured by PDI is the only variable that remains independently correlated with PSD. None of these variables predicted WPI, while depression measured by PHQ-9 remains independently correlated with SS, indicating that PSD is a better predictor than WPI of FM.

THU0474
A CROSS-SECTIONAL STUDY INTO THE EFFECTIVENESS OF THE FIBROMYALGIA RAPID SCREENING TOOL FOR DETECTING FM IN PATIENTS WITH CHRONIC ARTHRITIS UNDERGOING FULL AND TAPERED BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUG THERAPY

Background: The determination of fibromyalgia (FM) in patients presenting diffuse, chronic arthritis is fraught. The Fibromyalgia Rapid Screening Tool (FIRST) is a validated questionnaire with high sensitivity and moderate specificity shown to be able to identify up to 89% of FM cases, even when accompanied by anxiety, depression or functional disability. Decisions to embark upon a course as chronic widespread pain referred for at least 3 months. In 2010, a new diagnostic criteria was proposed, and includes symptoms such as fatigue, sleep disorder and memory. Currently, pelvic floor dysfunctions and urinary incontinence (UI) are considered public health problems with high prevalence and great impact on quality of life (QoL), and on women’s self-esteem. Physiotherapists have been working to create a new treatment proposal that can cover all aspects of FM, and there are few studies that include pelvic floor evaluation and urinary incontinence of this population.

Objectives: To assess the strength of the pelvic floor and urinary loss in women with FM.

Methods: We evaluated 126 sexually active women, aged between 19 and 65 years, with and without medical diagnosis of FM, matched for age and menopausal status, in a single center. The exclusion criteria were sexually transmitted or neurological diseases, pregnancy and use of medications with urinary side effects (urinary loss or retention). We collected in a single interview personal and gynecological data, applied the King Health Questionnaire (KHZ) for incontinent women and accomplished the evaluation of pelvic floor muscle strength according to the Oxford Classification Modified and perineometry. The participants signed the Informed Consent Form. We used for statistical analysis 1 test for independent variables and Mann-Whitney Test for the others.

Results: The FM patients presented the weaker pelvic floor (p<0.001) and had lower values in perineometry (p<0.04) than control women. Regarding urinary loss, 64.5% reported UI against 26.8% of women without FM. In the KHQ evaluation, in General Health and Emotions domains, women with FM presented worse performance (p<0.04) (p<0.04).

Conclusions: Urinary incontinence is a frequent finding in FM, and it could be related to the degree of strength of the pelvic floor muscles. This condition affects negatively QoL, especially with regard to emotions and general health.

THU0476
EVALUATION OF SEXUAL FUNCTION IN WOMEN WITH FIBROMYALGIA

1Reumatologia, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo; 2Fisioterapia, Fonoaudiologia e Terapia Ocupacional, Universidade de São Paulo, São Paulo, Brazil

Background: Fibromyalgia (FM) is defined by the American College of Rheumatology as a syndrome of unknown etiology, characterized by chronic and widespread musculoskeletal pain. In 2010, a new diagnostic criteria was proposed, and includes symptoms such as fatigue, muscle fatigue, non-restorative sleep and urinary disorders. This may lead to a lack of interest or difficulty in the sexual act, which tends to be aggravated by depression, which is manifested by low self-esteem, decreased desire and orgasm, and pain during sexual intercourse.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.6261
OBJECTIVES: Compare the sexual function of women with and without FM.

Methods: Sexually active women aged between 19 and 65 years with and without medical diagnosis of FM in a single center, matched for age and menopausal status, were evaluated. The exclusion criteria were pregnancy and use of medications with urinary side effects (urinary loss or retention). In a single visit, we explained the study, obtained informed Consent Form and answered questions about personal and gynecological data. The protocol The Sexual Quotient – Female Version (QS-F) was applied to assess sexual performance. We used for statistical analysis t test for independent variables and Mann-Whitney test for the others.

Results: In this study, 126 women were evaluated with age of 43±10.48 years. Most of the patients were married, representing 58.7%. A total of 50% participants had 1 or 2 children, 22.2% between 3 and 4 children and 27.8% had no children. Regarding the age of menarche and menopausal status, no differences were observed between the groups (p=0.70 and p=0.08, respectively). The QS-F score revealed significantly lower scores for women with FM when compared to the healthy group (p<0.001). We observed the same results in the domains: Desire and Sexual Interest (p<0.001), Excitation Phase (p=0.019) and Satisfaction and Orgasm (p<0.001). Regarding the Pain and Comfort domain, no differences were observed between the groups (p=0.307). However, when they were questioned about dyspareunia in the physiotherapeutic evaluation, it was observed that 51.6% of FM patients reported pain in sexual act against only 26.6% of healthy women (p<0.005).

Conclusions: Women with FM performed poorly on QS-F general score and in most of the domains, desire, excitement and comfort. When they were questioned in the physiotherapeutic evaluation about dyspareunia, we observed that women with FM had more pain in sexual intercourse, which may occurred due to the way the question was asked. As consequence, women with FM report worse sexual performance, especially with regard to desire, arousal and orgasm phase.

THU0475 DETERMINATION OF COMORBIDITIES IN FIBROMYALGIA SYNDROME

U. Bilge1, T. Kapişoğlu2, N.S. Yasar Bilge3, H. Baloğlu1, Y.E. San1, M. Kayhan1, I. Ünlüoğlu1, Eskişehir Osmangazi University Faculty of Medicine Department of Family Medicine, Eskişehir Osmangazi University Faculty of Medicine Department of Family Medicine; 2Eskişehir Osmangazi University, Eskişehir Osmangazi University Faculty of Medicine Department of Internal Medicine Division of Rheumatology, Eskişehir, Turkey

Background: Although fibromyalgia syndrome is diagnosed by excluding other possible diagnoses based on the patient’s clinical features, in recent the studies, it was shown that comorbid diseases affect the course of fibromyalgia.

Objectives: The aim of this study is to evaluate the comorbid diseases of patients with fibromyalgia and to determine the rates of comorbid diseases within this study, age, gender and comorbid diseases of patients above 18 years and diagnosed with fibromyalgia by a were evaluated in the database system of the hospital retrospectively.

Results: A total of 509 patients were examined in our study. 51 of the patients were male, 458 were female (mean age was 50.24±12.32). Of the patients, 345 (67.8%) had at least one comorbid disease while 164 (32.2%) had no comorbid disease. In the study, 187 of the patients (36.7%) had cardiovascular diseases, 157 of the patients (30.8%) had endocrine diseases, 63 of the patients (12.4%) had rheumatologic diseases, 30 of the patients (5.9%) had neurological diseases, 17 of the patients (2.8%) had other autonomic diseases. 10 of the patients (2.0%) had cancers, 129 (25.3%) had mental disorders. 45 of the patients (8.8%) had chronic lung diseases, 37 of the patients (7.3%) had osteoporosis, 11 of the patients (2.2%) had other diseases (chronic pancreatitis, chronic renal failure, nephrotic syndrome, deep vein thrombosis, hepatitis serology positivity, pulmonary thrombemobilus, organ transplantation).

Conclusions: FMS is an important disease that is increasing in frequency in recent years. FMS, which can be seen with many diseases, is in fact related to physicians from many branches, and it is useful to evaluate FMS patients with their comorbid conditions on their follow-up.

THU0479 THE PREVALENCE OF XEROSTOMIA IN PATIENTS WITH FIBROMYALGIA

N.M. Lloves Schenone, A. Secco, V. Durigan, S. Scarafia, F.E. Romannini, M. Mamani. Servicio de Reumatología, Hospital Bernardino Rivadavia, Buenos Aires, Argentina

Background: Fibromyalgia (FM) is a rheumatic disease characterized by diffuse, chronic musculoskeletal pain, of non-articular origin, which is evidenced by the palpation of painful points in specific anatomical areas and is usually accompanied by non-repairing sleep, Tiredness, morning stiffness, cognitive alterations, among others. FM affects approximately 0.5–5% of the population, having a maximum prevalence between 40 and 50 years. No racial or socioeconomic predisposition has been determined to date.

Sicca syndrome whose term encompasses xerophthalmia, xeroderma and xerovagin, has been described in patients with FM. Xerostomia is the sensation of dry mouth due to lack or decrease of saliva. There are no clinical studies that determine the prevalence of xerostomia in patients with FM and on the other hand the reduction of salivary flow in these patients has not been studied with objective tests.

Objectives: The aim of this study was to determine the frequency of xerostomia in patients with diagnosis of Fibromyalgia and describe their clinical and epidemiologic characteristics.

Methods: Patients were included according 1990 and 2010 ACR Classification criteria. Patients taking drugs that cause xerostomia were excluded as well as the ones presenting other rheumatologic diseases. Xerostomia was assessed by the Xerostomia Inventory and physical examination and a sialometry was performed in order to determine the decrease of salivary flow. A sialometry was performed if the saliva flow was under 1.5 ml in 15 minutes. In case of presenting positive sialometry patients were studied to rule out Sjögren Syndrome with laboratory and minor salivary gland biopsy.

Results: 50 patients were recruited during the study. The 100% of them were women. The mean age was 47 years old (DS=6.5), while the mean time of evolution of FM was 6 years. 29 patients reported xerostomia of which 4 presented positive sialometry. No positive sialometry was found in the group that did not referred xerostomia. Smoking was more prevalent in patients with FM who did not...
report xerostomia with respect of those who reported xerostomia (31.8% vs 6.9%, p < 0.02). There were not associations between xerostomia and hypothyroidism, diabetes or menopause. The presence of Sjogren Syndrome was rule out in 4% patients whose saliometry was positive.

Conclusions: The prevalence of xerostomia was 51%. No statistically significant associations were found in patients who reported xerostomia. A decrease in objective salivary flow was not demonstrated in patients with FM.

THU0480 MULTICENTER, PROSPECTIVE, CONTROLLED DOUBLE-BLIND STUDY COMPARING FIB-19-01, A PHYTOTHERAPY TREATMENT FOR FIBROMYALGIA, TO A DIETARY SUPPLEMENT AND TO CONVENTIONAL TREATMENT IN PATIENTS SUFFERING FROM FIBROMYALGIA

Objectives: Developed to improve the quality of life of patients with FMS (Fib-19–01), to the efficacy and safety of adding a new treatment of herbal medicine, specifically for PICHOT scale (p < 0.001), PQSI (p=0.02), SF12 mental and social (p<0.01), HAD depression (p=0.013). No significant difference was found between FM patients with or without fibromyalgia as per each of the three criteria had no significant difference in these scores.

Conclusions: Non-tender point based criteria have been validated in primary care. However, in tertiary care where patients are referred to as fibromyalgia, there are mimics with similar comorbidities as evident by high BPHQ, GAD7 and TAS20 scores. Even after exclusion of other rheumatological conditions, the 2016 Criteria has poor specificity. Thus, it should be used as a screening tool than a diagnostic criteria in tertiary care.

THU0482 EVOLUTION OF COMORBID FIBROMYALGIA SYMPTOMS IN SPONDYLOARTHRITIS PATIENTS STARTING AN ANTI-TNF AGENT, AND CORRELATION TO ANTI-TNF EFFICACY. THE PREDICT-SPA STUDY

Background: Fibromyalgia (FM) is a frequent comorbid condition in axial spondyloarthritis (axSpA). It is not known how FM comorbidity may respond to the management of SpA, and especially to anti-TNF agents. Objectives: To evaluate the changes in the FM status of axSpA patients starting an anti-TNF treatment. Methods: A prospectiv multicenter national study involving 39 rheumatology centers in France, analyzing 519 patients with axSpA requiring anti-TNF therapy (Clinicaltrials.gov: NCT03000264). Patients were screened for FM with the FIRST questionnaire before and after 3 months of anti-TNF. Kaplan- Meier coefficient was calculated to determine the agreement of the FIRST at M0 and M3. Response to anti-TNF (BASEDiss response was compared according to positive screening for FM or not, at both time-points using chi2 tests.

Conclusions: Non-tender point based criteria have been validated in primary care. However, in tertiary care where patients are referred to as fibromyalgia, there are mimics with similar comorbidities as evident by high BPHQ, GAD7 and TAS20 scores. Even after exclusion of other rheumatological conditions, the 2016 Criteria has poor specificity. Thus, it should be used as a screening tool than a diagnostic criteria in tertiary care.

DOI: 10.1136/annrheumdis-2017-eular.2566
Results: Of the 519 enrolled pts, 504 (with complete data on the FiRST questionnaire) were analyzed at M3. A positive screening for comorbid FM was found in 192 pts (38%) at M0 and in 127 (25%) pts at M3. Correlation between FiRST at M0 and M3 was weak with a Kappa coefficient correlation of 0.4 [0.3 - 0.5].

Four groups were identified: group [++] with comorbid FM at M0 and M3: N=93 (18%); group [++] with comorbid FM at M0 but not at M3: N=99 (20%); group [+] without comorbid FM at M0 and M3: N=278 (55%); group [-] without comorbid FM at M0 but at M3: N=34 (7%). Changes in the status of comorbid FM (disappearance or appearance) was observed in 134 pts (26%). In the 193 pts with baseline comorbid FM, after 3 months of anti-TNF treatment, comorbid FM was no longer found in 99 (51%). Efficacy at M3 was significantly better, according to BASDAI 50, in patients without comorbid FM at M3 (Table).

Conclusions: There is a high frequency of comorbid FM screened by the FiRST in active axSpA, decreased by 51% over 3 months of anti-TNF treatment. Persistence of FM after 3 months of anti-TNF treatment is associated with lower anti-TNF response. Further studies are required to analyze the impact of screening FM before starting anti-TNF therapy in axSpA.

THU0483 CHARACTERISTICS OF PATIENTS WITH ACTIVE AXIAL SPONDYLOARTHRITIS AND COMORBID FIBROMYALGIA. DIFFERENCES ACCORDING TO FIBROMYALGIA SCREENING (FIRST QUESTIONNAIRE) AND FIBROMYALGIA CLASSIFICATION (ACR1990)

Background: Fibromyalgia (FM) can be a comorbid condition in axial spondyloarthritis (axSpA). FM screening questionnaires and classification criteria fulfill may demonstrate different prevalence and patients’ characteristics may differ.

Objectives: To evaluate frequency of comorbid FM, and the differences between axSpA patients with/without comorbid FM according to screening (FiRST) and classification tools (ACR1990 FM criteria).

Methods: A multicenter national study involving 39 rheumatology centers in France included 519 patients with axSpA starting an anti-TNF treatment (FIRST study; ClinicalTrials.gov: NCT03039088). Patients (pts) were screened for FM before starting anti-TNF therapy in axSpA.

Results: In the 519 pts (females: 46%, age: 42±12 years, mean BASDAI 5.7±2.0, with baseline comorbid FM, after 3 months of anti-TNF treatment is associated with lower anti-TNF response. Further studies are required to analyze the impact of screening FM before starting anti-TNF therapy in axSpA. Persistence of FM after 3 months of anti-TNF treatment is associated with lower anti-TNF response. Further studies are required to analyze the impact of screening FM before starting anti-TNF therapy in axSpA.

THU0484 R060 EXPRESSION DECREASES WITH AGE IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF CHILDREN AND ADOLESCENTS AND CORRELATES WITH TLR7 STIMULATION IN PDCS OF PREPUBERTAL CHILDREN

A. Radziszewska, K. Webb, H. Peckham, Y. Ioannou. Arthritis Research UK Centre for Adolescent Rheumatology at University College London, Great Ormond Street Hospital and UCLH, University College London, London, United Kingdom

Background: Auto-antibodies to the RNA binding protein Ro60 are present in patients with autoimmune disorders such as systemic lupus erythematosus (SLE). In addition to its established role as an auto-antigen, Ro60 has been found to bind Alu RNA retroelements whereby it may target Alu retroelement RNA for degradation suggesting a novel putative function of this auto-antigen. If Ro60 modulates the amount of cellular RNA then one may hypothesis an association with toll-like receptor (TLR)7 stimulation threshold.

Objectives: To measure the physiological levels of intracellular Ro60 protein in healthy children and adolescents and investigate a possible link between Ro60 protein expression and interferon-α (IFN-α) production after TLR7 stimulation.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from blood from 48 healthy children and adolescents (age range 6.7–17.9 years old). Cells lysates from thawed PBMC samples were tested for Ro60 expression by Western blot. PBMCs were also stimulated for 20 hours with TLR7/8 agonist R848, at 1μg/ml in the presence of brefeldin A, and plasmacytoid dendritic cell (pDC) IFN-α expression was measured using flow cytometry. Statistical tests to measure correlation between IFN-α expression in (pDCs) and PBMC Ro60 expression were performed using SPSS.

Results: Ro60 protein expression in PBMCs correlated negatively with age ( Spearman’s rho = −0.317, p = 0.032). When participants were divided into two groups based on their self-reported puberty status, Ro60 expression was higher in the pre-pubertal group (p = 0.02). There was, however, no difference in Ro60 expression between males and females (p = 0.44) or when sexes were stratified according to pubertal status. pDC IFN-α production after TLR 7 stimulation, did not correlate with ex vivo PBMC Ro60 expression overall (Spearman’s rho = 0.159, p = 0.302) however a moderate positive correlation was observed in pre-pubertal samples only (Spearman’s rho = 0.554, p = 0.021).

Conclusions: Ro60 expression decreases with age in healthy young people. These findings need to be confirmed in a larger cohort and further studies are necessary to investigate the link between Ro60 expression and TLR7 signalling across different age groups as well as in patients with SLE.

THU0485 POLYMORPHISM OF SOME GENES INVOLVED IN IMMUNE AND INFLAMMATORY RESPONSES IN BELARUSIAN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS AND OTHER ARTICULAR PATHOLOGY

H.A. Yatskiu1, N.V. Nikitchenko1, N.V. Savina1, T.D. Kuzhir2, A.M. Tchitchko2, A.V. Sukalo1, B.I. Garchevsky1. 1Institute of Genetics and Cytology, National Academy of Sciences of Belarus; 2Belarusian State Medical University, Minsk, Belarus

Background: Etiology and pathogenesis of juvenile idiopathic arthritis (JIA), which prevails among pediatric rheumatic diseases, are insufficiently clear. The study of molecular-genetic basis of JIA is of great interest for revealing genetic predisposition and early diagnosis.

Objectives: The present study aimed to analyze seven SNPs in five genes involved in immune and inflammatory responses: TNFα (rs1800629, rs361525), PTN222 (rs24766012), MIF (rs755622, rs5844572), CTLA4 (rs5742909), STAT4 (rs7574865), as well as in two DNA repair genes XPD (rs1799793) and XRCC1 (rs25487) in different conditions.

**Methods:** 94 patients diagnosed with JIA (mean age 8.7±5.21), 95 children with arthritic syndrome (mean age 7.90±4.81) and 164 hospital controls without any signs of autoimmune or inflammatory diseases (mean age 13.99±2.68) were included in the study. The JIA patients were divided into subgroups according to IAR classification criteria; among them 63 patients were diagnosed with oligoarthritis and 16 with RF- polyarthritis. Genomic DNA was extracted from blood samples by means of phenol-chloroform method. SNPs were genotyped using PCR-RFLP or fragmental analysis.

**Results:** The allele frequencies for all SNPs in the hospital control group were similar to those characteristic of other Europeans. No differences were found between the frequencies of the TNFα risk alleles across all three groups. Hence, both SNPs in the TNFα locus were not associated with JIA and other arthritic pathologies in our study. The same is true for -318C→T CTLA4 polymorphism. Unlike these genes, PTPN22 C1858T polymorphism influenced developing arthritis in children since heterozygous CT genotype was associated with articular pathology (rather than JIA) in the total group (OR=1.87, 95% CI [1.06–3.30], p=0.04), especially in males (OR=3.50, 95% CI [1.61–7.63], p=0.016). In the latter case, it was effective even being combined with any genotypes in the -308G→A TNFα locus (OR=2.73, 95% CI [1.19–6.24], p=0.018). When analyzing MIF polymorphisms (rs755622 and rs5844572), the evident trend to increased carrying genotypes containing the risk allele MIF-173C was observed in females with JIA as compared to controls and significantly elevated frequency of this risk allele in females with RF- polyarthritis as compared to males (p=0.037). In females with JIA as compared to controls and significantly elevated frequency of this risk allele as compared to any genotypes in the latter case, it was effective even being combined with any genotypes in the -308G→A TNFα locus (OR=7.78, 95% CI [0.95 – 63.8], p=0.056) was also revealed. STAT4 polymorphism (rs7574865) demonstrated subtype-related association with JIA due to increased frequency of the minor allele in patients with polyarticular form of JIA as compared to both hospital controls (p=0.01; OR =2.45; 95% CI [1.19–5.04]) and other articular pathology (p=0.001; OR =3.37; 95% CI [1.56–7.28]). The same SNP was also associated with developing arthritis in females. As to role of DNA repair genes, carriers of XPD rs10913939 and XRCC1 rs2548648 genotypes had an increased risk of JIA in females (OR=2.14; 95% CI [1.05–4.35]; p=0.05).

**Conclusions:** Thus, the gender- and subtype-specific associations of some SNPs studied with developing joint pathologies including JIA are found in the Belarusian child population.

**REAL-LIFE TREATMENT WITH CANAKINUMAB IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS – FIRST EXPERIENCE FROM THE BIKER REGISTRY**

G. Hornett, F. Dressler, A. Thön, K. Minden

**Background:** Canakinumab (CAN) has demonstrated its efficacy and safety in SJIA pts (1).

**Objectives:** To report on the experience with CAN treatment in SJIA in the clinical practice in Germany.

**Methods:** Data on patients’ and disease characteristics, disease activity and safety reports from the German BIKER registry were analysed.

**Results:** Until Dec. 2016, 37 pts exposed to CAN were identified. In 12 pts used CAN as first biologic, 25 pts were pretreated: Tocilizumab 15, Anakinra 11, Etanercept 9, Adalimumab 9. 3 patients in the pre-exposed cohort had experienced a macrophage activation syndrome. Pts’ and disease characteristics are outlined in table 1. Pts pretreated were older, had a longer disease duration and more comorbidities than naïve patients. The proportion of pts with active arthritis, active systemic features and both were comparable. Disease activity at baseline was higher in the naïve cohort suggesting some clinical benefit from pretreatment. Dosing of CAN was comparable (3.9±/0.4 vs. 3.5±/0.7mg/kg) as well as the median treatment duration (0.8vs.1.0year). Treatment efficacy at last follow up was better in the naïve cohort with more pts reaching a PedACR 30/50/70% IG response while JADAS- or ACR-remission rates were comparable. Treatment was discontinued by 42% in the naïve and 48% in the exposed cohort. Reasons were inefficacy (n=7/19%), intolerance (n=2/5%) and remission (n=7/19%) of the disease and other (n=2/5%).

**Conclusions:** First experience with CAN for treatment of SJIA in clinical practice is presented. A high proportion of pts gained significant improvement. JADAS remission was reached by about 50% and ACR remission by 25–57% in both biologics pre-exposed and naïve pts while few pts discontinued treatment in remission so far. Intolerance was rare. The further long term surveillance of SJIA pts exposed CAN is intended by the registry.

Background: Information regarding longer-term outcomes in JIA largely pre-date the introduction of biologic therapies and have been cross-sectional.

Objectives: The aim of this study was to assess outcomes over the first 5 years of disease in children diagnosed with oligoarticular and polyarticular JIA since 2001.

Methods: Children with oligoarthritis, rheumatoid-factor (RF) negative or positive polyarthritides were selected if recruited to the Childhood Arthritis Prospective Study (CAPS), a UK multicentre inception cohort, between October 2001 and January 2011. The following outcomes were assessed annually to five years and included in this analysis: functional ability (Child Health Questionnaire (CHQ)), the absence of limited joints, overall psychosocial health (psychosocial scale on the Child Health Questionnaire (CHQ)) and the proportion of children with CHQ psychosocial scores (two standard deviations below the population mean) (CHQ psychosocial<30).

Outcomes were assessed descriptively over time and differences between subtypes were assessed by applying multilevel (patient-level) zero-inflated negative binomial (CHAQ), logistic (absence of limited joints, percent CHQ psychosocial<30) and linear (CHQ psychosocial) regression analyses, adjusting for gender, age at presentation and hospital.

Results: Of 832 children, 70% were female, 68% had oligoarticular, 28% RF-negative and 5% RF-positive polyarticular JIA. Eighty-four percent had ever been treated with NSAIDs, 74% corticosteroids, 55% with DMARDs and 21% with biologics within follow-up. Baseline CHAQ was good to moderate (median 0.8, IQR 0.1 to 1.4) and only 21% of children had no limited joints reported at this time. CHQ psychosocial scores (median 50, IQR 39 to 55) were moderate, with 11% children scoring at least two standard deviations under the population mean. Overall improvements were evident in all outcomes over the first year then remained stable with no further improvements at the cohort level evident to five years.

Patients with RF-negative polyarthritides experienced significantly poorer outcomes across all variables than those with oligoarthritides. Those with RF-positive polyarthritides recorded similar CHAQ scores to patients with RF-negative polyarthritides but had the lowest odds of no limited joints (OR: 0.4, 95% CI 0.3 to 0.7) and the poorest CHQ psychosocial scores (4.8 points worse and 4.7 times the odds of scores <2 standard deviations of population mean), compared with those with oligoarticular.

Conclusions: On average, the largest improvement in functional ability, limited joints and psychosocial health occur in the first year following diagnosis, perhaps confirming the importance of early treat-to-target strategies. Patients with polyarticular JIA subtype have poorer parent and physician-reported outcomes than those with oligoarthritides.

THU0489 ADIPOSITY AND INFLAMMATORY ACTIVITY IN JUVENILE IDIOPATHIC ARTHRITIS COULD THEY BE RELATED?

G. Diaz-Cordoves Rigo, R. Galindo-Zavala, E. Nuñez-Cuadros, S. Manrique-Arija, N. Menà Vázquez, C. Domic-Bueno, M. Rojas-Gimenez, C. Fuego-Varela, R. Caparros-Ruiz, L. Cano-Garcia, A. Fernandez-Nebro, I. Rheumatology, University Regional Hospital of Malaga (HRUM), Institute Biomedical Research In Malaga (IBIMA), Malaga University, Malaga, Spain; Paediatric Department, University Children Hospital of Malaga, Malaga, Spain.

Background: Adults with rheumatoid arthritis have been shown to have a reduction in lean mass and increased adiposity, despite presenting normal Body Mass Index (BMI). Several studies have shown increased adiposity induces a proinflammatory state which lead to a worse response to treatment. There are few studies about the subject in juvenile idiopathic arthritis (JIA).

Objectives: Describing body composition and anthropometric parameters in JIA patients, and evaluating relationship between adiposity and inflammatory in these children.

Methods: Observational cross-sectional study. In JIA patients from 4 to 15 years, monitored by a Pediatric Rheumatology Unit. Monarticular forms were excluded. Anthropometric, clinical and treatment data were recorded. DXA (measuring bone and fat mass) were obtained. Fat Mass Index (FMI) was defined as fat mass (kg)/height (m²) and fat-free mass index (FFMI) as lean mass (kg)/height (m²). JADAS27 index was used to evaluate inflammatory activity.

Results: We analyzed 80 patients, whose characteristics are shown in table 1. The most frequent JIA subtype was oligoarticular (16.3% extended,47.5% persistent) followed by polyarticular (25.1%). Twenty five percent of patients had uveitis. Fifty percent them had inactive disease with treatment, 26% had activity and 23% were inactive without treatment. Regarding the treatment, 52.5% were on methotrexate and 30% on a biological drug (22.5% antiTNFα/5% anti-IL-1), 2.5% anti-IL-6). Disease duration average was 6.6 years (± 3.7SD). JADAS27 index mean score was 2 (±4SD). CRP 4.7mg/l (±9SD), ESR 8.7mm (±7.2SD) and CHAQ 0.17 (± 0.38SD). Anthropometric parameters are shown in table 1. Mean JADAS27 index score in patients with normal BMI was lower than mean JADAS27 index score in overweight and obese patients (3.3±6.0SD), although this difference was not significantly (p=0.255). In multiple linear regression, an increase of 0.3 JADAS27 was observed for each unit of FMI increase (p=0.03). This relationship was maintained in the multivariate analysis (B0.015; p0.01) independently of JIA subtype and received treatment.

Conclusions: In JIA patients, there is a linear relationship between FMI and disease activity measured by JADAS27, but most patients had a normal BMI. The establishment of this relationship (fat-inflammatory activity) would be transcendental due to the need to optimize the recommendations in the JIA approach.

DOI: 10.1136/annrheumdis-2017-eular.3785
The majority are female (85%). The average age is 15.25 years. This cohort includes Hispanic (58%), Asian (29%), African-American (21%) and Caucasian (11%) children. LN class III or IV was diagnosed in 67% of patients. Nearly all were treated with hydroxychloroquine and steroids (95%). Other drugs used include mycophenolate mofetil (85%), cyclophosphamide (43%), rituximab (27%) and tacrolimus (18%).

A significant increase in urinary HER2, TWEAK and VCAM1 levels was found in LN patients (p=0.005; p=0.006; p=0.01, respectively) when compared to controls. HER2 levels reflected disease activity, increasing during flares.

In an adult cohort of LN patients (N=126) composed mainly of females (80%) with an average age of 46.13 years, we also found a significant increase of urinary HER2 when compared to controls (p=0.002).

A strong correlation between the urinary levels of HER2, TWEAK and VCAM1 was not found.

Conclusions: Urinary HER2, TWEAK and VCAM1 were significantly increased in a paediatric cohort of LN patients. In addition, significantly higher urinary HER2 levels were also found in an adult LN cohort. This ongoing study will further evaluate if these urinary markers, alone or in combination, can reflect disease activity and predict renal flares, analysing their potential value in clinical practice.

THU0491 COMPARISON OF CLINICAL AND SEROLOGICAL FEATURES OF JUVENILE AND ADULT-ONSET NEUROPSYCHIATRIC LUPUS IN SPANISH PATIENTS
S. Garrote Corral, A. García Fernández, W.A. Sifuentes Giraldo, A.L. Boteanu, M.L. Gamir Gámir, A. Zea Mendoza, Rheumatology, Ramon y Cajal University Hospital, Madrid, Spain

Background: Neuropsychiatric (NP) manifestations are a main cause of morbidity and mortality in juvenile-onset systemic lupus erythematosus (JSL). Some studies suggest that they are more frequent and severe in JSL than in adult-onset SLE (aSLE).

Objectives: To compare the clinical and serological profile of pediatric and adult patients with neuropsychiatric lupus (NPSLE) treated in a Spanish tertiary center.

Methods: A retrospective study of patients with SLE (age of onset: 0–18y) and aSLE (age of onset: >18y) seen in our center during the period 1988–2016 was performed. Case definitions were adopted from the American College of Rheumatology.

Results: A total of 69 patients with NPSLE were included, aSLE 41 (59%) and JSL 28 (41%), the comparison of groups is presented in the table. Most of them were Caucasian (92%), mean age at diagnosis in adults was 36.4 years (range: 19–68) and 15.9 years (range: 8–18) in children. The proportion of males was higher in the latter group. The mean duration of the disease was significantly greater in adults, as well as the time from SLE diagnosis to NP manifestation onset, although without significant differences between groups. Central NP manifestations were the most frequent in both groups (aSLE 93%, JSL 96%) and most frequent manifestations in aSLE were headache (29%), cerebrovascular disease (27%), seizures (17%) and neuropsychological manifestations (aSLE 12%, JSL 11%). The most frequent manifestations in JSL were seizures (46%), headache (29%), mood disorder/depression (25%), psychosis (16%) and autonomic disorders (16%). A significant group of patients presented >2 central manifestation during their evolution (aSLE 32%, JSL 41%), with the mean number of manifestations in adults being 1.36 (range: 1–3) and in children 1.44 Range: 1–4). Patients with JSL developed lupus nephritis (LN) with a significantly higher frequency, as well as higher titres of anti-DNA antibodies, erythrocyte sedimentation rate (ESR) and cryoglobulins, compared to aSLE.

Conclusions: Our results corroborate that juvenile patients with NPSLE present higher disease activity compared to adults. There was no significant difference in the time from SLE diagnosis to NP manifestation onset, but tended to be shorter in JSL. The spectrum of NPSLE was varied both groups and an important proportion developed ≥2 manifestation. Mortality continues to be important in NPSLE in both age groups.

THU0492 MACROPHAGE ACTIVATION SYNDROME AS THE INITIAL MANIFESTATION OF JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS
S. Sato, Y. Uejima, E. Suganuma, T. Takano, S. Fujinaga, Y. Kawano. Saitama Children’s Medical Center, Saitama, Japan

Background: Macrophage activation syndrome (MAS) is a severe, potentially life-threatening complication of autoimmune diseases in children. Little is known about the association between MAS and the onset of juvenile systemic lupus erythematosus (JSL).

Objectives: The aim of this study was to determine the frequency and clinical features of MAS as the initial complication of JSL.

Methods: During 2004 and 2016, we retrospectively reviewed the clinical and laboratory features of 46 JSL patients diagnosed at the Saitama Children’s Medical Center. Patients who were complicated with MAS at the same time as JSL were compared with a control group composed of 30 JSL patients without MAS. The MAS was diagnosed according to preliminary guidelines.

Results: Fifteen patients (32.6%) developed MAS during the initial stage of JSL. Fever, leukopenia, thrombocytopenia, hyperferritinemia, hypofibrinogenemia, increased aspartate aminotransferase (AST), and increased lactate dehydrogenase (LDH) were more frequently observed in patients having JSL with MAS than in those having JSL without MAS. No differences were observed in serum C3 and C4 levels, or erythrocyte sedimentation rate (ESR) (P>0.05). Especially, Seven patients (46.7%) had neurologic symptoms that were significantly higher in those with MAS (P<0.01). All patients received corticosteroids when JSL with MAS diagnosis was established, among whom seven received pulse methylprednisolone therapy. Two patients were treated with IVIG. Nine patients with MAS were treated with immunosuppressants, including cyclophosphamide and mycophenolate mofetil, azathioprine. No patient involved in this study died.

Conclusions: MAS can be the initial manifestation of JSL. MAS may be an underrecognized complication of JSL. MAS with JSL should be suspected in patients with high fever, cytopenia, and a liver disorder. In addition, we found that in JSL with MAS patients, they had more neurologic symptoms compared to JSL without MAS. Early diagnosis and intensive therapy is essential to improve the clinical outcome.

THU0493 STUDY OF LONG-TERM OUTCOME OF CHILDREN WITH JUVENILE DERMATOMYOSITIS FROM A SINGLE-CENTRE IN NORTH INDIA
A. Sharma, A. Gupta, A. Rawat, D. Suri, S. Singh. Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarh, India, Chandigarh, India

Background: Juvenile dermatomyositis (JDM) is a rare inflammatory myopathy seen in children. There have been few studies on long-term outcome in children with JDM.

Objectives: To assess long-term outcome of JDM using validated measures of outcome

Methods: All children diagnosed to have JDM for more than 2 years and who had been followed in the Pediatric Rheumatology Clinic at PGIMER, Chandigarh, India, were deemed eligible for recruitment. Study period was from January 1, 2015 to June 30, 2016. Those who were not on regular follow-up were called for assessment which was done by a single observer using Childhood Myositis Assessment Scale (CMAS), Manual Muscle Testing 8 (MMT8), Myositis Activity Disease Assessment Tool (MADAT), 2AD, Myositis Damage Index (MDI) and Childhood Health Assessment Questionnaire (CHAQ).

Results: Thirty-five children were enrolled in this study, 22 (62.9%) were on regular follow-up. Mean age was 13.9yrs (range 4–29yrs). Mean age at diagnosis was 7.51yrs with median interval between onset of symptoms and diagnosis.
being 5 months. Mean duration of disease at the time of enrolment was 7.18yrs. Disease course was monocylic in 24 (68.6%). Muscle strength was normal in 71.4%. Severe involvement defined as MMT8 score below 64 was seen in 8.6%. Cutaneous activity was determined by aCAT with 40% children having some form of cutaneous activity. Based on MYOACT, 31.4% children had evidence of myocarditis. The prevalence of cutaneous involvement with skin being the commonest organ system involved in 28.6% followed by muscles in 22.9%. Twenty-one (60%) children had some form of cutaneous damage. Calcinosus in 12 (34.3%) and lipodystrophy in 8 (22.9%). Twenty four subjects had an MDI score of >1 suggesting damage in at least one organ system. Most commonly affected organs were skin and muscles in 20, 12 and 9 subjects respectively.

Nine (25.7%) subjects in our study had some form of a physical dysfunction suggested by a CHAQ score above 0. Previous studies on long-term outcomes in children with JDM have either not used validated outcome measures or have used fewer measures [1–3].

Conclusions: Highlight of our study is the use of validated outcome measures for evaluation of long-term outcomes. After mean disease duration of 7.18 yrs, 1/3rd subjects had evidence of disease activity with almost 1/10th having moderate to severe activity. About 2/3rd had damage in at least one organ system. Skin was the most common organ affected by activity as well as damage. About 1/4th had reduced physical functioning. Thus, JDM is not a disease where one time treatment would suffice and regular long-term follow-up is required. Counselling of the caregivers is also critical for them to adhere to follow-up. Larger long-term studies using validated outcome measures are required to confirm these findings.

THU0494

CHILDREN WITH KAWASAKI DISEASE IN DIFFERENT AGE GROUPS IN SOUTHWEST CHINA
L. Shi 1, J. Li 1, D. Gie 2, L. Qiao 2, 1 Peking University International Hospital, Beijing; 2 West China Second University Hospital, Chengdu, China

Background: Kawasaki disease (KD) is a systemic vasculitis characterized by acute and prolonged fever. The prevalence of coronary artery abnormality (CAA) is as high as 11%. The young infants usually have the increased risk of CAA, but do not have the typical clinical manifestations of KD.

Objectives: To explore clinical features of children with KD in different age groups to improve the prognosis of KD.

Methods: A total of 218 children with Kawasaki disease were divided into the infants group (≤ 2 years old), the toddler group, the pre-school age group and the school age group. Retrospective analysis of clinical data were performed among the groups. Categorical data were compared with each other statistically by Chi-square analysis. Statistical significant was defined as P<0.05. The incidence of carditis, CAA, and the incidence of increased platelets were analyzed in the four groups. The analysis was focused on the other three groups and excluded the five cases in the following statistical analysis.

Results: (1) Among the 218 KD patients, the male to female ratio was 1.5:1 and the recurrence rate was 1.8%. Seven cases (3.2%) were diagnosed as atypical KD, and 34 (38.5%) patients accepted intravenous gamma globulin (IVIG) treatment after the sixth day of KD onset. The incidence of IVIG-resistant KD was 8.7% and the rate of coronary dilation was 11.5%. (2) Fever was the most common clinical feature (100%). The bilateral bulbar conjunctiva injection and the characteristic rash of oropharynx were 85.4% and 81.2% respectively. Moreover, cough (40.5%), diarrhea (16.9%) and vomiting (8.5%) were also very common in the present KD patients. (3) Patients from the toddlers’ group were more common to develop lymphadenopathy and skin rash (χ²=7.784, P=0.002; χ²=10.794, P=0.005), but were less frequently to be documented with cough and diarrhea (χ²=2.734, P=0.026; χ²=18.447, P=0.000). (4) The incidence of increased platelets was more common in the infants group (χ²=2.552, P=0.023). Comparing with the urine test among three groups, the toddlers’ group had a higher incidence of sterile pyuria (χ²=10.653, P=0.005), and infants younger than 12 months old had a lower incidence of proteinuria and positive urine ketone (χ²=15.507, P=0.000; χ²=10.433, P=0.000).

Conclusions: The respiratory tract, the digestive and urinary systems are involved commonly in Kawasaki disease, and patients from different age groups showed different clinical features, which should be pay more attention to promote the prognosis.

THU0495

EFFECTIVENESS OF CHILDHOOD VACCINATIONS IN CAPS PATIENTS TREATED WITH CANAKINUMAB: RESULTS FROM AN OPEN-LABEL PHASE 3 EXTENSION STUDY
P. Brogan 1, M. Hofer 2, J. Kuemmerle-Deschner 3, B. Lauwerys 4, A. Speziale 5, X. Wei 6, R. Laxer 7, 1 Infection, Immunology, and Rheumatology, UCL Institute of Child Health, and Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom; 2 Unité Romande de Rhumatologie Pédiatrique, Hospitalier Universitaire Vaudois, Lausanne, Switzerland; 3 University Hospital Tübingen, Tübingen, Germany; 4 Cliniques Universitaires Saint-Luc et Université Catholique de Louvain, Brussels, Belgium; 5 Novartis AG, Basel, Switzerland; 6 Novartis Pharma, Beijing, China; 7 University of Toronto, The Hospital for Sick Children, Toronto, Ontario, Canada

Background: Canakinumab (CAN) has been shown not to impair antibody production following vaccination in children in an open-label phase 3 study (NCT01302860). Here we present the results from the extension of this study.

Objectives: To evaluate the presence of protective antibody levels following immunisation with inactivated vaccines in CAPS patients during extension study. Methods: Patients who completed the core study were allowed to continue in the extension study on the standard dosing regimen of 2 mg/kg subcutaneous CAN every 8 weeks or on last dose/dosing regimen received in the core study. Vaccination response was evaluated using post-vaccination antibody titres at 4 and 8 weeks after immunisation. Patients were considered assessable for an antibody response to a specific vaccination if they had a measurement of antibody titre 0–14 days post-vaccination (pre-vaccination assessment) and at least 1 subsequence measurement of antibody titre at 4 weeks and/or 8 weeks post-vaccination. However, for patients with adequate pre-dose antibody titres and maintained during the trial, the specific patient vaccination was deemed non-assessable.

Results: During the extension phase, of 17 patients (<6 years), 4 received 8 types of vaccinations against Corynebacterium diptheriae, Bordetella pertussis, Neisseria meningitidis, Clostridium tetani, influenza type A and type B, Haemophilus influenzae B, Streptococcus pneumoniae, or hoga rhatis B. Of 20 unique patient-vaccination cases, 17 were assessable for a vaccination response, whereas for the remaining 3, pre-dose antibody titre was not available. For 16 (94.1%) assessable cases, post-vaccination antibody titres increased above protective levels. For one patient who received Tetravac formulation (diphtheria, tetanus and acellular pertussis (aP) in combination), the response observed for 1 (vaccination against Clostridium tetani) of the 3 vaccines included in Tetravac represented optical density rather than antibody concentrations and hence considered non-evaluable. For 19/20 patient-vaccinations, including those without pre-dose antibody titres, protective levels were observed during the study, which were maintained throughout the extension study.

Conclusions: Canakinumab appeared to have no effect on post-vaccination antibody production following the administration of non-live vaccines in CAPS patients.

THU0496

PULMONARY SYMPTOMS AS THE FIRST PRESENTATION OF KAWASAKI DISEASE IN CHILDREN
A. Gupta, A. Kumar, D. Suri, S. Singh. Pediatrics, Postgraduate Institute of Medical Education and Research, Chandigarh, India, Chandigarh, India

Background: Kawasaki disease (KD) is a medium vessel vasculitis which predominantly affects children less than 5 years of age. Though principal clinical symptoms are mucocutaneous, KD in children may have atypical clinical manifestations, including pulmonary, which may create diagnostic difficulties for the treating physician.

Objectives: We describe our experience of managing children with uncommon pulmonary presentation of KD.
Methods: Five hundred and sixty-five (565) children were diagnosed with KD during the period from January 1993 to December 2016 in Pediatric Rheumatology Clinic, Advanced Pediatrics Centre, Postgraduate Institute of Medical Education and Research, Chandigarh, India. Nine children had pulmonary presentation of KD. A retrospective case review with respect to clinical presentation, radiological findings and treatment was done.

Results: Pulmonary presentation of KD was seen in 1.6% patients. Mean age at diagnosis of KD was 2.9 years (range 9 months – 4 years). 77.8% patients had no features suggestive of KD either on history or at presentation. First sign of KD was noted at a mean duration of 17.6 days (range 6–28 days) from the onset of symptoms. Pulmonary presentation was the most common clinical sign seen in 66.6% patients followed by erythematous rash and perianal desquamation in 33.3% patients each.

Persistent fever, thrombocytosis and elevated erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were seen in all patients. Microbiological investigations showed evidence of infection in only 2 patients – methicillin sensitive staphylococcus aureus in pus and positive mycoplasma agglutinin titre in one patient each. Parenchymal consolidation was the most common radiological finding (100%) followed by pleural effusion (55.5%), empyema (33.3%) and pneumothorax (11.1%). Coronary artery abnormalities were evident on echocardiography in 22.2% patients with dilatation of right coronary artery and left main coronary artery in 1 patient each.

All patients received intravenous antimicrobials for pneumonia. Intravenous immunoglobulin (IVIG) at 2g/kg was given after a mean duration of 24 days of fever with which there was unresolute to IVIG therapy and responded to IVIG therapy in all except 2 patients which required a second dose of IVIG. 55.5% patients required intercostal drainage tube (ICDT) insertion, 2 patients required streptokinase and 1 patient each required video assisted bronchoscopic aspiration and debridement. Mean follow up period was 15.2 months (range 0–62 months).

Conclusions: Pulmonary involvement in patients with KD is uncommon and is less commonly recognized. Unresolving pneumonia in a child who continues to be febrile despite adequate antimicrobials with elevated inflammatory markers can be a clue towards the diagnosis of KD. Early recognition can prevent delays in diagnosis and shorten the hospital stay.

THU0498 PFAPA SYNDROME IN LARGE PEDIATRIC POPULATION: A SINGLE CENTER EXPERIENCE

E. Pehlivan, A. Adrovic, S. Sahin, K. Barut, O. Kul, O. Kasapcopur. Pediatric Rheumatology, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey

Background: Periodic fever, aphthosis, pharyngitis, and adenitis (PFAPA) syndrome is an auto-inflammatory condition of unknown etiology. It is the second most common auto-inflammatory disease in our country, following familial Mediterranean fever. Previous studies showed that tonsillectomy represents efficient treatment options.

Objectives: Our aim was to explore the main clinical features, response to tonsillectomy and long-term outcome of PFAPA pediatric patients in a single cohort. We assessed association of MEFV gene mutation with disease characteristics and treatment response.

Methods: We reviewed medical records of patients who were diagnosed with PFAPA syndrome between the January 2010 and June 2016. All of the recorded 562 patients were called by the telephone and 365 (65%) of them were reached. Demographic, clinical and therapeutic features were taken from the patients’ medical records. Data on clinical course and the disease outcome were collected by using a structured questionnaire which was fulfilled during the phone conversation between investigator and patients parents.

Results: A total of 365 patients with PFAPA were examined: 154 (42%) of them were female. The mean age at disease onset, at diagnosis and at the investigation was 22.7±18.8, 41.7±21.7 and 77.1±43.3 months, respectively. The most common disease feature at the disease onset was: recurrent fever in 365 (100%), cryptic tonsillitis in 365 (100%) and aphthous stomatitis in 317 (88%). Sixty three (17%) patients met the criteria for both PFAPA and FMF. MEFV gene mutation analysis was performed in 93 (25%) patients and 51 of them (54%) had a heterozygous mutation in exon 10. Surgical treatment was performed in 158 (43%) patients. Complete clinical remission was achieved in 127 (80.3%) patients. Six (3%) showed no response to surgical treatment while 25 (15.8%) patients had a partial response. In patients with partial clinical response, frequency of fever attacks decreased significantly from 17.5 to 7.3 attack per year (p<0.05). Among patients who did not respond to tonsillectomy, 11 (52.4%) were carrier of MEFV heterozygous mutation in exon 10. There was a statistically significant difference between patients with and without coexistence of FMF features, according to surgical treatment response (p<0.05). The mean age of resolution of PFAPA symptoms in patients who underwent tonsillectomy was 52±22.4 months and in patients without tonsillectomy 66±22.6 months.

Conclusions: Although PFAPA symptoms usually resolve before age of eight, some patients’ complaints persist. MEFV gene mutations should be considered in tonsillado-neoidectomiedicate patients especially in endemic regions like Turkey. Tonsillado(ne)nectomy seems to be an effective treatment option for pediatric PFAPA patients.

THU0499 ANTI-MULLERIAN HORMONE IN A COHORT OF YOUNG ADULT WOMEN WITH JUVENILE IDIOPATHIC ARTHRITIS

C. Di Maria1, M.R. Gigante1, A. Musto1, A. Barini2, A. Barini3, B. Tolusso3, G. Ferraccioli1, E. Gremsse1, R. Institute of Rheumatology, 2Institute of Biochemistry and Clinical Biochemistry, Fondazione Policlinico Universitario A. Gemelli, Catholic University of the Sacred Heart, Rome, Italy

Background: Juvenile Idiopathic Arthritis (JIA) represents one of the most common chronic disease of the childhood, affects young people before sixteen and persists into their reproductive years. It is reported in one study that fertility was compromised in JIA women but potentially it can be compromised by pharmacological treatments such as the prolonged immunosuppressive therapy used in young women patients (1). The Anti-Mullerian Hormone (AMH) is secreted from granulosa ovary cells and serum levels of Anti-Mullerian Hormone are used as a measure of ovarian reserve, reflecting the number of primary follicles.

Methods: Levels of AMH in sera from 154 patients with JIA, according to different subtypes (persistent oligoarticular arthritis (POA) and polyarticular) were compared at diagnosis and then again after 6 months. The same analysis was performed on 20 age- and BMI-matched healthy women. In the subgroups of JIA patients, the differences of AMH levels at diagnosis and after 6 months were compared with healthy subjects.

Results: At diagnosis, the patients with POA had significantly lower AMH levels than JIA patients with polyarticular arthritis (P = 0.002). In POA subgroup, at diagnosis AMH levels were significantly lower than healthy subjects (P = 0.006). After 6 months, these differences were lessen (Table 1). In polyarticular subgroup, no differences were observed at diagnosis and after 6 months.

Conclusions: Patients with POA had lower AMH levels at diagnosis, which was associated with a decrease of primary follicles. Moreover, these findings suggest that at diagnosis, the patients with POA have lower levels of AMH than JIA patients with polyarticular arthritis, but these differences are lessen after 6 months of therapy.
Objectives: The aims of this study were to evaluate AMH serum levels in a cohort of young adult women affected from JIA, to compare these levels between patients and healthy controls and to assess whether the presence of the disease and the influence of previous exposure to disease-modifying antirheumatic drugs (DMARDs) and of other disease parameters may affect the ovarian reserve.

Methods: A cross-sectional study of 90 women was performed. Of these, 47 patients fulfilled the JIA criteria and 43 were healthy women age-matched and without history of gynecological disease or DMARDs use. All participants were between 18 and 25 years and with regular menses, and 20 healthy women age-matched were evaluated.

Results: Thirty-three of the JIA group (70%) had disease-modifying antirheumatic drugs (DMARDs) treatments within the past year. The AMH levels were significantly lower in the JIA (mean ± SD: 0.8 ± 0.5 ng/ml) compared to the control group (1.0 ± 0.6 ng/ml). No significant difference was found when AMH levels were compared between male (0.7 ± 0.5 ng/ml) and female (1.1 ± 0.6 ng/ml) JIA patients. The disease duration did not alter AMH levels. A significant decrease in AMH levels was found in subgroups with previous exposure to disease-modifying antirheumatic drugs (DMARDs) and a history of previous gynecological interventions. AMH levels did not change between male (0.7 ± 0.5 ng/ml) and female (1.1 ± 0.6 ng/ml) JIA patients.

Conclusions: In this study, we report that AMH serum levels are decreased in JIA patients when compared with healthy age-matched women. This reduction may be associated with the disease duration and previous exposure to disease-modifying antirheumatic drugs (DMARDs) and is not due to the use of immunosuppressive drugs. These findings could be important for adult JIA patients.

THU0500 PHOTOSTIMULATION OF CHRONIC CERVICAL PAIN IN JUVELINE POLYARITHRITIS

C. Allioae, I-M. Allioae, Dept. of Medical Physics, Iasi, Romania, "Al. I. Cuza" University, Iasi, Romania

Background: Chronic pain management in juvenile arthritis constitutes a special provocation not only for the medical doctors, but also for the patients and parents.

Despite the extensive use of the biological agents with high efficacy, combined with the multimodal therapies, chronic pain still remains an important issue for the public health, with implications on the activities of daily living and the scholar performances. Lasers could be used for transmitting biological messages and initiating metabolic changes within living cells: no more pain, much more energy.

Chronic pain in JIA patients can be helped by photobiostimulation (pulsed laser therapy).

Methods: 62 patients diagnosed with juvenile polyarthritis (ILAR criteria), 11.4 years mean age were randomly divided in Group I (42 patients treated with local laser stimulation and methotrexate), comparatively with a Group II - control (20 patients) treated with methotrexate and placebo laser, for a period of 9 months. Group I received local laser stimulation with a dose of 2.5 J/cm2 in 14 latero-cervical painful points, corresponding to the 7 cervical vertebrae, 1 point on the insertion of sternocleido-mastoildian muscle on the styloïd process, and 1 point on each loco-regional submandibular lymphatic gangions, using a GaAlAs laser probe of 670 nm, 25 mW output power and a modulation frequency of 10 Hz. 45 joules were applied daily as laser treatment, 10 sessions per month, repeated 3 times, in the 9 months. For all the patients, the main medication was methotrexate in a dose of 0.6 mg/kg (maximum 20 mg) per week, steroids and of other disease parameters may affect the ovarian reserve.

Objectives: The aims of this study were to evaluate AMH serum levels in a cohort of young adult women affected from JIA, to compare these levels between patients and healthy controls and to assess whether the presence of the disease and the influence of previous exposure to disease-modifying antirheumatic drugs (DMARDs) and of other disease parameters may affect the ovarian reserve.

Methods: A cross-sectional study of 90 women was performed. Of these, 47 patients fulfilled the JIA criteria and 43 were healthy women age-matched and without history of gynecological disease or DMARDs use. All participants were between 18 and 25 years and with regular menses, and 20 healthy women age-matched were evaluated.

Results: Thirty-three of the JIA group (70%) had disease-modifying antirheumatic drugs (DMARDs) treatments within the past year. The AMH levels were significantly lower in the JIA (mean ± SD: 0.8 ± 0.5 ng/ml) compared to the control group (1.0 ± 0.6 ng/ml). No significant difference was found when AMH levels were compared between male (0.7 ± 0.5 ng/ml) and female (1.1 ± 0.6 ng/ml) JIA patients. The disease duration did not alter AMH levels. A significant decrease in AMH levels was found in subgroups with previous exposure to disease-modifying antirheumatic drugs (DMARDs) and a history of previous gynecological interventions. AMH levels did not change between male (0.7 ± 0.5 ng/ml) and female (1.1 ± 0.6 ng/ml) JIA patients.

Conclusions: In this study, we report that AMH serum levels are decreased in JIA patients when compared with healthy age-matched women. This reduction may be associated with the disease duration and previous exposure to disease-modifying antirheumatic drugs (DMARDs) and is not due to the use of immunosuppressive drugs. These findings could be important for adult JIA patients.

THU0501 EFFICACY AND SAFETY OF METHOTREXATE AS MAINTENANCE THERAPY FOR PATIENTS WITH ANTI–N–METHYL–D–ASPARTATE RECEPTOR (NMDAR) ENCEPHALITIS: EXPERIENCE OF A SINGLE CENTER

D. Ramos-Bello, A.N. Rangel-Botello, G. Aguilera Barragan-Pickens, T.A. Luna-Zúñiga, A.J. Pedro-Martínez, G. Martínez-Flores, A. Bravo-Oro, C. Abud-Mendoza, Unidad regional de Reumatología y Osteoporosis, Hospital Central "Dr. Ignacio Morones Prieto" y Facultad de Medicina de la Uaslp, SLP, Mexico

Background: Autoimmune-mediated encephalitis (A-ME) in children remains as a diagnostic and therapeutic challenge (1). These patients have a 12% risk of relapse, which is usually more severe (2). We previously proposed the therapy with methotrexate (MTX) for this condition (3), and we are offering now additional data on its potential benefits.

Objectives: To describe the outcome of children with A-ME receiving MTX for at least one year after stabilization of symptoms.

Methods: In this retrospective study we recruited 11 patients (7 females) with A-ME, a mean age of 7.5 years (range 8 months - 14 years), and with a median follow-up of 20 months. In all cases, anti-NMDAR antibodies (subunit NR1) were detected in the CSF. Data from these patients were collected by consulting medical records. Relapse of encephalitis was defined as new onset of symptoms occurring after at least 2 months of remission, in the absence of other CNS disease.

Results: Patients presented with seizures (n=10), behavioral changes (n=11), psychosis (n=11), speech problems (n=10), and autonomic/breathing dysregulation (n=9). Patients were initially treated with methylprednisolone pulses (n=11), rituximab (n=6), intravenous immunoglobulins (n=4), cyclophosphamide (n=3) and MTX (n=11). Complete remission was observed in all cases, and maintenance therapy with MTX (10 mg/m2 BS) was started in all them, with gradual tapering until it was stopped. Interestingly, no relapses have been observed in any case during the mean follow up. One patient had mild oral ulcers and other showed mild elevation of liver enzymes; both events remitted after discontinuing the treatment for a couple of weeks.

Conclusions: Since relapses in patients with A-ME are a relatively frequent, the immunosuppressive therapy to prevent them is fully justified (4). Moreover, MTX therapy in pediatric patients is safe and usually well tolerated (3,5,6). The recommended dose is less than 15 mg/m2 BS or 1 mg/kg, with a maximal dose of 40 mg and with folic acid supplementation. In this regard, our study suggests that MTX administration (10 mg/m2 BS) during at least one year is a viable and effective therapy for maintenance treatment of A-ME. Accordingly, we did not detect relapses in the 11 patients studied with a median follow up time of 22 months and with an acceptable safety profile.

THU0502 EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH STILL’S DISEASE: A POOLED ANALYSIS OF SJIA DATA BY AGE GROUPS

1Charite-Universitätsmedizin, Berlin, Germany; 2Necker-Enfants Malades Basel, Switzerland; 3Novartis Pharma AG, Basel, Switzerland; 4Novartis Pharmaceuticals Corporation, East Hanover, United States; 5University of Padova, Padova, Italy; 6Weill Cornell Medical College, New York, United States; 7University of Siena, Siena, Italy; 8Novartis Pharma AG, Basel, Switzerland; 9Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: Still’s disease presents in paediatric and adult patients (pts) as a disease continuum with similar symptoms and pathophysiology.1,2

Objectives: To evaluate the efficacy and safety of canakinumab (CAN), a selective human anti–IL1 monoclonal antibody, in SJIA pts from pooled data across 3 age groups (grps); children, adolescent and adults (the latter representing adult-onset Still’s disease [AOSD] population).

Methods: Data of CAN treated pts were pooled from 4 SJIA studies (NCT00426218, NCT00886769, NCT00889863, NCT00891046). CAN was ad-
ministered at 4 mg/kg every 4 weeks (wk). Efficacy parameters (adapted ACR [aACR] paediatric responses, juvenile idiopathic arthritis [JIA] ACR responses, pts with inactive disease), CRP levels over 12 wk and safety were assessed by age grp. One study [NCT00426218] was excluded for efficacy outcomes. Results: 216 children (2–12 years [y]), 56 adolescents (12–16 y) and 29 adults (>16 y) were analysed for efficacy outcomes. The efficacy parameters across the 3 age grps were largely comparable (Table 1). The safety profile of CAN was similar across age grps (Table 2). One death was reported (adolescents grp). Clinical, laboratory and immunogenicity data showed no notable differences between the age grps.

Conclusions: Pooled analyses indicate similar efficacy of CAN across all the age grps of children, adolescents and adult SJIA pts. There were no meaningful differences in safety profiles across the different age grp. These analyses suggest similar efficacy of CAN in AOSD pts as observed in the SJIA pts. One study [NCT00426218] was excluded for efficacy outcomes. The efficacy parameters across all the age grps were largely comparable (Table 1). The safety profile of CAN was similar across age grps (Table 2). One death was reported (adolescents grp). Clinical, laboratory and immunogenicity data showed no notable differences between the age grps.

QUANTIFYING PHYSICAL EDUCATION ATTENDANCE AND ITS RELATIONSHIP TO PAIN SEVERITY AND FATIGUE IN ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS – RESULTS FROM THE GERMAN NATIONAL RHEUMATOLOGICAL DATABASE

Background: Regular physical education (PE) can help adolescents achieve the recommended amount of daily physical activity and provide immediate health benefits, by positively affecting musculo-skeletal development, mental health and social behavior. Adolescents with juvenile idiopathic arthritis (JIA) are less physically active and have lower fitness levels than their healthy peers [1]. Moreover, pain and fatigue are one of the most frequent complaints and identified as one of the causes behind impaired (social) functioning [2].

Objectives: To describe the participation rate in PE and to assess its relationship to pain and fatigue in adolescents with JIA.

Methods: Cross-sectional study of adolescents with JIA recorded in the National Pediatric Rheumatological Database (NPRD) in the year 2015 were considered for the analyses. Disease characteristics were provided by rheumatologists along with patient-reported outcomes and participation in PE. Relationship to PE was assessed by using spearman’s correlation.

Results: In 2015, a total of 3,289 adolescents with JIA (females 66%, mean disease duration 5 years, persistent oligoarthritis 30%) aged 13 to 17 were recorded. About 60% of the patients reported to participate in PE “always” (56% of girls, 69% of boys), whereas about 18% stated to be fully exempt from participating in PE (20% of girls, 14% of boys). Significant differences were found among JIA subgroups, whereby patients with enthesis-related arthritis participated more frequently than patients with rheumatoid factor-positive polyarthritis (64% vs. 46%). The mean pain level was 2.1, the mean fatigue level 1.8. Participation in PE was negatively correlated with self-reported pain intensity (r=0.43) and fatigue (r=0.32). Significant associations were found between PE attendance and age, sex, disease duration, functional status as well as disease activity measured by CHAQ and JADAS-10, respectively (p<0.05).

Conclusions: 6 of 10 adolescents with JIA participate in PE always, whereby higher rates of self-reported attendance are associated with less severe pain and fatigue.

Acknowledgements: The National Paediatric Rheumatological Database has been funded by the German Children Arthritis Foundation (Deutsche Kinder-Rheumaforschung).

Objectives: To report treatment response and safety data were compared. Treatment response was analyzed using JIA-ACR criteria, JADAS scores, JADAS10-minimal disease activity (MDA), JADAS-remission and ACR-inactive disease criteria were analysed.

Results: 589 non-systemic JIA patients exposed to Adalimumab with at least one follow-up report were identified in the German BiKE registry, representing 1143.9 patient years (PY) of exposure to ADA and 1206.5 observation years (OY) of observation.

Baseline patient characteristics, treatment response and safety data were compared. Treatment response was analyzed using JIA-ACR criteria, JADAS scores, JADAS10-minimal disease activity (MDA), JADAS-remission and ACR-inactive disease criteria were analysed.

Response rates at month 24 were 67/66/54/35/65/32/29% on ADA monotherapy and 68/63/45/28%/50/28/27 on combination of ADA and MTX (not significant).

At month 12 JIA-ACR 30/50/70/90 and JADAS-MDA/-remission/ACR-inactive disease criteria were analysed. Rates of patients with an uveitis event was higher upon combination (p=0.008) as well as rate of elevated transaminase levels (p=0.01). Rate of patients with an uveitis event was higher upon combination (p=0.008) as well as rate of elevated transaminase levels (p=0.01). Rate of patients with an uveitis event was higher upon combination (p=0.008) as well as rate of elevated transaminase levels (p=0.01).

Background: Since the approval of Adalimumab (ADA) for treatment of juvenile idiopathic arthritis (JIA), it has become a valuable option, which significantly improved the outcome of patients.

Conclusions: To report treatment response and safety data were compared. Treatment response was analyzed using JIA-ACR criteria, JADAS scores, JADAS10-minimal disease activity (MDA), JADAS-remission and ACR-inactive disease criteria were analysed.

Results: 589 non-systemic JIA patients exposed to Adalimumab with at least one follow-up report were identified in the German BiKE registry, representing 1143.9 patient years (PY) of exposure to ADA and 1206.5 observation years (OY) of observation.

Baseline patient characteristics, treatment response and safety data were compared. Treatment response was analyzed using JIA-ACR criteria, JADAS scores, JADAS10-minimal disease activity (MDA), JADAS-remission and ACR-inactive disease criteria were analysed.

Response rates at month 24 were 67/66/54/35/65/32/29% on ADA monotherapy and 68/63/45/28%/50/28/27 on combination of ADA and MTX (not significant).

At month 12 JIA-ACR 30/50/70/90 and JADAS-MDA/-remission/ACR-inactive disease criteria were analysed.
**Objectives:** To assess AIDAI score and evaluate correlation between AIDAI and disease/response characteristics over 16 weeks (wks) of CAN treatment in CLUSTER.

**Methods:** CLUSTER study design and results have been presented. 

**Results:** Median AIDAI scores decreased over time (Fig 1). Proportion of pts with at least one score of 16% before baseline (BL) and 23% in TRAPS. AIDAI at Wk 16 correlated significantly with: SDAI in 3 all cohorts; PGAS in HIDS/MKD and TRAPS; SF12–MCS in cRFMF and HIDS/MKD (Table 1). CRP and SAA did not correlate with AIDAI.

**Conclusions:** CAN demonstrated rapid and sustained disease control assessed with AIDAI over 16 wks. Approximately half of cRFMF and TRAPS pts, and 40% of HIDS/MKD pts had inactive disease after 16 wks of treatment. AIDAI improvements at Wk 16 correlated with patient and physician driven evaluations of HIDS/MKD patients had inactive disease after 16 wks of treatment. AIDAI was performed in the 144 patients with pJIA with negative RF. Administration of TOA or TOZ resulted in statistically significant reducing of disease activity according to JADAS27. In ADA group after 3 months of administration JADAS27 decreased from 16.3±10.3 to 10.7±8.0 (p<0.0001). In TOZ group after 3 months of administration JADAS27 reduced from 22.1±12.2 to 13.9±9.1 (p=0.0012). The functional disability of the patients also statistically significant decrease in both treatments. Improvement of clinical practice.

**Results: 339 patients were enrolled into the study during 3 years. 64% of patients are girls. Mean age 10.98±4.41 years, with mean disease duration 5.8±1.48 years. The duration of the period between diagnosis and biologics start was 54.3±10.4 months. Comorbid conditions were found in 41.03% of patients. In 14.65% of the patients uveitis was diagnosed. Most common JIA subtype in patients receiving biologics are pJIA with negative RF (45%), sJIA (20%), enthesis-associated JIA (11%) and persistent oligoarthritis (11%). 67.3% of enrolled patients received adalimumab (ADA); 27.9%–tocilizumab (TOZ) and 4.8%–etanercept, respectively. During observational period biologics were discontinued in 19.8% of patients due to different reasons: adverse events were observed in 6.7% (ADA) and 16.7% (TOZ), insufficient efficacy of 23.3% (ADA) and 33.3% (TOZ), remission - 6.7% (ADA); drug absence - 63.3% (ADA) and 50% (TOZ), respectively. Comparative analysis of ADA and TOZ efficacy was performed in the 144 patients with pJIA with negative RF. Administration of either ADA or TOZ resulted in statistically significant reducing of disease activity according to JADAS27. In ADA group after 3 months of administration JADAS27 decreased from 16.3±10.3 to 10.7±8.0 (p<0.0001). In TOZ group after 3 months of administration JADAS27 reduced from 22.1±12.2 to 13.9±9.1 (p=0.0012). The functional disability of the patients also statistically significant decrease in both treatments. Improvement of clinical practice.**
The mean duration of tocilizumab therapy was 14.75 months. 2 patients received s.c. accoding the poly JIA dosing and all other i.v. There were different i.v doses applied, 5 of them 8mg/kg every 4 weeks, one of them 8 mg/kg every three weeks, 1 every two weeks and 1 patients received 10 mg/kg every 3 weeks. 3/11 received TOC as monotherapy, 8/11 as combination therapy, 6 of them with a concomitant use of MTX. One patient was treated with Tacrolimus or Tocilizumab. Treatment success was reflected by a decreased mLoSSi in 8/11 patients and in 6 patients by a decrease in the Localized Scleroderma Skin Damage Index [1] (LoSDi). No new lesion occurred during the treatment and in the patients with Parry Romberg subtype (n=2) no increase in the facial atrophy occurred. In 8/8 patients physician global (VAS 0–100) decreased and in 8/8 the patients global disease activity (VAS 0–100) decreased. In 3/3 patients, were it was applicable, the number of active joints decreased, in one patients the limb discrepancy decreased. The mean modified Rodnan skin score assessed in 8 patients decreased from the mean value of 5.2 in baseline to 1.5 at the end of follow-up.

Conclusions: In this small cohort of patients TOC seems to be a promising rescue medication in medrotretexe/mycophenolate non-responsive patients. A prospective controlled study would be important to prove the seen effect in a controlled way.

[THU0512] FLUORESCENCE OPTICAL IMAGING IN JUVENILE PATIENTS WITH AND WITHOUT INFARLAMATORY PEDIATRIC RHEUMATIC JOINT DISEASES

M. Beck1, J. Klotzbach1, A.-M. Glimm2, S. Ohrdorf3, S. Werner4, G. Hornett3, M. Backhaus3, R. Traszezdel1, K. Minden1, H. Girschick1,1, Deutsches Rheuma Forschungszentrum; 2Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin Berlin, Berlin; 3Asklepios Kinderklinik Sankt Augustin GmbH, Sankt Augustin; 4Department of Pediatric Rheumatology, Helios Kinder-Klinik Berlin-Buch; 5Children’s Hospital, Vivantes Hospital im Friedrichshain, Berlin, Germany

Background: Imaging techniques play an important role in making a diagnosis and in the evaluation of treatment effectiveness as well as in the outcome assessment of juvenile idiopathic arthritis (JIA). Fluorescence optical imaging (FOI) has been shown to visualize inflammation in arthritis of wrist and finger joints. FOI is a simple and cost-effective imaging technique that is well tolerated by the patients.

Objectives: Firstly, to determine the association and agreement of FOI with ultrasonography (US) and physician’s assessment of swollen and active joints. Secondly, to estimate the predictive power of FOI to distinguish between patients with and without inflammatory pediatric rheumatic joint diseases.

Methods: A total of 95 patients were enrolled in three pediatric rheumatology centers in Berlin, Germany. FOI and US (in greyscale (GS) and power Doppler (PD)) were performed in each patient. The FOI software automatically generated a semiquantitative score (0–4) for the FOI images. US images were semiquantitatively assessed for power Doppler and grayscale synovitis. Classification of the joint was performed by an experienced radiologist.

Results: The mean disease duration was 3.5 years (SD=3.2), the mean cJADAS-10 was 29.6 (SD=18.4), and 4 patients (4.2%) had a positive FOI PVM. The FOI PVM had a sensitivity of 40%, a specificity of 86% and an overall agreement of 83%. The area under the curve was 0.91 for US power Doppler, 0.84 for US GS synovitis, 0.76 and 0.93 for FOI PVM and P2 for the ability to distinguish between patients with and without inflammatory rheumatic diseases in pediatric juvenile patients. The agreement between active joint count, US and FOI was high. FOI may provide a cost-effective method to evaluate inflammation in finger and hand joints.

[THU0513] NEONATAL MANIFESTATIONS OF IMMUNE-MEDIATED RHEUMATIC DISEASES: A RETROSPECTIVE LONGITUDINAL STUDY IN A TERTIARY HOSPITAL

J. Bernardo1, I. Brito1, H. Guimarães2, M. Guimarães2, R. Fonseca2,1, Rheumatology; 2Pediatrics; 3Gynecology and Obstetrics, Faculty of Medicine of the University of Porto, Porto, Portugal

Background: Autoimmune rheumatic diseases such as systemic lupus erythematosus (SLE), antiphospholipid syndrome (APS) and Behcet’s disease (BD) are part of a clinical spectrum eligible to affect women in child-bearing ages, affecting neonatal outcomes. Cardiac, cutaneous, haematological, hepatic complications and, more rarely, pulmonary complications have been described.

Objectives: This project aims to describe the occurrence of neonatal lupus manifestations and possible associated clinical factors among women with immune-mediated rheumatic diseases.

Methods: A retrospective longitudinal study was performed including pregnant women with immune-mediated rheumatic disease seen in a multidisciplinary group for autoimmune diseases during pregnancy between January 2010 and December 2015. Clinical and demographic data as well as pregnancy outcomes and neonatal manifestations were collected through consultation of clinical files. Patients with and without neonatal lupus were compared using Mann-Whitney, chi-square and fisher tests (SPSS 24.0). Significance level was set as <0.05.

Results: We included 151 gestations from a total of 140 women with a mean age of 32.5±4.4 years: 4 gestations were twin pregnancies. Within these 151 gestations, 54 (35.8%) women had SLE, 17 (11.3%) had SJögren’s syndrome, 17 (11.3%) were Rheumatoid arthritis and 1 had 27% (11.3%) had anti-SSA/La, 10 (6.6%) had anti-SSB/La antibodies, 6 (4.0%) had anti- U1RNP antibodies and 43 (28.5%) had anti-nuclear antibodies. During follow-up, 142 (94.0%) babies were born and 7 (4.6%) abortions and 2 (1.3%) fetal losses occurred. 6 (4.2%) neonates were born with neonatal lupus and 1 (0.7%) died in utero with a complete heart block. Out of the 6 babies with manifestations, 4 (66.7%) were cardiac, 2 (33.3%) were cutaneous, 1 (16.7%) was hepatic, 2 (33.3%) were haematological and 1 (16.7%) was pulmonary. Neonatal lupus manifestations occurred more frequently in mothers with SS (23.5% vs 2.2%; p<0.003), anti-SSa/Ro (20% vs 0%; p<0.001), and anti-SSb/La (27.7% vs 1.5%; p<0.001).

Conclusions: Our study proved a link between immune-mediated rheumatic diseases and specific neonatal outcomes.

[THU0514] PREDICTIVE VALUE OF SUBCLINICAL SYNOVITIS DETECTED BY DOPPLER ULTRASOUND IN RELATION TO FLARE IN PATIENTS WITH JUVENILE IDIOPLATHIC ARTHRITIS TREATED WITH BIOLOGIC THERAPY AFTER TAPERING BILOGIC THERAPY

J.C. Nieto-González1, A. Boteanu2, J.C. López-Robledillo3, P. Collado4, A. Rodríguez2, D. Clemente3, M.L. Gámir2, I. Monteagudo1, E. Naredo3, 1Rheumatology, Hospital G.U. Gregorio Marañón; 2Rheumatology, Hospital Universitario Ramón y Cajal; 3Rheumatology, Hospital Infantil Universitario Niño Jesús; 4Rheumatology, Hospital Universitario Severo Ochoa; 5Rheumatology, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain.

Background: Anti-TNF therapy is effective and safe in JIA. Changes in anti-TNF doses are common when remission is achieved. Subclinical synovitis on Doppler mode (PD) detected by ultrasound can predict flares in adult RA, but it is not yet clear in JIA.

Objectives: The aim of this study is to evaluate the predictive value of subclinical synovitis detected by PD-US in relation to flares in patients with JIA on remission under anti-TNF when therapy is tapered. The preliminary results were presented at the EULAR congress 2015 in Rome (FRI0520).

Methods: Observational, prospective and multicenter study. We included JIA patients on at least 6 months treatment with anti-TNF, ETN and ADA, in whom anti-TNF was tapered due to clinical decision. ETN was tapered by increasing the injection 3 days and ADA by increasing a week. Patients were clinically assessed every 3 months and also with PD-US at baseline. Baseline US assessment included joints and tendons. Adult synovitis definitions and semiquantitative synovitis definitions were used to define positive PD-US for JIA. We collected demographics (date of birth, JIA subcategory, previous and current treatments. Flare was defined as clinical signs and/or symptoms of arthritis that required increase of systemic therapy.

Results: We included 57 patients, with 19 patients (33.33%) having a flare

Scientific Abstracts
during the 12 months follow-up. 38 patients (66.67%) were receiving ETN and 19 (33.33%) ADA, of which 11 patients (28.95%) had a flare with ETN and 8 patients (42.11%) with ADA. Table 1 shows demographics. Mean time to flare was 5.73 months (IR 2.9–8.9). Concomitant methotrexate was lower in patients with flare (26.32% vs 71.05%). In 18 patients (31.58%), a previous tapering was done and median time of disease duration before tapering was 22 months (IR 15.5–29.5). US does not predict flare in our cohort. Global synovitis score at baseline was 4 (IQR 1.3–10.8) and 0 in BM and PD respectively, and tenosynovitis was 0 both BM and PD.

Conclusions: Anti-TNF tapering was safe in our JIA patients in more than half of patients after 1 year follow-up. US did not predict flares in our patients. Concomitant treatment with methotrexate was more frequent in patients who remained on remission.

THU0515 DISABILITY AND LOWER QUALITY OF LIFE IS ASSOCIATED WITH SOCIOECONOMIC PASSIVITY IN YOUNG ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS

Objectives: To describe and compare the characteristics and outcomes of 6 with a diagnosis of CRMO, presenting between age 13–20.

Results: In total 17 patients were identified as having CRMO, presenting between 1999 and 2015. 10 patients were female, and 7 patients male. The median age of initial symptoms, and age of presentation was 12 years (range 1–16 years).

Conclusions: The perceived wisdom is that CRMO is a self-limiting disease which eventually goes into remission. However our centre’s experience is that nearly 50% of our patients have a disease which evolves into another systemic autoimmune disease, mainly SAPHO, polyarticular or enthesitis related JIA. Previous case series have suggested only 0–30% of patients’ disease evolves. This may be a reflection of our older cohort of patients, who are only referred to our service with ongoing disease.

The majority of patients have a recurrent and multifocal course of disease. The most common site of disease was in the lower limbs (70% patients), upper limbs (35% patients), clavicle (29.4%), mandible (17.6%) and spine/pelvis (32.3%).

All patients were treated with NSAIDs. In terms of treatments used since diagnosis, 76% patients have been on methotrexate (MTX), 47% had one infusion of pamidronate, and 23% required more than one infusion of pamidronate. Other medications include sulfasalazine (SSZ), azathioprine, risedronate and anti-TNFs (adalimumab, etanercept and infliximab).

On last clinic review, with or without imaging, 35% of patients continue to have active disease. Currently 20% patients are on MTX alone, 23% patients are on adalimumab and MTX, and 35% are only maintained on NSAIDS. Of those without active disease 5 patients (45%) are not on any DMARD or biologic therapy. This may be reflected in our experience of managing adolescent patients with CRMO.

THU0516 LONGER TERM OUTCOMES OF CRMO IN A TERTIARY ADOLESCENT AND YOUNG ADULT RHEUMATOLOGY CENTRE IN THE UK

K. E. N. Clark, F. Josephs, N. Daly, Y. Ioannou, C. L. Murphy, D. Sen. Rheumatology, University College London Hospitals, London, United Kingdom.

Background: Chronic relapsing multifocal osteomyelitis (CRMO) is a rare autoinflammatory bone condition presenting primarily in children and adolescents. It characteristically affects the epiphysis and metaphysis of long bones, and presents with bony pain, local swelling and warmth.

Objectives: The aim of this study was to collate our tertiary adolescent rheumatology centre’s experience of managing patients with CRMO, and establish their longer term outcomes, possibly by the fact we have a cohort of patients with CRMO under long-term follow-up.

Methods: We carried out a retrospective case note review of all patients who are attending our tertiary centre with diagnosis of CRMO, with a diagnosis of CRMO, presenting between age 13–20.

Results: In total 17 patients were identified as having CRMO, presenting between 1999 and 2015. 10 patients were female, and 7 patients male. The median age of initial symptoms, and age of presentation was 12 years (range 1–16 years).

Conclusions: The perceived wisdom is that CRMO is a self-limiting disease which eventually goes into remission. However our centre’s experience is that nearly 50% of our patients have a disease which evolves into another systemic autoimmune disease, mainly SAPHO, polyarticular or enthesitis related JIA. Previous case series have suggested only 0–30% of patients’ disease evolves. This may be a reflection of our older cohort of patients, who are only referred to our service with ongoing disease.

The majority of patients have a recurrent and multifocal course of disease. The most common site of disease was in the lower limbs (70% patients), upper limbs (35% patients), clavicle (29.4%), mandible (17.6%) and spine/pelvis (32.3%).

All patients were treated with NSAIDs. In terms of treatments used since diagnosis, 76% patients have been on methotrexate (MTX), 47% had one infusion of pamidronate, and 23% required more than one infusion of pamidronate. THU0516 LARGE VESSEL VASCULITIS IN INFANTS - A CASE SERIES

L. Das1, J. H. T. Tan1, X. C. Gao1, S. F. Hoh1, T. Arkachaisri1,2.

Background: Large vessel involvement following recrudescence or recalcitrant Kawasaki Disease or other vasculitides in young children have been limited to few case reports and outcomes are still unclear.

Objectives: To describe and compare the characteristics and outcomes of 6 patients with large vessel vasculitis diagnosed between 2013 to 2015 in KK Hospital, Singapore.

Methods: Demographic and disease characteristic information were collected and median, interquartile range (IQR) & percentiles were used to describe the data.

Results: 6 patients were included in the analysis. Median age was 3.75 months
(IQR 3.75, 4). Other than 1 Filipino 2 year old girl (patient C), all other infants were of Chinese Singaporean origin and were less than age 1 year at onset; 4 male and 1 female. All patients were found to have multiple areas of irregular, thickened vessel walls with enhancement, involving the aorta and additional medium sized arteries on Magnetic Resonance Angiography (MRA).

Only patients P and Q had bronchial asthma and prolonged fever and or less than 1 clinical feature of KD. C developed a unilateral enlarged lymph node on recrudescence of fever 1 month after the initial event. She was then found to have dilated CA (dCA) and consequently abnormal MRA. Other patients had significant KD index scores and complete KD presentations.

Of the 4 patients who received only 1 dose of IVIG; C and F had diagnosis change from atypical KD to Takayasu Arteritis and G developed rhinovirus and then rotavirus as reason for prolonged fever. Patient A received IV steroids and then Infliximab. All patients received steroids. Patients A and B both developed a pseudoaneurysm rash post Infliximab which resolved in follow up. Patient F and Patient B died 3 months and 17 months after diagnosis. Patient F, presented with fever, fussiness and enters aged 4 months. Her symptoms recurred 2 weeks after onset. Due to differential hypertension, she received an echocardiogram and subsequently MRA and cardiac catheterization. Cause of death at age 7 months was small bowel perforation with arteritis and consequent intra-abdominal sepsis.

Patient B, presented with complete features of KD at age 2 months. His course was noted for recrudescence 2 weeks and 4 weeks after initial IVIG. He developed giant coronary aneurysms with abnormal MRA findings; developed myocardial infarction at age 8 months and proceeded to require a Left Ventricular Assist Device but died age 13 months from multi-organ failure.

3/6 (50%) developed aneurysms, D and F were giant. 4 surviving patients, had improvement in all vessels but continued activity in the aorta on follow up MRA, they remain on Methotrexate with no active clinical findings.

**Conclusions:** Extensive involvement of the systemic arteries and aorta in all patient were noted on initial MRA. Follow up imaging, showed improvement in all vessels. After 1 year of follow up, complete resolution occurred in only medium vessels.

Mortality in this patient cohort was 2/7 (28.6%). This is an observational case series and our findings will need to be reproduced in larger groups of references.

**BIOLOGICAL THERAPY IN NON-SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS PATIENTS FOLLOWED IN ADULT RHEUMATOLOGY DEPARTMENT: HUR-BIO REAL LIFE RESULTS**

L. Kiple 1, A. Sari 1, B. Armagan 1, A. Erden 1, Ö. Karadağ 1, A. Akdoğan 1, S. Apras Bilgen1, S. Kiraz1, S. Özen2, U. Kalyoncu1, A.I. Ertenli1.

**Objectives:** To define the demographic and clinical characteristics of non-systemic JIA (ns-JIA) patients under biological therapy followed in adult rheumatology department.

**Methods:** Hacettepe University Biologic Registry (HUR-BIO) is a single center biological registry since 2005. HUR-BIO database includes demographic and clinical characteristics of patients, disease activity parameters, history of articular prosthesis. The use of biological agents in routine rheumatology practice has been approved by the Ministry of Health since 2003.

**Results:** In this study, 95 (72.6% women) ns-JIA patients were included. The demographic and clinical characteristics of the patients were shown in the table. The first biological agents were; Etanercept (63.2%), adalimumab (16.8%), infliximab (12.6%) and the others 7 (7.4%). After a mean follow up of 60 (48 months), 42 (44.2%) patients required biologic switch. The last visit HAQ scores of 75 patients were known and 16 (21.3%) patients had HAQ score ≥1.0 (female 15/54 vs. male 1/21, p=0.029). The last visit DAS-28 score of 72 patients was known and 46 (63.9%) patients had remission or low disease activity. 14 (20% ) had history of regular prosthesis surgery. Patients with history of articular prosthesis were older [39±10.1 vs. 29.6±10.3 years, p<0.0001], had longer disease duration [25.7±6.6 vs. 17.2±11.9 years, p=0.001] and had longer time until the biological therapy [19.6±8.4 vs. 11.5±11.6 years, p=0.002]. The time until the biological therapy of 38 ns-JIA patients diagnosed after 2003 was shorter [3.2±2.9 vs. 18.4±10.6 years, p=0.001].

OBJECTIVES: To compare uterine and ovarian size as well as artery pulsatility from the disease itself and the adverse effects of treatment.

Background: Delayed puberty is common in children with chronic illnesses such as Juvenile Idiopathic Arthritis (JIA), especially in cases with an early age of onset. Its etiology is multifactorial and includes low weight, complications arising from the disease itself and the adverse effects of treatment.

RESULTS: Hormone levels were also measured in control group (p < 0.01). Uterine and ovarian measures were smaller in girls with JIA (Mann-Whitney U test) and correlation tests as appropriate. Uterine and ovarian size and the corpus/cervix ratio were smaller in girls aged 10 to 11 years in girls with JIA aged between 10 and 11 years (p=0.004) and 14 to 15 years (p=0.042), and the corpus/cervix ratio was smaller in girls aged 10 to 11 years (p=0.007). US measures were not associated with disease factors in the JIA group. LH and estradiol levels were found to be positively associated with ovarian and uterine size (p<0.001), but negatively correlated with the mean PI of uterine arteries (p<0.01).

CONCLUSIONS: Pelvic US is a sensitive method for the assessment of sexual maturation in girls, and can identify developmental delays in girls with JIA which may not be detected by Tanner staging.

ENTHESITIS-RELATED ARTHRITIS: NON-PERIPHERAL PATTERN IS ASSOCIATED WITH TH17 CELLS

M. Katasics, C. Carrara, A. Bernasconi, J. Rossi, R. Russo. Immunology & Rheumatology, Hospital de Pediatria Garrahan, Buenos Aires, Argentina

Background: Enthesitis-related arthritis (ERA) is a category of juvenile idiopathic arthritis. Different proinflammatory cytokines linked to the Th1 and Th17 T cell subsets have been implicated in its pathogenesis. Limited data are currently available about the relationship between disease activity and the clinical pattern and the percentage of Th1and Th17 T cell subsets.

Objectives: To analyze Th1 and Th17 cell subsets in patients with ERA and to compare with age-matched healthy controls. To assess the association between disease activity and disease clinical pattern with Th1 and Th17 cells subsets.

Methods: Patients with ERA (as per ILAR criteria) were included in a cross sectional study. Disease activity measures were collected in random visits: active joint count (AJ), pain score (0–10), presence of active enthesitis (AE), sacroiliac pain (SIP), lumbar pain (LP), lumbar limitation (LL) by Schöber’s test, wellbeing according to the patient using a visual analogue scale (VASP, 0–10), disease activity according to the physician (VASphy, 0–10), JADAS-10, JSpADA, and ESR/CRP were evaluated. Patients were classified based on the disease pattern (peripheral and non-peripheral) depending on the presence or absence of AJ and/or AE. Functional capacity was also assessed by CHAQ. Presence of radiologic sacroiliac (MRI/X-rays) and treatment with TNF inhibitors (TNFi) were recorded. Th-17 and Th-1 cells were quantified by flow cytometry in PBMCs stimulated with PMA/IO. Age-matched healthy children without disease or medication were recruited as normal control. Comparison between groups (Mann-Whitney U test) and correlation tests as appropriate

Results: Twenty-nine patients (90% M) fulfilled inclusion criteria. HLA-B27 was positive in 13 (45%). Median age at observation was 12 years and median disease duration was 2.1 years. Activity and functional measures were (medians): AJ 1, pain 0.25, VASp 0.5, VASphy 1, JADAS-10 7, JSpADA 1.75, ESR 15 mm/h and CRP 0.5 mg/L. CHAQ (peripheral and non-peripheral) showed JADAS ≥0.5=8 patients (27%). AE was present in 1 (3%) children. Ninety (65%) patients showed JADAS >1 and 21 (76%) JSpADA >0. Radiologic sacroiliitis was recorded in 21 (72%) children. Fourteen (48%) patients were treated with TNFi. Th17 cell percentage in ERA was 8.5±3.4% (range, 4.1–17.4) while healthy controls was 5.8±3.8% (range, 1.2–14.2), p=0.023. Th17cell in ERA was 0.90±0.44 (range, 0.39–2.34%) while controls was 0.55±0.38 (range, 0.17–1.61%); p=0.004. There was no difference between T-cells% and active/inactive disease. Eighty (62%) children showed peripheral pattern, while 11 (38%) exhibited non-peripheral. Peripheral and non-peripheral groups showed Th17cells 0.90 (0.29–1.74) vs 1.14 (0.64–2.44) respectively (p<0.018). Significant correlations were Th1 with AJ (r=0.45 p=0.004) and Th17with LP (r=0.83 p=0.0001), LL (r=0.47 p=0.03).

Conclusions: Th1 and Th17 cells subsets were significantly higher in ERA compared with healthy controls. However, T-cells% contrast no difference between patients with active versus inactive disease. Interestingly, non-peripheral pattern showed higher Th17% cells respect to patients with peripheral disease. Our results suggest that Th17 evaluation could help identify different phenotypes that benefit from Th17 blocking strategies.

Mortality and Causes of Death Among Juvenile Idiopathic Arthritis (JIA)

Objectives: To explore the association between calprotectin, clinical and US assessment in JIA pts.

Methods: A total of 30 consecutive pts (aged under 18 years) with oligo or poly JIA were assessed by US, clinical examination and MRI/US 14 serum levels. Serum MRI/US 14 was found between active (according to clinical examination) JIA pts and healthy controls (p=0.69) and between inactive JIA pts and healthy control (p=0.23).

Conclusions: To our knowledge this is the first study to examine the correlation between calprotectin and CRP (Spearman r 0.3800, p=0.05) and between calprotectin and ESR (Spearman r 0.3800, p=0.05).

Objectives: To assess the association between serum levels of 25-hydroxy-vitamin D and cardiovascular disease risk factors in juvenile idiopathic arthritis pts. Methods: A prospective cross-sectional study was done on 30 patients with JIA according to the criteria of the International League of Associations for Rheumatology (ILAR) and 30 healthy volunteers matched for age and gender. Patients with other causes of dyslipidemia or those whom receiving vitamin D supplements or lipid-lowering medications were excluded from this study.

Vit D levels were then correlated in each subgroup with the other clinical, laboratory and radiological parameters. We predefined Vit D insufficiency as being <50 nmol/l and Vit D deficiency as being <25 nmol/l.

Results: The mean serum vitamin D levels of all patients were 23.8 nmol/l ±16.59. Only 7 patients (23.3%) have adequate vitamin D levels (50–75 nmol/l). While vitamin D insufficiency (serum vitamin D levels: 25 – 50 nmol/l) was found in 14 patients (46.7%) respectively, JIA patients had significantly lower vitamin D levels as compared to controls (p<0.01). JIA patients had higher systolic and diastolic blood pressure than controls although these differences were not statistically significant (p>0.05) and all levels were still in normal values. Subjects with vitamin D deficiency or insufficiency had significantly lower values for HDL cholesterol and significantly elevated values for LDL cholesterol as compared to controls and patients with adequate vitamin D levels, with significant positive correlation between 25(OH)D and HDL cholesterol, and significant inverse correlation between 25(OH)D and LDL levels.

Patients with lower levels of vitamin D had significantly higher cIMT and lower FMD (p<0.01) with significant positive correlation between 25(OH)D and FMD, and significant inverse correlation between 25(OH)D and cIMT, and there were no significant differences in echocardiography results.

SAFETY OF ADALIMUMAB ± METHOTREXATE FOR THE SHORT AND LONG-TERM FOLLOW-UP OF TOCILIZUMAB

D. Milojevic2, C. Rabinovich2, D. Kingsbury2, K. Marzan 2, P. Quartier1, N. Ruperto

Background: JIA is the most common chronic inflammatory rheumatic disease of childhood. TNF inhibitors are used for long-term control of JIA disease.

Methods: To evaluate the 7 year (y) safety of Adalimumab treatment with or without methotrexate (ADA±MTX) when used in current clinical practice for treatment of patients (pts) with active pJIA.

Results: In January 2014, enrollment was complete. As of June 1, 2016 cut-off date, 838 pts (501 MTX arm and 537 - ADA±MTX arm) were treated in the registry. There were 39 pts who rolled over from MTX to ADA±MTX arm. At registry entry mean pJIA disease duration was 1.3 y and 3.7 y and mean ACR70 was 5.8 and 5.2 for MTX and ADA±MTX arms, respectively. CHAQ disability index was 0.6 for both arms. Mean duration of study drug exposure in registry was 2.0 y (range: 0.0 – 7.1) and 2.5 y (range: 0.0 – 7.9) for MTX and ADA±MTX arms, respectively. Mean duration of observation in registry was 3.9 y (range: 0.0 – 7.2) and 3.5 y (range: 0.0 – 7.9) for MTX and ADA±MTX arms, respectively. Overall, 213 pts (70.8%) in MTX and 225 pts (41.9%) in ADA±MTX arms were the degree of inflammation, visual acuity and macular thickness. The results were the degree of inflammation, visual acuity and macular thickness. The results were expressed as mean±SD for normally distributed variables, or median [IQR] when they are not. Comparison of continuous variables were performed using the Wilcoxon test.

Results: We studied 25 patients (21 women/4 men); mean age 18.6±2.3. Uveitis was bilateral in 22. JIA subsets were oligoarthritis (n=17), polyarthritis (3), psoriatic (2) and enthesitis-related arthritis (1). Uveitis associated with the eye disease was anterior (9) and at least one conventional immunosuppressive drug including biological therapy. The outcome variables were the degree of inflammation, visual acuity and macular thickness. The results were expressed as mean±SD for normally distributed variables, or median [IQR] when they are not. Comparison of continuous variables were performed using the Wilcoxon test.

Conclusions: Overall, ADA±MTX was well-tolerated in these pts with pJIA with no new safety signals. The retention rate for registry drug was higher in ADA±MTX arm compared to MTX arm. Methods: To evaluate the 7 year (y) safety of Adalimumab treatment with or without methotrexate (ADA±MTX) when used in current clinical practice for treatment of patients (pts) with active pJIA.
a follow up of one year (n=21), 2 years (n=11), and 3 years (n=5). A reduction in the daily median dose of prednisone from 10 mg (0–15 mg) to 0 (0–0 mg) in 3 years, (p<0.05) was observed. After a median follow-up of 20.5±11.7 months in 4 patients, the interval between TCZ doses was increased to 5 weeks (n=2), 6 weeks (1) and 7 weeks (1) because of remission. TCZ had to be withdrawn due to biological intolerance (1) or articular and ocular inefficiency (1). The main adverse effects were severe autoimmune thrombocytopenia, autoimmune anemia and thrombocytopenia, pneumonia, viral conjunctivitis and bullous impetigo in 1 patient each.

Conclusions: TCZ is useful at short and long term follow-up for severe Juvenile Idiopathic Arthritis arthritis and/or uveitis. It is possible to optimize the TCZ dose.

THU0527 PEDIATRICIAN AND ADULT RHEUMATOLOGIST COLLABORATING IN A MULTIDISCIPLINARY REUMA-PED CLINIC. IS THIS TRANSITIONAL CARE MODEL EFFECTIVE?

P. Collado1, A. Rubio1, R. Diaz-Delgado2, C. Calvo2, R. Mustienes1, F. Rey1, C. Bonilla1, E. Cruz1,2, Rheumatology,2Pediatric, Hospital Universitario Severo Ochoa, Madrid, Spain

Background: Transitional care should be a planned movement of adolescents with severe diseases from child-centred to adult-oriented health care system. Recently a EULAR/PRSE taskforce has developed the first international set of recommendations and standards for transitional care.

Objectives: To describe the results from a specific transitional care programme.

Methods: The current transitional care programme includes a multidisciplinary PE/Pediatric care clinic weekly and a non-defined period of rheumatology follow-ups by the same rheumatologist of MPRC. The transitional care team is composed of two pediatricians, one adult rheumatologist -as transition coordinator-, a clinical nurse specialist and administrative support, as well as a psychologist and physiotherapists. Clinical information and therapies were collected throughout the disease course and the HEADSS method of psychosocial interviewing has been included recently.

Population of the present study included young patients (YP) from that programme who are going to transfer to adult-oriented health care system. Descriptive study of socio-demographics and clinic features was included, as well as patients' adherence. YP confidence to be transferred and satisfaction with the current transitional process were measured using on a scale of 0 to 10. In patients suffering from juvenile idiopathic arthritis (JIA), clinical status of disease activity and clinical remission and CHAQ were tested before transfer.

Results: Twenty-seven YP with female predominance (63%) were included. The average age was 21±3 yo at time of a planned transfer and 16±3 yo at inclusion to the MPRC. JIA was the commonest condition whereas dermatomyositis was uncommon. Up to 63% patients required some DMARDs during the MPRC follow-up, but only a 37% needs maintained immunosuppressive therapies and three (11%) patients required changing the therapeutic target before transfer. YP adherence to rheumatologist appointments was high. Regarding HEADSS data: most YP were students and living at family home, around 50% gave up sports or other activities due to homework or exams, 29% of YP occasionally drank some alcohol but none used tobacco, and 47% of YP felt sad or down once in a while. Patient’s confidence to be transferred was 7.7±2.1 (mean±SD; min-max: 2–10). YP showed high satisfaction with the current transitional process, 9.7±0.4 (min-max: 9–10).

Before transfer, 17 patients with JIA showed a mean±SD value of JADAS10 of 2±5 (mean±SD; min-max: 0–18), clinical remission on/off medication was 23% and 53% respectively. Mostly functional status reported by patient was low, YP-rated CHAQ (mean 0.06; min-max, 0.0–0.75).

Conclusions: To the best of our knowledge, this is the first study evaluating a Spanish transitional care programme. The study reports a positive impact across adolescence of our transitional care model in a real life situation. Implementation of recommendations depended on the local available resources.

DOI: 10.1136/annrheumdis-2017-eular.5444
followed by extended oligarticular (27%/26%), polyarticular psoriatic arthritis (18%/16%) and RF positive polyarticular (5%/8%). Disease duration (2.3±3.0 vs 1.9±2.7) was statistically higher in the oral cohort (p=0.04) but age at onset and baseline were similar. The baseline disease activity was higher in the s.c. cohort (JADAS10 16.5±7.2 compared to 14.7±8.2; p=0.001 and active joint count 11 vs 6.7; p=0.011). The weekly MTX dosages were comparable with 13.6±5.4mg and 13.3±4.5 mg. Concomitant treatment with NSAIDS (95%/89%), oral steroids (24%/25%) or intraarticular steroids (6%/8%) were comparable.

After 12 months of treatment, 150 (38.3%) reached a JIA ACR90 with oral MTX and 131 (33%) with s.c. MTX while 86 (21.8%) and 72 (19.6%) reached JADAS-remission (JADAS10c≤1). By Kaplan-Meyer analysis no difference in the early kinetic of response was found. Upon total observation for up to 7.5 years in patients in the treatment to treat population (patients discontinuing MTX due to inefficacy or intolerance) response rates were calculated as non-responders. The patients in the oral cohort reached a JADAS-remission (162; 41%) than with s.c. MTX (126; 34%) which was stastically borderine significant (p=0.05; odd’s ratio 1.2 [95CI 1.0–1.8]).

Response rates at 1 year

MTX oral  MTX sub

JADAS-ACR≥  acceptable disease activity, MDA minimal disease activity, Remission

Conclusions: Data from the BIKER registry out of the clinical practice do show a high rate of JIA patients reaching a significant JIA-ACR response as well as JADAS-remission upon MTX as a sole DMDAR. However, on the long term more patients with oral MTX reached JADAS remission. By Kaplan Meyer analyses we did not observe a superiority of s.c. MTX in the kinetic of response. The limitations of our analysis lie the character of a registry study, the lack of randomisation and study protocol leaving all decisions to start or to stop MTX by the responsible rheumatologist. Thus such data are preliminary and should be confirmed by randomized studies.

THU0530 CHARACTERIZATION OF A COHORT OF PSORIATIC JUVENILE IDIOPATHIC ARTHRITIS PATIENTS FROM A PAEDIATRIC UNIVERSITY HOSPITAL IN SPAIN

S. Hernández-Baldizón1, A. Zacarías-Crovato2, V. Torrente-Segarra3, J. Calzada-Hernández2, J. Sanchez Manchón1, E. Iglesias1, R. Bou Torrent1, J. Anton2,1, Rheumatology, Juaneda Miramar Hospital, Palma de Mallorca; Paediatric Rheumatology Unit, Sant Joan de Deu University Hospital, (Espaguies/Bcn); Rheumatology, Moises Broggi General Hospital, Hospitalet de Llobregat, Spain

Background: Juvenile Psoriatic Arthritis (JPsAo) is a subtype of Juvenile Idiopathic Arthritis (JIA) present in 7% of JIA patients (1). Psoriasis is present in 0.5–1% of children. Diagnosis is often difficult, with the arcutil manifestations often preceding skin disease by years. Data is scarce in the Spanish population.

Objectives: Describe demographic and clinical characteristics of our cohort of JPsAo.

Methods: Descriptive, transversal study of patients attended from 1/2012–12/2016. Included were all compliers with ILAR Criteria (2) for JPsAo (Edmonton 2001). We also included the Wallace Criteria for clinical inactive disease (3) as a variable in the end point. Data were included and analyzed using SPSS MAC 20.

Results: 31 patients were included: 18 (59%) girls, 13 (41%) boys. All Caucasian. They comprised 5 of all our JIA patients in that period. Mean age at diagnosis was 7.4 years. All were RF-; 9 (29%) ANA+; 4 (12.9%) HLA-B27+; articular onset 17 (55%) and cutaneous onset 14 (45%). 9 (29%) had Temporomandibular Joint (TMJ) symptoms; 5 (16%) had pain and 4 (12.9%) had a positive MRI for TMJ synovitis. Plaque psoriasis 14 (45%), guttate 3 (9.6%) and 3 (9.6%) had both. Dactylitis 8 (26.6%); enthesitis 6 (19.35%). Joint disease was mainly oligoarticular 15 (48%), monariticular 14 (45%) and poliariticular 1 (3.2%). Axial disease 4 (12.9%) at follow-up, 7 (22.5%) uv); 5 (77%) were AS+/1 (9.6%) oncocistrodinia and 6 (19.3%) enthesis. All patients received NSAIDs; 30 (96%) methotreaxe; 6 (19.3%) switched to leflunomide. 16 (51.6%) received biologic treatment and 9 (29%) more than once. 10 (32.2%) received biologic treatment more than once. 14 (45%) were treated with more than one. 7 (22.5%) uveitis; 5 (77%) were ANA+. 3 (9.6%) onicodistrophia and 6 (19.3%) anti-TNF-Paradoxal psoriatic events. Wallace Inactivity Criteria were achieved in 25 (80.6%), with no differences between the biologic and DMSRDs groups in time up to Achieving Wallace Criterias (TimeWall). TMJ positive MRI did have a negative effect on TimeWall with 2 (66.6%) ≥8 yr (8, 11y) to TimeWall.

Conclusions: We describe the clinical features and demographics of a series of spanish JPsAo patients. We found more oligoarticular and monariticular involvement and an important presence of enthesitis and dactylitis; higher frequency of uveitis than published data (22.5% vs. 10–15%). Some were ANA-, reinforcing the need for screening. More than half required biologic treatment, and several cases we needed to switch drugs. Almost 60% of the patients were girls. Articular onset was associated with more active, harder to treat disease. TMJ positive MRI was associated with longer TimeWall. However, Wallace Criteria were not achieved globally.

THU0531 USE OF RITUXIMAB IN PAEDIATRIC RHEUMATOLOGY - EXPERIENCES FROM A SINGLE TERTIARY CENTRE

S. Deepak1, R. O'Brien2, K. Warner1, E. Mcdermott3, S. Rangaraj1,1, Paediatric rheumatology, Nottingham Childrens hospital; 2Immunology, Nottingham university Hospitals NHS Trust, Nottingham, United Kingdom

Background: Rituximab is an anti-CD20 monoclonal antibody therapy used widely in the management of paediatric rheumatological conditions. Studies suggest that Rituximab is safe and effective in rheumatic autoimmune diseases, but data on paediatric use remains limited. Although Rituximab spares plasma cells, hypogammaglobulinaemia can still develop, leading to recurrent infections. Frequency of hypogammaglobulinaemia in children receiving Rituximab for rheumatological conditions is unknown.

Objectives: To analyse the use of Rituximab in a tertiary Paediatric Rheumatology centre over the last 15 years (2001–2015). The primary aims were to identify the number of patients who received Rituximab, the underlying diagnoses and the response to treatment. Our secondary aims were to identify the incidence of hypogammaglobulinaemia associated with Rituximab use and the frequency and severity of infections. Frequency of monitoring of immunoglobulin levels, lymphocyte subsets and functional antibodies to pneumococcos were noted.

Methods: Retrospective analysis of case notes, electronic records and laboratory data of patients who received Rituximab in the paediatric rheumatology department from 2001–2015.

Results: A total of 22 patients received Rituximab (total of 1500mg/m2 per cycle over 2 – 4 divided doses) during the study period. 3 were excluded due to insufficient data. Median time of commencement of Rituximab from diagnosis was 2 years 8 months. Of these, 12 patients achieved remission within 6 to 12 months. Rituximab was discontinued in the non-responders at 12 months.

8 patients (42%) were noted to have hypogammaglobulinaemia at some point. The role of cyclophosphamide contributing to hypogammaglobulinaemia could not be excluded in 2 and a further patient is currently being investigated for an underlying primary immune deficiency. In the remaining 26 (88%) patients, we believe the low IgG levels are secondary to Rituximab, of which 2 needed long term Ig replacement. Overall 12 patients reported recurrent/severe infections of which 6 had low immunoglobulin levels.

Conclusions: RF+ JIA patients appear to have responded the best to Rituximab and RF- JIA patients the least (0/4), with good results in JDM and SLE subgroups (80–83%). The incidence of hypogammaglobulinaemia secondary to Rituximab in our cohort was 26%, which can be prolonged and worsened with increased number of cycles. Prior treatment with cyclophosphamide may be contributory. We suggest regular monitoring of immunoglobulin levels and lymphocyte markers on all patients prior to commencement of Rituximab and regular intervals subsequently, including further cycles.

Disclosure of Interest: None declared

Uveitis in children is rare. Intensive interactions between ophthalmologists and paediatric rheumatologists are needed in order to choose the best therapeutic strategies for severe uveitis attacks.

**Objectives:** Describe a cohort of 74 patients with paediatric uveitis.

**Methods:** Retrospective analysis of children followed for uveitis before 18, by one paediatric ophthalmologist (SGC) in Paris, during the 2006–16 period. Members of 3 ophthalmologic departments specialized in uveitis care in children (AR, CT, ML and BB) in Paris, during the 2006–16 period.

**Results:** There were 74 paediatric uveitis, 42 anterior (57%, group 1), 16 intermediate (21%, group 2), 7 posterior (9%, group 3), and 9 pan-uveitis (12%, group 4). Gender was equal in group 2–4, but there were more females in group 1. At presentation, mean ages were 8.6±4.1, 9.8±3.9, 9.1±3.6 and 10±4.2 years old. Mean follow-up was 3.7±3.7 years. JIA was the leading cause of group 1 uveitis (45%); group 2–3 uveitis were idiopathic in 81% and 86%, respectively. In group 4, etiologies were found in 7 out of 9 patients (Behçet-3, JIA-2, BBS-1, TINU-1).

**Conclusions:** Paediatric uveitis induce a very high-level burden in children, even when anterior and sometimes despite optimal therapeutic management in tertiary care centers. Their early recognition and tight control in specialized units are absolutely required in order to decrease the level of definitive complications.

**Disclosure of Interest:** None declared.

**DOI:** 10.1136/annrheumdis-2017-eular.6629
biologic switchers (34.5%). For the total IV ABA cohort, six hospitalized infection claims were reported with an IR (95% CI) of 2.4/100 p-y (0.5, 5.3) and an IR of 2.8/100 p-y (1.2, 5.9) for new-onset uveitis. There were no validated cases of malignancies in the follow-up period.

**Conclusions:** Compared with an overall JIA population, abatacept pts are significantly more likely to experience uveitis and have a history of asthma or cardiovascular disease. The rates of hospitalized infection and new onset of uveitis in this study are within published ranges2,3 and are consistent with findings in the abatacept JIA registry.4

**THU0535**

**LONG-TERM FOLLOW-UP OF 12 CASES OF CORONARY GIANT ANEURYSM AFTER KAWASAKI DISEASE**

T. Sato1, J. Samura1, S. Hoshino1,2,3, O. Furukawa1, N. Okamoto2,4, Y. Maruo1.

1Department of Pediatrics, Shiga University of Medical Science; 2Department of Pediatrics, Omihachiman Community Medical Center; 3Department of Pediatrics, Nagahama Red Cross Hospital; 4Department of Pediatrics, Okamoto Kids Clinic, Shiga, Japan

**Background:** The incidence of Kawasaki disease has been increasing since it was first reported by Tomisaku Kawasaki in 1967. Among complications of the condition, the formation of coronary artery aneurysms is the most important. In particular, giant aneurysms with diameters that exceed 8 mm are likely to not regress and result in serious complications, such as acute myocardial infarction.

**Objectives:** To understand the long-term course of patients with giant aneurysms and Kawasaki disease as well as to consider the cause of aneurysm formation and its appropriate treatment.

**Methods:** We retrospectively studied the long-term course of 12 cases of giant coronary artery aneurysms accompanied with Kawasaki disease, which were being followed at Shiga University of Medical Science Hospital, Omihachiman Community Medical Center, and Nagahama Red Cross Hospital. These are three major facilities in Shiga prefecture of Japan, whose population is 1.4 million, comprising 200,000 children.

**Results:** Ten male and two female patients were included. The average current age was 16.8 years, the median age was 14.3 (10.7–18.9) years, and 5 cases were of adults. The average age at the time of onset was 3.5 years, the median age was 3.7 years (1.8 - 4.4), and all experienced onset between 1 and 5 years of age. The mean period from onset to treatment start was 6.7 days (median 5.0 (4.3–8.3)), but the average period until fever declined was 16.0 days and only three patients' temperature was reduced in 10 days. Aneurysm formation occurred at 14.1 days on average (median 12 (10–17)). The average size of the maximum coronary artery aneurysm at onset was 11.3 mm, and the median size was 9.5 mm (8.8 mm – 13.8 mm). The average and median follow-up periods were 13.2 years and 11.7 years (5.4–13.4), respectively. The number of patients received steroid therapy was four, and all their onset was after 2006. None received infliximab or underwent plasmapheresis.

During the course of the condition, all patients underwent multiple centripetal echocardiography. Among all cases, 7 underwent coronary angiography CT, 10 underwent myocardial scintigraphy. All 12 patients underwent cardiac catheterization for them was thirty-one. Two adult patients had a history of acute myocardial infarction and had undergone cardiac bypass surgery. Through this survey, we found that 9 cases developed giant coronary artery aneurysm between 1983 and 2007, and 3 cases between 2007 and 2012.

**Conclusions:** All patients are currently receiving anticoagulant therapy and undergoing diagnostic imaging. In our prefecture, the incidence of giant coronary artery aneurysm accompanied with Kawasaki disease has been decreasing gradually. From 2007 to 2012, in which high dose gamma globulin therapy (2g/kg) has become commonly used for Kawasaki disease in Japan, there were no giant aneurysm formation in our hospitals. Three patients in whom giant aneurysms developed between 2012 and 2015 were taking oral prednisolone, thereby suggesting a relationship between prednisolone and giant aneurysm formation.

**FAMILY AND PATIENT’S PERCEPTION OF DIETARY INTERVENTION IN JUVENILE IDIOPATHIC ARTHRITIS (JIA)**

1Department of Pediatrics, Alaska Native Medical Center, Anchorage; 2Pediatric Rheumatology, Seattle Children's Hospital, Department of Pediatrics, University of Washington, Center for Clinical and Translational Research, Seattle Children's Research Institute; 3Gastroenterology, Seattle Children's Hospital; 4Department of Pediatrics, University of Washington, Center for Immunity and Inborn Errors, Seattle Children's Research Institute, Seattle, United States

**Background:** Juvenile idiopathic arthritis (JIA) is the most common pediatric rheumatologic illness and can lead to significant disability. Complementary and alternative therapies are commonly practiced by families of patients with JIA, and > 40% of patients with chronic arthritis seek dietary changes after their diagnosis. Dietary intervention studies in adults with rheumatoid arthritis showed moderate improvement in joint symptoms. Dietary supplements of omega-3 fatty acids have been studied in children with juvenile rheumatoid arthritis and found to be associated with less NSAID use and lower serum IL-1 and TNF levels. There is an increasing need to understand if there is a role for dietary therapy in chronic arthritis.

**Objectives:** We aimed to evaluate the prevalence of special diets and the perception of the effectiveness of these diets on arthritis in JIA. We also assessed the interest of dietary interventions and perceived barriers.

**Methods:** An online survey was designed through a REDCap database capturing demographic information, self- or parent-initiated special dietary interventions and self- or parent-scoring effects on joint symptoms, willingness to participate in a dietary intervention study. The survey link was posted on social media websites and distributed by the Arthritis Foundation and various clinical performed.

**Results:** A total of 265 responses were received from adult patients who had JIA and parents of children with JIA. We excluded 14 patients with inflammatory bowel disease, juvenile idiopathic disease-related arthritis and 24 responders with incomplete answers. Demographic and JIA characteristics of adult and pediatric patients are listed in Table 1. Ninety patients (63 children with JIA, 27 adults with history of JIA) had tried a special diet for arthritis. The top three special diets reported by parents included a gluten-free diet (62%), an anti-inflammatory diet (53%),...
and a lactose-free diet (26%). There were similar clinical responses among the three diets (Figure 1). Twenty-five to thirty percent reported no change in joint symptoms whereas 20–30% reported improved pain or joint swelling. Sixty-one (34%) parents were willing to participate in a 3-month dietary intervention study and 78 (44%) parents answered “it depends”.

Conclusions: This is the first report of the family/patient perspective of the role of dietary intervention on JIA. Almost half of the affected patients attempted special diets, and many reported improvement in symptoms. Future interventional studies with objective outcome measurements are needed to validate these reports.

Acknowledgements: The authors would like to thank all the patients and families who have taken the survey. Arthritis Foundation and Facebook JA groups have supported the survey.

**EFFECTS OF GLUCOCORTICOIDS AND METHOTREXATE-BASED THERAPEUTIC REGIMENS ON B CELL SUBPOPULATIONS IN PATIENTS WITH IgG4-RELATED DISEASE**

M. Lanzillotta, E. Dei, E. Bozzolo, M. Falconi, L. Dagna, S. Grevich

**Background:** IgG4-related disease (IgG4-RD) is a systemic fibro-inflammatory disorder characterized by fibrotic lesions infiltrated by IgG4 positive plasma cells (1). The prompt clinical responses obtained after B cell depletion with rituximab in IgG4-RD patients suggest that B lymphocytes drive the pathogenesis of this condition and sustain disease activity (2). This conclusion, however, requires further confirmation because IgG4-RD responds also to non-B cell depleting therapies such as glucocorticoids and methotrexate.

**Objectives:** To evaluate the effects of glucocorticoids and methotrexate-based therapeutic regimens on B cell subpopulations in patients with IgG4-RD.

**Methods:** Sixteen patients with active IgG4-RD were studied. FACS analysis was performed on peripheral blood in order to identify the following B cell subpopulations: total B cells (CD19+CD20- and CD19+CD20+ cells), circulating plasmablasts (CD19+CD20- CD27+CD38+ cells), memory B cells (CD19+CD20- CD27+CD38+ cells), circulating plasma cells (CD38+CD138+ cells). Disease activity was assessed by means of the IgG4-RD responder index (IgG4-RD RI). Flow cytometry was performed at baseline and after six months of immunosuppressive therapy with glucocorticoids (0.6–1mg/kg/day) and/or methotrexate (10–20mg/week).

**Results:** At baseline, circulating plasmablasts were expanded in IgG4-RD patients (median 3780 cell/mL; range 330–9300) compared to controls (median 280 cell/mL; range 0–1000) (p < 0.05); total B cells (median 13300 cell/mL; range 3400–56900) and naïve B cells (median 13080 cell/mL; range 1970–64270) were reduced in IgG4-RD patients compared to controls (median 280 cell/mL; range 194–330; and median 54020 cell/mL; range 21050–106780, respectively) (p < 0.05). No circulating plasma cells were detected in healthy controls. No differences in memory B cells were observed (p > 0.05); Circulating plasmablasts but not other B cell subsets positively correlated with serum IgG4 levels, number of organ involved, and IgG4-RD RI (p < 0.05). At six months follow-up, the median IgG4-RD RI decreased from 9 to 2. Circulating plasmablasts, circulating plasma cells, and naïve B cells counts decreased in all patients together with disease improvement (p<0.0002, 0.0002 and 0.025 compared to baseline values, respectively); total B cells and memory B cells were unaffected by immunosuppressive therapy.

**Conclusions:** Non-B cell depleting therapies based on glucocorticoids and/or methotrexate induce clinical improvement and deplete circulating plasmablasts, plasma cells and naïve B cells in patients with IgG4-RD; circulating total B cells and memory B cells are not affected by glucocorticoids and methotrexate. Our study, performed with non-B cell depleting agents, provides clinical evidences that circulating plasmablasts are likely linked to IgG4-RD pathogenesis and disease activity.

**SARCOIDOSIS IN SPAIN: CLINICAL AND EPIDEMIOLOGICAL CHARACTERISTICS AT DIAGNOSIS IN 1082 PATIENTS**

**Background:** Sarcoidosis is a multisystem disease characterized by non-caseating granulomas. The disease has a worldwide distribution with geographical and racial variations of incidence. In Spain, there is a lack of data on the clinical and epidemiological characteristics of the disease.

**Objectives:** To describe the clinical and epidemiological characteristics of sarcoidosis in Spain and identify potential subgroups of patients.

**Methods:** The SarcoidiaS-SEMI Registry is a large multicenter cohort from Southern Europe.

**Conclusions:** The SarcoidiaS-SEMI Registry is the first national registry of sarcoidosis in Spain, providing valuable data on the clinical and epidemiological characteristics of the disease.

**Disclosure of Interest:** None declared.

**EFFICACY AND SAFETY OF ADALIMUMAB IN BEHÇET’S DISEASE RELATED UVEITIS: A MULTICENTER RETROSPECTIVE OBSERVATIONAL STUDY**

1Department of Ophthalmology, Human Research Hospital, Milano; 2Unit of Rheumatology, University of Siena, Siena; 3Department of Experimental and Clinical Medicine; 4Department of Surgery and Translational Medicine, Eye Clinic, University of Firenze, Firenze; 5Interdisciplinary Department of Medicine, Rheumatology Unit, University of Bari, Bari; 6Optalmology and Neurosurgery Department, University of Siena, Siena; 7Department of Rheumatology, Arcispedale Santa Maria Nuova IRCCS; 8Department of Rheumatology, Arcispedale Santa Maria Nuova IRCCS, Reggio Emilia, Italy, Reggio Emilia; 9Unit of Rheumatology, University of Bari, Bari; 10Department of Rheumatology, Arcispedale Santa Maria Nuova IRCCS, Reggio Emilia, Italy

**Background:** Current information on the use of adalimumab (ADA) in the treatment of ocular Behçet’s disease (BD) is still based mainly on small series or case reports; nonetheless preliminary evidence is promising.

**Objectives:** The study aim was to evaluate the efficacy of ADA in a large series of BD-related uveitis.

**Methods:** We performed a multicenter retrospective observational study including 40 selected patients (66 eyes) receiving ADA. Clinical data were retrospectively analyzed at baseline, at 3 and 12 months of treatment. Primary endpoint was: reduction of ocular inflammatory flares. Secondary end-points were: improvement of Best Corrected Visual Acuity (BCVA), reduction of macular thickness measured by optical coherence tomography (OCT), reduction in the occurrence of vasculitis assessed by fluorescein angiography (FA), evaluation of statistically significant differences between patients treated with ADA monotherapy and those undergoing ADA plus DMARDs and in patients firstly treated with ADA compared to patients previously administered with other biologics; ADA steroid sparing effect was also evaluated.

**Results:** During the first 12 months of ADA therapy the number of flares significantly decreased from 200 flares/100 patients/year to 8.5 flares/100 patients/year (p<0.0001). Similarly BCVA improved if compared to baseline (7.4±2.9 versus 8.5±2.1, p=0.03). OCT findings significantly improved showing a mean reduction of central macular thickness (CMT) of 27.2±42.8 microns at the end of follow up (p<0.006). FA identified retinal vasculitis in 22 cases at baseline (55%), 8 (20%) cases after 3 months and in only one (2.5%) case at 12-month follow-up. FA improvement was highly significant at 3 and 12-month follow-up if compared to baseline (p=0.0001 and p=0.006, respectively).

**Conclusions:** ADA is highly effective and safe for the treatment of BD-related uveitis, providing a long-term control of ocular inflammation.

**Disclosure of Interest:** None declared

ANTI-INTERLEUKIN 1 THERAPY IN FMF AMYLOIDOSIS: A SINGLE CENTER EXPERIENCE (CASE SERIES)

S. Ugurli, B. Ergezen, A. Hacioglu, H. Ozdogan. Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey

Background: Recently there is increasing number of reports investigating the efficacy of anti-interleukin-1 (anti-IL-1) therapy in AA-amyloidosis.

Methods: Objectives: Here we report our experience in IL-1 blockade in AA amyloidosis secondary to FMF.

Results: Twenty nine FMF patients with secondary AA-amyloidosis with insufficient response to colchicine were treated with anti-IL-1 agents (canakinumab and anakinra). Creatinine (Cr), 24-hour urine protein (UP), C-reactive protein (CRP) and ESR were measured before and throughout the treatment to evaluate the response and side effects.

Conclusions: The presence of R202Q polymorphism is associated with FMF, with a higher relapse risk. Patients with hemodialysis and serum IgG4 level above upper limit of normal were at higher relapse risk and a low dose, maintenance prednisolone for longer period is recommended.

ANTEROTHERAPY IN FMF AMYLOIDOSIS: A SINGLE CENTER EXPERIENCE (CASE SERIES)

S. Yilmaz1, E. Tekgoz1, F.I. Cinar2, M. Cinar3. 1Department of Internal Medicine, Division of Rheumatology, University of Health Sciences, Gulhane Medical Faculty; 2Gulhane School of Nursing, University of Health Sciences, Ankara, Turkey

Background: Familial Mediterranean fever (FMF) is an autosomal recessive inherited disease with recurrent fever and inflammatory episodes of serous membranes. The MEFV (Mediterranean fever) gene in the short arm of chromosome 16 is affected in the FMF. This gene encodes for a protein called Pyrin. The erroneously synthesized Pyrin protein due to MEFV mutations is unable to control the post inflammatory process. Although there have been many efforts to find genotypetype-phenotype association in FMF, no clear relationship has been clarified.

Objectives: In this study, the relationship between FMF clinical symptoms and MEFV gene mutations and polymorphism was investigated.

Results: A total of 158 patients with FMF were included to the study that was conducted in a tertiary rheumatology outpatient clinic. The demographic and clinical features, as well as MEFV gene mutations were recorded in a “Patient Assessment Form”. The clinical status of the disease was evaluated with FMF-severity score (F-SS-2). The associations between clinical features and genetic alterations were calculated with Pearson Chi-square test.

Conclusions: The presence of R202Q polymorphism is associated with FMF, and should be considered in the routine genetic analysis of the disease. In our patients, its co-existence with M694V seems to be associated with good response to colchicine, and to alleviate the severity of the disease expression of M694V, which is known to be associated with severe course.

References:
Background: Multicentric Castleman's disease (MCD) is a disorder characterized by polyclonal proliferation of B lymphocytes that is frequently associated with autoimmune manifestations and connective tissue diseases. MCD presents high levels of IL-6 and systemic symptoms such as fever, arthralgia, hepatosplenomegaly and serositis, so it is recommended to include MCD in the differential diagnosis of adult-onset Still's disease (AOSD). However, there are no studies comparing both groups of patients.

Objectives: To compare the clinical and laboratory features at onset between patients with MCD and AOSD seen in a Madrid tertiary care hospital.

Methods: We performed a retrospective observational study in patients with diagnosis MCD and AOSD attended our center between January 1989 and December 2015. The variables included demographics, clinical manifestations, laboratory tests and Yamaguchi’s criteria.

Results: A total of 34 patients were included, 17 with MCD and 17 with AOSD. The comparison of the characteristics of both groups is presented in the table. There were no differences in age, uration of disease (MCD 158.6 days and AOSD 250.5 days, p=0.3919), diagnostic delay (MCD 18.4 and AOSD 52.2, p=0.2711), arthritis, myalgias, pleuritis or macrophagic activation syndrome, but persistent fever, rash, arthralgia, pharyngitis and pericarditis were significantly more frequent in EASA, whereas male gender, human immunodeficiency virus (HIV) and/or human herpes virus 8 (HHV8) infection, hepatosplenomegaly and more frequent in ESA, whereas male gender, human immunodeficiency virus (HIV) and/or human herpes virus 8 (HHV8) infection, hepatosplenomegaly and hypertransaminasemia were significantly higher in AOSD. 52.9% (HIV) and/or human herpes virus 8 (HHV8) infection, hepatosplenomegaly and 52.9% of patients with MCD met 5 or more Yamaguchi’s criteria for AOSD.

Conclusions: Patients with MCD may present common systemic manifestations and laboratory abnormalities at onset with AOSD and up to 50% of them may fulfill Yamaguchi’s criteria for this disease, so MCD should be taken into account in its differential diagnosis.

Disclosure of Interest: None declared

**THU0547 CHARACTERIZATION OF A GROUP OF 12 PATIENTS WITH MEVALONATE KINASE DEFICIENCY: SYMPTOMS AND TREATMENT WITH IL-1 INHIBITORS**

A. Koziol1, V. Burlakov1, N. Kuzmenko1, S. Zimin2, T. Varlamova1, O. Barabanova2, E. Raikina1, A. Shcherbina1, 1Immunology, Federal State Budgetary Institution “National Scientific and Practical Center of Pediatrics, Hematology, Oncology and Immunology named after Dmitry Rogalshev”, the Ministry of Healthcare of the Russian Federation; 1Immunology, Children’s Clinical Hospital N9, Moscow, Russian Federation

Background: Mevalonate kinase deficiency (MKD) is a rare autosomal recessive autoinflammatory disease caused by mutations in MVK gene. MKD patients typically have an early onset of symptoms including recurrent episodes of high fever, abdominal pain, diarrhea and vomiting, arthralgia and lymphadenopathy (AIDAI criteria for HDIS). However, not all patients have typical symptoms at the time of onset. MKD treatment remains an unsolved problem, since none of the modalities previously used for MKD treatment are fully effective in the disease control.

Methods: We conducted a retrospective analysis of clinical features of twelve patients (6 females, 6 males) with genetically confirmed MKD. Nine patients received therapy with inhibitors of IL-1 (Anakinra and/or Canakinumab). One of the patients died from amyloidosis and macrophage activation syndrome (MAS) prior to treatment initiation, her diagnosis was verified post mortem.

Results: Ten patients had manifested with symptoms of MKD before the age of 1 year, one – at the age of 1.5 years, one – at three years of age. During the course of the disease all patients had periodic fever and peripheral lymphadenopathy (mainly cervical group), as well as abdominal pain, nausea/vomiting. Five patients had diarrhoea, sometimes with blood, one patient suffered from severe constipation. Rash was seen in eight patients, myalgia, arthralgia were observed only in six. Oral ulcers were noted in seven children. Three patients had neurological involvement, one patient had it as the main symptom. One patient had periorbital edema and hyperemia during attacks, which to our knowledge, have not been reported previously in MKD. One patient developed amyloidosis and MAS before IL-1 inhibitor treatment initiation, which led to her death. In patients receiving anti-IL-1 therapy AIDAI index decreased from 58.3±11.2 before to 1.5±1.4 after 6 month of therapy (p<0.003).

Conclusions: MKD symptoms can be variable and sometimes atypical, which requires physician's awareness. In our cohort of MKD patients anti IL-1 therapy was highly effective.

**THU0546 IMPACT OF BONE LOCALISATION ON THE PROGNOSTIC OF LANGERHANS CELL HISTIOCYTOSIS: A MONOCENTRIC RETROSPECTIVE STUDY**

1Immunology, Federal State Budgetary Institution “National Scientific and Practical Center of Pediatrics, Hematology, Oncology and Immunology named after Dmitry Rogalshev”, the Ministry of Healthcare of the Russian Federation; 1Immunology, Children’s Clinical Hospital N9, Moscow, Russian Federation

Background: Langerhans cell histiocytosis (LCH) is a rare condition, and mostly affects children. Bone is the most commonly involved organ, with bone lesions in 50% of patients. In a recent work, Aricò et al. described that the probability of survival in children suffering from a multisystemic LCH with risk organ involvement was reduced if patient did not have any bony lesion [1]. There is no such a study within the first 6 months of life, one – at the age of 1.5 years, one – at three years of age. During the course of the disease all patients had periodic fever and peripheral lymphadenopathy (mainly cervical group), as well as abdominal pain, nausea/vomiting. Five patients had diarrhoea, sometimes with blood, one patient suffered from severe constipation. Rash was seen in eight patients, myalgia, arthralgia were observed only in six. Oral ulcers were noted in seven children. Three patients had neurological involvement, one patient had it as the main symptom. One patient had periorbital edema and hyperemia during attacks, which to our knowledge, have not been reported previously in MKD. One patient developed amyloidosis and MAS before IL-1 inhibitor treatment initiation, which led to her death. In patients receiving anti-IL-1 therapy AIDAI index decreased from 58.3±11.2 before to 1.5±1.4 after 6 month of therapy (p<0.003).

Conclusions: MKD symptoms can be variable and sometimes atypical, which requires physician's awareness. In our cohort of MKD patients anti IL-1 therapy was highly effective.

Background: Familial Mediterranean fever (FMF) is a periodic fever syndrome caused by MEFV mutations. FMF may be associated with psoriasis in some cases. Previous study has shown that psoriasis was more common in the relatives of FMF patients [1].

Objectives: We aimed to investigate the prevalence of psoriasis among FMF patients and their relatives.

Methods: FMF patients followed at Hacettepe University Adult and Pediatric Rheumatology Departments between January and August 2016 were consecutively enrolled to this study. Demographic data, clinical manifestations, laboratory data and MEFV variant analysis were documented by medical file screening and face-to-face interview. The presence of psoriasis and psoriatic arthritis in patients and their relatives (first [Mother, father, children]-second [Brothers, grandchildren, grandfather and grandmother]-third degree [Nephew, uncle, maternal uncle, aunt, paternal aunt] relatives) and drug use history were also questioned. The patients were accepted to have psoriasis if the diagnosis was made by a dermatologist.

Results: 351 FMF patients (177 adults; 174 children) were included in this study (Table). 70.1% of adult patients were female, 29.9% were male. 53.4% of pediatric patients were female, 46.6% were male. The median age (min-max) of the adult patients was 35 (19–63), while the median age of the pediatric patient group was 10 (2–18). The onset age of symptom was 12 (0–39) in the adult group and 3 (1–14) in the pediatric group. The median age at diagnosis was 25 (2–52) in the adult group and 5 (1–18) in the pediatric group. Thirteen (3.7%) patients had psoriasis. Psoriasis was more common in adult patients than pediatric patients (p=0.02). Psoriasis was present in 22 (12.4%) of adult patients and 9 (5.2%) of pediatric patients (p=0.02). The frequency of psoriasis in one or more relatives of all FMF patients was found to be 8.8%.

Table: Demographic and clinical characteristics of 177 adult and 174 pediatric patients with familial Mediterranean fever (FMF)

Conclusions: IL-1 has an essential role for signaling early T helper 1 (Th17) differentiation and Ashida et al. have shown the presence of Th17 cells in the upper dermis of psoriasis-like lesions in a patient with FMF [2]. We may speculate that high IL-1 in FMF may cause Th17 activation and stimulation of keratinocytes; and this may be the reason for higher frequency of psoriasis in FMF patients. Thirteen (3.7%) patients had psoriasis; more common than the normal population (0.40%) (p<0.0001). FMF increases the likelihood of psoriasis in relatives of FMF patient. Thus, FMF patients should be questioned and carefully examined for psoriasis lesions and psoriasis family history.

THU0550 | TREATMENT AND OUTCOMES IN SPANISH PATIENTS WITH IGG4-RELATED DISEASE

REERIGG4, GEAS-SEMI, 1Systemic Autoimmune Diseases Unit, Hospital Universitari Vall d’Hebron, Barcelona, Spain; 2Muscle Disease Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, United States; 3Internal Medicine, Hospital General Universitario Gregorio Marañón; 4Internal Medicine, Hospital General Gregorio Marañón; 5Internal Medicine, Hospital Ramón y Cajal, Madrid; 6Internal Medicine, Hospital de Cabueñes, Gijón; 7Pathology, Clinicino Clínico Universitario, Santiago de Compostela; 8Vascularitics Research Unit, Hospital Clinic i Provincial, Barcelona; 9Internal Medicine, Hospital Río Hortega, Valladolid; 10Internal Medicine, Hospital de Manacor, Manacor; 11Internal Medicine, Complejo Hospitalario de Pontedeva, Pontevedra; 12Internal Medicine, Hospital la Fe, Valencia, Spain

Background: There is a lack of strong evidence on IgG4-related disease (IgG4-RD) treatment. There is only one clinical trial published, supporting the use of rituximab in American patients.

Objectives: To describe the treatments used in a series of patients diagnosed with IgG4-RD in Spain and to review the outcomes.

Methods: Clinical data were obtained from the Spanish Registry of IgG4-RD from October 2013 to January 2016, including 14 centers. Outcomes were assessed by a self-made response scale and the IgG4 responder index (RI). We categorized the outcomes as a total response (disappearance of the pseudotumoral lesions and absence of symptoms), partial response (<50% of regression of the tumefactive lesions or persistence of inflammation without symptoms) and no response if no changes were noticed. Treatment failure was considered if an increase of the activity, mass size or reappearance of symptoms were noticed among patients under treatment.

Results: Sixty-eight patients were included. Twenty-six (38%) were females, mean age 53.4 years. Thirty-six patients (52.9%) had systemic IgG4-RD involving >1 tissue. The most common involved tissues were: retroperitoneum (33%), orbito-facial region (28%), and maxillary and paranasal sinuses (24%). The main treatments used were: steroids (90%), surgery (45%) and azathioprine (19%).

All treatments were successful in achieving complete or partial response. The mean pre and post-treatment RI values were 6.7 (SD 4.6) and 1.9 (SD 2.6) respectively. There were no differences between systemic and non-systemic disease regarding the chosen treatments and the outcomes. The combination azathioprine-steroids was used in 12 patients. Fourteen percent of them relapsed (considering relapse as an increase of the inflammation, mass size or reappearance of symptoms, since the first month after the treatment withdrawal). The treatment failed in 28.6% of them. The combination steroids rituximab was indicated in 6 patients, showing no relapses and 1 treatment failure. The majority of patients treated with azathioprine or rituximab combined with steroids had a systemic disease (6.6 and 80%, respectively). Nearby all of them had already failed other previous treatments.

Conclusions: In our series, IgG4-RD has been treated with a myriad of drugs and procedures. The outcomes have been acceptable but the disease tended to relapse (21%) and the treatment failures were common (27%), probably due to the lack of well-defined treatment schemes supported by solid studies. Steroids were still the cornerstone of the treatment. Rituximab results were promising in our study but the number of patients was limited. Azathioprine, in combination with steroids, may be an accessible alternative treatment for IgG4-RD that should be explored. The RI correlated with the treatment outcomes and will have an important role monitoring future studies on IgG4-RD therapies.

THU0551 | ARTHRITIS IN SARCOIDOSIS - A MULTI-CENTRE STUDY FROM INDIA

Background: 10–15% of sarcoid patients have associated arthropathy. Chronic arthritis is less described than from varying from 1–2% [1]. Data on articular manifestations of the disease from India is sparse.[2]

Objectives: To study the clinical manifestations of sarcoid arthritis patients from India.

Methods: Case records of patients presenting to ten rheumatology centres from 2005 to 2016 with sarcoidosis were retrospectively reviewed. Joint involvement was assessed clinically, classified as acute or chronic depending on duration of symptoms lesser or greater than 6 months respectively.

Results: A total of 103 patients with sarcoid arthritis were reviewed. 58 patients were classified as Lofgren syndrome. Pattern of joint involvement revealed ankle as most commonly affected joint. Six patients were classified in the early diagnosis and adequate treatment, but also the close follow up is important in managing FMF patients.

THU0552 | COMPLIANCE TO COLCHICINE TREATMENT IN FAMILIAL MEDITERRANEAN FEVER RELATED AMYLOIDOSIS

B. Yurttas1, S. Ugurulu1, H. Ozdogan2,3. 1Department of Internal Medicine, 2Department of Internal Medicine, Division of Rheumatology, Istanbul University Cerrahpaşa Medical Faculty, Istanbul, Turkey

Objectives: To assess the colchicine compliance in patients diagnosed with Familial Mediterranean Fever (FMF) related amyloidosis in our center.

Methods: Forty one patients (18 male/23 female) were questioned with regards to colchicine compliance by using retrospective scanning of patient chart.

Results: The mean age at the symptomatic onset of FMF was 7.13±5.24 years. The mean age at the time of the FMF diagnosis was 21.2±14.85 years. The mean age at the initiation of colchicine treatment was 21.4±2.14.75 years and the mean age at time of diagnosis of amyloidosis was found 29.5±7.12.14 years. Mean duration of the disease was 31.70±11.84 years and the duration of delayed diagnosis was 14.35±13.84 years. Maximum dose of colchicine was 2.10±0.673 mg/day. Compliance of colchicine treatment was poor in FMF related amyloidosis during their follow-up (11/25, %44), rates of skipped doses were also high (17/25, %68). Compliance rates were high in patients whom FMF and amyloidosis were diagnosed simultaneously (12/13, %93), rates of skipped doses were also low (4/9, %44). One of the patients diagnosed with FMF after the diagnosis of amyloidosis was compliant, two of them were non-compliant; with regards to skipping doses, two patients were found to be compliant and therefore never skipped doses while one was skipping doses. The compliance to colchicine was high in all FMF patients once amyloidosis was evident (31/41, %75), and rates of skipped doses were also low (12/41, %30). In five FMF patients, amyloidosis was observed despite their compliance to treatment.

Conclusions: The overall delay of diagnosis in FMF patients with amyloidosis was found to be high. Particularly the FMF patients who were diagnosed with amyloidosis during their follow up were found to have lower rates of compliance.

Low Alkaline Phosphatase Levels: Could it Be Hypophosphatasia?

C. Tornero, P. Aguado, S. García, J. Tenorio, P. Lapunzina, A. Buño, J.M. Iturzaeta, C. Plasencia, I. Monjo, A. Balsa; 
1 Rheumatology; 2 Genetics; 3 Clinical Laboratory, la Paz University Hospital, Madrid, Spain

Background: Hypophosphatasia (HPP) is a rare inherited disorder of bone and mineral metabolism, caused by mutations in the ALPL (alkaline phosphatase liver type) gene, with reduction of activity of the tissue-specific isozyme of ALP (TNALP). The clinical presentation is variable and adult forms of the disease are usually milder than those affecting infants and children, easily overlooked or misdiagnosed, which can lead to erroneous therapeutic decisions.

Objectives: The primary objectives of our study are to estimate the prevalence of patients with adult forms of HPP in a group of patients with persistent hypophosphatasemia, to analyze their clinical and functional characteristics, and to compare these findings between those presenting or not these mutations.

Methods: In this Cross-sectional study, 1,536,711 ALP measurements owing to 386,356 patients were evaluated during a six-year period (2009–2015). Patients having at least two values below 35 IU/l and none above 45 IU/l constituted the study population. In total, 427 patients were included. Among them, 31 patients were excluded because of presenting causes of secondary HPP and 13 because of lost to follow-up. 108 patients were contacted by phone to fulfill a questionnaire about manifestations related to HPP and health assessment and in order to obtain blood samples to perform the genetic test.

Results: Demographic and clinical characteristics of both groups are shown in Table 1. Of the 108 patients evaluated, the genetic test results of 39 patients are available at this moment (the rest of the results are currently pending). 59% (23/39) tested positive for the genetic mutation. Despite data are still partial and although the results did not achieve statistical significance, we observed with a greater relevance a higher proportion of patients with HPP presenting with chronic bone pain, weakness, stress fractures and dental abnormalities. These data should promote a more proactive attitude towards detection of adult HPP.

Immunoglobulin G4-Related Disease in Hong Kong – Clinical Features, Treatment Practices and Associations

PH. Li, C. Ho, C.-S. Lau. Department of Medicine, Queen Mary Hospital, Hong Kong, Hong Kong

Background: Immunoglobulin (Ig) G4-related disease (IgG4-RD) is a systemic immune-mediated disease unifying what were previously considered to be unrelated individual organ disorders. The diagnosis and treatment of this characteristic fibroinflammatory condition continues to evolve, but generally remains an under-recognised disease. Local data outside Japanese and Caucasian populations is lacking and few studies have examined factors to predict disease severity or disease prognostication.

Objectives: We conducted this study to review the clinical features, treatment practices and factors associated with more extensive disease involvement in Hong Kong.

Methods: We retrospectively evaluated all patients with IgG4-RD over the past 13 years in our centre and combined this with patient data extracted from previous local publications. We analysed the clinical features, treatment practices and factors associated with the number of organ systems involved.

Results: One hundred and four patients (55 from our centre and 49 from literature review) were included. Patients were predominantly older men (mean age 61.9 years, male:female ratio 3:1). Hepatobiliary and pancreatic (40.4%), salivary gland (33.6%), lymph nodes (29.8%) and eye (19.2%) were the most common systems involved. Lymphadenopathy was associated with glucocorticoid use (OR=2.65, p=0.034). Over 90% of patients had a serum greater than 135 mg/dl and a G4-total IgG ratio greater than 8%. Pre-treatment serum IgG4 levels correlated with the number of organ systems involved (r=0.347, p=0.004), and specifically with salivary gland involvement (mean 1109 mg/dl vs. 599 mg/dl, p=0.012).

Conclusions: We identified pre-treatment serum IgG4-RD to be associated with multi-system disease, especially with salivary gland involvement, highlighting the potential for its use in disease prognostication and monitoring. The reason for this particular correlation remains uncertain but highlights the importance of screening for salivary gland involvement in all IgG4-RD patients, especially in the presence of higher serum IgG4 levels. We also describe the clinical features and treatment modalities of the largest cohort of IgG4-RD in Hong Kong thus far. Increased physician awareness and multidisciplinary efforts are required for optimal management of this masquerading disease. Future studies, especially focusing on treatment strategies within the contexts of different epidemiology and patient characteristics, are greatly needed.

Immunoglobulin G4-Related Disease in Hong Kong

Background: Validated disease activity scores and damage measurements were developed over time in order to allow a better way to evaluate patients and decide treatment plans. There are scores designed for a great variety of vasculitis like Birmingham Activity Score and others that are more specific like Behcet’s Disease Current Activity Form 2006.

Objectives: To evaluate the activity of the ability scores (BVAVs3rd and BDCAF) to predict damage, and the influence of immunosuppressive therapy on damage progression, as measured by VDI, in a group of patients with Behcet’s Disease.

Methods: A study was performed on a cohort of patients diagnosed with Behcet’s Disease under surveillance in one tertiary Rheumatology Centre, from a non-endemic area. All documented cases of Behcet’s Disease have been diagnosed according to The International Criteria for Behçet’s Disease. The Birmingham Activity Score (BVASv3, Behcet’s Disease Current Activity Form 2006 (BDCAF) and Vasculitis Damage index (VDI) were calculated for all patients. Spearman’s correlation coefficients were calculated between BVAVs3 Score, BDCAF, VDI and immunosuppressive treatment. Windows Excel/SPSS20.0 has been used to analyse the data.

Results: 20 patients were included in the study, with ages at the time of the...
SALIVARY GLAND ENLARGEMENT IN IGG4-RELATED 1, A. Angeles-Angeles 2, G. Hernandez-Molina 1.

SALIVARY GLAND ENLARGEMENT IN IGG4-RELATED DISEASE IS ASSOCIATED WITH MULTIORGAN INVOLVEMENT AND HIGH BASAL DISEASE ACTIVITY

E. Martín-Naës 1, A. Angelles-Angelles 2, G. Hernandez-Molina 1.
1Rheumatology, 2Pathology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Background: IgG4-related disease (IgG4-RD) is an immune-mediated condition which clinical spectrum encompasses single or multiple organ involvement. Enlargement of major and minor salivary glands is one of the main disease features. Whether salivary gland enlargement is associated with systemic involvement has not been previously evaluated.

Objectives: To elucidate if salivary gland enlargement is associated with systemic disease.

Methods: We included patients with an established diagnosis (definitive: organ involvement, biopsy proven without high IgG4 levels, possible: organ involvement, biopsy proven and high IgG4 levels, probable: organ involvement, high IgG4 levels without histology) of IgG4-RD according to the Comprehensive Diagnostic Criteria, who regularly attend a tertiary referral center in Mexico City (2000–2017). We retrospectively collected demographics, clinical (organ involvement, disease activity, damage) and radiologic data by the IgG4 Responder Index [IgG4-RD RI] at basal and at 6 months of follow-up, number of relapses, remission and treatment), basal laboratory (C3, C4, ESR, PCR, total eosinophil count, IgG4 levels) as well as imaging and histologic data.

Results: We included 32 patients, 17 (53.1%) men, mean age 50.2±14.1 years and median disease duration 20.5 months. Seven (21.9%) have a definitive diagnosis, 12 (37.5%) probable and 13 (40.6%) possible. Overall we identified 21 anatomic sites affected, mainly pancreas 56.2%, lymph nodes 56.2%, lacrimal glands 37.5% and bile duct 34.2%. Salivary gland involvement was present in 12 (37.5%) patients (2 parotid, 3 minor salivary gland and 7 both). Among these patients, only 5 (41.6%) referred dry mouth and in 7 patients (58.3%) glandular enlargement was the onset disease feature. Salivary glandular enlargement was identified only radiologically in 5 patients (41.6%) and both clinical and radiologic in 7 (21.9%). Patients with glandular enlargement had a higher number of affected organs (6.5 vs. 2, p=0.001) and absolute eosinophils count (348 vs. 137.5/mm3, p=0.03), a higher prevalence of lacrimal glands (75% vs. 15%, p=0.002), lymph nodes (91.7% vs. 35%, p=0.002) and lung involvement (33.3% vs. 0%, p=0.01), azathioprine use (83.3% vs. 30%, p=0.003), as well as a higher basal IgG4-RD RI (12 vs. 6, p=0.001) and a longer delay in diagnosis (64 month vs. 6.5 months, p=0.001). We did not find differences regarding gender, age, IgG4 serum levels, C3, C4, ESR, PCR, anti-nuclear antibodies, rheumatoid factor, anticyclic citrullinated peptide antibodies and anti-CCP antibodies (negative in all patients); number of relapses, remission at 6 months and damage. We performed a logistic regression analysis (only including the number of organs, the basal IgG4-RD RI and time of follow-up) and found an association of salivary glandular enlargement with the basal IgG4-RD RI (OR 1.63, 95% CI 1.12–2.35, p=0.009).

Conclusions: Our results highlight the systeic involvement of IgG4-RD. Patients with salivary gland enlargement should be routinely screened for systemic involvement.

THU0557

VENOUS VESSEL WALL THICKNESS IN LOWER EXTREMITY IS INCREASED IN MALE BEHÇET’S DISEASE PATIENTS WITHOUT VASCULAR INVOLVEMENT

F. Alibaz-Oner 1, A. Mutis 1, R. Ergelen 2, Z. Erturk 1, T. Ergun 1, H. Dirikseneli 1.
1Rheumatology; 2Radiology, Dermatology, Marmara University, School of Medicine, Istanbul, Turkey.

Background: Vascular involvement is seen in up to 40% of the patients with Behcet’s Disease (BD), especially in young males and is one of the major causes of mortality and morbidity. Lower extremity vein thrombosis due to vascular inflammation is the most frequent form of vascular involvement in BD. Recently, assessment of vessel wall thickness (VWT) and venous dilatation by US is suggested to be valuable in patients with vascular inflammation.

Objectives: In this study, we investigated whether vessel wall thickness or dilatation is present in young male BD patients prone to venous vascular disease.

Methods: Fifteen male patients with BD without major organ involvement followed in Marmara University Behcet’s Clinics, 14 healthy male controls and 14 male patients with Ankylosing Spondylitis (AS) were included the study. Bilateral lower extremity venous doppler ultrasonography (US) was performed by an experienced radiologist blinded to cases. No patient was under immunosuppressive treatment. Bilateral common femoral vein (CFV) wall thickness and great/small saphenous vein dilatations were examined. Behçet Syndrome Activity Score (BSAS) was used for the general assessment of disease activity.

Results: The mean disease duration was 9.1±6.3 years in patients with BD. BSAS was 28.9±19. Bilateral CFV wall thickness was significantly higher in BD patients compared to healthy controls and AS (p<0.001, p=0.002, respectively for right CFV; p=0.001, p=0.001, respectively for left CFV) (Table 1). The width of great and small saphenous veins were also higher in patients with BD, but without reaching statistical significance. There were no correlations between BSAS and wall thickness of any vessel.

VWT: Venous wall thickness.

Conclusions: In preliminary results of our study, an increased venous vessel wall thickness in lower extremity was shown in male BD patients without vascular involvement. As a similar change was not observed in controls, we think, increased VWT might be an early sign of venous inflammation in patients with BD rather than a result of non-specific systemic inflammation. Further studies with a larger group of patients is planned.

Background: Polymyalgia rheumatica (PMR) is an inflammatory rheumatic disorder which usually affects patients over 65 years old. Different poor prognostic factors are involved in prednisone response including rapid decrease of prednisone dose or female sex. To date, there is no data relating the impact of the age on therapeutic response in PMR.

Objectives: The aim of this study was to compare, in case of PMR, the response to prednisone in patients younger than 60 to patients over 65 years old.

Methods: This was a retrospective, monocentric study. We included patients suffering from PMR, meeting ACR 2012 criteria. Patients were classified into two groups, one group with patients less than 60 years, and one group with patients over 65 years. We registered demographic, clinical, biological, and imaging data as well as therapeutic response profile. The local inflammation was evaluated with PET scan, by studying each anatomical site usually affected by PMR. Then, the rate of inflammation was scored from 0 to 3, according to the intensity of uptake compared to liver. The treatment was standardized. The initial dose of prednisone was of 0.3mg/kg during the first two weeks, then, the dose was slowly decreased
PHOTOGRAPHS OF SKIN LESIONS IN PATIENTS WITH AOSD

Figure 1. Erythema nodosum in a patient with AOSD. The lesion was a small, red, nodular elevation that was tender on palpation.

Figure 2. Maculopapular rash in a patient with AOSD. The rash was erythematous and itchy, and it resolved spontaneously.

Figure 3. Purpura in a patient with AOSD. The purpuric spots were purple and painful, and they disappeared within 1-2 days.

Figure 4. Hidradenitis suppurativa in a patient with AOSD. The lesion was a painful, inflammatory nodule that drained pus.

Figure 5. Digital vasculitis in a patient with AOSD. The involved fingers showed swelling, redness, and pain.

Figure 6. Oral ulceration in a patient with AOSD. The ulcer was painful, and it healed without scarring.

Figure 7. Eyelid swelling in a patient with AOSD. The eyelid was edematous and red, and it improved with corticosteroids.

Figure 8. Mucosal ulceration in a patient with AOSD. The ulcer was painful, and it healed with topical and systemic therapy.

Figure 9. Acneiform lesions in a patient with AOSD. The lesions were inflamed and pus-filled, and they responded to oral antibiotics.

Figure 10. Palmar erythema in a patient with AOSD. The redness was non-tender and it resolved with topical therapy.

Figure 11. Mucous membrane ulceration in a patient with AOSD. The ulcer was painful, and it healed with systemic antibiotics.

Figure 12. Thyroiditis in a patient with AOSD. The thyroid gland was enlarged and tender, and it improved with antithyroid medication.

Figure 13. Dental abscess in a patient with AOSD. The tooth was painful, and it resolved with dental treatment.

Figure 14. Nodular subcutaneous mass in a patient with AOSD. The mass was firm and tender, and it disappeared with corticosteroids.

Figure 15. Arthritis in a patient with AOSD. The joint was swollen and tender, and it improved with non-steroidal anti-inflammatory drugs.

Figure 16. Uveitis in a patient with AOSD. The eye was red and painful, and it resolved with topical corticosteroids.

Figure 17. Pericarditis in a patient with AOSD. The heart was enlarged and tender, and it improved with corticosteroids.

Figure 18. Pulmonary involvement in a patient with AOSD. The chest X-ray showed infiltrates, and it improved with systemic corticosteroids.

Figure 19. Renal involvement in a patient with AOSD. The urine showed proteinuria and hematuria, and it resolved with corticosteroids.

Figure 20. Neurological involvement in a patient with AOSD. The patient had a stroke, and it improved with anticoagulation and corticosteroids.

Figure 21. Gastrointestinal involvement in a patient with AOSD. The patient had abdominal pain and diarrhea, and it resolved with systemic corticosteroids.

Figure 22. Cardiac involvement in a patient with AOSD. The electrocardiogram showed ST-segment elevation, and it improved with corticosteroids.

Figure 23. Hematological involvement in a patient with AOSD. The blood count showed thrombocytopenia, and it improved with corticosteroids.

Figure 24. Neurological involvement in a patient with AOSD. The patient had a stroke, and it improved with anticoagulation and corticosteroids.

INFLAMMATORY JOINT DISEASE TRIGGERED BY IMMUNE CHECKPOINT INHIBITORS

L. Tucker, S. Sacks, H. Al-Mossawi. Rheumatology, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background: Immune checkpoint modulation has changed the cancer therapy landscape in recent years [1]. Randomised controlled trials now demonstrate superiority to standard chemotherapy in squamous cell lung cancer, renal cell cancer [2], squamous cell head and neck cancer [3] and malignant melanoma [4]. However, blockade of these checkpoints results in a multitude of autoimmune sequelae including joint disease. As these therapies become first-line in oncology, they will likely place a significant burden on rheumatology services.

Objectives: To establish the prevalence of rheumatological manifestations of checkpoint blockade in a non-trial standard care setting.

Methods: All patients treated with Nivolumab or Ipilimumab (as single agent or in combination) in a standard care setting within a single centre were included and the number of suspected cases with rheumatological manifestations identified from the case records.

Results: 75 patients have been treated with Nivolumab single agent and 12 with combination Nivolumab plus Ipilimumab in Oxford over the last 15 months. Within that cohort, there were 7 suspected cases of joint disease giving a potential prevalence of 8%. Of those 7, 2 had confirmed disease requiring therapy, both had received Nivolumab/Ipilimumab combination. Both cases were rheumatoid factor and CCP negative. One case responded to prednisolone only, while the second case was refractory to steroids, methotrexate and infliximab but responded to IL-6 blockade with Tocilizumab.

Conclusions: We observed an approximate 8% prevalence of checkpoint mediated autoimmune joint disease within a relatively short follow up period of 15 months. The longer-term prevalence may be higher. Both patients requiring therapy had been exposed to Ipilimumab suggesting the inflammatory joint toxicity with this agent may be higher than that caused by Nivolumab.

Checkpoint immunotherapy is set to become the first-line standard of care in a number of cancers. This will lead to an increased demand for rheumatology services. The rheumatology community needs to develop strategies and trials in order to classify and treat these patients appropriately.

THU0565

MACROPHAGE ACTIVATION SYNDROME IN ADULTS WITH INFECTIOUS RHEUMATIC DISEASES

M. Olejárová 1, K. Jarošová 2, 1 Clinic of Rheumatology, 1st Medical Faculty, Charles University; 2 Institute of Rheumatology, Praha 2, Czech Republic

Background: Macrophage activation syndrome (MAS) is a rare hyperinflammatory condition characterised by macrophage activation and inflammation resulting in a multi organ damage. MAS is considered to be a type of secondary hemophagocytic lymphohistiocytosis. It is a life threatening complication of various autoimmune or autoinflammatory rheumatic diseases, particularly systemic juvenile idiopathic arthritis (sJIA). Clinical manifestations include hepatosplenomegaly, increase of liver function tests, pancytopeny, neurological manifestations etc. High doses of glucocorticosteroids (GC), cyclosporine A (CyA) and etoposide are a treatments of choice. In refractory cases biologics may be an option, too.

Objectives: To point out this very rare but severe complication may occur also in adult patients with rheumatic diseases.

Methods: We report 4 successfully treated cases of adult MAS in rheumatic patients seen in our clinic during the years 2009 – 2016. A review of the literature regarding the efficacy of biologics in MAS treatment is also presented.

Results: We have observed four patients with MAS, two with adult onset. Still disease (AOSD), one with rheumatoid arthritis (RA) and one with SJIA. All of the patients were young (20 -33 years, mean age 27.0±5.61 years) with the duration of the primary disease ranging from 9 months to 11 years (mean 4.1±4.01 years). Three patients were in remission of the primary diseases prior to MAS manifestation, only one female patient and most severe one had MAS refractory to the combination GC + CyA and must have been added biological therapy (tocilizumab). We reviewed also another cases of MAS treated with biologics which have been published.

Conclusions: Our cases illustrate that MAS may develop also in adult patient with various rheumatic diseases (JIA, AOSD, RA) despite the low activity or remission. It occurs particularly in younger subjects. As the MAS symptoms may overlap with the symptoms of the primary disease (JIA, AOSD) the diagnosis may be difficult. MAS must be suspected in inflammatory rheumatic diseases patients with sudden increase of CRP, extreme increase of ferritin, liver function tests and decrease of platelets. An immediate treatment with GC, CyA and etoposide is essential; biologics (anakinra, canakinumab or tocilizumab) may be beneficial in refractory cases.

CLINICAL AND GENETIC PHENOTYPES OF CHINESE PATIENTS WITH ADULT AUTOINFLAMMATORY DISEASES: REPORT FROM AN ADULT REFERENCE CENTER

M. Shen, D. Wu, X. Zeng. Peking Union Medical College Hospital, Beijing, China

Background: Autoinflammatory diseases (AUID) is a group of disorders characterized by dysfunction of innate immunity which caused by gene mutations leading to coded proteins changes, finally causing uncontrolled systemic inflammation. AUID are usually diagnosed during pediatric age. However, adult-onset disease or diagnosis during adulthood has been occasionally described. Moreover, AUID have been hardly reported in the Chinese population.

Objectives: We aimed to characterize the clinical and genetic phenotypes of Chinese adult patients with AUID.

Methods: We prospectively evaluated clinical and genetic features of adult patients (>16 years) with monogenic AUID in the period April 2015 to May 2016, at the adult AUID center, Department of Rheumatology, Peking Union Medical College Hospital. The definite diagnosis of each disease was deemed to be present if both clinical phenotypes and genetic confirmation were met.

Results: During the study period, a total of 37 adult patients with clinical phenotypes suspicious of monogenic AUID requested for a genetic study. A final diagnosis of monogenic AUID was achieved in 16 patients (43.2% of patients tested). Two additional patients were diagnosed with periodic fever, aphthous stomatitis, pharyngitis and adenitis (PFAPA) syndrome. Finally, all of 18 patients with AUID were diagnosed and followup in our center including 7 (38.9%) familial Mediterranean fever (FMF), 2 (11.1%) tumor necrosis factor-receptor associated periodic syndrome (TRAPS), 3 (16.7%) cryopyrin-associated periodic syndrome (CAPS), 3 (16.7%) NLPR12-autoinflammatory disease (NLPR12-AD), 1 (5.6%) Blau syndrome (BS), and 2 (11.1%) PFAPA.

Disease onset during adulthood was observed in 15 (83.3%) patients, and the final diagnosis was delayed with a mean time of 10 years. Adult AUID patients usually carried low-penetrance mutations and gene variants were presented as heterozygosis or compound heterozygosis.

Conclusions: Adult AUID is not uncommon. FMF, CAPS, and NLPR12-AD are relatively common monogenic AUID in Chinese adult patients. Adult-onset AUID may be related to the presence of low-penetration mutations, being characterized by nonspecific incomplete or atypical disease patterns, leading to a delay of diagnosis. The interpretation of gene analysis in adult suspected AUID should be performed with caution, and if possible, should be referred to expert physicians in the field in adult AUID center.

etanercept (2), golimumab (2), rituximab (2), abatacept (3), anakinra (1) and colchicum (1).

TCZ administration schedule was 8 mg/kg/4 weeks iv. (n=23), every 2 weeks (1) and subcutaneously 162 mg/2 weeks (1). TCZ was used in monotherapy (12) or combined with conventional immunosuppressive drugs (12). Most of intraocular inflammation parameters showed a rapid improvement after TCZ onset (Table), with corticosteroid-sparing effect (15.9±13.6 to 8.5±5.17 mg; p<0.001). Remission was achieved in 8 patients and improvement in 17. After one month of therapy, no side effects were observed.

Conclusions: TCZ seems a rapid effective treatment in refractory uveitic CME.

THU0568 | PREVALENCE AND AUTOIMMUNE RHEUMATIC DISEASE IN PATIENTS WITH AUTOIMMUNE/INFLAMMATORY SYNDROME INDUCED BY ADJUVANTS ASSOCIATED TO SILICONE BREAST IMPLANT

O. Vera Lastra, N.E. Torres-Oliva, G. Medrano-Rodriguez, M.D.P. Cruz-Domingo, J. Sepulveda Delgado, L.I. Jara, G. Medina. Internal Medicine, Hospital Especialidades CMN la Raza. Instituto Mexicano Seguro Social, Mexico City, Mexico

Background: Autoimmune/inflammatory syndrome induced by adjuvants (ASIA) has been associated with previous exposure to various agents such as silicone implants, which elicit chronic stimulation of the immune system against the synthetic material and can lead to the development of autoimmunity. This is particularly the case in genetically susceptible hosts.

Objectives: The aim is to describe prevalence, family background and main autoimmune rheumatic disease (ARD) associated to silicone breast implant (SBI).

Methods: We study a cohort of 150 patients with diagnosis of ASIA associated injection of mineral oil and silicone breast implant (SBI) in a tertiary Hospital, from 2011 to 2016. All patients were evaluated for the fulfillment of ASIA criteria. We only included patients with ASIA criteria associated with SBI plus criteria for an autoimmune rheumatic disease according to The American College of Rheumatology or EULAR. We excluded patient with ASIA and without ARD.

Results: There were 17 women patients with mean age 42.4±15.3 years, mean disease duration of disease 8±3 years. The clinical manifestation post SBI appeared 8±2 years later. The ARD were systemic sclerosis (SSc) 5, systemic lupus erythematosus (SLE) 3, rheumatoid arthritis (RA) 3, overlap syndrome 2 (SSc plus SS and SLE plus SSc, Sjogren syndrome 1, Takayasu arteritis 1, Still disease 1, antiphospholipid syndrome) UN update. Lupus 2017 Jan 1.

THU0569 | TREATMENTS OF UVEITIS IN A REFERRAL MULTIDISCIPLINARY UNIT IN NORTHERN SPAIN

P. Fanlo, H. Heras, O. Terry, G. Espinosa, A. Adan. *Autoimmune Sistemic Disease Unit, 1Ophthalmology, Complejo Hospitalario de Navarra, Pamplona; 1*Autoimmune Sistemic Disease Unit, 1Ophthalmology, Hospital Clinic, Barcelona, Spain

Background: Intraocular inflammation is one of the leading causes of visual impairment and blindness. Early and appropriate treatment is mandatory for avoiding complications.

Objectives: To describe the treatments prescribed in a cohort of patients with uveitis in a referral multidisciplinary unit from northern Spain.

Methods: Retrospective analysis of clinical records of patients evaluated in the Uveitis Multidisciplinary Unit of the Complejo Hospitalario of Navarra since January 2010 until March 2015. We analyzed the demographic characteristics and treatments received in the following 3 months after first visit.

Results: We identified 500 patients, 50% women with a mean age of 47.9 ± 16.4 years. The most frequent type of uveitis was anterior uveitis (65.4%), followed by posterior uveitis (17.6%), panuveitis (15.2%), and intermediate uveitis (1.8%). Considering the etiology, 31.2% were unclassified, followed by non-infectious systemic disease in 29.2%. During the 3-month follow-up, 904 treatments were prescribed. The most frequent treatment was oral prednisone (39%), followed by immunomodulatory treatment (27%), antimicrobial (14%), other treatments (10%) and less biological (3%), surgical (3%) and finally periocular (2%) and intravitreal (2%) treatment. Topical uveitic treatment: 350 patients received topical uveitic treatment, which accounts for 70% of patients. Among topical uveitic treatments, 15% of the samples were treated with topical steroids, 54% were topical steroids associated with another topical treatment, 2% were topical antiglaucomatous, 22% received other topical treatments and 27% of the sample did not receive topical treatment. Immunosuppressive treatment: 249 immunosuppressive treatments were prescribed. 50% of the patients received immunosuppressive treatment. Among the immunosuppressive treatments, 25% of the patients received oral steroids, 6% salazopyrine, 4% methotrexate, 5% azathioprine, 2% mycophenolate mofetil, 5% oral steroids associated with another immunosuppressant, 15% salazopyrine associated with another immunosuppressant, 1% other immunosuppressive treatment and 49% of patients did not receive any immunosuppressive treatment. Biologic Treatment: 25 patients in the cohort received biologic treatment, this represents 5% of patients. The biological treatment types were distributed as follows: 3% of the patients received adalimumab treatment, 1% received infliximab, 1% received other biological treatments, and 95% of the patients did not receive biological treatments. The number of treatments received per patient was analyzed and 50 patients (10%) received no treatment, 152 patients (30%) received 1 treatment, 189 patients (38%) received 2 treatments, 75 patients (15%) Had received 3 treatments, 23 patients (5%) had received 4 treatments, 9 patients (2%) had received 5 treatments and lastly 2 patients had received 6 treatments. The majority of patients received the combination of two treatments. Topical steroids and oral steroids were the most frequent treatments used.

THU0570 | ANAKINRA AS A SUCCESSFUL TREATMENT OF IDIOPATHIC RECURRENT PERICARDITIS: TAPER OR NOT TO TAPER? CASE SERIES AT THE UNIVERSITY OF SOUTHERN CALIFORNIA

P.S. Chhibar, G. Ehremann. Rheumatology, University of Southern California, Los Angeles, United States

Background: Idiopathic Recurrent Pericarditis can be challenging to treat in patients unresponsive to NSAIDs, aspirin, colchicine and immunosuppressive drugs. Patients become steroid dependent and tapering precipitates recurrences.

Objectives: To describe 2 adult cases of idiopathic recurrent pericarditis treated successfully with anakinra at the Keck Medical Center of USC.

Methods: Chart review of 2 patients with idiopathic recurrent pericarditis treated with anakinra at the Keck Medical Center of USC. Literature review on treatment of idiopathic recurrent pericarditis with anakinra.

Results: Case 1: 60-year-old Caucasian male had five episodes of idiopathic pericarditis in 2011. Serologic workup including ANA, anti-dsDNA, malignant and infectious workup was negative. Initially, patient responded to prednisone 0.4 mg/kg/day. Adding colchicine, azathioprine and methotrexate failed to prevent recurrence. Pericarditis developed whenever prednisone was tapered above 20 mg/day with bursts of CRP to 78 mg/dl. In 2012, Anakinra 100 mg sq daily resulted in immediate clinical response and normalization of CRP (1mg/dl). Prednisone and methotrexate were tapered with no recurrence. Gradually Anakinra was tapered to 3 times/week, then once a week, with no recurrence. Case 2: 37-year-old African male had 2 episodes of idiopathic pericarditis positive ANA 1:320, but negative anti-dsDNA, anti-smith, negative infectious and malignancy workup. Initially, patient responded to prednisone 0.6 mg/kg/day and colchicine. Tapering steroids below 40 mg/day resulted in recurrent pericarditis. Sequential addition of hydroxychloroquine, methotrexate, mycophenolate mofetil, and azathioprine failed to prevent recurrence, which followed in prompt resolution of symptoms, normalization of acute phase reactants and allowed successful tapering of steroids. Anakinra is being slowly tapered over the past year, with no recurrence.

Conclusions: Idiopathic recurrent pericarditis, which requires chronic corticosteroids, should be treated by adding another immunosuppressive agent. European Society of Cardiology guidelines recommend azathioprine, cyclophosphamide, methotrexate, hydroxychloroquine, cyclosporine or mycophenolate mofetil. Anakinra has demonstrated success in treating autoinflammatory and autoimmune diseases as well as idiopathic recurrent pericarditis.
Vassilopoulos et al reported three adult cases, where two were not treated with immunosuppressive drugs before anakinra and one had recurrence after anakinra was tapered. The Double Blind Placebo Controlled Clinical Trial AIRTRIP shows efficacy of anakinra in treating 11 patients with recurrent pericarditis over 14 months. It is unclear from this study if anakinra should be tapered or not. We suspect that once steroids and immunosuppressive drugs have been discontinued, anakinra should be gradually tapered over months, to avoid relapse. These experiences warrant further long term controlled trials in order to determine the efficacy and appropriate treatment regimen of anakinra for recurrent pericarditis.

**THU0571 THE CLINICAL FEATURES OF 223 BEHÈCHET’S DISEASE PATIENTS IN JAPAN**

R. Saito 1, K. Nishimura 1, H. Mukoyama 1, Y. Nakamura 1, T. Nagamoto 1, K. Akashi 2, A. Onishi 2, Y. Kogata 2, J. Saegusa 2, A. Morinobu 2, T. Yokota 1.

1 Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Kurashiki; 2Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe, Japan

**Background:** Behçet’s disease is a systemic vasculitis disease with oral and genital aphthous ulcers, ocular involvements, skin manifestations, arthritis, gastrointestinal manifestations, neurogenic diseases and vascular involvements. Patients with Behçet’s disease are known to distribute along the ancient Silk Road, including Japan.

**Objectives:** We evaluate the clinical features of Behçet’s disease in Japan.

**Methods:** We retrospectively investigated 223 patients (108 males and 115 females) who fulfilled the International Criteria for Behçet’s Disease (ICBD) from January, 2006 until May, 2015. We examined sex, onset age, disease type, clinical symptoms, laboratory data and medications.

**Results:** Median age at diagnosis was 36.0±12.8 years old. Oral ulcers were the most common manifestation (98.2%), followed by genital ulcers (82.4%), ocular involvements (53.2%), erythema nodosum (53.2%), acneiform lesions (51.8%), arthritis (38.6%), gastrointestinal manifestations (25.1%), neurogenic diseases (9.0%), and vascular involvements (8.1%). The relationship of HLA and disease involvements was studied in 123 patients (41.5% with HLA-B51 and 24.1% with HLA-A26 positive).

**Conclusions:** A higher incidence of gastrointestinal manifestations was observed in patients with Behçet’s disease in Japan. Patients with ocular involvements showed a higher association rate with neurogenic diseases, and lower with gastrointestinal manifestation. Most patients could continue TNFα inhibitor safely and effectively.

**THU0572 ASSOCIATION BETWEEN RETROPERITONEAL FIBROSIS AND MALIGNANCY: A POSSIBLE PARANEOPLASTIC SYNDROME**

S.J. Lee 1, J.S. Eun 1, E.Y. Lee 2, G.B. Bae 1, E.J. Nam 1, Y.W. Song 2, Y.M. Kang 1.

1 Internal Medicine, Division of Rheumatology, Kyungpook National University Hospital, Daegu; 2Internal Medicine, Division of Rheumatology, Seoul National University Hospital, Seoul, Korea, Republic Of

**Background:** Retroperitoneal fibrosis (RPF) are associated with malignancies. However it is unclear what is the incidence of malignancies and whether particular malignancies are more prevalent in RPF.

**Objectives:** The objective of this study was to examine standardized incidence ratios (SIRs) of cancers in patients with retroperitoneal fibrosis (RPF) compared with age- and sex-matched general population.

**Methods:** Medical records of 111 patients diagnosed as having RPF by computed tomography, positron emission tomography and/or histological evaluation were reviewed. Forty one cases of cancers, which were confirmed by biopsies, were identified in 35 patients with RPF. SIRs were calculated for cancers, cancer types, and age at cancer diagnosis and stratified according to RPF-cancer intervals compared with general population in Korea.

**Results:** The mean ± SD age at RPF diagnosis was 59.1±14.9 years, and 69.4% of the patients were male. The cancer SIR (95% confidence intervals) in patients with RPF relative to age- and sex-matched individuals in the general population was 3.18 (2.23 - 4.41) [2.65 (1.17 - 3.94) in men; 5.34 (2.76 - 9.32) in women]. The most frequent cancer was unspecified urinary organ cancers with SIR of 72.41 (23814 – 17113.53). SIRs of multiple myeloma [27.58 (3.34 – 99.64)], renal cell cancers [9.53 (1.15 - 34.42) and unspecified cancers [16.92, (2.05 - 61.12)] were also significantly higher than in general population. Whereas cancers were most frequently developed in the eighth decade of life, the peak SIR was observed in the fifth decade (8.41, 229 – 21.53). When stratified by RPF-cancer intervals, SIR was 6.85 (4.55 - 9.90) within 2 years of RPF diagnosis, while no significant increase in SIR was found out of 2 years. Malignancies (n=28) within 2 year of RPF diagnosis included unspecified urinary organ cancer (n=4), lung cancer (n=4), colon cancer (n=3), renal cell cancer (n=2), pancreatic cancer (n=2), unspecified cancer (n=2), rectal cancer (n=1), gallbladder cancer (n=1), non-Hodgkin lymphoma (n=1), multiple myeloma (n=1), prostate cancer (n=1), thyroid cancer (n=1) and gastrointestinal stromal tumor (n=1). Predominant origin of these malignancies were epithelial cell types [transitional cell carcinomas (n=4), adenocarcinoma (n=16)].

**Conclusions:** RPF was strongly associated with cancers, particularly within 2 years of RPF diagnosis. Our results indicate that cancer screening in patients with RPF should be performed regularly up to 2 years after RPF diagnosis.

DOI: 10.1136/annrheumdis-2017-eular.6168
characteristics of autoimmune diseases associated with sarcoidosis (sarcoidosis-overlap group) patients and isolated sarcoidosis (isolated sarcoidosis group) were analyzed and compared.

**Results:** Autoimmune disease was detected in 15 (11.5%) of 131 patients with sarcoidosis (15sjögren syndrome, 3 rheumatoid arthritis, 1 Still disease, 1 scleroderma, 4 dermatomyositis, 2 polymyositis, 1 temporal arthritis, 1 gout arthritis, 1 angitis and 1 hypertrophic osteoarthropathy). Most of these diseases occurred before (such as RA, AS, Still, FMF) and others after sarcoidosis diagnosis. Among 15 sarcoidosis patients with autoimmune disease 10 were female and 5 were male, the mean age was 50.8 years and mean disease duration was 10.6 months (range: 1-30 months). When compared with isolated sarcoidosis patients, more hand finger joint involvement, RF positivity, higher ESR and less NSAIDs usage were found in patients with sarcoidosis-overlap group (p=0.035, p=0.049, p=0.015, p=0.018 respectively). There was no statistically significant difference between the two groups when evaluated for demographic, clinical parameters and other treatment modalities.

**Conclusions:** Comorbid autoimmune diseases in patients with sarcoidosis may often be seen. These patients are characterized with more hand finger joint involvement, RF positivity, higher ESR and less NSAIDs usage. Therefore, in patients with a diagnosis of sarcoidosis, it is necessary for the physician to be careful and to make a wider differential diagnosis in terms of the presence of another underlying autoimmune disease. Multicenter, prospective studies involving large numbers of patients are needed to understand whether the association of sarcoidosis-autoimmune diseases is based only on coincidence or on a common etiological basis.

**CLASSICAL IMMunosuppression and Damage Progression in a Group of Patients Diagnosed with Behcet’s Disease**

S. Daia-Ilieescu, C. Buzatu, A. Borangiu, I. Saulescu, L. Groseanu, V. Bojnică, A. Balanescu, D. Predeiteanu, R. Ionescu, D. Opris-Belinski. Internal Medicine and Rheumatology, St. Maria Clinical Hospital, Bucharest, Romania

**Background:** Behcet’s Disease is a rare type of vasculitis that involves both arterial and venous blood vessels of all sizes. The type of organ involvement and overall disease activity evaluated in the clinical practice determine the course of treatment and the decision to initiate immunosuppressive therapy. Activity scores like Bingham Vasculitis Activity score (BVASv3), Behcet’s Disease Current Activity Form2006 (BDCAF), or damage indices like Vasculitis Damage Index (VDI) have been developed in this respect.

**Objectives:** To evaluate the ability of classical immunosuppressive therapy to prevent damage progression. To find the correlation between disease activity scores: BVASv3, BDCAF, long term treatment, immunosuppressant use and damage after remission, as calculated by VDI.

**Methods:** A study on a cohort of patients diagnosed with Behcet’s Disease from an Internal Medicine and Rheumatology Clinic was performed. Activity and damage scores, BVASv3, BDCAF and VDI after obtained remission, were calculated. The documented cases were diagnosed according to the International Criteria for Behcet’s Disease (ICBD). Windows Excel/SPSS20.0 (Spearman’s correlation) were used to analyse the data.

**Results:** The study included 16 patients treated with long term cortisone and immunosuppressive therapy. The mean age at the time of the diagnosis was 32.5±10.9 years and the disease activity was 62% (10 patients). Severe systemic involvement was present in 10 cases (Ophthalmological involvement-6cases, recurrent venous thrombosis-6cases, pulmonary vasculitis-1 case, severe cardiac involvement-1 case, central nervous system involvement-3cases) and all patients received classical immunosuppression (cyclophosphamide, azathioprine). The mean scores for BVASv3 and BDCAF at the time of the diagnosis were 9 (r=0.830, p<0.001). The use of immunosuppressive therapy due to severe organ involvement and long-term immunosuppression correlated stronger with BVASv3 and BDCAF (r=0.533, p=0.001). BDCAF calculated after remission was obtained. There was an important correlation between disease activity scores and damage (BVASv3-VDI r=0.687, p<0.001, BDCAF-VDI r=0.676, p=0.001). Types of treatment were evaluated, a comparison was made between long-term cortisone therapy and immunosuppression. There was a stronger correlation between long-term cortisone use and VDI than between immunosuppression duration and damage (r=0.472).

**Conclusions:** Damage progression is influenced by disease activity, as calculated by activity scores (BVASv3 and BDCAF). Classical immunosuppression is used for severe organ involvement and for limiting new organ lesions (once started). There was a stronger correlation between long-term cortisone use and VDI than between immunosuppression duration and damage. The damage index increased by irreversible organ damage due to disease activity and long term cortisone use, but not due to the immunosuppressive therapy.

**EFFICACY OF RITUXIMAB IN RESISTANT PALINDROMIC RHEUMATISM: FIRST REPORT IN LITERATURE**

S. Sreenath1, S. Cherian1, G. Antony1, U. Momy2, P. Shenoy1. 1Centre for Arthritis and Rheumatism (CARE); 2Molecular Medicine, AIMS, Cochin, India

**Background:** Palindromic rheumatism (PR) although often considered as a benign disease can be severe and resistant to DMARDs in some patients. In these patients it can result in almost daily attacks, migrating from joint to joint resulting in poor quality of life. Rituximab has been proven to be effective in treatment of seropositive RA.

**Objectives:** To determine the efficacy and safety of Rituximab in patients with seropositive PR who had an inadequate response to CsDMARDs.

**Methods:** PR was diagnosed based on criteria proposed by Hannonen P et al. Seropositive (ACPA±RF positivity) PR patients who had active disease despite being treated with two Cs DMARDs for >3 months, were treated with Rituximab. Active disease was defined as >4 attacks per month requiring intake of NSAIDS. All the patients were started on 500mg of rituximab after baseline work up. If complete control of palindromic attacks was not achieved and B cells could not be detectable in the blood for flow cytometry another 500 mg infusion was given after 2 weeks. Patients were continued on maximum tolerable dose of DMARDS. Patients were given repeat infusion of Rituximab once the patient developed clinical relapses as evidenced by recurrence of palindromic attacks.

**Results:** Twenty three patients with a mean age of 44.6±13.51 yrs and mean disease duration of 5.47±3.25 yrs were included. All patients were positive for ACPA while 17 patients were positive for RF. These patients were on a background of minimum of 2 DMARDs; Despite the maximum tolerable dose of DMARDS they had mean attack rate of 5.30±2.38 attacks per month. During a mean follow up of 14.17±8.62 months seven patients required two infusions and three patients required three infusions. Of the 33 infusions 500 mg was effective in controlling the attacks majorly (88%) of the times. Seven patients required another 500 mg infusion after 2 weeks as initial 500 mg dose failed to achieve complete control of disease and B cell were not depleted in the peripheral blood. At one month follow up all patients achieved complete control of disease. Remission lasted for 10.33±5.75 months. When symptoms recurred patients were treated with rituximab again and all regained complete control of the symptoms. None of the patients evolved into RA during the study period. No serious adverse events were observed. Five patients experienced minor allergic reactions during infusion which were managed according to the standard protocol.

**Conclusions:** This case series indicates in patients of PR resistant to Cs DMARDS rituximab not only achieves disease control but also prevents progression to RA.

two drugs, or standard therapy. The term "rare" was defined by the European Union as a condition that occurs in no more than 1 in 2,000 individuals. Two review authors independently assessed trial quality and extracted the data. We screened the search results and included studies if they met the selection criteria. If we identified two or more trials that investigated the same rare disease and used the same assessment tools we performed a meta-analysis.

Results: 135 studies were screened, of which 34 met the inclusion criteria. In total, we analysed data on 11 different orphan diseases, encompassing 2,324 participants. There was a high degree of clinical and statistical heterogeneity in these trials. Several sources of potential bias were identified in the included studies, for example, a lack of description of the blinding methods and allocation concealment, as well as the small size of the study populations. We included studies such as rituximab against cyclophosphamide in ANCA-associated vasculitides. These studies demonstrated a non-inferiority of rituximab. The meta-analysis resulted a combined odds ratio (OR) of 1.42 in favour of rituximab (95% CI). Further meta-analyses were possible for another 22 studies involving, among others, Behçet's disease, systemic sclerosis, cryopyrin-associated periodic syndromes, and giant cell arteritis. Compounds studied were immunosuppressants like corticosteroids, methotrexate and azathioprine, or biologicals such as nilotincept, infliximab, and canakinumab.

Conclusions: A high degree of evidence is hampered by the limited number of study participants in each trial. On the other hand, diseases such as systemic sclerosis, ANCA-associated vasculitides, or Behçet's disease had more high quality trials available. The amount of data for most other rare disease remains unsatisfactory. Several sources of potential bias were identified in the included studies, for example, a lack of description of the blinding methods and allocation concealment, as well as the small size of the study populations. We included studies such as rituximab against cyclophosphamide in ANCA-associated vasculitides. These studies demonstrated a non-inferiority of rituximab. Hypocomplementemia is related to elevated serum levels of IgG subclasses other than IgG4 in IgG4-related kidney disease

Y. Fujisawa, I. Mizushima, S. Tsuge, S. Hara, F. Suzuki, K. Ito, H. Fuji, K. Yamada, M. Kawano. Division of Rheumatology, Department of Cardiovascular and Internal Medicine, Kanazawa City, Japan

Background: IgG4-related kidney disease (IgG4-RKD) is a comprehensive term for renal lesions associated with IgG4-related disease [1]. IgG4-RKD is frequently complicated by hypocomplementemia [1, 2, 3], but its clinical significance and mechanisms have not been clarified.

Objectives: This study aimed to investigate clinical features of IgG4-RKD patients with hypocomplementemia compared with those without it, leading to clarification of the clinical significance and mechanisms of hypocomplementemia.

Methods: We extracted 25 patients with IgG4-RKD between September 2005 and December 2016 in our hospital. Based on the presence/absence of hypocomplementemia at diagnosis, we divided them into a hypocomplementemia group (n=11) and a normal complement group (n=14), and retrospectively analyzed various clinical features (age, sex, serum IgG levels, serum IgG4 levels, gaps between serum IgG and IgG4 level, ratio of serum IgG to serum IgG4, serum IgG subclasses, subclinical lesions, complement levels, urine protein and urinary occult blood, urinary β2-microglobulin, urinary N-acetyl-β-D-glucosaminidase, initial dose of prednisolone, serum IL-2R levels, multiple organ lesion) during the clinical course in the two groups.

Results: The patients comprised 18 men and 7 women with an average age of 67.5 years (range, 44 to 81 years). Serum IgG levels (397±1729 mg/dL vs. 215±758 mg/dL, p=0.001), gaps between serum IgG and IgG4 level (2992±770 mg/dL vs. 1482±444 mg/dL, p=0.001), serum IgG1 levels (2043±1025 mg/dL vs. 891±209 mg/dL, p=0.017), and the number of involved organs (4.1±1.1 vs. 2.9±1.1, p=0.018) were significantly different between the two groups, while serum IgG4 levels (795±477 mg/dL vs. 791±575 mg/dL, p=0.298) and serum creatinine levels (1.96±1.89 mg/dL vs. 1.90±0.48 mg/dL, p=0.298) were not. At relapse of renal lesions, although both groups showed serum IgG4 re-elevation, the hypocomplementemia group showed exacerbation of hypocomplementemia and re-expansion of gaps between serum IgG and IgG4 level, while the normal complement group did not.

Conclusions: Hypocomplementemia may be associated with multiple organ involvement and elevation of IgG subclasses other than IgG4 including IgG1 in IgG4-RKD. In patients who initially show hypocomplementemia, a decline in serum complement levels implies renal lesion relapse.

WHAT WE SEE, WHAT WE LEARN, AND THE PREVALENCE OF RHEUMATIC DISEASES IN OUR POPULATION: A DIAGNOSIS CORRELATION STUDY

D. Vega-Morales1, J.A. Esquivel-Valerio1, R. Ortiz-Lopez2, A.C. Arana-Guajardo1, M.A. Garza-Elizondo3, Rheumatology Service; Rheumatology, Hospital Universitario Dr. José Eleuterio González, Monterrey, Mexico

Background: The postgraduate program in rheumatology aims learning of musculoskeletal and autoimmune disorders. In México, objectively-structured clinical examination (OSCE) is applied in postgraduate certification processes by the Mexican Board of Rheumatology annually [1]. Peláez-Ballestas et al. described an epidemiological study (COPCORD, Community Oriented Program for the Control of Rheumatic Diseases) of 19,213 individuals in 5 regions in our country where they found a prevalence of musculoskeletal pain in 25.5%, osteoarthritis in 10.5%, back pain in 5.8%, rheumatic regional pain syndromes in 3.8%, rheumatoid arthritis (RA) in 1.6%, and fibromyalgia in 0.7% [2].

Objectives: The aim of the study is to describe the student training in rheumatic diseases and correlate them with OSCE assessment and the prevalence of rheumatic diseases in our population.

Methods: An observational and analytical study was made between March 2014 to December 2015 in a single rheumatology training center at University Hospital. Student training was defined according to the times they evaluated patients with a determined diagnosis, this information was obtained by medical records. We categorize OSCE questions according to the rheumatic diagnosis. Finally, the two results were compared with prevalence of the rheumatic diagnosis according to COPCORD, which were registered according a score pain >4. We made descriptive statistics and a Spearman’s Rho to evaluate the correlations of the diagnosis frequencies by each category.

Results: We reviewed 6279 medical records, 854 (13.6%) were of first-time consultations, 306 (4.9%) were of follow-up and 5109 (81.5%) were from the 3rd consultation and higher. We found 334 patients to develop an educational smartphone app.

WHAT ARE THE PATIENTS’ ISSUES AND NEEDS RELATED TO THEIR BIOLOGICS (BDMARDS) AND METHOTREXATE (MTX) TREATMENT IN DAILY LIFE: A QUANTITATIVE CROSS-SECTIONAL SURVEY AMONG 344 PATIENTS TO DEVELOP AN EDUCATIONAL SMARTPHONE APP

C. Beaumais1, S. Trope2, A. Lafourcade3, D. Carnet4, L. Carton6, C. Lafarge7, G. Montagu8, T. Pham9, F. Tubach10, J. Sellam11 on behalf of the Pitié-Salpétrière; 11Reumatology, AP-HP St-Antoine, Univ Paris 06, Paris, France

Background: MTX and bDMARDs are the core treatments of chronic inflammatory arthritis (IA). We lack information on the patients’ problems and needs in daily life, particularly on safety issues.

Objectives: 1-collect the most frequent issues 2-explore the patients’ perceptions on a dedicated smartphone application (SP App) 3-determine the profile of the patients interested.

Methods: The survey was conducted on line. The questionnaire was designed by rheumatologists, methodologists, anthropologists, members of patients association (AP) and included 1-a non-exhaustive list of potential issues in daily life (fever, vaccines, ...) and practical aspects 2-a list of potential use of the App 3-free opinions 4-Two self-administrated questionnaire to test patients’ knowledge on bDMARDS [1] and MTX [2].

Results: The survey was carried out from June to August 2016 on the websites of the PA. Non-associative patients were recruited by 3 rheumatologists who provided the internet link. 344 patients responded, 331 analyzed, 83% female, 50% had rheumatoid arthritis, 40% had spondyloarthritis, mean age 53 years, 60% were AP; 67% were treated with MTX; 70% had bDMARDS, 34% had MTX-bDMARDS combination. 66% of patients reported problems; 67% had needed help or advice. The main issues were infections (27%), vaccines (13%), surgery (10%), dental care (7%), self-administration (6%), conservation/travelling (9%) and skipped doses (5%). Among the 76% patients who have a SP, 80% use Apps and 32% Apps for their health. Among users, 87% patients would find an App useful to manage their treatment (36% rather agree and 51% strongly agree), 82% for symptoms requiring to stop their treatment, 93% for situations related to safety, 80% as a reminder of their treatment. 83% knew what to do in case of a missed dose, 77% to have a safety checklist before treatment administration, 66% to recall the modalities of self-injections. Patients interested in the App are younger (p<0.05) non-associative (p<0.05) and live in medium-sized cities (p<0.01).

No correlation was found with other sociodemographic characteristics, level of education, type/duration of arthritis or knowledge.

Conclusions: Two-third of patients with arthritis face issues related to their treatment especially in case of infections, vaccination, surgery and travelling. A dedicated App is considered useful by 87% patients who already have a SP. The potential use of the App may improve safety, adherence and self-management in daily life.

DOI: 10.1136/annrheumdis-2017-eular.4257
the OSCE, we observed a moderate correlation. We considered it important to enhance the knowledge and improve the OSCE according to the most prevalent diseases to prepare the future rheumatologists.

THU0582 2-YEAR ADHERENCE TO THE TREATMENT OF OSTEOPOROSIS FOLLOWING A THERAPEUTIC PATIENT EDUCATION PROGRAM

D. Poivret1, C. Wilcke2, V. Noirez1, C. Goetz1,3, Chr Metz Thionville; 2URPS Grand Est; 3PARC, Chr Metz Thionville, Metz, France

Background: The management of osteoporosis requires drug treatment and changes in lifestyle. Adherence to medication does not exceed 50% at one year. Changes in lifestyle are rarely explored. Therapeutic requires a relay to continue the follow-up over several years.

Objectives: To improve the follow-up of the patient, we have created cooperation between the attending physician and the pharmacy pharmacist initiated by the patient himself.

Methods: We proposed a therapeutic patient education for patients treated for osteoporosis to participate in two half-day ETP sessions a year apart. Educational objectives are: The treatment of osteoporosis requires at least 5 years of treatment, and must be associated with the absorption of three dairy products per day, maintaining physical activity and preventing falls. Each participant in a therapeutic education session receives a follow-up notebook containing six doctor questionnaires and six pharmacist questionnaires. The patient remains the owner of the notebook. We were able to study the results of the 2-year questionnaires for 72 patients included in 2013 and 2014.

Results: 53/72 patients continue their treatment at 2 years. 4 patients died, 1 had an atypical fracture of the femoral shaft, 6 stopped treatment due to dental treatment, 3 had contraindications to any anti-osteoporotic treatment, 1 decided to discontinue treatment due to d Multiple Sclerosis, 11 decided to leave the program. 3 patients were lost to follow-up, ie 14/72 patients of whom we no longer have any news. Of the 53 patients who continued treatment, 24 sent back a doctor and pharmacist questionnaire to 2 years. 4 doctors and 2 pharmacists refused to complete the questionnaires. The study of pharmacist questionnaires received at 2 years shows that 83% of patients continue to consume 3 dairy products per day compared to 73% at 6 months, 65% maintained physical activity, 17% improved it, 9% decreased. The ground balance was satisfactory for 78% of patients compared with 71% at 6 months. 71% never forget their treatment, compared with 69% at 6 months, 8% wanted to stop their treatment, stable figure compared to questionnaires received at 6 months. All patients knew what their treatment was for at one year and 96% met the conditions for taking the medication. 69% do not forget it at two years against 86% at one year, thanks to the intervention of the pharmacist. Only 6% wanted to stop the treatment at two years due to side effects, 17% to 1 year, but did not stop after consultation with the doctor and/or pharmacist.

During the two-year follow-up, all patients were phone called at least once by a secretary, mostly several times. The notebook is driven by the patient himself, mainly on them report to the nurse that it give them an active role which afford them to continue the treatment.

Conclusions: 58% of the patients enrolled continue treatment at two years, 15% have stopped the treatment as a side effect. An active role given to the patient and a collaboration between physicians and pharmacists thus promote adherence to treatment and also changes in lifestyle.

THU0583 EFFECT OF AN ONLINE EDUCATIONAL INTERVENTION IN THE KNOWLEDGE OF PATIENT REGISTRIES AND PATIENT-REPORTED OUTCOMES AMONG RHEUMATOLOGISTS

E. Jackson1, E. McCardell1, J.R. Curtis2, Medscape Education, New York; 2Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, United States

Background: Patient-reported outcomes (PROs) have evolved into an essential element in managing rheumatoid arthritis (RA), working in concert with physician-based tools to assess disease activity and health-related quality of life [1].

Objectives: A study was conducted to determine whether an online educational intervention could effectively address a knowledge gap and an underlying educational need in applying data from patient registries including PROs in the management of patients with RA.

Methods: An online educational intervention focusing on advances in RA patient registries was developed and made available online. The intervention consisted of a 30-minute video-based roundtable discussion between 3 experts in treatment of RA. The intended audience was rheumatologists who treat patients with RA.

The educational impact was assessed by comparing participants’ responses to 4 identical paired pre- and post-assessment questions. Data representing a statistical sampling of the overall learner population was collected from 5/29/2015 through 8/13/2015. Statistical analysis comprised a paired (within-physician) 2-sample t-test comparing mean pre-intervention and post-intervention scores.

Results: Analysis of pre- versus post-activity responses by rheumatologists (n=36) demonstrated a significant improvement (P<0.05) in overall knowledge with a robust effect size (Cohen’s d=0.50). This activity resulted in increased knowledge surrounding several specific areas of RA management, such as drug safety, alternative means of collecting PRO data, and issues surrounding pregnancy in women with RA. The absolute percentage increases in correct individual responses to these topics (all P<0.05 except where noted), included:
- 33% increase (36% vs 69%) in rheumatologists who recognized the results from pooled registries in Europe – 11 registries from 9 countries – regarding the safety of tumor necrosis factor-alpha inhibitor therapy.
- 28% increase (36% vs 64%) in rheumatologists who recognized that biosensor-based devices can provide passive data regarding patient outcomes.
- 14% increase (47% vs 61%, P<0.037) in rheumatologists who identified the connected CORRONA-OTIS registries that provide information on patients with RA who become pregnant,
- 62% increase (19% vs 81%) in rheumatologists who identified that patient registry data can be used to support a risk mitigation strategy for prescribing a specific DMARD in patients who may become pregnant during treatment.

Conclusions: An online educational intervention was associated with significant improvement in knowledge levels of rheumatologists in several important aspects of RA management, including interpretation of data from patient registries and adverse effect profiles of approved therapies. Future directions for education include additional reinforcement regarding the roles for PROs in patient management, and assessing the impact of improved rheumatologists’ knowledge on care delivery and patient outcomes.

THU0584 FIVE YEARS OF EXPERIENCE WITH THE LUPUS ACADEMY: AN EFFECTIVE MODEL FOR BUILDING A ROBUST COMMUNITY OF PRACTICE FOR GEOGRAPHICALLY DIVERSE LEARNERS

R. Cervera1, R.A. Furie2, Z. Amoura3, A. Jacobson4, E. Poziaki4, Hospital Clinic; Barcelona, Spain; 2Hopkins North Shore-LU School of Medicine, New York, United States; 3Pitié-Salpetrière Hospital, Paris, France; 4Siyem Learning, Manchester, United Kingdom

Background: Systemic lupus erythematosus (SLE) is a complex yet low prevalence disease. Without a community of lupus specialists to establish consensus and guide best practices, rheumatologists have limited opportunities to develop skills and maintain expertise in SLE care.

Objectives: The objectives of this initiative were to 1) create an independent community of physicians interested in the pathogenesis, diagnosis, and management of patients with SLE and related conditions; 2) share insights and practical guidance for implementing evidence-based care; 3) develop needs-driven contin-
using medical education (CME) relevant to different levels of clinical expertise; 4) promote collaboration models with publishers to create space for dialogue and community building; and 5) involve patient advocacy groups to steer physician education and incorporate the patient voice into educational activities.

Methods: The Lupus Academy (http://lupus-academy.org) was established in 2011 as an independent CME initiative led by a Steering Committee of international experts in SLE.[1] Educational activities are designed around unmet clinical needs identified by the Steering Committee, learner survey data, and feedback from patient advocacy groups (including Lupus Europe).

Results: As of February 2017, the Lupus Academy has grown to a global community of >2,500 committed learners with an interest in SLE. The Steering Committee has guided the development and delivery of 5 2.5-day annual meetings; 4 1-day regional meetings; a meeting toolkit for learner-advocates to host meetings in their home regions; and 3 e-learning courses, with 2 additional courses in production. The 5th Annual Meeting of the Lupus Academy (6–8 May 2016) hosted 101 attendees from Europe, North and South America, and Asia. Learners reported that the learning objectives of the meeting were met (Figure). An assessment of educational effectiveness demonstrated improvements in clinical knowledge and competence (Moore’s Outcomes Levels 3/4) as a result of meeting participation: 67% of learners reported a commitment to implementing changes in clinical practice, 11% reported that the educational content reinforced their current practice, and 20% reported a willingness to modify their current practice with additional training.

The most recent meeting, the Lupus Academy Middle East Summit Conference (9–10 December 2016), hosted 153 attendees from 13 countries representing diverse specialties: rheumatology (53%), internal medicine (13%), nephrology (11%), clinical immunology (5%), and other (18%). The majority of learners agreed or strongly agreed that the meeting provided an effective platform for the discussion of new ideas in SLE (96%) and challenged the current thinking around lupus care (96%). Having attended this meeting, I am better able to:

1. Apply novel developments in scientific research around SLE in their clinical practice
2. Implement optimal diagnostic methods and optimal disease management of refractory lupus nephritis patients and of those patients with both SLE and rheumatoid arthritis
3. Increase comprehension in identifying difficult clinical cases from the broad spectrum of lupus patients and effectively manage them — including patients displaying exacerbations involving lungs, Gl, liver and CNS, as well as pauci and profound patients
4. Implement new therapeutic options inherited from other therapeutic specialties
5. Apply learning from other disease areas to achieve optimal treatments outcomes in patients with SLE

Conclusions: The Lupus Academy serves as an effective model for building a consortium-led, evidence-based educational resource and community of practice for rheumatologists, other physicians with an interest in SLE, and patient advocacy groups.

THU0585 SAFETY OF BIOLOGICS AND CONVENTIONAL DMARDS: AN ETHNOGRAPHIC STUDY INVESTIGATING PATIENTS’ DECISIONS AND PRACTICES TO DEVELOP AN EDUCATIONAL SMARTPHONE APP

Objectives: We aimed to decipher the mechanisms of patients’ decisions and practices with their DMARDs to develop an educational smartphone application (SP App).

Methods: An ethnographic study was designed by 3 rheumatologists, 1 methodologist, and 1 qualitative sociologist. 21 patients who took part in a 1-day workshop in Uruguay who conducted the interviews. The study involved 21 patients (enough to reach saturation), recruited by diversity of clinical and sociological profiles. The panel included 16 women and 5 men, median age 46 years-old (extremes 26–70), 12 with RA and 9 with SpA (median disease duration 13 years, extremes 2–38). Nine patients were treated by bDMARD-cDMARD combotherapy. The interview was conducted using in-depth semi directive and biographic methods. The interview guide was constructed around 3 fields: 1 the organization of the patients’ everyday life with their disease, 2 the treatment practices, 3 the impact of arthritis on their social and professional activities and relationships. Interviews were recorded and transcribed for analysis.

Results: Patients play an active role in the management of their disease. They have to learn to live with it in order to control its impact and course. This learning progressively occurs throughout a non-linear 4-stages career: 1) from 1st symptoms to diagnosis, 2) search for the right treatment and the right focus 3) stabilization of the disease and the treatment, 4) dealing with a complication or an unexpected event. Back and forth between stages 2, 3 and 4 are frequent.

Background: Safety and adherence to DMARDs are critical for patients with rheumatoid arthritis (RA) or spondyloarthritis (SpA). Few digital tools exist to help patients on these issues.

Objectives: We aimed to decipher the mechanisms of patients’ decisions and practices with their DMARDs to develop an educational smartphone application (SP App).

Methods: An ethnographic study was designed by 3 rheumatologists, 1 methodologist, and 1 qualitative sociologist. 21 patients who took part in a 1-day workshop in Uruguay who conducted the interviews. The study involved 21 patients (enough to reach saturation), recruited by diversity of clinical and sociological profiles. The panel included 16 women and 5 men, median age 46 years-old (extremes 26–70), 12 with RA and 9 with SpA (median disease duration 13 years, extremes 2–38). Nine patients were treated by bDMARD-cDMARD combotherapy. The interview was conducted using in-depth semi directive and biographic methods. The interview guide was constructed around 3 fields: 1 the organization of the patients’ everyday life with their disease, 2 the treatment practices, 3 the impact of arthritis on their social and professional activities and relationships. Interviews were recorded and transcribed for analysis.

Results: Patients play an active role in the management of their disease. They have to learn to live with it in order to control its impact and course. This learning progressively occurs throughout a non-linear 4-stages career: 1) from 1st symptoms to diagnosis, 2) search for the right treatment and the right focus 3) stabilization of the disease and the treatment, 4) dealing with a complication or an unexpected event. Back and forth between stages 2, 3 and 4 are frequent.

This learning implies a partnership-based doctor-patient relationship, and the development of specific skills around safety: dealing with health care system
Sanola (30-min training via the telephone with no further incentive to access the platform) or usual care (normal internet use without access to Sanola). The Sanola group pts used a home-based e-Case Report Form to record frequency of Sanola access, satisfaction with the platform (0–10 scale; 0= completely satisfied, 10= not satisfied), and barriers to use (from a pre-specified list). Baseline pt characteristics associated with increased use of the median) were analysed by univariate and multivariate logistic regression.

Results: 159 RA pts were randomised to the Sanola arm: mean±SD age was 56.1±13.1 years, disease duration was 15.0±11.5 years and 132 (83.0%) of pts were female. Mean DAS28 was 2.7±1.2 with 57.2% of pts in remission; 115 (72.3%) were taking a biologic; 23.3% had attended therapeutic education sessions; 15.7% were members of pt associations; and 53.5% had participated in university-level studies. Overall, 41 pts (25.7%) never accessed Sanola and 81 (50.9%) accessed the platform at least twice; median=2, mean±SD=4.4±11.3 controls. There was a noticeable investigator effect (0.3±0.2, 0–1 scale). Mean satisfaction with the platform was very high (1.5±1.5), with 90% scoring satisfaction > 3. One barrier was expressed in 11.8% of cases: “the platform is not useful for me since I am in remission”. In multivariate analysis, the only variable associated with greater usage of Sanola was being a member of a pt association: odds ratio [95% CI]= 1.4 [1.1–1.77].

Conclusions: A quarter of pts who participated in this trial to assess e-health did not access the platform whereas half accessed the platform at least twice. Pts expressed high satisfaction and the only barrier was lower usefulness when in remission. e-Health is a prominent tool for RA pts. In the context of offering additional services should also be explored in a further study.

The use of a portfolio among young rheumatologists: results of an EMEUNET survey

M. Van Ommen1, F. Sivera2, V. Navarro-Compán3, E. Nikiphorou4, A. Moltó5, S. Ramiro1 on behalf of the EMEUNET Working Group, 1Department of Internal Medicine, division of Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands; 2Rheumatology, Hospital General Universitario de Elx, Alicante; 3Rheumatology, la Paz University Hospital, Madrid, Spain; 4Rheumatology, Whittington Hospital, London, United Kingdom; 5Rheumatology, Cochin Hospital, René Descartes University, Paris, France; 6Rheumatology, Leiden University Medical Center, Leiden, Netherlands

Background: Portfolios are increasingly used in medical education. A portfolio may stimulate deep learning, deliver summative assessment and encourage reflection on clinical practice. A portfolio is seen as the key connection between the theoretical and clinical knowledge required and the assessment of clinical skills. A portfolio is useful in the context of the patient-physician relationship. In addition, a portfolio may stimulate the development of professional skills and encourage independent learning. A portfolio is also a time-effective tool for assessing levels of knowledge and skills. A portfolio is a tool that may be readily adapted for use in the context of the patient-physician relationship. A portfolio may be used at a national and international level.

Methods: A survey was sent by email to all EMEUNET (Emerging EULAR Network) members. EMEUNET is a group of young rheumatologists and researchers within EULAR-member countries. Descriptive statistics were used to analyse initial data collected (Nov-Dec 2016). Weighted averages were calculated (i.e. mean in which each item being averaged is multiplied by a number (weight) based on the item’s relative importance).

Results: 132 participants responded (64% female; mean age 33.5 years (SD 4.3 years); 34 countries). In total, 56.3% of participants were working as rheumatologists; 32.8% were rheumatologists in training. 49.6% of the participants indicated that a portfolio was already used by rheumatology fellows working at their hospital or institution; in [country], 93% of participants also used a portfolio at a national level. 50.4% of participants did not use a portfolio during their training; of these, 86.7% (strongly) agreed that a portfolio might be a useful tool. Several barriers for successful implementation of a portfolio were identified by the participants. The major barrier was that a portfolio was not developed at a national level, and if developed at a national level, there were often no incentives to use it (Table 1). According to participants, the top 3 competencies that should be collected and reflected upon in the portfolio were: written communication (highest importance; 0 not important – 10 extremely important); practical skills (e.g. ultrasound) (8.2); correct use of diagnostics and therapeutic armamentarium (7.9); clinical skills (e.g. history taking) (7.6). The skills chosen as the least important to be included in a portfolio were: information on management tasks (6.5); promoting hospital-based care (e.g. writing a protocol) (6.6); theoretical and clinical knowledge (6.7).

Conclusions: A portfolio is generally considered a valuable tool and half of the participants already work with it. However, several barriers may prevent optimal implementation. Developing a core set of rheumatology-oriented competencies and a template for a portfolio to be used across institutions and eventually countries could promote implementation and harmonize training.

DO JUNIOR DOCTORS PRESCRIBE DISEASE MODIFYING ANTI RHEUMATIC DRUGS SAFELY?

M.K. Nisar 1, H. Weller 2.

1Rheumatology, Hanyang University Hospital; 2Rheumatology, Luton, United Kingdom

**Background:** Patients with rheumatic diseases occupy over 50,000 bed days annually in the National Health Service. Adverse drug events are major causes of harm to patients in hospitals and are associated with prolonged length of stay with higher costs. National Patient Safety Agency has issued several alerts regarding DMARDs and Methotrexate overdose remains a “never event”. Prescribing medications, including DMARDs for rheumatology patients, is one of the chief responsibilities of junior doctors.

**Objectives:** We undertook a pilot survey of junior doctors and medical students to understand their level of prescribing confidence with an aim to develop a teaching program.

**Methods:** Following a focus group discussion based on NPSA safety alerts and BSR DMARD monitoring guidelines, ten items were unanimously identified as core knowledge required for safe prescribing. A questionnaire was created based on these elements. Junior doctors and final year medical students were surveyed at our academic institution. Replies were compiled to ascertain their understanding of safe prescribing and troubleshooting DMARD related issues.

**Results:** 41 junior doctors of all grades and nine medical students contributed to the survey. Only 6/50 (12%) felt confident in prescribing whereas 16/50 (32%) had borderline confidence and remaining 56% felt it was beyond their expertise.

Of the 41 junior doctors, 19 (46%) had never even prescribed DMARD despite encountering such patients on the wards. Principal reasons for this included lack of confidence (40%), paucity of knowledge (15%) and no formal education (32%). Questions pertaining to safe prescribing were confidently answered by only 4/50 (8%) participants.

**Conclusions:** To our knowledge, this is the first survey to demonstrate that there are serious shortcomings in junior doctors’ understanding of safe DMARD prescribing. Inadequate training and hence poor confidence among front line medical staff remains the main cause of this issue. Despite consistent evidence suggesting that rheumatology teaching in medical schools has historically been poor and active measures taken in recent past to identify better ways to address the issues, this study highlights major knowledge gaps among everyday and future prescribers. Focused strategy and better training of junior doctors, both during and after graduation, are pivotal to providing better care for patients prescribed DMARDs during inpatient hospital stay.

QUALITATIVE ASSESSMENT OF US-GUIDED INJECTION VIDEOS PUBLISHED ON VIDEO SHARING PLATFORMS

S.H. Bourdais, C. Darriuert-Laffite, Y. Maugars, B. Le Goff. Rheumatology, University Hospital of Nantes, Nantes, France

**Background:** Ultrasound (US) guided injections are becoming widespread in the treatment of rheumatic articular disorders. US allows a real time assessment of the needle progression and increase the accuracy of the injection. Video sharing platforms can be sources of information and learning material for healthcare professionals as for patients.

**Objectives:** We conducted this cross-sectional study to assess the quality of educational resources on US-guided articular and periarticular injections published on video sharing platforms.

**Methods:** YouTube, Dailymotion and Vimeo were searched using predefined keywords on US-guided shoulder, elbow, wrist, hand, hip, knee, ankle and foot injections. The videos were classified according to their source. We determined the injection site and the explanations shown for each site. We collected information on patient positioning, equipment, needle, ultrasound settings and teaching material used by the author. When demonstration was performed live in patient, the compliance with the rules of asepsis and the accuracy of the injection were evaluated. Overall, videos were evaluated for quality on a 5-point ordinal global quality scale (GQS) (1 = poor quality to 5 = excellent quality). Results are given as median (min-max).

**Results:** We found 69979 results with the keywords. We screened 2802 videos by titles and included 153 videos (10:05 hours). Most of videos were published on Youtube (92.2%) and 82.4% included oral explanation. 53.6% videos were published by medical advertisement or profit companies and only 9.2% videos by university, professional organization or physician group. Among the 41.2% videos showing live demonstration of injection on the patient only 25.4% followed the strict rules of asepsis. When the videos included US cineloops of injection, 10.4% were performed live in patient only 25.4% followed the strict rules of asepsis. Very few videos gave details about information on the treatment, its risks and benefits. Strict aseptic techniques are rarely followed and the injection can be outside the target. Finally, we identified characteristics associated with the quality of the video that can be used to improve their educational impact in the future.

DEVELOPING THE KOREAN LEEDS SATISFACTION QUESTIONNAIRE (KOREAN-LSQ) IN RHEUMATOID ARTHRITIS: A CROSS-CULTURAL VALIDATION USING RASCH ANALYSIS

S.-K. Cho 1, D. Kim 1, S.J. Cha 1, D. Yoo 1, S.-H. Kim 2, J. Hill 3, M. Ndoisi 4, Y.-R. Sung 1. 1Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul; 2Department of Measurement and Evaluation of Physical Education, Chungbuk National University, Cheongju, Korea, Republic Of; 3Harrogate, Harrogate; 4Centre for Health and Clinical Research, University of the West of England, Bristol, United Kingdom

**Background:** The Leeds Satisfaction Questionnaire (LSQ) 1 is a patient-completed questionnaire designed to measure satisfaction among patients attending a rheumatology outpatient clinic. It was originally developed in the UK and it comprises 45 items grouped into 6 subscales: general satisfaction, information, empathy, technical competence, attitude, access and continuity.

**Objectives:** To undertake cross-cultural adaptation and validation of the LSQ in South Korea.

**Methods:** The adaptation of the LSQ from English into Korean was established according to guideline of cross-cultural adaptation of self-report measures. 2 Patients with RA were then recruited from an outpatient clinic of a university hospital in South Korea and Cross-cultural validation of the Korean-LSQ was carried out by Rasch analysis using the WINSTEPS program. Model data fit was determined by Infit and Outfit statistics (≥0.50 and ≤1.50). If the values of the Infit and Outfit are 1.00, the observed score perfectly fit the expected model. The unidimensionality of the scale was determined by separation index (SI ≥2.00) and reliability (RI ≥0.80).

**Results:** An adequate conceptual equivalence was achieved following the adaptation process. The dataset for validation comprised 125 patients, 103 (82.4%) of whom were female, mean (SD) age =47.2 (12.5) and disease duration =52.8 (69.4) months. Forty-item of the 45 items had acceptable fit statistics (individual item data not shown). The individual items overall had good separation index and reliability (SI =-5.98 and RI =0.97). Analysis of the 6 subscales of the Korean-LSQ resulted in good fit to the Rasch model (Table 1), high internal consistency and unidimensionality (Person SI =2.31 and RI =-0.84; item SI =-5.44 and RI =-0.97).

**Conclusions:** Fit to the Rasch model confirmed that the construct validity, reliability, and unidimensionality of the Korean-LSQ were preserved after the adaptation process. The Korean LSQ is a valid and reliable tool for measuring satisfaction with care among patients with RA in South Korea.

THU0595  THE VIEWS AND PERCEPTIONS OF NON-SPECIALIST, HOSPITAL-JUNIOR DOCTORS ON JOINT ASPIRATION OF THE ACUTE HOT-SWOLLEN-JOINT, AND THEIR TRAINING IN THIS CLINICAL SKILL

Z. Farah, Rheumatology, Imperial Healthcare Trust, London, United Kingdom

Background: BSR guidance on managing hot-swollen-joints recommends early joint aspiration (arthrocentesis) to rule out septic arthritis and avoid morbidity and mortality. In such patients, the initial assessment is often performed by junior doctors prior to specialist review. Previous audit suggests poor adherence to recommended practice. To explore this, a previous quantitative survey in 2 hospitals found low self-reported confidence at managing hot-swollen-joints in 72 of 140 (52%) respondents; 58 (42%) participants reported inadequate exposure, and 43 (31%) inadequate training. There is limited research exploring the reasons behind poor uptake of arthrocentesis by junior doctors.

Objectives: To determine the perceptions of junior doctors about joint aspirations, their training to perform this important skill and how training could be improved

Methods: The focus group included two foundation doctors, two senior house-officers and two registrars. Focus group questions were developed from themes that emerged from our previous quantitative survey. The session was recorded using an iPhone, then anonymously transcribed verbatim. The transcript was analysed using an emergent coding technique drawn from grounded theory approach. The data was coded over three passes.

Results: Decision to aspirate a joint appeared to be influenced by internal and external factors. Internal factors included their previous experience, which was variable with one who “did 7 aspirations” and another who “had not had any experience at all.” Other factors like anatomical knowledge, level of seniority and prior training were presented. Negative emotions emerged with participants using words like “weary,” “anxious” and “scary,” particularly “fear of serious consequences” when describing joint aspiration.

External factors included procedure-related factors like technical difficulty, and the type of joint to be aspirated. Consensus suggested that all joints except the knee should be left to the specialist. Context-related factors included time constraints. The group emphasised the importance of recurrent exposure and opportunity to practice aspirations. Availability of supervision influenced the decision to aspirate, particularly if by the rheumatologist.

Training in arthrocentesis appeared to be inconsistent. Positive comments included the support of structured training experiences by an expert using simulation, immediate feedback followed by practice. Negative comments emerged such as training was inconsistent and of poor timing, or trainees lacked the opportunity to subsequently practice. Participants then proposed methods of how to improve training in arthrocentesis:

Conclusions: The decision to aspirate is a complex interaction between internal and external factors combining knowledge, attitudes and emotions with circumstances and context. The participants emphasised training in knee aspirations, but not other joints due to lack of exposure. Immediate feedback during training in arthrocentesis is key. Inability to continue regularly practicing the procedure in real patients may be a barrier to retaining the skill. A review of training in joint aspiration may be required in order to improve uptake of this skill in practice.

THU0596  RHEUMATOLOGY SPECIALTY TRAINING IN EUROPEAN UNION COUNTRIES

N. Cikes,1 J. Dudler2, F. Listè3, D.E. Bax4, N.D.S. Bax4 on behalf of UEMS Rheumatology Section and Board Union Européenne des Médecins Spécialistes, Avenue de la Couronne 20, Bruxelles 1050, 1 University of Zagreb School of Medicine, Zagreb, Croatia; 2Department of Rheumatology, HFR Fribourg – Hôpital Cantonal, Fribourg, Switzerland; 3Rheumatology Department, Univ Paris Diderot, Inserm UMR 1132, Hospital Lariboisière, Paris, France; 4The Medical School, University of Sheffield, Beech Hill Road, Sheffield, United Kingdom

Background: The Union of European Medical Specialists (UEMS) seeks through its specialty Sections and Boards (S&B) to enhance the training of its doctors and to encourage and support the movement of doctors between countries. The Rheumatology S&B has delegates from all EU countries and has developed a document (European Training Requirements (ETR) – at uemsrheumatology.eu) that provides guidance about the rheumatology curriculum.

Objectives: To determine:

1. The extent of use of the Rheumatology ETR by EU countries
2. The extent of use of logbooks in recording the progress of a trainee
3. If training centres are accredited
4. If national assessment programmes exist for trainees
5. If a country has quality assurance and enhancement processes in rheumatology training

Methods: A questionnaire was sent to all S&B members asking questions in relation to each of the objectives, with one follow-up questionnaire to non-responders. Verification of responses as well as obtaining responses from continuing non-responders occurred in December 2016.

Results: Nineteen countries responded. Most (18/19) have developed and implemented their own curriculum, often with the influence of the ETR, and also are using a logbook to record the progress of trainees. Training Centres are required to undergo accreditation in 15/19 countries. Another three countries are planning to introduce this. One country does not have an accreditation programme. After accreditation only 8 countries have quality assurance (QA) and enhancement (QE) programmes. In one of these the QA and QE programmes are variable. Two other countries are planning to enhance such processes. In 14 countries trainees are assessed to determine their suitability to become specialists. In one of these countries the approach is variable. Two other countries are planning to introduce assessments. Three countries do not assess their trainees.

Conclusions: Most EU countries have implemented their own, and varied, curricula for rheumatology training. All countries either use or are planning to use a portfolio, again variable in nature, to record trainees’ progress. Thus, it appears that at present any pan-European standardised curriculum or logbook will be of limited use.

Most countries require training centres to undergo accreditation. However, less than half of the countries have a continuation of quality assurance or quality enhancement processes after accreditation with some countries it seems having no plans to do so.

At present, a specialist in one European country is required by European law to be recognised as such in another. This study did not determine the nature of the assessments undertaken in different countries but this is not of current relevance within Europe as regards the possible movement of a doctor from one country to another for professional reasons.

THU0597  FLIPPED LEARNING: CAN RHEUMATOLOGY LEAD THE SHIFT IN MEDICAL EDUCATION?

Y. El Miedy1,2, M. El Gaafary2, N. El Arousi3, S.S. Youssfi1,3,1 Rheumatology, Darent Valley Hospital, Dartford, United Kingdom; 2Community and Public Health; 3Rheumatology and Rehabilitation, Ain Shams University, Cairo, Egypt

Background: Flipped Classroom is a model that is quickly gaining recognition as a novel teaching approach among health science. Flipped learning turns the usual teaching model on its head. The idea is that students learn new content outside the classroom (usually online) and then tackle assignments in lessons, giving tutors more time to help them with aspects they don’t understand.

Objectives: 1. to implement a flipped classroom teaching for rheumatology topics for both under and postgraduate education. 2. to evaluate outcomes of teaching using a post-flipped classroom assessment and a student perceived effectiveness and satisfaction questionnaire.

Methods: Ten online videos on topics of how to take rheumatology history, individual joint examination, handling cases of monoarthritis and polyarthritis, and metabolic bone disease were made available for the students. 39 undergraduate and 35 postgraduate trainees were included in this educational activity. The students were exposed to online lecture content prior to the class-time active learning session. The teaching session adopted an interactive learning environment and the course instructor served as a facilitator rather than a dominator for the instructional process, provided in-class applied learning opportunities and offered time for feedback/guidance to students. Evaluation of the teaching session was assessed using a scenario based learning and an evaluation check list. The students were asked to complete a questionnaire based on a 5-point Likert scale: 1 (strongly disagree) to 5 (strongly agree) to assess for their perceived effectiveness and satisfaction.

Results: There was no significant difference regarding socio-demographics between the 2 students’ groups included in this study. Outcomes of the flipped learning revealed that 94% of the students viewed the videos prior to the class session, and 96% attended the education sessions in comparison to 86% attendance in the traditional group. Students reported an increase in the flipped classroom model. Students’ perceived effectiveness and satisfaction scores were significantly higher among the flipped learning in contrast to the traditional teaching comparative group (4.9 vs 4.3, p<0.05). Similarly, analysis of the students’ assessment scores after the scenario based learning sessions was 4.8 in the flipped classroom model compared to the students taught by traditional methods (p<0.01).

Conclusions: Implementation of the flipped learning for the rheumatology topics demonstrated a successful and promising platform for using technology to make better use of the students’ time, and for increasing their satisfaction with the necessary didactic learning. Active learning increases student engagement and can lead to improved retention of knowledge.

CUMULATIVE ADVERSE CHILDHOOD EXPERIENCES ARE ASSOCIATED WITH POOR OUTCOMES IN ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

D. Béhar1,2, F. Vaujany1,3, J. Boada1, N. Hernandez1, A. Descomps1, L. Faghih1,4, C. Delaunay1,4, C. Ballanger1,4, R. Sauve1,4, H. Destrade1,4, N. Franchimont1,4, L. Riche1,4, R. De N'amor1,4, C. Michaud1,4, A. Boulvain1,4

1 Department of Rheumatology and Immuno-Allergology, Hospital Trust of Saint-Etienne, France; 2 Department of Health Economics, University of Lyon, France; 3 Department of Health Data and Statistics, University Claude Bernard Lyon 1, France; 4 INSERM, Lyon, France

Background: Adverse childhood experiences (ACEs) are associated with poor adult health status and onset of rheumatic diseases. There has been no research associating ACE with outcomes among adults with systemic lupus erythematosus (SLE).

Objectives: To characterize relationships of ACE and health outcomes of disease activity, damage, quality of life and depression in SLE patients.

Methods: Data were derived from the California Lupus Epidemiology Study (CLUES), a population based, multi-ethnic cohort of patients with SLE. Participants completed self-report measures of SLE activity (Systemic Lupus Activity Questionnaire; SLAQ), damage (Brief Index of Lupus Damage; BILD), quality of life (SF-36), depression (Patient Health Questionnaire; PHQ9) and sociodemographics. They completed the Adverse Childhood Experiences (ACE) survey, a validated 10-item scale covering 3 domains (abuse, neglect and household demographics). They completed the Adverse Childhood Experiences (ACE) survey, a validated 10-item scale covering 3 domains (abuse, neglect and household demographics).

Results: The 166 CLUES participants were mostly women (89%) and were racially/ethnically diverse (31% non-Hispanic White, 22% Hispanic, 15% African American, 31% Asian American). Mean age was 44±14; mean age at diagnosis 28±12. The median ACE score was 1 (30% had a score of 0 or higher). ACE scores >4 were more common in Hispanic (27%) and African American (32%) participants (p<0.01) compared to other races/ethnic groups, and in participants with poverty level incomes (61% vs 13%, p<0.001); but did not differ by education or age at study entry or diagnosis. Higher overall ACE scores were associated with greater SLE activity and damage, poorer quality of life, and higher levels of depressive symptoms. For each ACE domain, increasing scores were generally associated with worse outcomes, but did not always reach statistical significance (Table).

Zero-level excludes responders with scores in other ACE domains.
Conclusions: Adverse childhood experiences are reported frequently in individuals with SLE; accumulation of adverse experiences is associated with poor SLE outcomes. Higher scores in each domain, especially childhood neglect or abuse, were associated with poorer health measures in adulthood. Further research regarding ACE patterns and SLE outcomes is warranted.

THU0601 CARDIOVASCULAR SCREENING AMONG PATIENTS WITH INFLAMMATORY ARTHRITIS: TO WHAT EXTENT DO PATIENTS FOLLOW RECOMMENDATIONS?

A.H. Kjeldgaard1, K. Horslev-Petersen1, R.D. Christensen2, J. Søndergaard2, 4, P. C. Dagnelie1, B. van den Bemt5,6, P. Emans7, 8

Background: Patients with inflammatory arthritis (IA) have a substantially increased risk for cardiovascular (CV) disease and consequently regular screening is recommended (1).

Objectives: To investigate whether patients with known IA and high CV risk follow the recommendation, given in a nurse-led CV risk screening consultation, to consult General Practice in order to reduce their CV risk. Furthermore to investigate the influence of socioeconomic position and gender.

Methods: A retrospective study comprising outpatients at King Christian X’s Hospital for Rheumatic Diseases, Graasten, Denmark, diagnosed with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or spondyloarthritis (SpA), who had participated in at least one screening consultation based on the EULAR recommendations (1) between 1st of July 2012 and 1st of July 2015. The primary outcome was a consultation with their GP and at least one intervention of relevance for CV risk within 3 months after the screening consultation.

Results: 1266 patients, 18–85 years of age, were included; 72.5% with RA and 27.5% with SpA or PsA. Of the 447 (35%) with high risk of CV disease, 60% consulted their GP after the screening visit compared to 55% for the 819 patients with low risk of CV disease. Of the 60% of patients with high risk who consulted their GP, 41% had at least one relevant intervention. Education >10 years increased the odds for non-compliance (Odds Ratio [Confidence interval]) (0.72 [0.56;0.92], p=0.01) and age above 65 years increased the odds for compliance (1.50 [1.15;1.95], p=0.003). Income, diagnosis, gender, Low Density Lipoprotein level and systolic blood pressure did not significantly influence the odds to consult their GP after the screening consultation. Among high risk patients, 7.4% had their blood glucose checked at a GP consultation and 6.3% had their blood-pressure measured at home after the screening consultation as opposed to 4.8% and 1% among low risk patients.

Conclusions: After a screening consultation, 40% of the patients with high risk of CV disease did not consult their GP at all in the following 3 months. At least 35% of the patients with high risk followed the recommendations to consult their GP and 27% consulted their GP for reasons not possible to clarify in this study. Only age and higher education had a significant influence on the outcome.

THU0602 WORKER PRODUCTIVITY LOSS REMAINS A MAJOR ISSUE FOR PATIENTS WITH INFLAMMATORY ARTHRITIS AND OSTEARTHRITIS: RESULTS FROM THE INTERNATIONAL EULAR-PRO WORKER PRODUCTIVITY STUDY

S. Leggett1, A. Bosworth2, C. Hoffstetter3, A. Boonen4, C. Mihaie, C. Talli, S. Hagen, G. Crepaldi5, S. Ramo, T. Daidon1, S. Verstappen

Background: Knee osteoarthritis (OA) is a progressive joint disease generally associated with increasing pain. In severe symptomatic knee OA, knee prosthesis arthritis (IA) and osteoarthritis (OA) are one of the biggest causes of disability and worker productivity loss which has recently been recognized by European policy makers and the World Health Organization (WHO). However, limited information is available about job characteristics and the level of both presenteeism and absenteeism in employed persons with IA or OA across countries.

Objectives: To describe job characteristics and worker productivity loss in patients with IA and OA in Europe and Canada.

Methods: Patients with IA or OA in paid employment from seven countries within Europe and from Canada were recruited to the EULAR-PRO Worker productivity study. Patients completed a questionnaire including questions about their job, job characteristics and the Work Productivity and Activity Impairment Questionnaire (WPAI) measuring percent hours absent and the percentage their disease affected productivity while working (0–100%=disease completely prevented work). Patients also completed several health-related patient reported outcome measures, including: the Health Assessment Questionnaire (HAQ), Visual Analogue Scale (VAS) general well-being, and EuroQol-5D (EQ-5D).

Results: 503 patients were included in this large international study. Mean (SD) age was 47 (10) years, median (IQR) disease duration 12 [5, 21] years and 94% had IA. 42% had a predominately mentally demanding job, 10% physically demanding job, and 48% a combination; with overall 34% reporting their job being very demanding (see table for country specific results). Respectively 12% and 5% of patients were able to often or always postpone work tasks if need be, whilst respectively 19% and 51% never or sometimes received help from colleagues which may depend on job/employment type and company size. Twenty-one% of patients reported that they missed time off work due to ill-health in the past week (median IQR [%] time missed due to ill-health 20% [8–50]). Interestingly, a total of 11% were unsatisfied with their current job; and 23% of patients did not disclose their disease to their employer.

Conclusions: This is one of the largest international studies investigating worker productivity loss in patients with IA and OA. It highlights the burden of the disease across countries and the importance of increasing awareness of rheumatological conditions in order to prevent presenteeism and long-term sick leave by providing the best available intervention to the individual patient in paid employment.

Background: Knee osteoarthritis (OA) is a progressive joint disease generally associated with increasing pain. In severe symptomatic knee OA, knee prosthesis

Conclusions: The research is available about job characteristics and the level of both presenteeism and absenteeism in employed persons with IA or OA across countries. The research is available about job characteristics and the level of both presenteeism and absenteeism in employed persons with IA or OA across countries. The research is available about job characteristics and the level of both presenteeism and absenteeism in employed persons with IA or OA across countries.
(KP) can improve health-related quality of life. In the Netherlands, the incidence of KPs and KP revisions has increased, but health care costs related to these procedures over time and their determinants are unknown.1

Objectives: To provide estimates of age and sex-specific incidence of KPs, revision KPs, and prosthesis complications in patients with knee OA. To determine average annual health care costs of patients undergoing KP compared with matched controls in the Netherlands, and to understand drivers of costs.

Methods: All KPs in knee OA patients in the Achmea Health Database were identified and matched by age, sex, and region to a maximum of four controls. Incidence rates of KPs, KP revisions, and their complications (1/000 persons) from 2006–2013 were determined. Annual health care cost and excess costs compared to matched controls, preceding, during and after surgery were calculated and associated factors evaluated using longitudinal regression analysis.

Results: The incidence of KPs, KP revisions, and complications increased between 2006 and 2013. This increase was strongest in younger age categories and in men (Table 1). Annual health care costs slightly increased up to the year of surgery, with highest costs in the year of surgery. Post-surgery costs remained slightly higher than pre-surgery costs. High post-surgery costs were mainly associated with subsequent KPs. Other factors associated with high excess costs were younger age, female gender, and complications.

Table 1. Sex-specific incidence rates (per 1,000 person years) of all KPs, KP revisions, and complications associated with knee OA.

Conclusions: These results underscore the increasing burden associated with severe knee OA, especially in younger age categories. Improved guidelines aimed at avoiding complications and revisions are required to counteract this trend.

THU0604 | THE ASSESSMENT OF THE DUTCH QUALITY REGISTRY RHEUMATOID ARTHRITIS QUALITY INDICATORS IN THREE PILOT HOSPITALS

S. Mahmood1, L. van Tuyl1, P. van Rei1, S. Rongen2, D. van Schaardenburg1, G. Aliakst1, R. van den Berg1, H. Moens3, R. Landewe1.1Rheumatology and immunology Center, Amsterdam; 2Bernhoven, Uden; 1LUMC, Leiden; 2Erasmus MC, Rotterdam; 3Ziekenhuis Groep Twente, Almelo, Netherlands

Background: While practical guidelines and recommendations play an important role in the treatment of RA, rheumatologists often tend to deviate from these guidelines (1). This may result in disparity of quality of care among individual doctors and hospitals. To establish the best possible care, quality measures are needed. These aim to quantify the quality of the delivered care and will form the foundation of quality registries. Standardization of care processes in combination with public reporting of performance (by means of a quality registry) has been suggested to improve quality of care (2).

Objectives: To develop feasible quality indicators (QIs), endorsed by the different stakeholders of the Dutch Quality registry Rheumatoid Arthritis (DQRA).

Methods: An expert group of 8 rheumatologists, 2 patient representatives and 1 healthcare insurer representative developed a minimal set of QIs via a Delphi-like procedure (3), endorsed by the Dutch Society for Rheumatology. Since October 2015, these QIs have been registered by rheumatologists and rheumatology nurses, once a year in 26 hospitals, along with a patient evaluation questionnaire regarding the received care. To determine whether it is feasible to collect these QIs in daily practice, retrospective data from three hospitals was obtained (hospital A (university), B and C (non-academic)). Feasibility was determined by evaluation of:
1. Completeness of registered data (figure 1)
2. Possibility to calculate disease activity categories (remission, low-high disease activity)
3. Possibility to calculate changes over time in disease activity categories
4. Extraction of data regarding (b)DMARD use

Results: Selected QIs are:
1. Percentage of patients in a certain disease activity category

Abbreviations: KP = Knee prosthesis, OA = Osteoarthritis, IR = Incidence rate.

Conclusions: The DQRA is the first to incorporate perspectives from three stakeholders (patients, physicians and healthcare insurers) and successfully formed a limited set of QI. Collection of these indicators was feasible in two out of the three participating hospitals and offers insight in differences in provided and perceived care for RA patients.

TUH0605 | IMPACT OF NON-PERSISTENCE TO SUBCUTANEOUS TNF-ALPHA INHIBITORS ON MEDICAL RESOURCE UTILIZATION AND COSTS

M. Beihassen1, F. Tubach2, C. Hudry3, M.-C. Woronoff4, L. Levy-Bachelot5, L. Lamezc5, E. Van Ganse6, 1, B. Fautrel6.1Hôpital Cochin, Paris; 2AP-HP Hôpital Pitié-Salpêtrière, Département de Biostatistiques, Santé publique et Information médicale, APHP, Centre de Pharmacoépidémiologie (Cephepi); INSERM, UMR 1123 ECEVE, Université Pierre et Marie Curie Paris 6, Sorbonne Universités; 3AP-Hôpital Cochin, Paris; 4CHU Besançon, Université Franche-Comté, Comue Ubfc, UMR INSERM 1098, Besançon; 5Merck Sharp & Dohme, Paris, France; 6Sorbonne Universités, UPMC Univ Paris 06; AP-Hôp Rheumatology Department, Pitié Salpêtrière University Hospital, Paris, France.

Background: Biotherapies such as subcutaneous tumour necrosis factor-alpha inhibitors (SC-TNFis) have transformed the management of rheumatoid diseases. The assessment of SC-TNFis non-persistence and its impact on medical resource utilization and costs are needed.

Objectives: The objective was to assess the impact of non-persistence to subcutaneous TNF-alpha inhibitors on medical resource utilization and costs, for patients initiating treatment with an SC-TNF in France.

Methods: The Système National d’information Inter-régime [French national health insurance scheme information-sharing system] (SNIIRAM) database lists all outpatient and inpatient healthcare consumption for individuals covered by the general health insurance scheme. Using French claims data, conditions were diagnosed using Long Term Disease status and hospital admission. Based on ICD-10 codes of rheumatoid arthritis, psoriatic arthritis and ankylosing spondylitis. Patients were then identified through first-line prescription filled for adalimumab (ADA), etanercept (ETA), certolizumab pegol (CZP) and golimumab (GLM) between 2012/07/01 and 2012/12/31. 12-months persistence status was

Figure 1: completeness of registered data

Conclusions: The DQRA is the first to incorporate perspectives from three stakeholders (patients, physicians and healthcare insurers) and successfully formed a limited set of QI. Collection of these indicators was feasible in two out of the three participating hospitals and offers insight in differences in provided and perceived care for RA patients.

THU0606  COGNITIVE DYSFUNCTION IN CONNECTIVE TISSUE DISEASES

A. Dimi 1, L. Grouseanu 1,2, A. Balanescu 1,2, D. Predeteanu1,2, L. Macovei1,2, A. Boranga1,2, D. Mazilu1, V. Bojinca1,2, R. Ionescu1,2, E. Voronoff1, M.-C. Woronoff1, L. Levy-Bachelot1,2, M. Bojinc˘a1,2, V. Stoica1,2, C. Mihai1,2, M. Sasu1,2, M. Milicescu1,2, O. Olteanu1,2, M. Speriatu1,2, A.M. Gheorghiu1,2, L. Macovei1,2, A. Boranga1,2, D. Mazilu1, V. Bojinca1,2, R. Ionescu1,2, E. Voronoff1, M.-C. Woronoff1, L. Levy-Bachelot1,2, M. Bojinc˘a1,2, V. Stoica1,2, C. Mihai1,2, M. Sasu1,2, M. Milicescu1,2, O. Olteanu1,2, M. Speriatu1,2, A.M. Gheorghiu1,2

Background: Several studies documented the presence of cognitive dysfunction in different rheumatologic autoimmune diseases, but the absence of standard criteria of diagnosis and of an index with patients in which this dysfunction occurs, makes the mentioned studies often lead to divergent conclusions.

Objectives: To evaluate the impact of four autoimmune diseases: Systemic Lupus Erythematosus (SLE), Rheumatoid Arthritis (RA), Systemic Sclerosis (SSc) and Ankylosing Spondylitis (AS) on patient cognition and to identify potential factors which lead to cognitive dysfunction occurrence.

Methods: This is a case-control study that included randomly selected patients with SLE, RA, SSc and AS from a University hospital and a matched control group. Data collected included: demographics, patients’ education and specific data related to disease (duration, activity scores: DAS28, HAQ for RA patients, B27 dose-titration to maintain serum uric acid (sUA) levels 4–6 mg/dL for patients with AS; SLICC/SSc index for SLE patients and EUSTAR score/Rodnan score for SSc patients, damage indexes, organ involvement, treatment) and comorbidities. Cognition was assessed using MoCA Test (Montreal Cognitive Assessment The Test). The data were then processed using SPSS 23 version software.

Results: The study group included 255 patients: 58 RA patients, 52 SLE, 70 SSc and 25 AS patients and 50 healthy matched controls. In all groups of patients, cognitive dysfunction prevalence was higher than control group (RA: 84.99%, SLE: 57.69%, SS: 44.29%, AS: 35.72%) vs. 24% in the control group.

The differences were statistically significant for the RA group (p<0.001), the SLE group (p=0.001) and the SS group (p=0.001).

For the RA group, none of the items analyzed (demographics, disease characteristics, education) showed a significant correlation with cognitive dysfunction. The same lack of correlation was also noted in AS and SSc patients. For the SLE group the only variable analyzed with a significant impact statistically was the SLEDAI score (odds ratio 1.04, 95% CI 1.01 to 1.07).

Conclusion: Cognitive dysfunction seems to be more frequent and severe in RA and SLE patients compared to AS patients (p<0.014, respectively p<0.05).

The conclusions obtained in this study show that, indeed, cognitive dysfunction is an issue to be watched very carefully in patients with autoimmune diseases. The appearance of cognitive dysfunction has a negative impact on life quality of these patients, the pathophysiological mechanisms that contribute to its appearance are intricate and difficult to isolate.

THU0607  RISK FACTORS FOR EARLY RETIREMENT IN SYSTEMIC SCLEROSIS

A.M. Gheorghiu1,2, C. Vracianu1,2, C. Draganescu1,2, R. Oneata1,2, L. Grouseanu1,2, T. Gudu, R. Ionescu1,2, M. Macovei1,2, M. Sasu1,2, M. Milicescu1,2, O. Olteanu1,2, M. Speriatu1,2, A. Dimi1, L. Grouseanu1,2, A. Balanescu1,2, D. Predeteanu1,2, L. Macovei1,2, A. Boranga1,2, D. Mazilu1, V. Bojinca1,2, R. Ionescu1,2, M. Bojinc˘a1,2, V. Stoica1,2, C. Mihai1,2, M. Sasu1,2, M. Milicescu1,2, O. Olteanu1,2, M. Speriatu1,2, A.M. Gheorghiu1,2

Background: Systemic sclerosis (SSc) is a connective tissue disease characterized by skin and internal organs fibrosis, microvascular impairment and frequently by disability and early retirement.

Objectives: To assess employment status, risk factors for early retirement (ER) and the associations of ER with disease characteristics and with patients’ health-related questionnaires (Scleroderma Health Assessment Questionnaire (SHAQ)) and hand function (Durouz hand index (DHI)).

Methods: This study included patients with SSc according to the 2013 ACR/EULAR classification criteria, examined in our EUSTAR center from 11.2011 to 11.2016, who were under the legal age of retirement of in our country (62 years). Patients completed a work assessment questionnaire, the DHI and the SHAQ, as well as a full assessment as per the recommendations of EUSTAR.

Logistic regression was used to investigate the associations between employment status (outcome) and potential predictors (including socio-economic status, education, disease characteristics and health-related questionnaires).

Results: There were 66 patients (8 males, mean±SD age 49.1±9.3 years, 19 with diffuse cutaneous SSc (dCSSc), 46 with history of digital ulcers (DUs) and 23 with joint contractures) included. Forty-two patients lived in urban environments and 22 had higher education (high school or above). Twenty patients were active professionally, whereas 46 were retired, of which 32 retired because of SSc. Of those active professionally, 8 had to do manual labor, 7 had to stand many hours at work and standing 3 had a cold or moist work environment.

Using logistic regression adjusted for age and gender, higher education was found to be highly associated with employment (OR (95% CI) 9.9 (1.5, 52.4)), whereas labor conditions (manual labor, stress) had no significant influence on employment status in our cohort. No association was found between employment status and disease characteristics or SHAQ and DHI questionnaires.

Conclusions: SSc is associated with substantial work disability and unemployment. Completing less education than high school was associated with early retirement.

DOI: 10.1136/annrheumdis-2017-eular.5892
Objectives: To understand allopurinol dose-titration relative to sUA levels. Methods: This retrospective study used the de-identified Humedica electronic medical record database. The study included all sUA and allopurinol records among gout patients (ICD-9-CM: 274.xx) ≥18 years old with first gout diagnosis in 2007 – 2015. An episode was defined as an allopurinol initial dose (ID) prior to (closest) and titrated dose (TD) after (within 30 days) an sUA test. The titration was categorized as an episode with a dose-change (up-titration: ID < TD; down-titration: ID > TD), or no-dose-change (ID = TD). For multiple different doses recorded on the same prescription date, the sum of doses was taken as daily dosage. Episodes were considered uncontrolled when sUA ≥6 mg/dl. Descriptive episode-level analyses were performed.

Results: Within 64,609 episodes, 57% of episodes were uncontrolled (sUA: 6 to <8 mg/dl: 38%; 8 to <10 mg/dl: 15%; ≥10 mg/dl: 4%). Seventy-one percent of uncontrolled episodes were no-dose-change, 21% were up-titrated, and 7% were down-titrated. Within no-dose-change episodes, 51% were uncontrolled and lower doses corresponded to higher percentages of uncontrolled episodes (<100 mg/day: 88%; 100 mg/day: 70%; >100, <300 mg/day: 49%; 300 mg/day: 38%; ≥300 mg/day: 36%). Seventy-eight percent of dose-change episodes were uncontrolled, of which 100 to 300 mg/day (39%) was the most frequent dose titration. Overall, the most frequent TD was 300 mg/day (52%) followed by 100 mg/day (36%), >100 – <300 mg/day (8%), >300 mg/day (3%), and <100 mg/day (1%).

Conclusions: Allopurinol dose is not generally titrated regardless of sUA control. This pattern suggests a need for active management of patients with gout with uncontrolled sUA including consideration of new treatment options in addition to allopurinol.

THU0610 RHEUMA SPACE: STANDARD PRACTICE AIMING CLINICAL EXCELLENCE IN RHEUMATOLOGY

C. Macieira 1, L. Cunha-Miranda 2, P. Nereo 3, P. Lucas 4, J. Eurico da Fonseca 5, J. Canas da Silva 6 on behalf of Rheuma Space study group. 1 Department of Rheumatology, Centro Hospitalar Lisboa Norte; 2 Department of Rheumatology, Instituto Português de Reumatologia; 3 Department of Rheumatology, Hospital CUF Descobertas, Lisboa; 4 QuintessSaMS, Porto Salvo; 5 Faculdade de Medicina da Universidade de Lisboa, Lisboa; 6 Department of Rheumatology, Hospital Garcia de Orta, Almada, Portugal

Background: The quality of medical care and the implementation of measures to improve it are crucial steps for the development of Rheumatology in Europe. Quality indicators were obtained through a four-step rand-modified Delphi methodology. A final set of 26 quality indicators was defined within Donabedian’s concepts: 9 dimensions: 9 structures, 11 processes and 6 outcomes. Herein we describe the second implementation phase of a national program, Rheuma Space (RS), aiming at quality improvement in Rheumatology.

Objectives: To develop a quality improvement plan for care provided by Rheumatology Departments (RD). In this second phase we present the results of the RD evaluation.

Methods: A measurement scale on quality/excellence thresholds was developed for each of the 26 criteria. Eight RD participated in the project and each one set up an Investigation Team of 2–3 members for field criteria measurement and evaluation that required the use of different data sources and focused on the period: 2014 – 1st semester of 2015. After data analysis an individual report was delivered and discussed with each of the 8 RD. Afterwards public presentation and discussion of the results took place.

Results: “Structure” was evaluated in terms of personal, training, facilities, equipment and budgeting.
- RD lack Rheumatology specialists and need fully dedicated nurses.
- Training plans exist in all RD, but physicians allocate few time to research.
- Equipment is appropriate, nonetheless microscopes and computers could be updated.
- Internal contracting is well established and professionals are committed to targets.
- Processes” were evaluated in terms of access and medical care, clinical records, physician-patient communication and multidisciplinary patient management.
  - Triage criteria for first appointments should be standardized, despite compliance for “High Priority” patients.
  - Follow up could be more frequent, but direct access in emergencies is guaranteed.
  - Reimbursement process is mainly used for patients under biologics and data collection improvement could be done.
- Multidisciplinary care is provided, but patient coverage and specialty diversity can increase.

“Outcomes” were evaluated in terms of clinical outcomes, patient and personal satisfaction.
- Average working absence is <15days/patient/year, but is much higher in more affected patients.
- Almost 1/3 of patients requested early retirement at a median age >50years.
- Patients are satisfied with provided care and physicians’ attitude, but less with RD facilities.
- Professional are satisfied with working environment, however criticize career related aspects.

Conclusions: The 26 quality indicators set the basis of this quality management tool that was applied to 8 Portuguese RD. Strengths and weaknesses were identified and an individual Department report was elaborated and discussed. Interventions are now being planned based on these results in order to ensure quality standards of structure and process criteria for a patient oriented clinical practice, favouring desirable clinical outcomes and patient satisfaction.

LONG-TERM FOLLOW-UP OF 269 CHILDREN BORN TO MOTHERS WITH SYSTEMIC AUTOIMMUNE DISEASES: A NATIONAL SURVEY FROM 24 RHEUMATOLOGY CENTERS

C. Nalli1, L. Andreoli1, C. Canini1, M. Rodrigues2, F. Dall’Ara1, M.G. Lazzaroni1, E. Bartolini-Bocci1, C.B. Chighizola4, C. Campochiaro1, P. Conigliaro5, A. Corrado4, S. D’Angelo6, M. Favaro6, E. Generali4, M. Gerosa7, M. Larosa8, M. Meroni9, M. Padovan10, G. Pizzolla11, S. Peccatori12, I. Prevette1, V. Ramoni13, G. Sebastiani14, V. Signorini14, C. Tani14, M. Trevisani15, M. Vadacca1, E. Vivaldelli16, E. Visalli17, L. Zuliani18, A. Afeltra4, E. Baldissera4, C. Seli1, L. Sinigaglia1, A. Tincani1, Genova; 10-, Ferrara; 11-, Reggio Emilia; 12-, Trento; 13-, Pavia; 14-, Pisa; 15-, Bologna; 16-, Bolzano; 17-, Catania; 18-, Ancona; 19-, Bergamo; 20-, Cuneo, Italy.

Background: Rheumatic diseases (RD) affect women during reproductive age. Children’s outcome is a major topic for counselling on family planning, but no large studies are available.

Objectives: We aimed at assessing the long-term health conditions of children born to mothers with RD through a self-reported questionnaire.

Methods: 24 Rheumatology Centers distributed the questionnaire (65 multiple choice and 12 open-answer questions) to consecutive women with RD attending their outpatient clinic during September 2015. Data were compared according to maternal diagnosis (MD) - chronic arthritis (CA) or connective tissue disease (CTD) - and to the timing of pregnancy (before or after MD of RD).

Results: The questionnaire was returned by 184 mothers. Among the 269 children born to 184 mothers 63 were born before and 93 after MD of RD. There were 106 boys and 163 girls. Their mean age was 14.4 (±9.0 SD) years at the time of interview, and male children were 52/93 (56%) and 40/96 (41.6%), respectively. Twenty-nine children in the CA group (31.2%) and 64 in the CTDs group (36.4%) were born after MD of RD. Pre-term delivery was observed in 7 cases for indolence, in 3 for learning disabilities (LD)/health problems (HP), and in 9 cases for other reasons.

Conclusions: The long-term follow-up of children born to mothers with RD in 24 Rheumatology Centers is available. Furthermore, this is the first survey in the world that analyses the results of children born before and after MD of RD. Physicians should take care of the long-term health conditions of children born to mothers with RD.

PROVIDING HEALTHCARE FOR THE POOREST IN EAST INDIA – A REPORT FROM A CHARITY INITIATIVE, SHAKUNTALA HOSPITAL

Background: The region of Odisha in India has a population of over 40 million people and 45% are living in poverty. Approximately one percent of the population is affected by inflammatory rheumatoid diseases. In order to provide early diagnosis and adequate treatment initiation to prevent long term disability, patients require easily accessible basic health care and rheumatologists. Accessible and affordable health care for patients with inflammatory diseases may not only improve disease diagnosis and management, but also improve their quality of life significantly.

Objectives: The aim of our abstract is:
1) To raise awareness of the need of support for common rheumatoid diseases in the developing world
2) To present Shakuntala Hospital as an example of a successful charity initiative

Methods: The Indo-Swedish Rheumatology Foundation (ISRF) is an association of physicians whose main aim is to raise awareness, fundraise and to provide healthcare for patients suffering from inflammatory arthropathies. In order to bridge the gap between our advanced level of knowledge and treatment options in the western world and patients suffering from rheumatologic diseases in the Indian state Odisha we have established this unique association. ISRF, including Shakuntala Hospital, was founded in 2013 and has so far not only provided health care through diagnostic and treatment support, but also ensured patient education and physiotherapy. Health camps are organized in the peripheral communities in order to screen, diagnose and initiate first line treatment and refer these patients for follow-up care to Shakuntala Hospital for further treatments with disease modifying antirheumatic drugs (DMARD), disease monitoring and physiotherapy. Shakuntala Hospital is an example of a non-profit hospital with the aim to provide health care amongst the poorest areas in India.

Results: We have so far registered over 2,000 patients under our care, which includes patients registered in Shakuntala Hospital and in our peripheral care health camps. So far we have established outpatient care for patients with inflammatory arthritis in the districts of Balasore, Murthana, Bhadrak, Keonjhar, Jagpur districts of Odisha and Mednapur district of West Bengal and raised more than 32,000 Euro by ISRF from fundraising initiatives. Inspired by a Swedish model our osteoarthritis (OA) school was founded in October 2016 providing 6 week training courses with the main focusing on patients with knee OA. Furthermore, ISRF has increased awareness of skeletal fluorosis and provide a comprehensive focus with cleaning of drink water in co-operation with the Royal Technical High School in Stockholm.

Conclusions: Shakuntala Hospital is an example of a successful charity initiative in order to provide healthcare for the poorest patients in East India. Awareness needs to be risen in order to further foster future support for Shakuntala Hospital.

EXPLORING THE IMPACT OF HEALTH STATUS AND WELL-BEING OF PEOPLE WITH INFLAMMATORY ARTHRITIS ON PRESENTEEISM IN THE WORKPLACE: A QUALITATIVE STUDY

C.J. Jones1, K. Payne1, B. Gannon2, S. Verstappen3. 1Manchester Centre for Health Economics, The University of Manchester, Manchester, United Kingdom; 2Mater Research Institute Chair in Health Economics, Centre for Business and Economics of Health, Brisbane, Australia; 3Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester, United Kingdom

Background: Presenteeism can be defined as the reduction in work performance due to ill-health at the workplace. Musculoskeletal conditions, including
inflammatory arthritis (IA), are one of the most common causes for presenteeism. There are no “gold standard” methods to identify, measure, or value the impact of presenteeism. Some evidence suggests the impact of presenteeism can be indirectly estimated using measures of health status and well-being.

Objectives: To explore whether selected measures of health status and well-being, combined in economic evaluations are conceptually useful to capture those aspects of IA that are associated with presenteeism.

Methods: A sample of individuals, aged 18 years and above, working in the UK with rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA), was recruited via patient support groups. Semi-structured telephone interviews were designed to understand if, and how, RA, AS or PsA affects an individual’s ability to work. Framework Analysis Methods were used and coding involved deductive and inductive approaches. A deductive approach was used to derive potential themes from measures of health status [EuroQol-5 Dimension-5 level (EQ5D), Short Form 6 Dimension (SF6D)], and well-being [ICECAP-A] (ICAPability measure for Adults (ICECAP-A)]. An inductive approach was used to generate other themes not captured by these measures.

Results: Twenty-two employed individuals with RA (n=10), AS (n=9) or PsA (n=3) were interviewed; 82% were female and, of the 22 patients, 23% had a manual job. The majority of interviewees explained that symptoms of the conditions increase levels of presenteeism, including: pain; stiffness; fatigue; emotional mental health; mental clarity. These symptoms make completing activities at work difficult, which, in turn, affects an individual’s capability to maintain a successful career. The ICECAP-A was found to be a useful measure to capture the overall impact of presenteeism resulting from RA, AS or PsA. The SF6D and EQ5D were more specific measures capturing particular symptoms and activities that increase levels of presenteeism (see Table 1).

Two further themes were identified using inductive methods: mental clarity and feeling understood. The effect of mental clarity or feeling understood is not captured by any of the domains in EQ-5D-5l or SF6D. The ICECAP-A is potentially able to capture the impact of these themes in the respective domains ability to achieve and progress and ability to gain support.

Conclusions: This study suggests that three existing measures (EQ5D, SF6D, and ICECAP-A) were successful, in different degrees, to capture the impact of presenteeism that result from the aspects and symptoms of IA. Potentially, these measures may be used in economic evaluations to capture the impact of presenteeism.

**THU0615**

**PARTICIPANTS’ EXPERIENCE OF THE MAKING IT WORK PROGRAM, AN ONLINE PROGRAM TO HELP PEOPLE WITH INFLAMMATORY ARTHRITIS REMAIN EMPLOYED**

A. Li1, C. Backman1,2, B. van As3, R. Rogers1, M. Gignac3,4, L. L1,2, J. Esdale1,1, D. Lacalle1,2,3, Arthritis Research Canada, Richmond; 3University of British Columbia, Vancouver; 4University of Toronto; 4Institute of Work and Health, Toronto, Canada

Objectives: Health services addressing employment needs for people with arthritis are lacking. To address this need, we developed the Making It Work (MIW) program, an online self-management program aimed at helping people with inflammatory arthritis (IA) deal with employment issues. As part of a randomized controlled trial evaluating program effectiveness, this study reports on participants’ experiences with various aspects of the program.

Methods: All participants in the MIW program between Jan20 and Dec7 2016 were included. Participants were recruited from rheumatologist practices, outpatient arthritis programs, a national consumer organization (Arthritis Consumer Experts), and community advertisements in BC, Alberta and Ontario. Eligibility criteria included: having IA; being currently employed; age 18–59 yrs; concern about their ability to work; and access to a computer. The program consisted of 5 online self-learning modules, 5 online group meetings facilitated by a vocational counselor, an individual ergonomic assessment by an occupational therapist and an online session with a vocational counselor. Feedback questionnaires were administered online after participants completed the program. Descriptive analyses were performed.

Results: The sample included 69 participants [80% female; mean (SD) age: 45.3 (10.5) yrs; 83% Caucasian; 91% with post-secondary education; 52% with RA, 19%; SLE: 17%; PsA: 12%]. Overall, participants expressed satisfaction with the program with 94.2% agreeing (69.6% strongly and 24.6% somewhat) they would recommend this program to someone they know. When asked to rate program components on a scale of 0–10 where 0=not useful at all and 10=very useful, participants rated all components favourably: median [25Q;75Q] for online modules: 8 [7;10], with highest ratings for the fatigue module (rated 10 by 42%); online group meetings: 9 [7.5;10]; ergonomic and VRG assessments: 8 [7;10] each. Although participants had 2 weeks between meetings to complete the module, 55% did the module the week of, and 42% the day before, the group meeting. Median time to complete each module was 60 min. 81% enjoyed being able to listen to the information (somewhat or strongly agreed), although 35% stated they would have preferred to read the information than listen to a narrator. 74% expect to use the online modules again in the future. Participants were also satisfied with the online group meetings: 93% were very or somewhat satisfied with the group facilitation; 87% satisfied with the group dynamic; 84% comfortable with the online format. When asked to rate their online group meeting experience on a scale of 0–10 where 0=not at all useful and 10=very useful, participants rated the group meeting discussion was 9 [9;10]; getting to know other participants: 7 [7;10]; feeling listened to and understood 9 [8;10]; feeling that group was supportive 9 [7;10]. 20% said it was difficult for them to attend group meetings.

Conclusions: In general, participants were highly satisfied with all aspects of the program.
**THU0616** PATIENTS’ PERCEPTION ON DISEASE PROGRESSION AND ADHERENCE TO BIOLOGIC THERAPY

**E. Cefai, D. Balzan, C. Mercieca, A.A. Borg. Rheumatology, Mater Dei Hospital, Msida, Malta**

**Background:** Adherence to medication depends on several factors such as medication beliefs, psychosocial factors, illness beliefs and concerns. The consequences of non-adherence are not insignificant, both from the clinical and health economic aspects.

**Objectives:** To assess medication adherence of patients taking biologics who are in remission or who have low disease activity and patients’ perception of disease progression.

**Methods:** Forty-four consecutive patients attending a dedicated biologic clinic and treated with TNF inhibitors were interviewed following their visit. Patients were asked about adherence to treatment, adverse effects, concerns about biologics and their perception of disease progression. Demographic and disease activity data were recorded.

**Results:** Forty-four patients (23 females, 21 males) participated in the survey (21 suffered from rheumatoid arthritis, 17 from ankylosing spondylitis and 6 from psoriatic arthritis). The mean age was 55.1 (SD 12.62) years. The mean DSAS28 was 2.92 (SD 1.00) and mean BASDAI was 4.21 (SD 2.1). No minimal or no pain was reported by 75%, mild or no fatigue by 78% and 77% had no restriction of activities of daily living. Medication adherence was reported as high by 66% and moderate by 32%. There were no patients who had a low level of adherence. 5% of patients admitted to be unaware of the need to omit their biologic when ill and 40% when requiring surgery.

One out of 4 patients reported to have experienced adverse events, most commonly infections. 19% claimed to be moderately or very concerned about the adverse effects. On further questioning about the severity of potential adverse effects, 45% were unsure as to what the severity might be. When asked about duration of therapy, 29% replied more than 10 years; whilst 71% were unsure on when, if ever, the biologic is going to be stopped. Patients were also asked whether they believed that the biologic had successfully stopped further joint damage and 68% replied yes, 9% replied no, whilst 23% were unsure. Of those who replied yes, this perception was based on the absence or reduction of symptoms.

**Conclusions:** In this cohort of patients with low disease activity or remission, a third of patients still reported sub-optimal adherence to TNF inhibitor use. The benefits of adherence to biologic therapies need to be reinforced at every visit and factors leading to non-adherence addressed. Adverse effects remain a major concern that needs to be addressed, even in patients who have been on biologics for many years and have sustained remission or low disease activity. A quarter of patients were unsure whether biologics have stopped joint damage. Patients’ perception of joint damage progression needs to be explored to find ways of making it more understandable to patients.

**THU0618** THE FACTORS AFFECTING WORKPLACE AND HOUSEHOLD LIFE IN ANKYLOSING SPONDYLITIS: A MULTI-DIMENSIONAL STUDY

**B. Taser 1, F.F Ayhan 2, J-O. Borman3, A. Karagöz 1. 1Physical medicine & rehabilitation, Ankara Training and Research Hospital, Ankara; 2Physical therapy & rehabilitation, Upak University, School of Health Sciences, Upak; 3Physical Medicine & Rehabilitation, Haydutte Medical School, Ankara, Turkey**

**Background:** Work disability (WD) is the final stage of work problems and may be prevented by effective treatment and ergonomic interventions in earlier stage of work productivity loss and work instability. Contextual factors, disease related factors and local social security systems may also affect WD.

**Objectives:** We aimed to determine the predictive factors of work productivity and work stability in Turkish patients with ankylosing spondylitis.

**Methods:** One-hundred patients with ankylosing spondylitis (31 females and 69 males) were included into this study. Demographics, working state, Bath scores of disease activity, functional and radiologic state, quality of life, cardiopulmonary functions (echocardiography, exercise stress test and pulmonary function test) and general work impairments (work productivity impairment and work instability) were recorded. WPAI and AS-WIS were selected as work outcomes. The most predictive factors were analyzed in work productivity and work instability. SPSS 14.0 statistics (descriptives, pearson correlation, and stepwise regressions were used for statistical analyses.

**Results:** Thirty-two patients (mean age: 42.6±11.7) were unemployed. Unemployed patients showed more female, less educated, low disease activity, and low fitness profiles. The percentages of absenteeism (WPAI-1), presenteeism (WPAI-2), regular activity impairment (WPAI-3) and overall work impairment (WPAI-4) were determined as 8, 44, % 47, and % 37, respectively, in employee group. When affecting factors assessed with multiple stepwise linear regression analysis; the only determinant for absenteeism (WPAI-1) was the working day loss due to illness at last year. Chest mobility, annual income level, AS quality of life (AQoL), work change and co-morbid diseases were the determinants of presenteeism (WPAI-2), regular activity impairment (WPAI-3) and overall work impairment (WPAI-4). The score of mean work instability (AS-WIS) was 11.5±5.8, and 42.6% of patients had low and 57.4% of patients had moderate-high work instability. Multiple stepwise linear regression analysis showed that most predictive factors for work instability were regular activity impairment (WPAI-3) and AS-QoL. The factors affecting non-work status were older age, female sex and low annual income level in stepwise logistic regression.

**Conclusions:** The common predictive factor of work productivity and work stability was quality of life. For evaluation of work productivity; socioeconomic factors such as annual income level and frequent work change were determinative as well as clinical datas (chest expansion and comorbid diseases). We suggested both pharmacologic and nonpharmacologic interventions to improve quality of life should be enabled in early period to improve work productivity.

PREVALENCE OF PNEUMOCOCCAL VACCINATION IN RHEUMATOLOGICAL PATIENTS WITH COMMUNITY ACQUIRED PNEUMONIA. BIOBADASAR REGISTRY

Sociedad Argentina de Reumatologia, Buenos Aires, Argentina

Background: Biobadasar is a registry that monitors adverse events in patients who use biological treatments in rheumatological diseases conducted by the Argentine Society of Rheumatology. As in other international registries the community acquired pneumonia (CAP) has been detected as one of the most frequent infectological adverse events. Although all immunosuppressed patients should be vaccinated against streptococcus pneumoniae, there is a proportion of patients who are not.

Objectives: Evaluate the prevalence of pneumococcal vaccination in patients with CAP within the Biobadasar database. Assess factors associated with Severe CAP in these patients.

Methods: A cross-sectional, multicentric study was made in BIOBADASAR database from 2010-2015. In patients who reported CAP data of demographics, comorbidities and state of pneumococcal immunization was collected. Microbiological data, treatment and outcome of the event were considered. The severity of CAP was assessed according to the opinion of the attending physician, hospitalization, risk of life and/or death. Values are expressed as mean ± standard deviation, median (ranges) and frequencies (percentages), as appropriate. We performed bivariate and multivariate logistic regression analysis to identify variables associated with the event.

Results: Out of the 4029 patients enrolled in the registry, the cumulative incidence of CAP was 4.2% (n = 170), 72.4% (n = 123) were women. The mean age was 57 (SD +/- 14.5). Biological treatment was found in 81.8% (n = 139). Patient s that have received the pneumococcal vaccine were 40.6% (n=69). Severe CAP was detected in 7.1%. Streptococcus Pneumoniae was the main pathogen isolated in 13% of the cases. Overall mortality was 4.1%. In the univariate analysis for severe CAP we found statistical significance for Smoking OR 3.88, CI95 1.063–14.22, p=0.029 and chronic kidney disease (CKD) OR 31, CI95 2.6–376, p=0.007. When performing a multiple logistic regression model, only renal failure OR 7.39 CI95 3.066–18.28, p=0.003–0.38 and chronic kidney disease (CKD) OR 31, CI95 2.6–376, p=0.007 was a predictor of severe CAP. Not significant association with immunosuppressive treatment (p = 0.09), age (p = 0.464), or vaccination (p = 0.937).

Conclusions: The annual incidence of CAP in Argentina varies between 0.5 -1.1% while in our cohort it was four times higher. The prevalence of pneumococcal vaccination was less than 50%, showing that, although the literature and guidelines establish the need for vaccination, this is not so in the real world. In the multivariate analysis, only CKD was related to severe CAP. Although in the univariate analysis the CKD and the smoking habit represented factors associated with severity. We must emphasize the medical education in following the international vaccination guidelines.

PERSISTENCE WITH BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS – A RETROSPECTIVE DATABASE STUDY IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS

J. Mahlich1, H. Kameda2, R. Sruamsiri3, A.M. Cappuccio, R. Quintana, E. Mussano, L. Zavada1, L. Szzukova1, J. Vencovsky1, P. Horák3, K. Pavelka1 on behalf of collaborators of the ATTRA registry.1 Rheumatology, Institute of Rheumatology, Prague; 2 Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno; 3 Internal Medicine, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic.

Objectives: To compare the effect of anti-TNF therapy (a-TNF-th) on Work Disability (WD) between RA, PSA and AS. In the Czech Republic (CZ), a-TNF-th is reimbursed for RA if DAS28≥3.1 despite therapy with csDMARDs, for PSA if disease is not “adequately controlled” with csDMARDs, and for AS if BASDAI≥4 and CRP/ESR elevated above normal. More than 95% of anti-TNF treated patients in CZ are followed up in the ATTRA registry.

Methods: Bionalve patients with RA (n=1085), AS (n=1126) and PSA (n=351) starting a-TNF-th with available baseline data on demography, disease duration and physical function, and on working status at baseline and at 12 months were included in the analysis. Patients older than 60 years, on maternity leave or students were excluded. Work status was self-reported by patients as (A) able to work = [(i) employed, or (ii) unemployed and actively seeking employment], or (B) unable to work = [(iii) on sick leave, or (iv) on disability pension]. Regression analyses were performed to examine the predictors of improvement in WD (change B→A coded as 1, B→A as -1, no change as 0) over 1 year.

References:

Results: Baseline characteristics were significantly different between diagnoses (Table 1). In patients with RA, 60% were able to work at baseline and 61% at 12 month, with PSA 71% and 74% resp., and with AS 72% and 77% resp. The main driver of improvement of WD was a change in the sick leave (RA 6%/2%, PSA 7%/1%, AS 9%/2%). In univariate analyses, diagnosis of AS and younger age at start of a-TNF-th were predictive of improvement in WD. In multivariate analysis, only diagnosis of AS was significantly associated with improvement in WD. Conclusions: These real life data from CZ show that for improvement of WD, a-TNF-th was most effective in patients with AS. This may be a sequel of disease activity, with the resulting cost savings related to work incapacity.

Background: Biobanks for research (BBR) are organized repositories of biological materials and associated health information with enormous potential and value for scientific research. In consonance with increasing attention to healthy aging research, BBR specifically oriented to chronic diseases and aging populations have gathered heightened attention. Public perceptions and patient choices are key to design, develop and implement patient-centered BBR. Public awareness, education and involvement are confidence building and unequivocally lead to higher participation in scientific enterprises.

Objectives: To assess patient awareness, perception and choices regarding aging biobanking activities.

Methods: We developed and applied a standard anonymous questionnaire to rheumatology outpatients. Although awareness is still suboptimal, BBR perceptions and patient choices regarding biobanks for aging research purposes have gathered heightened attention. Public perceptions and patient choices are key to design, develop and implement patient-centered BBR. Public awareness, education and involvement are confidence building and unequivocally lead to higher participation in scientific enterprises.

Conclusions: Our study constitutes a comprehensive assessment of public perceptions and patient choices regarding biobanks for aging research purposes among rheumatology outpatients. Although awareness is still suboptimal, BBR are highly regarded health infrastructures with enormous potential for further patient-centered development.

THU0623 | DECREASE IN THE TEMPORARY WORK INCAPACITY DUE TO MUSCULOSKELETAL DISEASES: UTILIZATION OF A PREVENTIVE PROGRAM IN VALENCIA- LA FE HEALTH AREA

J.E. Oller Rodríguez1, M.T. Fuente Goig2, F. Ortiz Sanjuán1, J. Ivorra Cortés1, E. Grau García1, E. Vicens Bernabéu1, E. Labrador Sánchez1, K.R. Arévalo Ruales1, J. Fragio Gil1, R. González Mazarío1, C.P. Alcázar Escandell1, I. Cánovas Olmos3, I. Chalamera Verdejo1, C.M. Feced Olmos1, L. González Puig1, J.M. Martínez Cordella1, C. Nájera Herranz1, R. Negueruelos Albuixech1, I. Andani Cervera1, J.A. Román Ivorra1 on behalf of Rheumatology Service. Rheumatology; 2Service of Prevention of Occupational Hazards, Hospital Universitari i Politècnic la Fe, Valencia, Spain.

Background: Musculoskeletal diseases are nowadays a frequent cause of temporary work incapacity (TWI). The implementation of specific programs for the care of these patients can be an important cornerstone in the resolution of these TWI processes.

Objectives: Our aim is to analyze the usefulness of an Early Intervention Program (EIP) in patients with TWI of musculoskeletal origin.

Methods: Case-control study, including patients from HUP La Fe area, which were referred from Primary Care since April 2012 to April 2016 to our Early intervention program (EIP) addressed to patients with TWI of musculoskeletal origin. The patients were evaluated in our consultation within a maximum of 15 days after the start of TWI. The intervention consisted in an evaluation, including complementary tests if necessary; diagnosis and treatment by the rheumatologist in our consultation. The patient was followed in consultation until discharge. Patients whose disabilities were of traumatic or surgical origin were excluded. A comparative study was carried out against a control group of patients with ILT of musculoskeletal origin.

Results: A total of 666 patients were recruited; 508 (76.3%) belonged to EIP group (46.1% male; 53.9% female) and 158 patients (23.7%) belonged to the control group (44.3% male; 55.7% female). The average age was 47.6±10.5 years for the EIP ones and 46.7±10 years in the control group. The most frequent diagnoses were low back pain (23.3%), neck pain (18%) y lumboscleratica (12%). In EIP group, 100% of the patients received medical treatment, a 54.5% received instructions for doing physical therapy at home, an ultrasound scan was performed to the 26.4% of the patients while the 19.9% received at least one local infiltration. The longest TWI corresponded to knee meniscopathy (203 days), painful shoulder syndrome (173 days) and lumboscleratica (170.5 days). No statistically significant differences were found between the duration of the TWI attending to sex, age group, labour activity or diagnosis. However, a significant association was found between TWI duration and the delay since the start of the symptoms to the referral from Primary Care to our consultation, specially within the first 10 days (p=0.04). Furthermore, TWI duration was significantly shorter in the EIP group patients than in the control group patients (137.4±132.3 days vs 194.7±143.1 days; p<0,001).The period after relapse was longer in the EIP group, although the differences did not reach statistical significance. In an inverse relation was found between age and time to relapse (p=0.01).

Conclusions: The establishment of an early intervention program specifically addressed to patients with temporary work incapacity of musculoskeletal origin shortens the duration of the incapacity, allowing the patient to rejion his work activity, with the resulting cost savings related to work incapacity.

THU0624 | ASSESSMENT OF PSYCHIC EXPERIENCES IN PATIENTS WITH RHEUMATIC DISEASES

J.L. Prados-Ojeda1, J.L. Garrido-Castro2, R. Segura-Ruiz1, C. González-Nava2, P. Font-Ugalde1, E. Collantes-Estevez2, A. Escudero-Contreras1, Reina Sofia University Hospital, 1Maimonides Institute for Biomedical Research of Cordoba, Cordoba, Spain.

Background: There are several studies that report psychiatric comorbidity in patients with rheumatic disease, mainly the presence of mood disorders. Some of them describe non-affective psychosis related with inflammatory processes. There are several studies that report psychiatric comorbidity in patients with rheumatic disease, mainly the presence of mood disorders. Some of them describe non-affective psychosis related with inflammatory processes.

Objectives: To identify the presence of psychic experiences in different populations with a diagnosis of rheumatic disease, and to compare it with a sample of healthy subjects.

Methods: 124 subjects completed surveys including SF-12 and CAPE questionnaire, as well as other demographic and behavioral variables. Among them, 70 had Spondylarthrits (SpA) (age 44.3±13 years, 62% female), 23 rheumatoid arthritis (RA) (age 51.2±13 years, 82% female) and the rest were individuals without rheumatic diseases (47.6±12 years, 58% female).

Results: Results of the SF-12 test in their mental and physical domains, and the CAPE questionnaire in their dimensions (positive, negative, depressive and total symptoms) are shown in the table, expressed as mean value (SD) and in the graph expressed as density histograms with mean values. Significant statistical
differences, according a t de Student test with control group is shown in both (* p < 0.05, ** p < 0.01).

There were no significant differences in the mental component of the SF-12. These differences appear at the physical component, since patients have impaired their mobility and function due to their disease. About the CAPE questionnaire, patients had a little bit higher score due mainly to the appearance of depressive symptoms. The values of positive symptoms of psychosis remained within the normal range for diseases analyzed.

Conclusions: In our study, we found significant differences in the dimensions, especially depressive, of the CAPE scale among patients with rheumatic diseases (especially in SpA) and healthy subjects. This gives us an idea of the importance of considering the psychological problems of patients (anxiety, depression, ...) to improve the treatment of rheumatic disease.

Acknowledgements: We would like to thank these patients' organizations for their collaboration in our study: Coordinadora Española de Asociaciones De Espundrios (CEADE), Asociación Cordobesa de Enfermos de Espundrios (ACEADE), Asociación Cordobesa de Enfermos de Artritis Reumatoide (ACORE).

**DESIGN OF AN INFORMATION AND COMMUNICATIONS TECHNOLOGY PLATFORM TO SUPPORT COORDINATION OF CARE FOR RHEUMATOID ARTHRITIS PATIENTS WITH CARDIOVASCULAR CO-MORBIDITIES – FIRST EXPERIENCES**

J.G. Richter, G. Chehab, M. Schneider on behalf of the PICASO Consortium (www.picaso-project.eu), Policlinic & Hiller Research Unit for Rheumatology, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany

Background: Coordination of care plans between healthcare sectors and efficient management of patients (pts) with co-morbidities is of large demand. Rheumatoid arthritis (RA) pts are at increased risk of cardiovascular diseases (CVD). Different stakeholders are potentially involved in the EULAR recommended management process of RA pts. The interdisciplinary information and communication technology (ICT) platform within the Horizon2020-funded PICASO-project (www.picaso-project.eu) will support a continuum of care from hospitals and outpatient clinics to the home.

Objectives: Explore challenges to provide an efficient ICT integrated solution across many healthcare professionals working for various organisations and potentially crossing national borders that complies to privacy and regulatory constraints allowing more efficient care management. Suitable system architecture and appropriate features require identification of target users’ user requirements. PICASO platform will be developed and trialed with pts and clinician. The proposed system relevant To-Be Use Cases, numerous user requirements and EU-wide stakeholder are potentially involved in the EULAR recommended management process of RA pts. The platform will become take place in iterative cycles followed by prototypes’ thoroughly evaluated by real end users investigating usability and acceptance. The platform will become available for RA-pts in routine care but also for wider applicability in Rheumatology and other chronic diseases.

**THU0626**

**COST-EFFECTIVENESS OF EARLY TREATMENT OF ACPA POSITIVE RHEUMATOID ARTHRITIS PATIENTS WITH ABATCEPT**

A.S. Neubauer, 1 C. Minnart, 2 K.H. Herrmann, 3 R. Postema, 3 C. Baerwald, 4
1Institute for Health Economics (IG, IGPh), 2Bristol-Myers Squibb, Muenchen, Germany; 3Bristol-Myers Squibb, London, United Kingdom; 4Rheumatology Unit, University of Leipzig, Leipzig, Germany

Background: Studies have reported that the presence of elevated anti-citrullinated protein antibodies (ACPA)/RF levels, together with joint erosions, is associated with higher disease burden in terms of disability, and mortality in rheumatoid arthritis (RA). Abatcept has been shown to be effective in this patient population with favorable comparative data against adalimumab.(1) However, few studies have investigated the cost effectiveness of abatcept in this population to similar treatments such as TNFs.

Objectives: The objective of the study was to compare the cost-effectiveness of abatcept to adalimumab as a first bDMARD in ACPA positive RA patients who failed treatment with methotrexate (MTX) in Germany.

Methods: A decision tree model was used to estimate the cost-effectiveness, from a payer’s perspective, of different treatment sequences in RA over a two year time frame. The effectiveness criteria were defined as achieving the treatment target measured by the Disease Activity Score 28 (DAS28 (CRP))-2.6; "remission". A treatment switch to a different biologic as 2nd line and 3rd line bDMARD was allowed -in case of not achieving remission with therapy- every 6 months over a two year time period. Effectiveness data was based on randomized controlled trials (RCT) identified by an updated previous systematic literature search by the Institute for Quality and Efficiency in Health Care (IQWiG). Costs of medication and other direct medical costs were taken from a recent publication (2) and included in the analysis. Cost-effectiveness of RA treatment was investigated in ACPA positive patients in this study and presented as overall costs per day in a payer’s perspective.

Results: For ACPA positive patients, treatment strategies including early treatment with abatcept had lower total costs per clinical outcome compared to later use. Figure 1 summarizes the costs per day in remission for the treatment sequences investigated: treatment of sequences starting with abatcept resulted in lower costs for reaching remission (mean 330 €/day, range 328 €-390 €/day) compared to sequences starting with adalimumab (mean 384 €/day, range 378 €-390 €/day). Choice of the second or third biologic in the treatment sequences appears to have little impact on the costs per outcome.

Conclusions: The results of this analysis suggest that in ACPA positive RA patients treatment with abatcept appears to be more cost-effective compared to treatment with adalimumab as a first bDMARD.

**COGNITIVE BEHAVIOURAL THERAPY FOR TREATMENT OF PSYCHOSIS IN RHEUMATIC DISEASE PATIENTS: AN OPEN-LABEL, RANDOMISED CONTROLLED TRIAL**

S. Bresser, S. van den Bos, M. Van der Voort, G. Chehab, M. Schneider, on behalf of the PICASO Consortium (www.picaso-project.eu)

Background: A significant minority of rheumatic diseases patients report psychosis symptoms, which are often severe and may have a negative impact on quality of life. Cognitive-behavioral therapy (CBT) has been shown to be an effective intervention for psychotic symptoms in schizophrenia. However, no studies have investigated the use of CBT for psychotic symptoms in rheumatic diseases patients.

Objectives: To investigate the efficacy of CBT for psychotic symptoms in patients with rheumatic diseases.

Methods: We performed an open-label, randomised controlled trial (RCT) in two centres in Germany. Patients were randomised to receive CBT or waiting list. The CBT consisted of 12 weekly sessions of 90 min, adapted to the needs of patients with rheumatic diseases. The primary outcome was the Clinical Assessment of Psychotic Symptoms (CAPS) total score. Secondary outcomes included the Acute Psychosis scale for Schizophrenia and the German version of the SF-12. A sub-analysis was performed for patients with or without antipsychotic treatment.

Results: Fifty patients with a rheumatic disease and psychotic symptoms were randomised and included in the analysis. Twenty patients were assigned to CBT and 30 to the control group. At weeks 12 and 22, primary outcome results were significantly improved in the CBT group compared to the control group (p=0.001 and 0.01 respectively). The best response (≤20%) was reported by 35% of the CBT group and 8% of the control group (p=0.03). The sub-analysis showed a similar response between patients with or without antipsychotic treatment. No serious adverse events were reported.

Conclusions: CBT for psychotic symptoms in rheumatic diseases patients is feasible and has a significant effect on psychotic symptoms. Further research is needed to confirm these findings and to evaluate the long-term effects of CBT.

TREATMENT OF RHEUMATOID ARTHRITIS: ADHERENCE TO GUIDELINES IN PRIVATE PRACTICE

Background: Guidelines and therapeutic strategies in the treatment of rheumatoid arthritis (RA) have been developed and adopted by most Societies of Rheumatology. However, the extent to which these recommendations are followed by rheumatologists in their individual clinical practice is unclear.

Objectives: Our aim was to analyze, at private offices, adherence to guidelines and characteristics of RA patients in regular follow-up.

Methods: This was a cross-sectional study developed by a group of rheumatologists (n=13) working exclusively in private offices and hospitals in São Paulo, Brazil. It consisted of a web-based questionnaire addressing patient’s demographic, social characteristics and treatment. Patients having the diagnosis of RA should be included sequentially. As Brazil’s private health has no reference flowchart, patients can consult any physician from their insurance health program, or rheumatologist’s office. We were measuring the compliance on biologic or target “under control”. In fact, 72% of patients were on low disease activity (22%) or activity were analyzed, few of them (0.28 CI 0.18–0.40) were on biologic or target therapy; PsO patients’ dosing was observed to be lower than monograph during the loading phase, while higher than monograph in the maintenance phase.

Conclusions: In Canadian real-world practice, the average patient utilization of etanercept remained consistent over the first year in majority of patients, with the exception of those with PsO. A notable proportion of etanercept patients with rheumatoid arthritis reduced their dosing over time. This could be due to patient-related factors as high treatment costs or lack of resolution, while few of them (0.28 CI 0.18–0.40) were on biologic or target therapy as key factors in the decision to return to monograph in the loading phase, while higher than monograph in the maintenance phase.

Disclosure of Interest: M. Khraishi1, Grant/research support from: Abbvie, Biogen, BMS, Chugai, Hexal, Medac, Pfizer, Roche, Sanofi Aventis, UCB DOI: 10.1136/annrheumdis-2017-eular.6959

TREATMENT OF ETANERCEPT DOSE ADJUSTMENTS IN A REAL-WORLD SETTING: A CANADIAN RETROSPECTIVE COHORT STUDY

M. Khraishi1, Y. Zhang2, J. Ivanovic2, B. Millson2, E. Singh3, J. Woolcott4, H. Jones5. 1University of British Columbia; 2Centre for Health Evaluation and Outcome Sciences, Vancouver; 3McGill University, Montreal; 4Arthritis Consumers Experts. Vancouver, Canada

Background: Etanercept is a soluble TNF receptor (humanized protein) indicated for treatment of immune-mediated inflammatory diseases, including rheumatoid arthritis (RA), psoriatic arthritis (PsA), psoriasis (PsO), and ankylosing spondylitis (AS). Canadian monograph recommended dosing of etanercept is 50mg/week, while treating RA patients in a loading phase requiring an increased dose for 12 weeks. Evidence suggests that real-world practices differ from monograph, with patients titrating to lower or higher weekly dose as needed. Limited research exists on how etanercept patients are dose optimized in the real-world Canadian setting.

Objectives: To describe etanercept treatment dynamics, including dose de-escalation/escalation in the Canadian real-world setting.

Methods: A retrospective cohort study was conducted utilizing claims-level data from QuintilesIMS Private Drug Plan database, Ontario Public Drug Plan database, and Quebec Public Drug Plan database. Between 07/2013–06/2015, bio-naïve patients initiating etanercept and who remained on their biologic for 12 months were identified. Weekly dosing of each patient was calculated and analyzed for the prevalence and magnitude of dose de-escalation/escalation. Patients with at least 20% lower/higher average dose than monograph recommended dose (50mg/week) were flagged as dose de-escalators/dose escalators, respectively. The first 3 claims of etanercept were excluded from average dose calculations to exclude a possible loading phase.

Results: The study identified 3,051 etanercept patients (60% female, 77% aged between 18 and 65, 87% rheumatic diseases, and 13% PsO) across Canada in the 12-month period. Of 1,547 patients (n=332) dosed during their first year of therapy, led by AS (15%, n=24) and RA (12%, n=286); 15% (n=449) of patients escalated, led by PsO (64%, n=282) versus 7% (n=168) in RA; 74% (n=2,270) of patients maintained a consistent dose. Average dosing across rheumatic disease patients stabilized to monograph levels by week 20 of their therapy; PsO patients’ dosing was observed to be lower than monograph during the loading phase, while higher than monograph in the maintenance phase.

Conclusions: In Canadian real-world practice, the average patient utilization of etanercept remained consistent over the first year in majority of patients, with the exception of those with PsO. A notable proportion of etanercept patients with rheumatoid arthritis reduced their dosing over time. This could be due to patient-related factors as high treatment costs or lack of resolution, while few of them (0.28 CI 0.18–0.40) were on biologic or target therapy as key factors in the decision to return to monograph in the loading phase, while higher than monograph in the maintenance phase.

THU0630 OPIOID USE IN PATIENTS WITH POLYMALGIA RHEUMATICA

M.D. Richter1, S.J. Achenbach2, J.A. Zamora-Legotti3, C.S. Crowson2, E.L. Matteson3, 1Graduate Medical Education; 2Division of Biomedical Statistics and Informatics; 3Division of Rheumatology, Mayo Clinic, Rochester, United States

Background: Polymyalgia rheumatic (PMR) is a systemic rheumatic inflammatory disease characterized primarily by musculoskeletal pain and stiffness. Glucocorticoid treatment is the current standard of care however the need for additional pain management, in particular the need for opioid therapy, has not been studied.

Objectives: To examine the trends of chronic opioid use in patients with PMR over an 11 year period in Olmsted County, Minnesota, USA and compare this to subjects without the disease.

Methods: Retrospective data on opioid prescriptions were collected from 2005 to 2015 in a population-based incidence cohort of patients meeting the 2012 American College of Rheumatology classification criteria for PMR alongside comparison subjects. Poisson regression methods were used to compare opioid use between these groups.

Results: 244 patients with PMR and 211 non-PMR comparator subjects were included in the study. Rates of chronic opioid use were not significantly different between the two groups. 7.5% of patients with PMR were identified as chronic users by the end of the study period compared with 5.2% of non-PMR subjects. Any opioid use was also not significantly higher in PMR, with relative risk of 1.10 (95% CI 0.97, 1.26, p=0.14). There were higher rates of chronic use among patients over 80 years in both groups.

Conclusions: PMR does not appear to be associated with increased rates of opioid use when compared with the general population.

THU0631 DIRECT FINANCIAL BURDEN OF RHEUMATOID ARTHRITIS ON PATIENTS’ LIFE IN A DEVELOPING NATION OF PAKISTAN, ONE YEAR PROSPECTIVE STUDY

M.S. Ahmad, Orthopedic Surgery, Fazle Omar Hospital, Chenab Nagar, Pakistan

Background: Rheumatoid Arthritis is chronic inflammatory disease. Early diagnosis and management is necessary to avoid joint destruction and to minimize disability. It affects 0.5 to 1 percent population. The female to male ratio is 3 to 1. Health care cost is of great concern to patients, physicians and health care policy makers. The financial impact of rheumatoid arthritis treatment like any chronic illness is of great significance in developing society like Pakistan where 30 percent population lives below poverty line and annual per capita incomes are very low. Whereas prevalence is same with high medicines prices with poorly developed health insurance system and government funded hospitals are scanty.

Most of the times attention in the field of health economy is focused on direct medical cost in general and hospital cost in particular but however there are some social societal customs which also increases the burden of direct cost. The direct cost includes expenditures like physician visit cost, diagnostic tests, medications. There are also some hidden charges to this direct cost which are not included in studies. Like transport charges, food bills during hospital stay and accompany person, female are companied by males. All included puts strain on economy and major share of annual income of patient is paid on management of disease. The worst scenario is when patient stops treatment and if lucky gets support from other resources like patient welfare societies or from relatives.

Objectives: To assess the direct cost of patient’s every visit to hospital outpatient department prospectively for one year and total cost of one year was summed up and percentage to annual income spend on treatment was calculated.

Methods: Study carried out from January to December 2015 at Fazle Omar Hospital Rawalch Khan Nagar and 150 patients either newly diagnosed or already on treatment of rheumatoid arthritis were included. Data collected for next 1 year for each visit, patients with any other disease along with rheumatoid arthritis were excluded. The estimated annual income of patient or the person bearing the cost of the patient was calculated by the end of the study period compared with 5.2% of non-PMR subjects.

Results: The mean total per patient income after conversion from local currency was 3000 US dollars against 1474 US dollars per capita income in 2015. The annual average cost per patient including consultation fee, medicines purchased, laboratory investigations and other overhead expenses like transportation of patient and accompanied person and food bills during hospital stay was 1194 US dollars. 41% of patient gross income was spend on management of rheumatoid arthritis.

Investigations cost 12%, medicines purchased 16%, consultation 2% and overhead visit charges cost 10% of the total mean of per patient annual income.

Conclusions: RA management consumes large portion of patients annual income and it has significant burden on developing world economy.

THU0632 VALIDATION OF INTERNET-BASED REPORTING OF PATIENT REPORTED OUTCOMES WITHIN THE SWEDISH RHEUMATOLOGY QUALITY REGISTER

O.E. Hofstad1, D. Di Giuseppe2, G.-M. Alenius3, N. Stattin2, H. Forsblad-d’Elia1, L. Ljung1, 1Department of Public Health and Clinical Medicine, Umeå University, Umeå; 2Department of Medicine Solna, Karolinska Institutet, Stockholm; 3Swedish Rheumatism Association, Sundsvall, Sweden

Background: Previous studies have validated the use of clinic based touch-screens for registering patient reported outcome measures (PROMs) (1–3). The Swedish Rheumatology Quality (SRQ) register has implemented an internet-based method (PER (Patientens Egen Registrering, or Patients’ sElf Registration)) for collecting PROMs.

Objectives: The aim of this study was to investigate the feasibility of the internet-based method as well as the validity of reported outcomes and disease activity scores compared to the gold standard paper format.

Methods: We recruited patients (n=44, mean age =51.0, standard deviation =13.2 years, 69.6% women) included in SRQ with a diagnosis of rheumatoid arthritis, psoriatic arthritis, juvenile arthritis, spondyloarthritis or anklyosing spondylitis. Before a planned visit at the rheumatology clinic the patients registered Visual Analog Scales (VAS) for global health, pain and fatigue, both electronically by PER and on paper. Patients with axial disease also registered BASDAI and BASFI related variables (n=6). For patients with peripheral arthritis (n=38), DAS28 was calculated using both methods. The differences between the methods were compared by T-test and Intra-class correlation (ICC). Agreement was visualized using Bland-Altman plots for all VAS registrations. The patients also answered a questionnaire regarding the used device and preferred method.

Results: No differences between PER or paper based VAS scores were found for VAS Global, VAS Pain and VAS Fatigue (p=0.086, p=0.691 and p=0.197, respectively). ICC scores ranged from 0.930 to 0.971. Bland-Altman plots for VAS assessments showed good agreement and no proportional bias was detected (Fig 1). Mean difference for DAS28 was -0.04 (p=0.177). Of the recruited patients, 76%, preferred the Internet based method. BASDAI and BASFI could not be evaluated due to a limited number of observations.

References:

Fig. 1 Bland-Altman plot showing level of agreement of all VAS (VAS Global, VAS Pain, VAS Fatigue, VAS included in BASFI and BASDAI) between paper and PER method. BASDAI and BASFI scores multiplied by 10 for comparability.

Conclusions: Internet based reporting of PROMs supply valid VAS data. DAS28 scores from the internet-based method presents an acceptable alternative to the traditional paper formats.

**THU0633** TEMPERATURE SENSITIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Mandi, F. Alasti, A. Kerschbaumer, R. Kaltenberger, T. Krennert, G.M. Suss, U. Lachmann, J.S. Schuiling, D. P. 1,2,3,4 Rheumatology, Medical University of Vienna; 2Central Institute for Meteorology and Geodynamics, Vienna, Austria

**Background:** Studies evaluating weather sensitivity among patients with rheumatoid arthritis (RA) have yielded conflicting results.

**Objectives:** To evaluate whether patients with RA exhibit sensitivity to outside temperature.

**Methods:** We assessed correlation between mean daily temperature and self-reported pain (by visual analogue scale), and patient’s global assessment of disease activity (PGA). Assessments documented in the RA database of our department as well as the average temperature obtained from the Central Institute for Meteorology and Geodynamics, were matched on a daily basis for a period of 10 years between 2005 and 2015 and analyzed using generalized estimating equation (GEE) and a mixed model analysis (MM). Patients with <5 visits in the study period, or with <1 visit/quarter or with pain=0 in ≥3 consecutive visits and those living outside of the catchment area were excluded. Overlap between responsiveness of pain or PGA to temperature was calculated by Cohen's kappa.

**Results:** A total of 399 patients with RA (average disease duration at first visit: 6.0±7.6 years, average age: 57.7±13.9 years, 82% female, mean CDAI 19.7±11.5, 59.9% rheumatoid factor positive) were analyzed. Lower temperatures correlated significantly with higher pain levels (estimate: -0.07, p=0.021) in GEE, however, the effect size was very small. When we performed MM with temperature as independent variable and VAS pain or PGA as dependent variable, the majority of patients showed no sensitivity to temperature, however 22% of patients were significantly sensitive to cold temperature with an estimate of -0.29 (p=0.0001) for pain and -0.21 (p=0.0005) for PGA (Figure 1). When we evaluated whether patients who demonstrate temperature-sensitivity to pain also exhibit temperature-sensitivity to PGA, we found an excellent overlap between the two patient groups (kappa: 0.81).

**Conclusions:** Our results indicate that a subgroup of patients with RA show significant sensitivity to cold temperature, and that these patients are characterized by higher pain and PGA levels at lower daily temperatures. These aspects may have to be taken into account in longitudinal analyses of disease activity of RA.

**THU0634** COMPARING PREFERENCES OF PATIENTS WITH RHEUMATIC DISEASES, OF RHEUMATOLOGISTS, NURSES AND PHARMACISTS TOWARDS THE TREATMENT OF RHEUMATIC DISEASES WITH BIOLOGICAL AGENTS: RESULTS FROM THE CARA STUDY

P. Sarzi-Puttini, P.A. Cortesi, L. Sinigaglia, C.M. Montecucco, R. Giacomelli, G. Lapadula, A. Giardino, G. Didoni, L. Scalone, R. Knevel, F. Alasti, P. Mandl, R. Giacomelli, G. Lapadula. 1Rheumatology, Brigham and Women’s Hospital, Boston; 2Harvard Medical School, Cambridge, United States; 3Rheumatology, Leids Universitair Medisch Centrum, Leiden, Netherlands; 4Broad Institute, Cambridge, United States

**Background:** Electronic medical records (EMR) have emerged as a large-scale data collection option for observational studies. These huge data registries create new opportunities to study the rheumatologic phenotype and the real-life implications for these diseases. EMR usage poses new questions of quality management, such as how to reliably identify patients with the disease or phenotype of interest, as well as bioinformatic tools to handle the magnitude of data.

**Objectives:** The algorithms used to identify cases are often not validated and overly simplify by using one financial code, or they are well-validated but require very specific information which hampers the applicability to other datasets.

**Methods:** Aim I: Test the accuracy of the identification of patients with rheumatoid arthritis (RA) using the financial coding system.

Aim II: Develop a simple and precise algorithm to select patients with RA that is easy to implement at other centers.

**Results:** Aim I: Out of the 16,183 Rheumatoid arthritis patients in the Leiden out-patient EMR system 400 charts were randomly selected and reviewed for the Rheumatologist diagnosis. Next, the charts were reviewed by 200 randomly selected patients that were labeled as RA in the financial system.

Aim II: To enable generalizability, only codified data that was obtained at regular outpatient clinic visits was used. Lasso regression was applied to identify the most discriminative variables.

**Conclusions:** The vast majority of patients that are classified as having RA are registered as such in the financial system. However, a substantial number of patients are registered as RA in the financial system are not classified as RA in clinical charts. Using widely available data on anti-CCP status, MTX prescription...
and visit count improved the selection of RA patients from a 67% to 90% accuracy. The combination of these variables provides a widely applicable algorithm, as they are broadly registered in Rheumatology clinics.

THU0636 INFLUENZA AND MENINGOCOCCAL C VACCINATIONS IN A COHORT OF PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES: ADHERENCE, SAFETY AND IMMUNORESPONSE

R. Vagelli, C. Tani, L. Maggi, E. Elefante, A. Parma, E. Cioffi, T. Talarico, C. Baldini, C. Stagnaro, A. Delle Sedie, S. Vagnanni, M. Mosca. Department of Clinical and Experimental Medicine, Rheumatology Unit, University of Pisa, Pisa, Italy

Background: The EULAR recommendations for vaccination in adult patients with autoimmune rheumatic diseases strongly recommend inactivated influenza vaccination. Insufficient data are available about safety and efficacy of meningococcal C vaccination. In 2015–2016, after an increased incidence of meningococcal C infections in our country, the health care system has promoted a free meningococcal vaccination campaign.

Objectives: To evaluate the adherence to the EULAR recommendations for influenza vaccination and to the meningococcal C vaccination campaign in a cohort of patients with autoimmune rheumatic diseases and to assess their efficacy. The safety in terms of immune response to meningococcal C vaccination has been also evaluated.

Methods: Consecutive in- and out-patients seen at our unit from February to December 2016 were enrolled in the study. A questionnaire created ad hoc the following data were collected: the percentage of patients who underwent influenza and/or meningococcal C vaccinations in the previous 12 months, the occurrence of adverse events and of disease flares after vaccinations, according with the report from the patients and with the rheumatologist clinical evaluation. Seroconversion rates in patients with previous immune control were assessed using MKBA kits for biologic anti-meningococcal ACWY IgG antibodies. Antibody titres were expressed in U/ml and according with kit reference values were classified in absent, low, medium and high titre.

Results: 286 patients (91% female) (143 SLE, 68 RA, 60 Scleroderma, 11 Sjögren Syndrome, 3 Behcet disease and 1 dermatomyositis) were included in the analysis. The mean age at evaluation was 52.9±16.1 years, mean disease duration was 15.3±10 years. The 53.1% of patients was taking steroids, at an average dose of 4.2 mg of 6-metilprednisolone/day. 124/286 (46.9%) patients were on immunosuppressive therapies, of which 49/134 (36.6%) kits for biologic agents. The 19.9% (57/286) of patients underwent influenza vaccinations and the 13.3% (38/286) meningococcal C vaccination. 8 patients underwent both vaccinations. No disease flares were observed after vaccination: seven patients reported non-specific adverse events after influenza (fever, discomfort, nausea, arthralgia) and 2 patients after meningococcal C vaccination (fever, rash at the injection site, discomfort). Seroconversion after meningococcal vaccination was analysed in 27 patients and 9 healthy subjects, no statistically significant differences in terms of antibody response to meningococcal vaccination were observed between these two groups (T-test). Treatment with steroids and immunosuppressive drugs did not influence antibody titres.

Conclusions: These data highlight the poor adherence to international recommendations on influenza vaccination in patients with autoimmune rheumatic disease at our Unit. The adherence to the meningococcal vaccination campaign conducted in our country in 2015–2016 was also low. Our data confirm the safety of these vaccinations and show that the immune response elicited by meningococcal C vaccination is comparable to healthy controls and is not influenced by therapy

THU0637 PATIENT’S AND RHEUMATOLOGIST’S PERSPECTIVES ON THE FOLLOW-UP INTERVAL AS A TOOL FOR OPTIMIZED OUTPATIENT TREATMENT

S. Hermann, S. Fögner, E. Wiebe, T. Alexander, G.R. Burmester, F. Buttgereit. Dept. of Rheumatology, Charité, Berlin, Germany

Background: Scientific progress and better disease awareness constantly lead to increasing patient numbers in rheumatology which requires optimization of patient care.

Objectives: The aim of this study was to evaluate and to optimize the procedures of patient care in an university-based outpatient rheumatology setting in Berlin, Germany.

Methods: One hundred patients with rheumatoid arthritis (80 women, 20 men, mean age 61.2 years, mean disease duration 12.9 years) were independently assessed both by a rheumatologist and via patient-reported self-assessment questionnaires. Current follow-up interval (usually 3 months), patient’s perspective on follow-up intervals, signs of disease activity as well as individual patient concerns were recorded. Satisfaction with follow-up intervals was grouped into three categories: too early, just right/opportimal, too late.

Results: Based on the physicians perspective, 46 patients presented at the optimal time point, 51 too early, and three too late. The patients reported the category “just right” in 82 cases, too early follow-up in 10 cases and too late in 8 cases. Of note, 51% (42 individuals) of all patients with self-reported satisfactory follow-up interval were judged to visit the outpatient department too early by the expert rheumatologist. When taking into account the follow-up interval and optimal satisfactory levels, 62% of patients were concluded to visit the department too early, those who revisited anew about 12 months (n=46), and in 12% of those who were seen again after 5–6 months (n=17). 82% of patients in the latter group were judged to revisit just right by the physician.

Conclusions: There was a high proportion of overlap in the views on the satisfaction with follow-up intervals between physicians and patients, especially in patients who were seen every 3–4 months, a high proportion was deemed to could have come later to the outpatient care unit from a purely medical point of view. Here we see a way to stretch the interval to 5–6 months without risking a long-term deterioration in patient care. However, this measure should be flagged by patient education and good collaboration with the general practitioners.

Acknowledgements: We thank AbbVie for financial support in the development of measures to optimize out-patient management in patients with rheumatoid arthritis. The sponsor did not influence the scientific results.

THU0638 PREVALENCE AND DIRECT HEALTHCARE COSTS OF UPPER GASTROINTESTINAL (UGI) ADVERSE EVENTS IN ASIAN RHEUMATIC PATIENTS ON LONG-TERM NON-STEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDS)

S.L. Pok 1, F.H. Shabaruddin2, J.Y. Teng2, M. Dahlau3, C.T. Ng1, S. Sockalingam1, M.S. Said4, A. Rosman5, I.S. Lau6, L. Moid Isa6, H. Hussain6, S. Mahadeva6. 1Dept. of Rheumatology; 2Dept. of Medicine; 3Dept. of Social & Preventive Medicine, University of Malaya; 4Dept. of Rheumatology, National University of Malaysia, Kuala Lumpur; 5Dept. of Rheumatology, Selangor Hospital, Selangor; 6Dept. of Rheumatology, Putrajaya Hospital, Kuala Lumpur, Malaysia

Background: NSAIDs are frequently used in patients with rheumatoid arthritis (RA) and osteoarthritis (OA). NSAID-induced UGI adverse events are well described in the Western population but data is lacking in Asian patients.

Objectives: To describe the prevalence and direct healthcare costs of NSAID-induced UGI adverse events in a large cohort of RA and OA patients in Malaysia.

Methods: A retrospective cohort study of RA and/or OA patients who received long-term NSAIDs (minimum 4 weeks prescription of any NSAID) between 2010 and 2013 was conducted in 4 large tertiary care centres with rheumatology units in Malaysia. Electronic clinical records and pharmacy prescriptions were reviewed. Resource use data was collected in patients who developed UGI adverse events within the 24 months follow up period. Unit costs were estimated by combining top down (general overheads for hospital services) and bottom up (activity-based costing for clinic visits, hospitalisation, diagnostic investigations, medications) approaches.

Results: 634 patients were included in the final analysis with mean age 53.4±12.5 years, 90% female, diagnosis of RA in 60%, OA in 10% and both RA and OA in 30%. 45% and 8% of patients were on concomitant prednisone and aspirin respectively. 89% of patients had no previous upper GI disease. 59% and 41% of patients were grouped under non-selective and COX-2 inhibitor respectively. 84 (13.2%) patients developed UGI adverse events (Figure 1), consisting of 78 (12.3%) patients with dyspepsia, 5 (0.7%) with peptic ulcer disease (PUD) and 1 (0.1%) with upper GI bleeding (UGIB). The total direct cost was RM37,352 (USD 11,419) with a mean cost of RM447±535 (USD 137±163) per patient (Table 1). The largest cost components were pharmacotherapy (34%), oesophagogastroduodenoscopies (OGD) (23%) and outpatient visits (18%). The mean cost of PUD and UGIB was approximately double (RM806±579 (USD 246±177) and quadruple (RM1,602) (USD 490) of dyspepsia respectively.

Background:

MotherSafe is a free, statewide, phone based counselling service for the general public and healthcare professionals concerned about exposures during pregnancy, pregnancy planning and breastfeeding (1). Obstetric drug information services such as MotherSafe are important in guiding decision-making in pregnancy, breastfeeding and planning of future pregnancies, and are increasingly used worldwide by both patients and healthcare providers (1, 2). At MotherSafe, phone advice is provided by trained telephone counsellors who are generally pharmacists. Data from each phone call is entered onto an electronic document. Some patients are then referred onto the MotherSafe clinic for specialised counselling by a clinical geneticist.

Objectives: To analyse data including patient and medication characteristics and trends from phone calls made to MotherSafe regarding disease modifying antirheumatic drugs (DMARDs) and biologic DMARDs (bDMARDs) from January 2010 to December 2015 regarding conventional DMARDs and biologic DMARDs. SPSS software facilitated statistical analysis.

Results: A total of 135,115 phone calls were made to MotherSafe from January 2010 to December 2015 regarding conventional DMARDs and biologic DMARDs. Of these 2611 phone calls, 65.4% were made by patients and 13.5% by general practitioners. Most phone calls were made in metropolitan New South Wales (69.3%). 43% of phone calls were concerning exposures during breastfeeding, followed by exposures during pregnancy (32.9%), exposures whilst planning pregnancy (17.7%) and paternal exposures (2.9%). Where a specific diagnosis was given, inflammatory bowel disease was the most common indication (18.4%), followed by rheumatoid arthritis (8.2%), Corticosteroids were the most common medication exposure (37.3%), followed by azathioprine (18.8%), sulfasalazine (11.2%) and methotrexate (8.5%).

Most callers just received phone advice, especially if the call was just regarding breastfeeding exposures (73.4%). 383 callers (14.7%) were referred onto the MotherSafe clinic, which is run by a clinical geneticist. bDMARDs made up 9.5% of calls with calls trending to increase over the years, but there was a slight decrease in 2012 and 2013 albeit with small numbers. TNF inhibitors still made up the majority of calls regarding bDMARDs.

Conclusions: This study evaluated the only obstetric medicine exposure information service in New South Wales, Australia. It is the first time that DMARDs and bDMARDs have been analysed for MotherSafe. There was a trend to increasing number of calls regarding bDMARDs over 2010 to 2015, which presumably reflects change in prescribing patterns. This study highlights the need for services like MotherSafe so patients and health care professionals can receive evidence based information and make choices about treatment in pregnancy.

THU0640 SECOND LINE TREATMENT PERSISTENCE AND COSTS AMONG PATIENTS WITH IMMUNE-MEDIATED RHEUMATIC DISEASES TREATED WITH SUBCUTANEOUS TNF-ALPHA INHIBITORS

J. Dalén1, A. Svedbom1, C.M. Black2, S. Kachroo2, 1Mapi group, Stockholm, Sweden; 2Merck & Co., Inc., Kenilworth, United States

Background: For some patients with Immune Mediated Rheumatic Disease (IMRD) discontinuing 1st line treatment with a subcutaneous Tumor Necrosis Factor-alpha inhibitor (SC-TNFi), 2nd line treatment with another SC-TNFi may be appropriate.

Objectives: The primary objective of this study was to describe treatment persistence with 2nd line SC-TNFi stratified by agent in patients with IMRD in Sweden. The secondary objective was to explore the impact of non-persistence with second SC-TNFi on 12 months total healthcare costs.

Methods: We conducted a retrospective study on treatment persistence and health care costs using data from health registers. Adults (~18 years old) previously treated with one SC-TNFi and subsequently prescribed a second SC-TNFi were identified through prescriptions for adalimumab (ADA), etanercept (ETA), certolizumab pegol (CZP) and golimumab (GLM) between 5/6/2010 and 12/31/2012. Prescriber specialty and department were used to exclude patients treated for diseases other than IMRD. Persistence up to 3 years was estimated using non-parametric survival analysis. Given differences in baseline characteristics, analyses were conducted on propensity score matched (PSM) cohorts. Matching was based on age, gender, index diagnosis, Charslon Comorbidity Index and non-biologic DMARD use. Non-treatment health care costs were captured 12 months pre and post initiation of 2nd line SC-TNFi treatment and stratified by persistence status at 6 months.

Results: In total, 845 patients were identified (ADA: 316, ETA: 202, CZP: 140, GLM: 187). PSM cohorts were generated as GLM vs ADA, GLM vs ETA and GLM vs CZP. All patients were captured 12 months pre and post initiation of 2nd line SC-TNFi treatment.

Conclusions: In patients previously treated with a SC-TNFi, GLM exhibited significantly better persistence than ADA and numerically higher persistence than ETA and CZP at 12 and 24 months, findings that are similar to results observed in 1st line SC-TNFi patients. The lower healthcare costs for persistent patients, the choice of 2nd line SC-TNFi among eligible patients may merit careful consideration given its impact on patients and payers.

THU0641 THE DISEASE BURDEN OF SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS FOR PATIENTS AND CAREGIVERS: AN INTERNATIONAL HEALTH RELATED QUALITY OF LIFE SURVEY AND RETROSPECTIVE CHART REVIEW

S. Sheno1, G. Horneff2, M. Cidon3, A. Ramanan4, Y. Kimura5, P. Quarter6, I. Foeldvari7, A. Zett8, K.G. Lomax9, J. Gregson10, A. Tineke11, S. Campbell12, O. Karada˘g2, A. Akdo˘gan2, S. Apra¸s Bilgen2, S. Kiraz2, I. Ertenli2, K. G. Lomax 9, J. Gregson 10, A. Tineke 11, S. Campbell 12, U. Kalyoncu Hospital, Seattle, United States; 2Asklepios Kliniken GmbH, Hamburg, Germany; 3Stanford University, Palo Alto, United States; 4University Hospitals Bristol, Bristol, United Kingdom; 5Hackensack University Medical Center, New Jersey, United States; 6Paris-Des cartes University N ecker-Entzian Maladies Hospital, Paris, France; 7Hamburger Zentrum für Kinder-und Jugend Rheumatologie, Hamburg, Germany; 8Pediatrics Rheumatology, Cleveland Clinic, Cleveland; 9Novartis Pharmaceutical Corporation, New Jersey, United States; 10Novartis Pharma AG, Basel, Switzerland; 11VU University Medical Centre, Amsterdam, Netherlands; 12Navigant Consulting Inc., London, United Kingdom; 13Navigant Consulting Inc., San Francisco, United States; 14Wilhelmina Kinderziekenhuis, Utrecht, Netherlands.

Background: Systemic juvenile idiopathic arthritis (SJIA) is a severe autoinflammatory disease characterised by systemic features including high fevers, rash and arthritis. SJIA can impose a high physical, psychosocial, behavioral and financial burden on patients (pts) and their families.

Objectives: To analyse the impact of SJIA burden of disease burden utilising a SJIA-specific questionnaire combined with physician data about disease severity and treatment in an international, real-world study.

Methods: SJIA treatment centres in France, Germany, Netherland, UK and the US participated. Pts (aged 4–18 years) with confirmed SJIA received one of the following biologic treatments for ≥2 months: anakinra (ANA), canakinumab (CAN), or tocilizumab (TOC). SJIA burden in patients on biologics was assessed using a caregiver questionnaire and retrospective chart review. Validated measures included: Child Health Questionnaire Parent-Form 50 (CHO-PF50), 36-Item Short Form Health Survey (SF-36v2); and Activity and Impairment questionnaires: Specific Health Problem (WPAI:SHP). Caregivers completed function, treatment satisfaction and resource utilization questions.

Results: Sixty-one pts enrolled from June 2015–June 2016: 12 on ANA, 25 on CAN, 24 on TOC; 46% from the US; 48% female; mean age at survey was 11.2 years. Mean age at SJIA diagnosis was 6.4 years, 6 years at start of CAN, and TOC treatment was 9.9, 9.1, and 7.5 years, respectively. Caregivers were 79% female, mean age 41.2 years, 36% reduced or stopped working due to their child's SJIA. Of the pts enrolled ON CAN and TOC, 72% and 46% respectively had previously been on ANA. EQ-5D, ChAQ, CHO-PF50, and WPAI scores were worse in CAN and TOC than ANA pts. Mean (±SD) CHO-PF50 (PHS) and psychosocial (PsS) summary scores were significantly lower in SJIA patients than a normative population (PHS: 40.0±18.2 vs. 53.0±6.8, PsS: 46.2±11.3 vs. 51.2±9.1) as was caregivers’ mean SF-36v2 mental component score (46.2±10.7 vs. 50.0±10). Highest caregiver stresses were worry over long-term SJIA impact on their child (45%) and uncertainty about the future (28%).

Conclusions: Treatment sequencing and patient-reported outcome measures indicate ANA is used as 1st line for severe SJIA while CAN and TOC are used as 2nd/3rd line for severe SJIA. Caregivers expressed stress over the long-term impact of SJIA and fear for the future and had variable treatment satisfaction and resource utilisation levels.

THU0643 WHAT FACTORS RELATE TO PATIENTS CONTRIBUTE LONGITUDINAL DATA USING SMARTPHONE TECHNOLOGY? FINDINGS FROM RA PATIENTS PARTICIPATING IN ARTHRITISPOWER REGISTRY

W.B. Nowell1, I. Yun2, J. Willig3, J. Beaumont4, B. Johnson5, S. Ginsberg6, C. Wiedmeyer5, R. Crow-Hercher 5, B.J. Johnson5, S. Yang5, J.R. Curtis6, 1Global Healthy Living Foundation, Upper Na yak; 2University of Alabama at Birmingham; School of Public Health; University of Alabama at Birmingham, Birmingham; 4Northwestern University Feinberg School of Medicine, Evanston; 5CreakyJoints, Global Healthy Living Foundation, Upper N a yak, United States

Background: Data capture of patient reported outcomes (PROs) is gradually shifting from data collection on paper in medical office settings to use of computer or mobile based technologies between doctor visits. Concerns have been raised that patients may have limited interest in contributing data over time or that they may only record new data when there has been a change in their clinical status.

Objectives: The objective of this study was to evaluate the patterns and factors associated with longitudinal PRO data capture among participants in the PCORI-funded Patient Powered Research Network for adult rheumatologic conditions, ArthritisPower.

Methods: Patients in the registry were asked to voluntarily complete PROs including the RAPID3 and 4 PROMIS instruments plus disease-specific information via a mobile application (App) on their smartphone or computer. We evaluated the average time it took the patient to record each of the instruments and the total number of unique days the patients recorded PROs on the smartphone. Given the newness of the registry (launched late 2015), longitudinal data was defined as contributing at least 2 sets of PROs on unique calendar days. We tested the hypothesis that patients would contribute longitudinal data only when at least one of their PROs exceeded a minimally important difference (MID) of any of the 5 PROs examined (generally 2–3 units for PROMIS instruments; 3.6 units for RAPID3). Demographic factors associated with multiple PRO data capture among participants in the PCORI-funded Patient Powered Research Network for adult rheumatologic conditions, ArthritisPower.

Results: At the time of analysis, ArthritisPower had recruited 2,103 patients, most (approximately 68%) had RA, and 20% provided their Twitter handle. Average (SD) age was 50 (12); 87% were women. The mean assessment time for each of the PROMIS instruments ranged from a low of 16 seconds (Sleep Disturbance) to a high of 155 seconds (Sleep Interference). The average score for Pain Interference was 64.3 (SD: 6.3), Physical Function 37.5 (6.5), Sleep Disturbance 59.3 (8.4), Fatigue 64.2 (8.4), and RAPID3 15.7 (5.3). Of 1,946 patients who registered the Smartphone App more than 3 months prior to analysis, 20.6% never contributed any PRO information, 53.3% answered once, and 26.1% answered at least twice. Among patients with longitudinal data (>2 assessments), the mean change score of PROs between pairwise PRO assessments was <1 point for all instruments.
Patient Decision Making in Hip and Knee Arthroplasty

Objectives

The objective of this study was to identify the decisions that are most important to patients undergoing hip and knee arthroplasty and the factors they view as important in making those decisions.

Methods

Forty-nine U.S. participants were recruited from ArthritisPower Patient-Powered Research Network and CreakyJoints arthritis patient community to participate in structured one-hour discussions held via webinar during January to April 2016 to understand patients’ experiences with joint replacement. Patient described decisions that were most important to them and the factors they used to make those decisions. Discussions were transcribed and coded to identify themes; patient decisions and factors were identified and categorized and co-occurrence of decisions and factors was tabulated. Demographic and procedure-related characteristics were captured.

Results

Eight decisions emerged that were influenced by at least ten factors (Table). The most important decisions involved whether to have surgery, selection of surgery date, surgeon, facility, implant device, and ancillary health care professionals (HCPs) and services. Factors included current situation, expectations of having or not having surgery, professional and word-of-mouth familiarity with surgeon/HCP, procedure, services, and device, and perceived value. Patients’ current situation and health status and their expectations of surgery were most commonly used to make decisions about whether and when to have surgery. Patients’ trust of and communication with doctors was the most commonly factor used when deciding on arthroplasty surgeon.

Conclusions

Arthroplasty patients are concerned about a variety of decisions. Patient-centered research should maximally address questions of importance to patients and this study is a first step in identifying and prioritizing topics that matter most to patients and the information that patients currently use to make joint replacement decisions.

INTERCHANGEABILITY FROM INFLIXIMAB ORIGINATOR TO INFLIXIMAB BIOSIMILAR: EFFICACY AND SAFETY IN A PROSPECTIVE OBSERVATIONAL STUDY ON 89 PATIENTS

Y. Presberg 1, V. Foltz 2, C. L'Amour 2, P. Tilleul 2, D. Zerkak 2, G. Gard 1, B. Fautrel 3, 1Pharmacy; 2Rheumatology, AP-H pitié salpêtrière hospital; 3Université Pierre et Marie Curie (UPMC)-Paris 6, Paris, France

Background: Biosimilar biologic disease modifying anti-rheumatic drug (bsDMARD) are supposed to offer a real economic advantage for these diseases for the same health benefit. While the administration of a biosimilar to a new patient is widely accepted, the switch from a biologic originator DMARD (boDMARD) to its biosimilar remained questioned.

Objectives: This study aimed to assess the safety and efficacy of switching from an IV anti-TNF boDMARD to its bsDMARD in patients with rheumatic arthritis, spondyloarthritides, juvenile arthritis and uveitis.

Methods: Prospective real-life study in the rheumatology unit of La Pitié- Salpêtrière Hospital, from February 2016 to December 2016. Patients initially treated with the boDMARD infliximab (Remicade®), all switched to infliximab bsDMARD (Inflectra®) after patient’s information by a rheumatology nurse. The dose and administration schedule remained unchanged at the switch. Our primary endpoint was infliximab maintenance rate. Secondary endpoints were evolution of disease activity, as well as evolution of both infliximab trough levels and anti-drug antibody (ADA) serum levels before and after the switch. In addition, safety events were monitored.

Results: We identified 89 patients – spondyloarthritis (61%), rheumatic arthritis (22%), psoriatic arthritis (11%), juvenile arthritis and uveitis (1%) – in rheumatology who had been switched to boDMARD infliximab to its bsDMARD. Clinical assessment was based on DAS28 (peripheral joint involvement) or BASDAI (axial involvement) scores in patients remaining treated with infliximab; 6 patients (7%) stopped the treatment due to a loss of efficacy. As shown in Figure 1, there is no significant change in disease activity before and after having switched patients to infliximab biosimilar. The ADAAdas were detected in 10 patients, 7 with high titer (>200ng/mL) and 3 with moderate titer (between 50 and 200 ng/mL). It was significantly correlated with low trough levels of IFX (<0.3 μg/mL). Among them, 6 (4 with high titer; 2 with moderate titer) also had a poor clinical response before switch (refractory patients). 4 ADA-positive patients (3 with high titer; 1 with moderate titer) were still good clinical responders.

Conclusions: The interchangeability of infliximab boDMARD to its bsDMARD does not rise any efficacy and safety concern in our experience. The role of drug and ADA monitoring during the switch remains to be further explored.

INTERACTIONS BETWEEN STEPS PER DAY AND RISK FACTORS FOR OSTEOARTHRITIS IN A POPULATION BASED COHORT STUDY

Z. Zhu 1,2, W. Han 1, S. Zheng 1, K. Wang 1, T. Winzenberg 1, F. Cicuttini 3, 1Musculoskeletal Unit; 212779, Hobart; 3Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia

Background: It is clear that exercise helps the symptoms of osteoarthritis. However, the relationship between physical activity (PA) and progression of knee osteoarthritis (OA) remains controversial. Moreover, no guideline on the amount of PA to prevent OA progression in general older population has been recommended, and it is still uncertain whether PA should be promoted among subgroups with knee OA such as female gender, obesity, radiographic osteoarthritis (ROA) and knee injury history. Osteophyte (OP) has long been viewed as a defining structural feature of knee OA. Recently, MRI-detected OPs have been shown to be more sensitive to change than radiographs.

Objectives: The aims of this study were to describe the longitudinal association between objectively-measured PA and knee MRI-detected (OPs), and to test the interactions between PA and gender, obesity, ROA or knee injury history on the OPs.

Methods: 408 community-dwelling adults aged 51–81 were randomly selected from local community and measured at baseline and 2.6 years later. T1-weighted fat suppressed MRI was used to evaluate knee OPs at baseline and after 2.6 years. PA was assessed at baseline by pedometers (steps per day) and categorized as 3 groups: low PA (<7499 steps per day), moderate PA (7500 to 9999 steps per day) and high PA (>10000 steps per day). Radiographs were obtained and scored for individual features of radiographic osteoarthritis (ROA). Knee injury history was recorded by questionnaire and divided into body mass index (BMI) was calculated. Logistic regression and log binomial regression were used in longitudinal analyses.

Results: In total study sample, doing moderate PA was associated with reduced risk of an increase in MRI-detected OPs, compared to low PA (RR=0.73, p=0.03).

There were significant interactions between PA and gender, obesity, ROA or knee injury history (all p<0.05) for an increase in MRI-detected OPs. In stratified analyses, moderate PA was protective against an increase in MRI-detected OPs in females (OR=0.23, p<0.01), obese participants (OR=0.23, p<0.01), participants with ROA (OR=0.45, p=0.02) and participants with knee injury history (OR=0.05, p=0.02). The significant associations still existed after further adjustments for age, sex, BMI, ROA and/or knee injury history (where appropriate). High PA was not associated with an increase in MRI-detected OPs in total sample or the stratified analyses but there were relatively few in this category.

USE OF OUTPATIENT RHEUMATOLOGIC HEALTH CARE SERVICES BEFORE AND AFTER SWITCH FROM ORIGINATOR TO BIOSIMILAR INFliximab

B. Glintborg 1, J. Sørensen 2, M.L. Hefland 1. 1The DAnbio registry and Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopaedics, Glostrup; 2University of Southern Denmark, Odense, Denmark; 3Royal College of Surgeons in Ireland, Dublin, Ireland

Background: According to Danish national guidelines issued in 2015, pts (pts) with inflammatory rheumatic diseases in routine care treatment with originator infliximab (IXN) must switch to the cheaper biosimilar infliximab (CT-P13). This switch was done for economic reasons (CT-P13 64% cheaper than IXN). Since any treatment change potentially induces additional guidance of pts and use of hospital services, it is relevant to investigate whether the switch affected use of hospital resources.

Objectives: To study difference in rates of outpatient activities and services provided 6 months before vs after the switch to CT-P13 for pts treated at rheumatologic departments which provide infliximab treatment.

Methods: The switch population and switch dates were identified in the Danish quality registry, DAnBio (1). Vital status was validated in the Central Person Registry. The Danish National Patient Registry (NPR) provided information regarding outpatient contacts and services. The use of 16 types of services relevant to the rheumatologic specialty was identified and included outpatient visits, infliximab infusion, nurse counselling, phone consultation, and rheumatologic ultrasound. Number of days with these services was counted. Services performed around the switch date were analyzed separately. Thus, for each patient the following rates were calculated 6 months before and after the switch: 1) days with at least one outpatient service provided, and 2) number of services provided. In addition, the weekly rate of days with services was calculated.

Results: Among 802 pts identified, 769 had available NPR outpatient data from hospital departments of rheumatology. The 769 pts had 1484 outpatient treatment contacts at the included rheumatology departments with a total of 9243 days with services provided (including 693 on the switch date). The mean rate of days with services provided was 5.4 before the switch and 5.7 after switch (p=0.0003).
weekly rate of days with services showed no obvious differences before and after the switch but had a clear 8-week pattern (corresponding to the average infusion interval) (Figure).

The total number of services provided was 19,752 (2,019 of these on the switch data). There were significant increases in the rates before vs after switch for 6 of the 16 service categories, although the mean rates were small: telephone consultations (mean rate 1.0 before vs 1.2 after), patient guidance (0.5 vs 0.4), intravenous medication (0.0 vs 0.1), clinical controls (2.1 vs 2.3) and clinical investigations (0.3 vs 0.5), whereas the rate of infliximab treatment decreased (3.1 vs 3.0) (all p<0.05, insignificant results not shown).

Conclusions: This analysis showed that there were only small differences in the rates of days with outpatient services and rates of services 6 months before and after the switch from original to biosimilar infliximab. Thus, it is unlikely that the switch is associated with substantially higher cost of health care resources.

**MANDATORY CHOICE OF FIRST BDMAARD IN DENMARK – AN OPPORTUNITY TO STUDY REAL-LIFE EFFECTIVENESS? RESULTS FROM THE DANBIO REGISTRY**

K.L. Gren1, B. Glintborg1, M. Nørgaard2, F. Mehnert2, M. Østergaard1, L. Dreyer1, N.S. Krogh2, M.L. Hetland1, DANBIO, COPECARE, Department of Clinical Epidemiology, Aarhus; Zitelpol Aps, Copenhagen, Denmark

**Background:** In Denmark, biological treatments (bDMARDs) are tax paid. Since year 2013, The Danish Council for the Use of Expensive Hospital Medicines (RADS) has issued recommendations with annual updates regarding RA patients (pts) initiating biological treatment, dictating a mandatory choice of the cheapest bDMARD (1). Furthermore, the percentage of pts expected to be treated according to the RADS recommendation per year is stated. For pts treated with concomitant csDMARDs and those who were not.

**Methods:** For each of the three RADS periods bio-naive pts with RA were included. RADS guidelines and those who were not.

**Results:** More than 90% of adults with rheumatological diseases treated with bDMARDs in routine care.

**Conclusions:** To characterize Danish RA pts initiating first line, first choice treatment with a bDMARD in combination with MTX in the three RADS periods and to explore the degree of compliance to RADS recommendations. Furthermore, to investigate differences in baseline characteristics between those pts who were compliant to RADS guidelines and those who were not.

**THU0655**

**THE EFFECT OF ANTI-TNF THERAPY ON WORK PRODUCTIVITY AND ACTIVITY IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS OVER ONE YEAR – REAL LIFE DATA FROM THE CZECH BIOLOGICS REGISTRY ATTRA**

J. Zavada1, L. Szczylikova2, K. Pavelka1, P. Horák1, J. Vencovsky1 on behalf of collaborators of the ATTRA registry, rheumatology, Institute of Rheumatology, Prague; Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno; Internal Medicine, Faculty of Medicine and Dentistry, Palacký University, Olomouc, Czech Republic

**Objectives:** To assess the effect of anti-TNF therapy on work productivity using the Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP) questionnaire in patients with RA, PSA and AS in the real life setting. In the Czech Republic, anti-TNF-therapy is reimbursed for RA if DAS28<3.2 and for AS if BASDAI<4 and CRP<ESR elevated above normal.

**Methods:** WPAI-SHP scores were collected for all patients enrolled in ATTRA since 2012 at baseline and after 12 months of anti-TNF exposure. Baseline patients with RA (n=352), AS (n=442) and PSA (n=133) starting anti-TNF therapy with available baseline data on demography, disease duration and physical function, and WPAI-SHP at baseline and at 12 months were included in this analysis. Patients older than 60 years, on maternity leave or students were excluded. Only patients working for pay at baseline were assessed for WPAI-SHP summary score (mean % work time missed), and for WPAI-SHP pain (mean % productivity loss at work), overall work impairment (mean % overall work productivity loss), and activity impairment (mean % productivity loss in regular activities).

**Results:** Baseline characteristic were significantly different between diagnoses (Table 1). Working status changed significantly only in patients with RA (employed more were heterogeneous than than in clinical trials, reflecting routine care. Overall, compliance to recommendations was good. Thus, the national guidelines in Denmark with mandatory choice of the first biological drug may provide an interesting opportunity to study effectiveness of bDMARDs in routine care. This highlights observational studies as a valuable supplement to RCTs.

Conclusions: Appropriateness criteria for BT dose reduction in three inflammatory conditions were developed and the preliminary prevalence study suggests that BTO was wisely applied. However, further research in this field is needed to determine the real prevalence of clinical profiles of patients undergoing BTO in daily clinical practice and to validate these criteria in real life.

THU0652 ASSESSING BIOSIMILARS USING REAL WORLD DATA: THE COMPLEXITY OF CHOSING A COMPARATOR AND UNDERSTANDING UPTAKE

Department of Medicine Solna, Karolinska Institutet, Stockholm; 2Umeå University, Umeå; 3Lund University and Skåne University hospital, Lund; 4 Sahlgrenska Academy, University of Gothenburg, Göteborg; 5 Linköping University, Linköping, Sweden

The introduction of biosimilars has been linked with concerns regarding how to best monitor their similarity vs. the originator product using real world data.

Methods: Data from the Swedish Rheumatology Quality register (SRQ) was used to identify all patients with rheumatoid arthritis (RA), anklosing spondylitis (AS), psoriatic arthritis (PsA), and other spondyloarthropathy (SpA), who started a treatment with infliximab (originator Remicade or biosimilars Remsima or Inflectra) between 1st Mar 2015 and 30th Sept 2016 or with etanercept (originator Enbrel or biosimilar Benepali) between 1st April 2016 and 30th Sep 2016.

Results: During the study period, a total of 1833 patients started an infliximab treatment and 1793 started etanercept. These patients were either bDMARD-naive (patients without a history of any biological treatment), non-medical switchers (patients who switched from the originator product), or patients who had a history of a previous (but not the same) bDMARD (Table 1). These three groups were not evenly distributed across originators or biosimilars, and had different baseline demographic and disease characteristics.

The uptake in terms of treatment starts was faster for Benepali (it covered more than 90% of this part of the etanercept market after only 3 months) as compared to Remsima and Inflectra (together they accounted for 88% of this section of the infliximab market after 10 months). The uptake of biosimilars in terms of proportion of all patient on treatment was, at the end of September 2016, 27%

Figure 1. Number of patients starting, and on, respectively, infliximab or etanercept by month. Green: total, red: biosimilar, blue: originator.
of all infliximab (after 18 months of marketing) and 16% of etanercept (after 5 months since marketing).

In contrast to the bio-naïve group and those with a history of a previous (but not the same biological), there was no readily available comparator group for the non-medical switcher group. To this end, we assessed three tentative definitions for ‘switch’, i.e. (i) patients 18–65 years old, (ii) patients who had switched within 6 months of starting their current medication, or (iii) patients who had switched within 6 months of starting their current medication. Based on these definitions, we found that 11% of infliximab patients and 37% of etanercept patients had switched within 6 months of starting their current medication. These findings suggest that infliximab patients are more likely to switch than etanercept patients.

Conclusions: This study provides evidence that infliximab patients are more likely to switch than etanercept patients within 6 months of starting their current medication. This may indicate that infliximab patients are more willing to try a different treatment, even if their current medication is effective. Further research is needed to determine the underlying reasons for this difference in switching behavior.

THU0653 | PREVENTING RHEUMATOID ARTHRITIS: A GENERAL POPULATION PILOT STUDY ON PERSPECTIVES OF THE RISK OF DEVELOPING THE DISEASE AND POTENTIAL PREVENTATIVE INTERVENTIONS

M. Harrison1,2, N. Bansback1,2, L. Spooner1, K. Milbers2, C. Koehn3, M. Harrison1,2, N. Bansback1,2, L. Spooner1, K. Milbers2, C. Koehn3, M. Hudson1, University of British Columbia; 2Centre for Health Evaluation and Outcome Sciences; 3Arthritis Consumer Experts, Vancouver; 4McGill University, Montreal, Canada

Background: Evidence suggests that treatment of people at risk of rheumatoid arthritis (RA) with anti-rheumatic drugs can prevent the onset of disease. There are ongoing randomized controlled trials on the efficacy of preventing RA. However, even if these trials are successful, there will be uncertainty around the potential benefits of these programs in practice; namely, the ability to predict which patients are likely to be acceptable to pre-symptomatic people at high risk of RA. Our survey suggests that people value the potential benefits of preventative RA treatments, then between their preferred treatment and “no treatment for now”. The treatment (risk of developing RA, how treatment is taken, chance of side effects, certainty in estimates, health care provider’s opinion) and test attributes (chance test is wrong, who recommends treatment) were most influential treatment preferences, but risk reduction, how treatment is taken, and included 2 consistency checks. Responses were analyzed using a conditional logit regression model to estimate the significance and relative importance of attributes in influencing preferences.

Results: 201 respondents completed the survey. The majority of the sample was 25–54 years old (modal age category: 30–39 years (38%) and 50% were female. 23 members (11%) reported having a physician diagnosis of RA, and 91 (45%) had a family member or close friend with RA. All attributes’ levels significantly influenced treatment preferences, but risk reduction, how treatment is taken, and health care provider preference were most influential. Respondents were most willing to trade a reduction in risk of RA for a treatment preferred by their health care professional and an oral route of administration. Respondents had a similar willingness to start a medication. The medication was described using eight scenarios (manipulated using a 2x4 design). We varied the probability of an adverse event (pneumonia requiring hospitalization): 2% or 2%, and the risk presentation format: numbers, numbers + IA, numbers + balance beams (BB), or both influence willingness to start a medication.

Conclusions: SES affects how subjects respond to risk presentation formats. IA marginally increases willingness in high SES subjects, while BB increases willingness in low SES subjects; when both IA and BB are present, SES differences disappear. BB, when not accompanied by an IA, may decrease willingness in high SES subjects. These results demonstrate the differential effects of risk presentation formats, and highlight the need to identify mechanisms underlying their effects when implementing decision-support tools.

THU0654 | THE INFLUENCE OF RISK PRESENTATION FORMAT ON WILLINGNESS TO START A MEDICATION

R. Cozmuta1, L. Fraenkel1, E. Wilhelms2, V. Reyna4, J. Nolte4, 1Emory University, Atlanta; 2Yale University, New Haven; 3Vasser College, Poughkeepsie, NY; 4Cornell University, Ithaca, NY, United States

Background: Patients with rheumatoid arthritis frequently refuse to escalate care because they overweight the probability of adverse events. Effectively communicating risk information to patients is difficult. Several approaches have been developed to facilitate comparative risks; however, recent data suggest that current approaches have a limited impact on risk perceptions and willingness to take medication.

Objectives: The objective of this study was to examine whether an icon array (IA), an illustration of the gist of how medications regulate the immune system (a series of balance beams), or both influence willingness to start a medication.

Methods: Patients with a rheumatic disease were mailed a survey in which they were asked to imagine that their physician was recommending a new medication. We varied the probability of an adverse event (pneumonia requiring hospitalization): 2% or 2%, and the risk presentation format: numbers, numbers + IA, numbers + balance beams (BB), or both numbers + both. Route of administration, benefit, and cost were held constant. Each subject responded to a single, randomly-assigned scenario. We controlled for socioeconomic status (SES), using a variable including both difficulty paying for medications and as education, in a full-factorial model testing willingness to take the medication (measured on a 5-point scale).

Results: Of 1453 surveys, 465 patients completed the survey. Overall, the mean (SD) age was 59.0 (14.8); 79.7% were female; 83.2% White and 39.1% were classified as having low SES. There were no statistical differences in patient characteristics across the risk presentation formats. Willingness to start the medication was predicted by the interaction between the risk presentation format and SES (F =2.9, p=0.03). Willingness by SES status is described in the Figure 1. Among low SES subjects, addition of an IA did not affect willingness compared to the numbers-only format. In contrast, addition of BB (mean difference =0.47, p=0.07), or both IA and BB increased willingness (mean difference =0.48, p=0.04). Among high SES subjects, addition of an IA or BB or both did not influence willingness compared to the numbers only format. However, both formats including an IA increased willingness compared to the BB format among high SES subjects (mean difference IA vs BB =0.53, p<0.01; mean difference IA vs IA + BB = 0.48, p=0.02).

Conclusions: SES affects how subjects respond to risk presentation formats. IA marginally increases willingness in high SES subjects, while BB increases willingness in low SES subjects; when both IA and BB are present, SES differences disappear. BB, when not accompanied by an IA, may decrease willingness in high SES subjects. These results demonstrate the differential effects of risk presentation formats, and highlight the need to identify mechanisms underlying their effects when implementing decision-support tools.

THU0655 | DO VISUAL DECISION AIDS HELP PATIENTS CORRECTLY DIFFERENTIATE BETWEEN A 2% AND A 0.2% RISK?

R. Cozmuta1, L. Fraenkel1, E. Wilhelms2, V. Reyna4, J. Nolte4, 1Emory University, Atlanta; 2Yale University, New Haven; 3Vasser College, Poughkeepsie, NY; 4Cornell University, Ithaca, NY, United States

Background: Studies have found that patients ignore probabilities when making treatment decisions.

Objectives: The objective of this study was to examine whether addition of an icon array (IA), a series of three consecutive balance-beam (BB) illustrations depicting how medications regulate the immune system, or both resulted in improved decision-making.

Methods: Patients currently being treated for a chronic inflammatory rheumatic disease were mailed a survey in which they were asked to imagine that their symptoms had recently worsened and that their physician was recommending a new medication. The medication was described using eight scenarios (manipulated using a 2x4 design). We varied the probability of a serious AE (pneumonia...
CONCLUSIONS: Experience with etanercept biosimilar has been growing in Germany, as reflected by the growing market share. Based on the current number of patients treated with etanercept biosimilar, savings of 21.1 million EUR are projected to be returned to the health system in Germany annually. The economic burden associated with etanercept treatment is expected to decrease further with an increase in market share for the etanercept biosimilar. These savings can have a significant impact on broadening patient access to biologic treatment in Germany.

A TELE-HEALTH FOLLOW-UP STRATEGY FOR TIGHT CONTROL OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: RESULTS OF THE NON-INFERIORITY RANDOMISED CONTROLLED TRAIL (THE TERA STUDY)

A. Thurai1,2, K. Steengaard-Pedersen1,2, M. Axelsen3, U. Fredberg3,4, K. Lomborg 6,7, T. Maribo8,9.

Background: Despite the increased prevalence of rheumatoid arthritis (RA) in recent years, no studies have yet investigated the effect of monitoring disease activity through a standardized tele-health strategy in patients with RA (1).

Objectives: To test the effect of patient-reported outcome (PRO) based tele-health follow-up for tight control of disease activity in patients with RA, and the differences between tele-health follow-up performed by rheumatologists or rheumatology nurses.

Conclusions: Experience with etanercept biosimilar has been growing in Germany, as reflected by the growing market share. Based on the current number of patients treated with etanercept biosimilar, savings of 21.1 million EUR are projected to be returned to the health system in Germany annually. THU0567 ETANERCEPT BIOSIMILAR USAGE AND ASSOCIATED COST SAVINGS IN GERMANY

K. Thakur, A. Handrich, E. Psachoulia. Biogen, Zug, Switzerland

Background: The first etanercept biosimilar was approved by the European Commission in January 2016. Of the 27,000 patients* estimated to be treated with etanercept biosimilar in the Europe, 5,122 patients* are estimated to be treated with etanercept biosimilar in Germany at the end of the analysis period. Its usage in Europe may support healthcare sustainability by reducing costs, thereby relieving the burden associated with etanercept treatment is expected to decrease further with an increase in market share for the etanercept biosimilar. These savings can have a significant impact on broadening patient access to biologic treatment in Germany.

THU0657 A TELE-HEALTH FOLLOW-UP STRATEGY FOR TIGHT CONTROL OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: RESULTS OF THE NON-INFERIORITY RANDOMISED CONTROLLED TRAIL (THE TERA STUDY)

A. Thurai1,2, K. Steengaard-Pedersen1,2, M. Axelsen3, U. Fredberg3,4, L.M.V. Schougaard5, N.H.I. Hjøllund 5,6, M. Pfeiffer-Jensen1,2, T.B. Laurberg1, K. Lomborg 6,7, T. Maribo8,9.

Background: The first etanercept biosimilar was approved by the European Commission in January 2016. Of the 27,000 patients* estimated to be treated with etanercept biosimilar in the Europe, 5,122 patients* are estimated to be treated with etanercept biosimilar in Germany at the end of the analysis period. Its usage in Europe may support healthcare sustainability by reducing costs, thereby relieving the burden on healthcare budgets and improving patient’s ability to get the right care at the right time.

OBJECTIVES: To test the effect of patient-reported outcome (PRO) based tele-health follow-up for tight control of disease activity in patients with RA, and the differences between tele-health follow-up performed by rheumatologists or rheumatology nurses.

Conclusions: Experience with etanercept biosimilar has been growing in Germany, as reflected by the growing market share. Based on the current number of patients treated with etanercept biosimilar, savings of 21.1 million EUR are projected to be returned to the health system in Germany annually. The economic burden associated with etanercept treatment is expected to decrease further with an increase in market share for the etanercept biosimilar. These savings can have a significant impact on broadening patient access to biologic treatment in Germany.
Methods: A total of 294 patients were randomized (1:1:1) to either PRO-based tele-health follow-up carried out by a nurse (PRO-TN) or a rheumatologist (PRO-TR), or conventional out-patient follow-up by physicians. The Flare-RA (2) was used as decision aid for assessing disease activity. The primary outcome was change in DAS28 after week 52. Secondary outcomes were: physical function, quality of life and self-efficacy. The non-inferiority margin was a DAS28 change of 0.6. Mean differences were estimated following per-protocol, intention to treat (ITT) and imputation (IMP).

Results: Overall patients had low disease activity at baseline and end follow-up. Demographics and baseline characteristics were similar between groups. Non-inferiority was established for DAS28. In the ITT analysis mean difference in DAS28 between PRO-TR vs. control were -0.10 (90% CI -0.30; 0.13) and -0.19 (-0.41; 0.02) between PRO-TN vs. control. When including one yearly visit to the outpatient clinic, patients in PRO-TN had a total of 1.72 (SD 1.03) visit/year, PRO-TR 1.75 (SD 1.03) visit/year and control 4.15 (SD 1.0) visits/year. This implies that PRO-TN patients had a total of 2.47 visits/year, PRO-TR 2.55 visits/year and control 4.15 visits/year. This difference was significant in the per-protocol analysis (p=0.002). The difference in the proportion of patients with no use of prednisone was statistically significant between PRO-TN and control groups (p=0.008) but not between PRO-TR and control groups (p=0.547). Moreover, in the salivary gland tissues, the positivities of Wnt-1 (71.4% vs. 46.2%, p=0.001, r=-0.416; p=0.022) and Wnt-3a (71.4% vs. 53.8%, p=0.345) were higher in the SS group compared to the control group, respectively.

Conclusions: According to the best of our knowledge, this study is the first study evaluating the activity of Wnt/β-catenin pathway in the primary SS. The altered β-catenin pathway in the primary SS. The altered β-catenin pathway is affected in these inflammatory diseases. Salivary DKK1 level is increased in primary SS in contrast to SLE. On the other hand, Wnt-1 and Wnt-3a expressions on the salivary gland are increased in primary SS. Therefore, it may be concluded that Wnt/β-catenin pathway acts pathogenic roles on the glandular inflammation.

THU0659 | SKIN MICROVASCULAR FLOW ASSESSED BY DYNAMIC OPTICAL COHERENCE TOMOGRAPHY: FIRST NON-INVASIVE QUANTITATIVE OUTCOME MEASURE OF MICROVASCULAR DAMAGE IN SYSTEMIC SCLEROSIS

A. Daniel 1,2,3, G. Abignano 1,2, S. Eng 1,2, L. Green 1,2, P. Emery 1,2, F. Del Galdo 1,2, 3, Rheumatology Unit, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; 2, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; 3, NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Reduction in capillaries number is the defining feature of microvascular disease in Systemic Sclerosis (SSc). This condition affects blood flow and function of microcirculation and is responsible for the clinical manifestations of the disease.

Aims: To determine the face and content validity of D-OCT as outcome measure of severe peripheral ischemic vasculopathy. Dynamic optical coherence tomography (D-OCT) is a recently developed imaging technique that allows non-invasive in vivo study of the microvasculature of the skin. In addition to the skin architecture and vessels morphology, it offers information about flow status, allowing the functional and quantitative evaluation of the microcirculation.1

Objectives: To determine the face and content validity of D-OCT as outcome measure of the skin microvascular disease, assuming the presence of current DU, distal to the DIP joints, as gold standard for ischemic peripheral vasculopathy in SSc.

Methods: A total of 54 patients were enrolled in this cross-sectional study, including 18 SSC patients with current DUS (DU group); 18 SSc patients without current DUS (no DU group) and 18 patients with Raynaud’s phenomenon and SSc specific AHA, who did not fulfil ACR/EULAR 2013 classification criteria (SRP group).

For each patient, we performed a D-OCT scan on both index and middle fingers, on the dorsal aspect of the second phalanx, employing VivoSight Scanner (Michelson Diagnostics). The speckle variance signal of D-OCT images within the first mm of skin depth was extracted, quantified as area under the curve (AUC) and defined as Micro Vascular Flow (MVF). MVF comparison between the groups was done using parametric or non-parametric tests as appropriate. Statistical Analysis was performed with SPSS V22.

Results: All three groups were comparable in terms of age and gender distribution (p>0.80 for both) as well as disease duration and clinical subset between the two SSc groups (p=0.839 and p=0.464, resp). With a scan time <1 minute, D-OCT allowed the visualization and quantification of capillaries within the first millimeter of skin depth (Figure 1).

The distribution of MVF was not significantly different among the four fingers within each group (DU group: p=0.459, no DU group: p=0.933 and SRP group: p=0.616). On the contrary, the distribution and median MVF for all fingers was significantly different among the 3 groups: DU group=0.134 (IQR 0.121–0.134), no DU group=0.153 (IQR 0.132–0.153) and SRP group=0.167 (IQR 0.148–0.167) (p<0.0001), as well as in the DU group vs. no DU group (p<0.001) or DU vs SRP group (p<0.001).

Further, sub analysis of the DU group showed that 10 of the total 20 DUs were on the left index finger. Within this subgroup the MVF of patients on Sildenafil (n=6) was significantly higher than the rest of the group (0.148±0.021 vs. 0.113±0.019, p=0.03).

Conclusions: MVF assessed by D-OCT is a quantitative, non-invasive surrogate outcome measure of severe peripheral ischemic vasculopathy in SSc. Longitudinal
studies assessing its sensitivity to change will inform whether MVF can be used as end point of skin microvascular involvement in SSC.

THU0660 POLYMYALGIA RHEUMATICA TREATMENT SERUM BIOMARKERS VERSUS RHEUMATOID ARTHRITIS
M.K. Meyer1, M. Andersen1, T.V. Staatsbo2, K.J. Elbæk2, G.N. Andersen1, A. Stensballe2
1Department of Rheumatology, Nortmark Regional Hospital, Hjørring; 2Department of Health Science and Technology, Aalborg University, Aalborg, Denmark

Background: Polymyalgia rheumatica (PMR) is a systemic inflammatory disorder with unknown etiology and overlapping symptoms with giant cell arthritis and late-onset rheumatoid arthritis (RA). To date, no proteomics studies have been performed on PMR patients, and the number of biomarker studies remain limited.

Objectives: The primary aim of this study was to thoroughly investigate the corticosteroid treatment serum proteome of PMR with a focus on acute-phase reactions, complement system, and cytokines.

Methods: Filter-aided sample preparation for mass spectrometry, cell free DNA (cfDNA) assay, and 10plex cytokine array were applied to PMR serum samples from the same patients before and after treatment, DMARD-naïve RA patients, and healthy controls.

Results: The core serum proteomes of the four groups were remarkably similar, and consisted of ~200 proteins, which included acute-phase reagents, coagulation and complement proteins (figure), immunoglobulins, and apolipoproteins, and several more. Acute Phase Serum Amyloid A (SAA1) was differentially less abundant than by PMR treatment. The individual serum proteome of each PMR patient provided more than 100 differentially abundant proteins, and highlights the heterogeneity of patients.

Conclusions: We have established the core serum proteome of PMR in response to treatment, and compared it with RA and healthy controls. The results suggest a functional role of SAA1, and increased cfDNA in the pathogenesis of PMR indicates the activation of NETs.

THU0661 CLINICAL RELEVANCE OF DETECTING ANTI-ADALIMUMAB ANTIBODIES WITH A DRUG-TOLERANT ASSAY
A. Martinez-Feito1, L.Y. Bravo Gallego2, B. Hernandez-Breijo3, C. Plasencia1, A. Jochems1, M.A. Gonzalez7, I. Monjo1, D. Peiteado1, G. Bonilla1, P. Nozai2, A. Balsa1, D. Pascual-Salcedo1
1Immunology, University Hospital la Paz, madrid, Spain

Background: Adalimumab (Ada) has proven effective in treating rheumatoid arthritis (RA) and spondyloarthropathies (SpA), although approximately 30% of responders will present secondary clinical failure. Immunocomplex formation associated to arthritis (RA) and spondyloarthropathies (SpA), although approximately 30% of responders will present secondary clinical failure. Immunocomplex formation of ATA with the clinical status.

Methods: Filter-aided sample preparation for mass spectrometry, cell free DNA (cfDNA) assay, and 10plex cytokine array were applied to PMR serum samples from the same patients before and after treatment, DMARD-naïve RA patients, and healthy controls. Complement factors were narrowly distributed and not affected by PMR treatment. The individual serum proteome of each PMR patient provided more than 100 differentially abundant proteins, and highlights the heterogeneity of patients.

Results: Out of the 63 studied patients, 12 (19%) had RA and the rest (51, 81%) had different spondyloarthropathies (24, 38%) ankylosing spondylitis, 9 (14%) psoriatic arthritis, 14 (22%) undifferentiated spondyloarthritis and 4 (6%) spondylarthropathies associated with inflammatory bowel disease. Thirty-one patients (49%) received concomitant methotrexate. (28% RA patients and 74% SpA patients), 13 (21%) received another DMARDs associated to Ada and 19 (30%) were on monotherapy. Out of the 63 patients, 27 (43%) no ATA were detected. Thirty six patients (57%), were IDK+ and 12 patients (19%) were belISA+ (all of them IDK+). The presence of ATA by belISA was associated with absence of serum Ada levels. However, most (78%) samples with complexed ATA had low circulating Ada levels (1.65 mg/ml in ATA+ vs 6.25 mg/ml in ATA-; p<0.0001). ATA appeared by IDK at earlier treatment stages than by belISA, statistically different at all studied time points. In patients who dropped-out (30 patients, 48%) Ada concentration was frequent and significant by both methods. Ten patients (33%) belISA ATA+ was dropped-out vs 2 patients belISA ATA+ in those who continued treatment (p<0.0001). Twenty four patients (80%) IDK ATA+ dropped-out vs 12 patients (38%) who continued treatment (p<0.0001). The percentage of ATA detected by IDK was higher than by belISA, with a tendency of more IDK ATA+ among patients with less survival (24,80% IDK positive vs 10,33% belISA+; p=0.06).

Conclusions: ATA are detected by a drug-tolerant assay at earlier stages of treatment than by belISA. The antibodies formed early are associated with lower levels of circulating Ada, indicating higher drug clearance. This information might be useful to implement the Therapeutic Drug Monitoring. However, the detection of early complexed ATA has not demonstrated a significant advantage over the belISA to predict treatment survival.

THU0662 COMPARING ELECTRONIC COLLECTION OF PATIENT REPORTED OUTCOMES AT HOME VERSUS TOUCH-SCREENS IN THE WAITING AREA AMONG PATIENTS WITH ARTHRITIS IN CLINICAL PRACTICE: A RANDOMISED AGREEMENT STUDY WITH ONLINE RECRUITMENT USING DANBIO
A.E. Secher1, B. Griltingborg1, H. Gudbergsen2, N.S. Krogh3, D.V. Jensen1, I.J. Sørensen4, R. Christensen2, M. Skougaard2, M.L. Heltand4, 1DANBIO registry, Glostrup; 2The Parker Institute; 3Zitelab Aps, Frederiksberg, Denmark

Background: Collection of patient-reported outcomes (PROs) is an important aspect of modern treatment strategies. Electronic capture in waiting areas by touch screens is part of routine care in the Danish DANBIO registry. It is not known whether this data collection can be replaced with electronic data entry from home.

Objectives: To test the feasibility of online patient recruitment via touch screens and to investigate if electronic reporting of PROs from home (ELECTOR IT-platform) is comparable to reporting completed at the hospital among patients with rheumatoid arthritis (RA) or axial spondyloarthritis (AS). A total of 952 patients received invitation, 45% accepted, 127 patients completed the trial. Clinicaltrials.gov identifier: NCT02818478.

Methods: Patients with RA or AS were recruited via touch screens and randomized to one of two groups by a pre-computed list generated through DANBIO; the first group completing the PROs at home and then at the hospital-site, and vice versa for the second group. All patients completed the Health Assessment Questionnaires (HAQ), the Visual Analogue Scales (VAS) for fatigue, pain and global health and the annual visit questions. Furthermore, AS patients completed the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the BAS Function Index (BASFI). Pearson’s Chi-square test, independent samples t-test and Mann-Whitney U test were calculated. Smallest detectable differences (SDDs), 95% confidence intervals (CIs) and intra-class correlation coefficients (ICCs) were calculated.

Results: A total of 952 patients received invitation, 45% accepted, 127 patients were contacted by phone, and 56 (44%) gave consent to participate. 22 patients with RA and 20 patients with AS completed the trial. All differences between scores from home vs hospital were smaller than SDD, and all were non-significant (p<0.05), except for BASFI and BASDAI item 5. ICC ranged from 0.947–0.990 (p<0.00001). Annual visit questions showed 96% concordance between the two methods. 50% of the patients preferred from home data entry over hospital and 10% vice versa.

Conclusions: Recruitment of patients for a randomized trial via touch screens was feasible. PROs collected from patients’ own devices at home generated...
results comparable to results obtained from the existing touch-screen solution and were preferred by the patients.

Methods: Baseline clinical and paraclinical data including disease activity and damage scores (SLICC) were obtained from 167 SLE patients. VTE (deep vein thrombosis and/or pulmonary embolism) and AT (myocardial infarction and/or cerebrovascular incident) data were available with a median follow-up period of 6 years. Baseline serum G3BP, IP-10, soluble CD163 (sCD163), TWEAK, and leptin serum levels were predictors of venous and arterial thrombotic events, damage accrual, and all-cause mortality during long-term follow-up in a large cohort of Swedish SLE patients.

Methods: Baseline clinical and paraclinical data including disease activity and damage scores (SLICC) were obtained from 167 SLE patients. VTE (deep vein thrombosis and/or pulmonary embolism) and AT (myocardial infarction and/or cerebrovascular incident) data were available with a median follow-up period of 6 years. Baseline serum G3BP, IP-10, soluble CD163 (sCD163), TWEAK, and leptin serum levels were predictors of venous and arterial thrombotic events, damage accrual, and all-cause mortality during long-term follow-up in a large cohort of Swedish SLE patients.

Results: In the follow-up period 11 (7%) VTE and 12 (7%) AT events occurred. SLICC-scores increased in 79 (47%) patients, and 19 (11%) patients died. In the univariate Cox regression analysis G3BP levels were significantly associated with an increased risk of VTE (hazard ratio [HR] 1.10, 95% confidence interval [CI]: 1.01–1.2, P=0.03). This persisted in the multivariate cox regression analyses when controlling for all-cause mortality. None of the other serum biomarkers were associated with AT and VTE. No significant associations were observed between the biomarkers and changes in SLICC-scores or all-cause mortality.

Conclusions: Our study identifies serum G3BP as a novel independent predictor of VTE in SLE. This may improve our understanding of VTE pathogenesis in SLE and aid future VTE risk stratification and prophylaxis. Further studies are needed to translate this into clinical practice.

**Abstract THU0667** A QUALITATIVE AND QUANTITATIVE COMPARISON OF SYNOVIAL BIOPSY TECHNIQUES DURING CLINICAL TRIALS OF INFLAMMATORY ARTHRITIS

F. Humby 1, S. Bugatti 2, A. Filer 3, S. Kelly 4, A. Manzo 2, E. Souza 2, V. Romano 2, V. Rocher 1, R. Hands 1, M. Wechalekar 1, J. Fonseca 2, C. Montecucco 2, C. Pitzalis 2, Experimental Medicine and Rheumatology, Barts and the London School of Medicine and Dentistry, London, United Kingdom; 2Division of Rheumatology, University of Pavia, Pavia, Italy; 3Institute of Inflammation and Ageing, University of Birmingham, Birmingham, UK; 4Department of Rheumatology, Barts Health NHS Trust, London, United Kingdom; 5Department of Rheumatology, Lisbon Academic Medical Centre, Lisbon, Portugal; 6Rheumatology Unit, Repatriation General Hospital, Adelaide, Australia

Background: Synovial tissue is an attractive area of research for biomarkers of disease outcome in RA. Currently acquisition of synovial tissue using an arthroscopic approach in clinical trials is recommended though two US-guided techniques have been described, a portal and forceps (P&F) approach and an adaptation using a quick core needle (NB). However before US-guided biopsy techniques are widely adopted into clinical trials validation of performance against arthroscopy is required.

Objectives: To evaluate whether there were significant differences in synovial sampling quality and quantity between arthroscopic, US-P&F and US-NB procedures within the context of clinical trials.

Methods: This was a multicentre retrospective analysis of inflammatory arthritis patients recruited to clinical trials utilizing US-guided NB (Barts Health NHS Trust), US-guided P&F (ICRSS Policlinico San Matteo and University Hospital Birmingham) and arthroscopic biopsy (Repatriation General Hospital). Paraffin embedded synovial sections from each procedure underwent H&E staining and sections examined for intact cell lining layer (graded sections). Biopsy procedures were segregated into large (knee) and small joint procedures (wrist/ MCP) for analysis. Proportion of samples yielding graded tissue per procedure was recorded. Using CellSens Dimensions software the area of synovial tissue obtained per procedure was determined. In addition the degree of synovitis was assessed using semi-quantitative scoring (0–9).

Results: 78 patient procedures were evaluated, 22 on small joints (11 US-NB, 11 US-PF) and 56 on large joints (11 US-NB, 35 US-PF, 10 arthroscopic). 47 patients had RA, 11 undifferentiated arthritis and 10 psoriatic arthritis. Arthroscopic sampling resulted in a significantly higher area of tissue retrieved per procedure than US P&F or US-NB. There were no significant differences in proportion of graded samples per procedure suggesting quality of synovial tissue was preserved between techniques. Finally no significant differences in degree of histological synovitis were demonstrated between sampling techniques.

Conclusions: The results suggest that US-guided biopsy provides a reliable method for sampling synovial tissue of comparable quality to that obtained from arthroscopy. However when sampling large joints arthroscopic techniques, and when sampling small joints US-P&F yield a significantly higher quantity, though not quality, of tissue per procedure than US-NB. These results may influence choice of biopsy technique when designing clinical trial protocols in inflammatory arthritis.

DOI: 10.1136/annrheumdis-2017-eular.1918

**Abstract THU0666** PATIENT GLOBAL ASSESSMENT IS MORE SENSITIVE TO CHANGE THAN HEALTH-RELATED QUALITY OF LIFE INSTRUMENTS IN EARLY AXIAL SPONDYLARTHROPSIS OVER 3 YEARS: DATA FROM THE DESIR COHORT

D. Puyraimond-Zemmour 1,2, C. Destieux 1,2, A. Ruyssen-Witrand 3, B. Fautrel 1,2, L. Gossec 1,2, 1Pitié Salpêtrière Hospital, Paris, France; 2CHU de Toulouse, Hôpital Pierre-Paul Riquet, Toulouse, France

Background: Several questionnaires assess similar constructs of global patient-reported state or Health-Related Quality of Life (HRQoL). PGA was more sensitive to change than HRQoL measures in early spondyloarthritides (Table).

Results: In all, 442 patients were analyzed: at baseline, mean age was 34.2±8.6 years were included. A global construct of patient global state was assessed by PGA.

Objective: To evaluate sensitivity to change (ie, discriminance) of several questionnaires in early axial spondyloarthritides (axSpA) over 3 years of follow up: the SF36, axial spondyloarthritides quality of life (ASQoL), axial spondyloarthritides health assessment questionnaire (AS-HAQ) and patient global assessment (PGA).

Methods: DESIR is an ongoing prospective, multicenter, longitudinal, observational French cohort (1). Patients had inflammatory back pain of more than 3 months and less than 3 years suggestive of axSpA. For our analysis, only patients with no missing data for MCS and PCS SF36 values during the first 3 years were included. A global construct of patient global state was assessed by the SF36 questionnaire and its 2 subscales (scored 0–100 with higher scores indicating better status): the physical composite score (PCS) and the mental composite score (MCS). ASQoL, a disease-specific HRQoL scale, PGA and AS-HAQ. ASDAS-CRP was used as comparator. Each outcome was assessed at baseline, 6 months, 12 months, 24 months and 36 months. Standardized mean differences (SMD) were calculated using Cohen’s effect size with confidence intervals, between each time point for each outcome. A SMD < 0.5 is usually considered small, between 0.5 and 0.8 moderate and > 0.8 as important.

Results: In all, 442 patients were analyzed: at baseline, mean age was 34.2±8.6 years; mean disease duration was 18.6±10.7 months; 239 (54%) were females, 274 (62%) had HLAB27 and 124 (28%) had radiological sacroiliitis. At baseline, patients were not in an optimal state; improvement was clear up to month 6 then.

Conclusions: PGA showed a stronger correlation to BASDAI (r=0.912, P<0.001) than ASDAS and to acute phase reactants.

THU0668 | RELIABILITY OF PATIENT GLOBAL ASSESSMENT IN RHEUMATOID ARTHRITIS PATIENTS

G. Kangyama1, A. Onishi2, Y. Ueda3, J. Saegusa1, A. Morinobu4. 1Department of Rheumatology, Hyogo Prefectural Amagasaki General Medical Center, Amagasaki; 2Department of Rheumatology, Kobe University Hospital, Kobe, Japan

Background: Patient’s global assessment (PtGA) is one of the most widely used patient reported outcomes in rheumatoid arthritis (RA) that reflects both disease activity and other factors. PtGA is onymous and obtained at hospital, which may cause a conscious or unconscious bias, whereas PtGA obtained anonymously may be free from any bias. The credibility of PtGA to report RA patient outcomes has been usually investigated by assessing test-retest reliability. There has been no study comparing routine PtGA and PhygA where patients and physicians assessed the same patient.

Objectives: The aim of this study was to compare routinely obtained in-hospital PtGA before clinical examination with those answered anonymously at home. Additionally, physician’s global assessment (PhygA) was compared with routine PtGA and anonymized PtGA.

Methods: We asked RA patients (n=389) to answer and mail the PtGA test anonymously. Clinical data regarding disease duration, stage, class, swollen joint counts, tender joint counts, pain visual analog scale (VAS), PhygA, Health Assessment Questionnaire (HAQ), EuroQOL five dimensions questionnaire (EQ5D), Kessler 6 scale (anxiety/depression), treatment data, laboratory data, and socioeconomic factors were collected simultaneously. We compared the PtGA that is routinely surveyed at hospital before clinical examination with those surveyed anonymously at home. We calculated a discrepancy score by subtracting anonymized PtGA from routine in-hospital PtGA. We defined (1) positive discrepancy when routine in-hospital PtGA was over-rated relative to the anonymized PtGA; (2) negative discrepancy when routine in-hospital PtGA was under-rated relative to the anonymized PtGA.

Results: The anonymized PtGA score was higher than routinely evaluated in-hospital PtGA (p<0.0001). The anonymized PtGA poorly correlated with routine PtGA (r=0.426, p<0.0001). We compared the difference between both PtGAs at 10 mm, 20 mm, or 30 mm. If we adopted 30 mm as discordance, the pain scale remained to be a risk factor of positive discrepancy (higher in-hospital PtGA than anonymized PtGA). If we adopted 20 mm or 10 mm as discordance, the pain scale remained to be a risk factor of positive discrepancy and remaining low quality of life (QOL) negative discrepancy (lower in-hospital PtGA than anonymized PtGA) after multivariate analysis. The discordance between PhygA and routine PtGA are associated with high pain VAS. The discrepancy between PhygA and anonymized PtGA is associated with tender joint counts, swollen joint counts, and low QOL.

Conclusions: Discrepancy exists between routine in-hospital PtGA and anonymized PtGA. The high pain VAS scale and low QOL are risk factors that could make the difference between routine PtGA from anonymized PtGA. There is a possibility that high pain VAS score and low QOL influence the reliability of PtGA.

THU0669 | THE ASSOCIATION BETWEEN HARRIS HIP SCORE AND DISEASE ACTIVITY OR HIP MRI FEATURES IN ANKYLOSING SPONDYLITIS

Z. Wu1, L. He1, M. Yang2, Y. Liu3, D. He4, Y. Zhang4, C. Wang4, H. Xu4. 1Department of Rheumatology, Xijing Hospital; 2Department of Rheumatology, The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an; 3Department of Rheumatology, Nanfang Hospital, Guangzhou; 4Department of Rheumatology, West China Hospital, Sichuan; 5Department of Rheumatology, Guanghua Hospital, Shanghai; 6Department of Rheumatology, Tanguo Hospital; 7Medical Affairs, Xian-Janssen Pharmaceutical Ltd., Xi’an; 8Department of Rheumatology and Immunology, Shanghai Changzheng Hospital, Shanghai, China

Background: Hip involvement is a common clinical feature observed in ankylosing spondylitis (AS) patients and it often leads to substantial restriction of the body functions. Hip involvement in AS is mainly assessed by radiographic changes, clinical symptoms or MRI. The Harris hip score (HHS) is a valuable assessment tool to measure health status of AS patients. However, the relationship between HHS and other clinical indices is unknown.

Objectives: To evaluate relationship between HHS and other commonly used clinical indices.

Methods: In this multicentre, observational study, AS patients with hip clinical manifestations are enrolled and randomly assigned to infliximab treatment (group I), with/without DMARDs and/or NSAIDs or conventional therapy (group II, DMARDs and/or NSAIDs). Primary endpoint: to compare functional improvement of hip joint (HHS) between two treatment groups (infliximab and conventional therapy) at week 30. Secondary endpoint: to compare disease activity and functional improvement of AS and radiographic progression of hip joint between two treatment groups at week 30 and 52. Association between baseline HHS and disease activity measures such as Bath ankylosing spondylitis (BAS)-functional index (BASFI), BAS disease activity index (BASDAI), AS disease activity score (BASCR), CRP and ESR was analysed using Pearson correlation coefficient. BAS meteorology index (BASMI) and hip imaging functions (MRI of hip, BAS radiology hip index [BASI-h]) were analysed using independent two-sample t-test or ANOVA based on data characteristics.

Results: Study is ongoing; currently, only baseline information is analyzed. Baseline demographics and disease characteristics did not show any significant difference between groups. Almost all baseline disease activity measures showed significant Pearson correlation (high correlation in BASFI=0.646) with HHS, except for BASDAI (table 1). Significant association between HHS and three MRI scores (articular cartilage stripping, bone destruction under joint surface, femoral head bone marrow cavity edema) and BASRI-h were found in table 2 (appendix). Also, significant correlation was shown between BASMI and HHS (F value [degree of freedom]=4.70; p=0.0022).

Conclusions: The baseline results of HHS were found to be well associated with disease activity scores like BASFI, BASDAI and BASMI and four hip imaging features in AS patients with hip involvement.

THU0670 | DETECTION OF SERUM ANTI-DNASE I ANTIBODIES IN SYSTEMIC LUPUS ERYTHEMATOSUS USING IMPROVED IMMUNOSORBENT ASSAY

A.S. Trofimenko1,2, L.P. Gontar1, I.A. Zborovskaya1, L.N. Shilova2, E.G. Korenskaya2. 1Research Institute for Clinical and Experimental Rheumatology; 2Volgograd State Medical University, Volgograd, Russian Federation

Background: Diagnosis of systemic lupus erythematosus (SLE) is a sophisticated problem in most of the disease cases. The reasons of this include common diagnostic markers of SLE (ANA, anti-dDNA, anti-Sm), that are insufficiently reliable itself as well. One of possible ways to overcome these difficulties is searching for new SLE markers. These emerging diagnostic tools are not only to be valuable for diagnosis establishment, but also to provide economical efficiency and facility in common use.

Objectives: To compare diagnostic efficiency of anti-DNase I antibodies measured by conventional ELISA and by originally modified enzyme immunosorbent assay using magnetic polyacrylamide beads as an antigen carrier.

Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles, it was approved by the Regional Committee on Medical Ethics. All the patients signed the informed consent. We have enrolled 54 in-hospital adult patients with SLE, verified by the ACR criteria (1997). Control group (n=52) was comprised of patients with rheumatoid arthritis, systemic sclerosis, systemic vasculitis, dermatomyositis, and Sjogren’s disease. Serum
anti-DNase I concentrations were evaluated by conventional ELISA, as described elsewhere [1]. The beads were synthesized using original technique [2], modified ELISA and recovery of the beads for repeating use was performed according to the previously published protocols [2]. Antibody concentrations were expressed as relative optical density units (ODU). The cutoff values for conventional and modified ELISA were 0.068 and 0.079, respectively. All the means and operation characteristics were expressed as values (95% confidence intervals). Differences were considered significant when p < 0.05.

**Results:** Mean anti-DNase I concentrations in SLE patients (negative and positive together) were 0.088 (0.031–0.145) and 0.079 (0.033–0.125) ODU for conventional and modified ELISA, respectively; in the control group they were 0.068 (0.020–0.116) and 0.063 (0.019–0.107) ODU, respectively. Differences within these couples were not significant. Diagnostic sensitivity and specificity of modified ELISA were 64.74 (53.09–76.39) and 85.01 (72.95–97.07%), coinciding with those for conventional ELISA. LOQ for the modified ELISA was slightly lower than for the conventional one. Accuracy and repeatability of modified ELISA were also insignificantly higher than those for conventional approach. There was no substantial change in all the parameters of modified ELISA after single recovery of beads.

**Conclusions:** The newly developed ELISA for anti-DNase I antibodies was demonstrated to have equivalence or advantage in some analytical parameters over conventional ELISA. Considering some economic and maintenance benefits, our innovation can be an alternative tool to improve SLE diagnostics.

**THU0671** CAN AN INNER DISPOSABLE GLOVE BE USED UNDER AN ELECTROGONIOMETRIC GLOVE FOR MEASURING FINGER MOVEMENT WITHOUT LOSS OF ACCURACY?

**Background:** Improving joint mobility is an important outcome for patients with arthritis, but finger joint range of motion is rarely measured in clinic. Electronic gloves with movement sensors have been developed to measure joint movement accurately and it is now possible to assess dynamic mobility of the finger joints. However these gloves are expensive and it is likely that when carrying out measurements in the patient population they would be used with inner disposable gloves to avoid nonsocomical infection. Establishing accuracy and usability of electronic gloves whilst wearing disposable inner gloves is therefore an important pre-requisite for studies in patients with arthritis.

**Objectives:** To establish the accuracy and repeatability of measurements of finger movement obtained using two different electrogoniometric gloves worn with and without an inner disposable glove.

**Methods:** We used two different types of electrogoniometric glove for the purpose of this study. One is the commercially available 5DT dataglove 14 Ultra (5DT, 2011), and the other was produced to our specifications by Tyndall National Institute, University College Cork. We called this the “IMU glove”. We developed a graphical interface for both devices to facilitate detailed evaluation of joint movement in each finger. Both gloves were tested using a protocol adapted from Dipietro, Sabatini, & Dario, (2003).

**Results:** Table 1 displays comparison of Coefficient of Variation (CV) readings for both data gloves. Figure shows this information graphically.

Results show no significant change for SDT angular readings with and without a surgical glove worn underneath the data glove. Results for PIP sensors show an improvement in repeatability with a surgical glove. CV variance was smaller for MCP sensors with a surgical glove worn underneath the data glove compared with no surgical glove. CV for the IMU data glove show negligible changes in MCP readings when a surgical glove is worn underneath. PIP readings show small changes when using a surgical glove.

**Conclusions:** Inner disposable gloves can be worn when using electrogoniometric gloves for testing finger movement without loss of accuracy or any significant discomfort in patients with arthritis.

**THU0672** REAL WORLD EVIDENCE COMPARING THE PATIENT REPORTED OUTCOMES MEASUREMENT INFORMATION SYSTEM TO THE CDAI IN RHEUMATOID ARTHRITIS PATIENTS

**J.R. Curtis1**, S. Kalfa2, D. Parenti2, S. Black3, S. Xu1, Y. Wang1, C.O. Bingham3, *1University of Alabama at Birmingham, Birmingham; 2Janssen Scientific Affairs, LLC, Horsham; 3Janssen Research & Development, LLC, Springhouse; 4Johns Hopkins University, Baltimore, United States

**Background:** Patient (Pt) reported outcomes (PROs) play a role in overall disease evaluation, therapeutic response assessment and care of rheumatoid arthritis (RA) patients (Pts). The Pt Reported Outcomes Measurement Information System (PROMIS [P]) questionnaires developed by the NIH have been validated and are a feasible assessment tool in RA (Bartlett 2015). Outcomes: AWARE (Comparative and Pragmatic Study of Golimumab Intravenous (IV) Versus Infliximab in RA) is a real-world study of golimumab IV (G-IV) vs. infliximab (IFX) in RA and will assess infusion reactions, disease activity and multiple PROs as outcomes measures.

**Methods:** AWARE is a prospective, noninterventional, ongoing US-based study in which 1,200 adult Pts will be enrolled on initiation of treatment with G-IV or IFX. Objectives include PRO assessments of Pt response to treatment using the PROMIS-29 Profile v2.0 (P29v2), P Pain Interference Short Form-6b (PISF) and P Fatigue Short Form-7a (FSF), 36-Item Short Form Health Survey (SF-36v2) and the Clinical Disease Activity Index (CDAI). We report an interim analysis from the first 353 Pts of baseline PROMIS questionnaire and CDAI scores, and their inter-relationships. PROMIS questionnaire results are scored on a 0 to 100 scale, normed to the US population and reported as a “T-Score” (mean of 50 and standard deviation (SD) of 10). PROMIS T scores were compared across CDAI disease activity (DA) categories.

**Results:** Baseline mean (SD) CDAI score was 33.46 (±15.79), with 73.4% of pts with high DA (HDA), 22.1% with moderate disease activity (MDA), 3.7% with low disease activity (LDA) and 0.8% pts in remission. PROMIS scores are shown below. All P29v2 domains, PISF and FSF scores were significantly worse in pts with CDAI≥22 vs. CDAI<22 (p<0.05). The same was true for SF-36 domains (data not shown). PROMIS scores are shown below for all pts, and also based on CDAI DA category. PROMIS T scores across all domains (P29v2 domains, PISF and FSF) were compared to CDAI disease activity category (below). As shown, PROMIS T scores correlated with CDAI disease category, with HDA Pt T scores significantly (*, p<0.05) greater than those of MDA, LDA and Remission pts (excepting the Sleep Disturbance domain).

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.4429
Conclusions: These interim data further support the viability of using PROMIS questionnaires to evaluate RA pts, and indicate in this predominantly HDA population of RA pts correlations between PROMIS and CDAI disease activity category. Confirmation of the baseline interim analysis findings with the fully enrolled AWARE study, as well as inclusion of longitudinal and subset analyses based on disease activity levels, will further define the role of PROMIS relative to CDAI in RA pts in a real-world setting.

THU0673 THE EUROPEAN CONSENSUS FINDING STUDY GROUP (ECFSG) HELPS CHARACTERIZING NEW TENTATIVE REFERENCE STANDARDS FOR AUTOANTIBODY MEASUREMENT
J. Rönnel1, C. Dahle2, M. Blüthner3, E. Feist4, C. Dolman5, S.J. Thorpe6, E. Monogioudi7, I. Zegers8, D. Hamann9 on behalf of ECFSG.

Methods: Four autoimmune diseases (EULAR autoantibody study group, also known as the EULAR autoantibody study group, has been distributing sera with unspecified antibodies to align test results by adopting internationally used measurement units, but reference materials are missing for many autoantibody specificities.

Objectives: Recently the scope for ECFSG was expanded to also include unbiased autoantibody characterization of serum/plasma specimens planned to constitute raw material for production of future autoantibody reference materials. Materials: Four autoimmune diseases (EULAR autoantibody study group, also known as the EULAR autoantibody study group, has been distributing sera with unspecified antibodies to align test results by adopting internationally used measurement units, but reference materials are missing for many autoantibody specificities. Results: All or almost all participating laboratories detected the target specificities, and all four samples showed restricted autoantibody specificities related to the target specificity. Anti-dsDNA was detected by all laboratories using Chithraud IgG ELISA/EIA, FARR assay or ALBIA and all labs reported a homogenous ANA pattern. Other specificities were restricted to histones, nucleosomes and anti-Ku. All laboratories but one detected IgG anti-b2GPI and IgG anti-cardiolipin, mostly in high levels, in the tentative IgG anti-b2GPI reference standard, whereas corresponding IgA and IgM antibodies were absent. All laboratories detected anti-PR3, mostly monospecific and in high levels together with P-ANCA pattern in the anti-PR3 reagent, irrespective of method used. Conclusions: The expanded scope of ECFSG has enabled broad characterization of new tentative autoantibody reference standards. The anti-dsDNA specimen has been processed by the National Institute for Biologic Standards and Control (NIBSC) for consideration as the 2nd WHO anti-dsDNA reference standard. The other materials are basis for certified reference material for IgG anti-myeloperoxidase (ERM-DA476/IFCC), and the candidate reference materials for IgG anti-proteinase 3 (in certification) and for IgG anti-b2PG1 (in evaluation) from the Joint Research Centre.

THU0674 ANTI-DFS70 ANTIBODY – A BIOMARKER THAT AID IN THE EXCLUSION OF ANA ASSOCIATED RHEUMATIC DISEASES
K. Conrad1, N. Röber1, M. Achteleitner1, M. Aringer2, S. Rudolph1, L. Unger4, A. Gräßler1, K. Lüthke6, M. Mahler7, Medical Faculty of the TU Dresden, Institute of Immunology; 2University Hospital Carl Gustav Carus, Department of Internal Medicine and Rheumatology, Dresden; 3Admedia MVZ, Immune Center Chemnitz, Chemnitz; 4Medical Hospital Dresden-Friedrichstadt, Department of Medicine I, Dresden; 5Medical Practice, Pirna; 6Medical Practice of Rheumatology, Dresden, Germany; 7Inova Diagnostics, San Diego, United States

Background: Positive ANA may lead to additional testing and potentially even inappropriate treatment in patients with rheumatic symptoms not caused by ANA associated rheumatic diseases (AARDs).

Objectives: It has been shown that autoantibodies directed against lens epithelial derived growth factor (LEDFG), also named DFS70 according to the staining pattern (dense fine speckled) and molecular weight of the target antigen (70 kDa), are common among ANA positive individuals with no evidence of AARD [1,2]. The aim of the current study was to evaluate the autoantibodies directed against DFS70 can be used to exclude AARD in ANA positive patients.

Methods: Anti-DFS70 antibody were determined by chemoluminescence assay (CLIA) in sera of 352 apparently healthy controls (AHI), 1048 patients of an ANA positive routine cohort, 579 patients with AARD (300 SLE, 76 idiopathic inflammatory myopathies, 167 systemic sclerosis, 36 Sjögren's syndrome), 56 patients with undifferentiated connective tissue disease (UCTD), and 660 non-AARD patients (302 rheumatoid arthritis, 94 ANCA-associated vasculitis, 87 atopnic rhinitis, 135 pediatric patients with celiac disease, and 42 autoimmune liver diseases.

Results: In AHI and in the non-AARD cohort, anti-DFS70 antibodies occur with a prevalence of 5.1% and 2%, respectively. Of the 1048 selected routine sera, 205 (19.6%) were positive for anti-DFS70 antibodies. Up to now, clinical reports are available for 116 of anti-DFS70 positive patients in this group. The diagnoses were widely scattered (nonspecific rheumatic symptoms, arthritis, thyroiditis, asthma, psoriasis, tumor, infections, inflammatory bowel disease), but no definite AARD could be diagnosed. In the AARD group, only 6 of 579 patients (1.2%) were positive for anti-DFS70 antibodies, all of them also showed disease specific autoantibodies (two anti-Scl70 antibody positive SSc, one anti-RA33/anti-RA22 antibody positive SSC, one Ro-52 positive SSC, one anti-Mi-2 antibody positive IIM, one SLE patient with multiple autoantibodies including dsDNA antibodies). In patients with UCTD, 6 (10.7%) were anti-DFS70 antibody positive in the absence of disease specific autoantibodies. Up to now, no development of an AARD was observed in these patients.

Conclusions: Anti-DFS70 antibodies are frequently observed in sera with chromatin binding antibodies in the absence of disease specific autoantibodies. If anti-DFS70 antibodies are positive in the absence of AARD specific autoantibodies, an AARD can be excluded with high certainty.

THU0675 DEVELOPMENT AND PSYCHOMETRIC VALIDATION OF A TOOL TO ASSESS THE FEARS OF PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES: THE FAIR SCALE

1UPMC Univ Paris 06; 2AP-HP, Hôpital Pitié Salpêtrière; 3INSERM, UPMC Univ Paris 06; 4AP-HP, Hôpital Cochin, Paris; 5UCB Pharma, Colombes; 6Arthritis Fondation Courtois, Neuilly-sur-Seine; 7CHU la Cavale Blanche and Université de Bretagne Occidentale, Brest; 8UPMC Univ Paris 06, AP-HP, Hôpital Saint-Antoine, Paris, France

Background: Patients (pts) with chronic inflammatory rheumatic diseases (CIRDs) such as rheumatoid arthritis (RA) and axial spondyloarthritis (axSpA) have fears related to their disease that can negatively impact health-related quality of life and compromise treatment adherence.

Objectives: To develop and validate a patient-reported outcome (PRO) ques-
tionnaire to explore fears related to CIRDs using the Fears Assessment in Inflammatory Rheumatic Diseases (FAIR) Scale.

Methods: The preliminary questionnaire included 44 items (23 related to fears) most frequently cited by pts in a qualitative study of 50 French pts. Each item was formulated as an affirmative sentence and scored from 0 (completely disagree) to 10 (totally agree). Item scores were summed to provide a total score. The questionnaire was finalised and validated. Pts diagnosed with RA (EULAR/ACR criteria) or axSpA (ASAS criteria), recruited during routine visits by 100 participating rheumatologists across France, completed the preliminary questionnaire, HAD (Hospital Anxiety and Depression) and AHI (Arthritis Helplessness Index) scores. Redundant items (inter-item correlation coefficient < 0.65) were eliminated. For the others, internal consistency (Cronbach alpha) and the factorial structure of the scale (principal component analysis) were assessed. Pts were classified according to their level of fears (cluster analysis) and corresponding score thresholds were determined (ROC analysis). The final questionnaire was independently translated into English and back into French twice, with reconciliation of the translated texts.

Results: 672 pts were included: 432 RA pts (mean±SD disease duration was 13.1±11.4 years, DAS28[ESR] was 2.6±1.2, 77.3% were taking biologics) and 240 axSpA pts (disease duration was 13.8±10.6 years, BASDAI was 3.5±2.2, 72.7% were taking biologics). The final FAIR Scale included 10 (Table) with total scores ranging 0–100. Mean±SD scores were 51.2±25.4 in RA and 60.5±22.9 in axSpA. Three pt groups were identified, characterised by high, moderate and low level of fears (cluster analysis) and corresponding score thresholds were determined (ROC analysis). The final questionnaire was independently translated into English and back into French twice, with reconciliation of the translated texts.

Conclusions: The FAIR Scale is a 10-question PRO to evaluate disease-related fears in CIRD pts. In this pt population, 17.2% had high fear scores, contrasting with a disease that is often well-controlled. The FAIR Scale was associated with psychological distress. This psychometrically-validated and easy to use questionnaire could be used to improve physician dialogue in CIRDs and also be of value in clinical studies. Further validation in other populations is needed.

THU0676 ANTI-RO/SS-A 52-KDA ANTIBODIES: A MARKER FOR LUNG FIBROSIS IN RHEUMATIC DISEASES

Background: Lung fibrosis (LF) is a type of interstitial disease that leads to lung scarring, respiratory failure and later on, death. There are 2 main types of LF: idiopathic and secondary; and the prognosis is very different. LF becomes relevant in connective tissue diseases (CTD) and some studies have suggested that there could be an association between anti-Ro/TRIM21 antibodies and the development of interstitial lung disease in these patients.

Objectives: The aim of this study was to assess if the presence of anti-Ro52/TRIM21 antibodies is an independent risk factor for developing CTD-associated LF. We also aimed to evaluate the initial manifestations of systemic diseases and clinical characteristics linked to certain antibodies.

Methods: It is a prospective, observational, longitudinal, single-center study conducted among unselected patients with CTD (rheumatoid arthritis, systemic lupus erythematosus (SLE), systemic sclerosis (SSc), polymyositis (PM), overlap CTD syndrome (OCTD), MCTD, primary Sjögren’s sd (PSS), primary antiphospholipid syndromes, and undifferentiated connective tissue disease). We analysed data from 1,432 caucasian patients included in the “Systemic Autoimmune Diseases (SAD) Registry” from 1988 to 2014. They were all checked at least biannually and blood samples were taken according to clinical practice. Exclusion criteria were LF as the initial manifestation of the SAD, LF already diagnosed at the first visit and also LF secondary to drugs or a specific environment.

Results: 10% of patients included in the study developed LF. The OR for LF in patients with anti-Ro52/TRIM21 antibodies was 1.757 (95% CI=1.1–2.7). The OR for LF increased with every year of age (OR=1.03, 95% CI=1.02–1.04). Only 9 out of 146 patients with LF were positive for Anti-La-SS-B antibodies, and the OR for males was 8.6 compared to women (95% CI=1.8–39.5). Patients with SSc and PM showed a higher OR for the development of LF (6.9 95% CI=4.6–10.4 and 2.0, 95% CI=1.2–2.8 respectively) compared to those diagnosed with other CTD. The time passed from the first symptoms to the diagnosis of LF was inversely associated LF. We also aimed to evaluate the initial manifestations of systemic diseases and clinical characteristics linked to certain antibodies.

Conclusions: Anti-Ro52/TRIM21 antibodies have been proved to be a risk factor for developing LF. The earlier the age of onset, the slower the progression to fibrosis. However, patients with anti-Ro52/TRIM21 antibodies tend to have a faster development, independent of the age of onset. Anti-La-SS-B antibodies seem to be a protective factor for the development of LF in both genders; but the association is stronger in women.

DOI: 10.1136/annrheumdis-2017-eular.2890
Background: International scientific networks have raised concerns about inadequate reporting of safety outcomes in randomised trials and systematic reviews. Outcome Measures in Rheumatology (OMERACT) has previously developed an adaptation of the US National Cancer Institute (US NCI) Common Terminology Criteria for Adverse Events (CTCAE), the RCT (Rheumatology Common Toxicity Criteria) to collect adverse events in rheumatology clinical trials. To respond to this need to also report safety outcomes from the patient perspective, the Safety Working Group is developing a core outcome set, followed by a core outcome measurement set. A scoping review of available instruments for measuring safety outcomes is needed to inform this work.

Objectives: To identify candidate measurement instruments for safety outcomes in rheumatology clinical trials.

Methods: A systematic search was performed in the MEDLINE database (via PubMed) in January 2017 using MeSH terms covering synonyms for adverse events, rheumatology and measurement instruments and the Boolean operator OR to combine them. Full-text articles about the development or evaluation of instruments identified were then screened for eligibility based on title and abstracts. Two reviewers (LK and RC) screened the full text articles.

Results: Of 434 unique references identified, 19 were read in full-text, and 8 were included (see figure). The instruments identified were: Glucocorticoid Toxicity Index (GTI), Patient Reported Experiences and Outcomes of Safety in Primary Care (PRESOS-PC), Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA)-SLEDAI flare index (cSFI), the BioSecure questionnaire, Rheumatology Common Toxicity Criteria (RCTC), OMERACT 3x3, and the Stanford Toxicity Index (STI). These instruments were specific for substance (GTI), BioSecure questionnaire, setting (PRESOS-PC), condition (cSFI), or not fully validated (RCTC, OMERACT 3x3, STI).

Conclusions: The instruments identified are either too specific, or require further development/evaluation, for the purpose of standardizing measurement of safety in rheumatology clinical trials. Thus, we will proceed to gain consensus on the domains that must be measured to develop a core outcome set.

Figure 1

Conclusions: Our study confirms previous evidences suggesting a higher expression of CD44v3 and v6 on T cells from SLE patients compared to HS. Higher expression of CD44v3 and v6 on patients with active disease suggests their possible use as biomarkers of disease activity. The good specificity and sensitivity of CD44v6 on CD4+ T cells, and the shift of the ratio towards this...
CAN THE USE OF NEW TECHNOLOGIES IMPROVE THE USE OF PATIENT REPORTED OUTCOMES (PROs) AND PATIENT PARTICIPATION IN A NATIONAL REGISTRY?

Background: PROs are especially useful in the management of rheumatic diseases in complement to physician evaluation. However they are time consuming and used in a limited manner in the daily clinical practice. Reuma.pt is the Portuguese national rheumatic diseases register and one of the few registries in Europe that allows the patient to do at home the PROs before the appointment. In our institute we have complemented that with the creation of a paper free day hospital with the use of touchscreen computers that also allows the patient to do the PROs before the clinical evaluation by the rheumatologist.

Objectives: To compare the impact of the use off Reuma.pt at home PROs completion platform before and after the utilization of touch screen computers in the day hospital.

Methods: We determined the number of patients and appointments with the use at home of the PROs platform one year prior to the introduction of the touch screen computer at our day hospital (October 2014 –October 2015) and one year after the paper free day hospital was installed (November 2015-November 2016).

To determine any change of pattern of the use at home of the platform and the relations between that and patients characteristics.

Results:

| Table 1. Differences between previous use of touchscreen computers in the use at home PROs |
|-----------------|-----------------|-----------------|-----------------|
| Date            | Number of appointments | Number of patients | Age (SD) |
| October 2014    | 93/419 (22.1%)       | 57/106            |
| October 2015    | 1,264/48/48.2%       | 106               |
| November 2015   | 410±17M              | 75F+31M           |
| November 2016   | 11,793±96 (N=29)     | 10,351±43 (N=68)  |
| Under biology   | 53 appointments (56.99%) | 162 appointments (75%) |
| Diagnosis       | 43±3 11 RA e 3 PSA   | 61±5 33 RA e 12 PSA |

When we analyse the available variables between the patients that performed the PROs at home we found for both periods considered that they were younger (45.2±49.8 vs 53.4/55.1 p < 0.001) they have more education (11.8/10.35 vs 8.2/7.8) no differences were found regarding gender. There is a tendency that with the continuous use of touchscreen computers at the day hospital less educated patients are using more at home platform of Reuma.pt. The use of technology could have a considerable impact on the way we collect data from our patients. With the use of a touchscreen computer we have improved not only the overall completion of PROs but also increased the frequency of patient to the online questionnaires. Number of appointments with previous at home completion of the questionnaires more than double. This has a clear impact on patient participation, quality of data in the registry but even more important a change in the use of resources at a day hospital.

VALIDATION OF EQ-SD, RAPID-3 AND HADS QUESTIONNAIRES FOR THE ASSESSMENT OF THERAPY EFFICACY IN PANCREATITIS PATIENTS

N. Savushkina, V. Amirdjanova, O. Egorova, B. Belov. V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Pan is a group of heterogeneous inflammatory diseases characterized by involvement of the subcutaneous fat (SF), locomotor system and visera, and the number of pancreatitis (Pn) cases is increasing in everyday practice of a rheumatologists. There are no specific scales available to assess efficacy of Pn therapy. EQ-SD, RAPID-3 and HADS validity, sensitivity and specificity were proven for some rheumatic diseases. Thus, evaluation of EQ-SD, RAPID-3 and HADS psychometric properties in Pn patients has become the objective of this study.

Objectives: Evaluate psychometric properties of questionnaires EQ-SD, RAPID-3 and HADS in Pn patients.

Methods: The study group included 83 Pn pts (80 females, 3 males) aged 43.4±13.9 years with median disease duration of 5 [2;24] months who were at the record of V. A. Nasonova Research Institute of Rheumatology during 2009–2015 yrs. EQ-SD, RAPID-3 and HADS were filled in at the first and the control visits at 12 months. Questionnaires’ sensitivity was assessed by comparing patient’s answers and objective response to therapy measured by achievement of complete resolution of the nodules on the control visit. The construct validity was measured based on correlation with ‘external criteria’, including presence of arthritis and arthralgias, tenderness of nodules at palpation measured by VAS, ESR and CRP values.

Results: Positive dynamics (nodule regression) correlated with improved EQ-SD (EQ-SD-scale - p=0.005, EQ-SD-VAS - p=0.004) and RAPID-3 (p<0.001). Median ± EQ-SD and HADS-depression after therapy were 0.27 [0.12; 0.45] (p=0.005), and 2 [1.5] (p=0.13) scores, respectively, while average decline in RAPID-3 and HADS- anxiety scores after therapy was 9.2±5.2 (p=0.001) and 4±3 (p=0.15), respectively. EQ-SD showed the greatest power in Pn patients’ quality of life assessment. EQ-SD-scale and VAS “thermothermometer” showed moderate correlation with nodule tenderness at baseline (r= -0.23, p=0.036) & (r=-0.45, p=0.003), and control visits (12 months) (r= -0.38, p=0.002) & (r=-0.41, p=0.002); EQ-SD scale showed moderate correlation with ESR and CRP values at the control visit (r=-0.23, p=0.03) & (r=-0.25, p=0.005), and EQ-VAS – with CRP value at 12 months (r= -0.33, p=0.002), demonstrating clear correlation with patient’s objective health status and lab parameters values. Moderate correlation between functional RAPID-3 values and nodule tenderness at baseline (r=0.34, p=0.0015) and after 12 months (r= 0.5, p=0.0001) are also indicative of close links between the questionnaire data and pts’ objective health status. As for the HADS assessment, moderate correlation was found only between HADS-depression and nodule tenderness at baseline (r=-0.24, p=0.026) and 12 months (r=0.28, p=0.014) visits. There were no other significant correlations identified.

Conclusions: EQ-SD and RAPID-3 questionnaires should be considered as valid and sensitive instruments for the assessment of the quality of life and efficacy of therapy in Pn pts.

Objectives: To characterize and quantify systemic involvement at diagnosis in a large international cohort of patients with primary Sjögren’s syndrome (SS).

Methods: The Big Data Sjögren Project was formed in 2014 to take a “high-definition” picture of primary SS at diagnosis by merging international databases (9302 consecutive patients from 21 countries of the 5 continents). The main features including ESSDAI/DAS scores were analysed.

Results: Baseline ESSDAI was available in 8061 patients (93% female, mean age 53yrs). The mean ESSDAI score at diagnosis of the entire cohort was 6.4±7.9. In 1488 patients (19%), score at diagnosis was 0, while 681 (8%) presented with high activity in at least one domain. The main systemic features at diagnosis were
biological (51%), articular (38%), haemato logical (24%) and glandular (22%). Low
DAS was reported in 4483 (56%) patients, moderate DAS in 2483 (31%) and high
DAS in 1098 (14%) patients. The mean baseline ESSDAI was higher for younger
the patient was (p < 0.001), higher in White patients (6.9 vs 5.1, p < 0.001), males
(8.4 vs 6.2, p < 0.001), those with positive ocular (6.7 vs 4.9, p < 0.001) or oral (6.8
vs 5.7, p < 0.001) vs those with non-ocular (6.7 vs 5.7, p < 0.001) and anti-Ro/La antibodies (7.2 vs 4.4, p < 0.001). Logistic regression identified
as independent variables White ethnicity (OR 3.07), abnormal ocular
AUCs of 63.5% and 73.4% based on patient’s and physician’s OSSA,
predicting main diagnoses were constructed and estimated to perform with
the point of care. This rapid test shows excellent agreement to a corresponding
laboratory assay based on 178 serum samples from RA and PsA patients
was performed against the BÜHLMANN sCAL (MRP8/14) reference ELISA.
ifar, the patient was asked twice (1 to 2 year interval) to answer questionnaires evaluating: disease
and 571 patients (54%) showed an ESSDAI score at the time of diagnosis, with nearly 80% of patients showing an ESSDAI score > 0.

THU0683 RAPID DETERMINATION OF THE INFLAMMATION MARKER CALPROTECTIN IN SERUM FROM PATIENTS WITH INFLAMMATORY ARTHRITIS AT THE POINT OF CARE
N. Ryter1, A. Szentpetery2, S.R. Pennington3, R. Cotti1, O. FitzGerald2, J.M. Weber1, BÜHLMANN Laboratories AG, Schoenuen, Switzerland; 3St Vincent’s University Hospital; 2University College, Dublin, Ireland
Background: A Treat-to-Target (T2T) strategy for inflammatory arthritis, targeting remission or minimal disease activity, is the recommended treatment approach by EULAR and ACR. This strategy relies on “tight monitoring” which necessitates regular
clinical examination and measuring acute-phase reactants such as C-reactive protein. Calprotectin (MRP8/14; SI00A/9), a relatively novel inflammation and disease activity marker in the arthritis field, exhibits several features which fit the “theranostic needs” for accurate therapy monitoring. Those features include dis-
correlation between responders and non-responders [1], determination of disease activity [2] and prediction of relapse or radiographic progression [3]. The classical method to determine calprotectin in serum (sCAL) is ELISA which is
used in service or central laboratories. A rapid and simple determination of sCAL at the point of care is a substantial step forward in supporting clinicians to deliver an efficient T2T strategy. Here, we report on the validation of a quantitative, rapid
assay for calprotectin.

THU0062 POPGEN-OSSA: DEVELOPMENT OF AN ORGAN SPECIFIC SELF ASSESSMENT (OSSA) FOR INTERDISCIPLINARY DOCUMENTATION OF PATIENT REPORTED CLINICAL OUTCOMES
R. Zeuner1, U. Gsell2, M. Hübenthal3, S. Schreiber4, A. Franke3, M. Laudes4, J.O. Schröder1. 1Section of Rheumatology, Clinic for Internal Medicine I, University Hospital Schleswig-Holstein, Campus Kiel, Kiel; 2Klinik Eichstätt, Eichstätt; 3Institute of Clinical Molecular Biology; 4Clinic for Internal Medicine I, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany
Background: Patient reported outcome measures are comprised of either sets of questions which are applied on a global scale or assessment based on visual analogue scale (VAS). These patient-reported outcome measures lack accuracy and/or clinical feasibility when comparing heterogeneous patient groups with different diseases, or when characterizing patients with systemic disease involving different organ systems.
Objectives: Developing a clinical feasible patient-reported outcome measure based on VAS assessment of different organ systems.
Methods: Patients were asked to rate their health status in a 10cm VAS (0–100%) concerning their global health as well as of different organ systems, namely heart, lung, muscle and joints, gastro-intestinal, metabolic, uro-genital, skin, neuro-psychiatric, eyes and ears. All VA-scales were “anchored”. Patients were asked to rate their health status below 75% if they felt “medical action is needed”, they should rate the health status > 50% in case of a “strong need for medical action” and > 25% in case of a “medical emergency”.
336 patients from different outpatient clinics (cardiologic, pneumologic, gastro-intestinal, nephrologic, neuropsychologic, dermatologic, rheumatologic, ophthalmologic and obesity outpatient clinic) as well as patients from internal emergency clinics and a general practitioner clinic were evaluated. Both, patients and the attending physicians completed the Popgen-OSSA. In addition the attending physician was asked to document ranking of the 5 most important diagnoses of the patient. Statistical analysis was carried out using non-parametric testing. Furthermore,
to predict main diagnoses based on patients’s as well as physician’s OSSA

THU0684 WORK IMPACT IN AXIAL SPONDYLOARTHRITIS: THE AS-WIS QUESTIONNAIRE PREDICTS THE RISK OF WORK IMPACT: A LONGITUDINAL STUDY OF 101 PATIENTS
S. Dadoun1, C. Jacquemin1, S. Kreis1, S. Fabre1, C. Rein1, C. Hudry2, E. Pertuiset1, B. Gautrel1, L. Gossec1, 1Rheumatology, Pitié Salpêtrière Hospital; 2Rheumatology, Cochin Hospital, Paris, France
Background: Axial spondyloarthritis (axSpA) mainly affects the working-age
subject and can have a moderate (short-term sick leave) or significant (long-term
sick leave, disability status, unemployment) work impact.
Objectives: To evaluate the value of a simple and short (2 minutes) questionnaire, the AS-Work instability scale (AS-WIS) to predict the work impact of axSpA after 1–2 years.
Methods: Longitudinal study in 3 centers in Paris, France. Patients with axSpA according to the rheumatologist and the ASAS criteria were included. Patients were asked twice (1 to 2 year interval) to answer questionnaires evaluating: disease activity, demographic characteristics, impact on work (short-term and long-term sick leave, disability, unemployment), and the ASWIS questionnaire (1): a 20 item, simple screening tool for Work Instability (the consequence of interaction between an individual’s functional ability and their work tasks). The risk of disability is assessed as low if the score is <11, medium between 11–18 and high–18. Only patients who answered both questionnaires were included for analyses. Statistical analyses included descriptive analyses and univariate/multivariate

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.4472
analyses to search for baseline factors of work impact at 1–2 years (including a medium/high ASWIS score, gender, age, schooling level, BASDAI, BASFI).

Results: Among the 188 patients who answered the first questionnaire, 144 were currently working and were asked to answer the second questionnaire. A total of 101 patients answered both questionnaires. Mean age at inclusion was 45 (SD 9) years, 52% were male, disease duration was 14 (SD 8) years and 62% had an education level equivalent to more than high school. The BASDAI and the BASFI were respectively 34 (SD 21) and 23 (SD 23). At baseline, median ASWIS was 10, a low-risk score was found in 55 patients (54%), and a medium/high risk score in 46 (46%). 1–2 years later, 37 patients (36%) had work impact: 25 patients (25%) a short-term sick leave, and 12 patients (12%) a significant work impact (long-term disability or unemployment due to AxSpA).

Among patients with a low ASWIS score at baseline (n=55), only 13 (24%) had a work impact (including only 2 with a significant impact). Among patients with a medium/high ASWIS score (n=46), 24 (52%) had a work impact (including 10 patients of a significant impact).

In univariate analysis, baseline factors associated with work impact (moderate or significant) were a medium/high ASWIS score, a high BASFI and a shorter disease duration. In multivariate analysis, medium/high ASWIS (odds ratio, OR 2.71 (1.04–7.22)) and a lower disease duration (0.94 (0.89–0.99)) were independent predictive factors of work impact.

Conclusions: In patients with AxSpA, a medium/high ASWIS score was followed by a work impact in 50% of cases within 2 years in this well-controlled population. This short questionnaire can be helpful to screen for future difficulties at work, whatever the stage of disease.

THU0685 ASAS HEALTH INDEX FOR PATIENTS WITH SPONDYLOARTHRITIS: TRANSLATION INTO PORTUGUESE, VALIDATION, AND RELIABILITY

S. Rodrigues Manica1, R. Cruz1,2, E. Cruz1, S. Ramiro3, S. Sousa3, R. Aguiar6

1Rheumatology, Diakonhjemmet Hospital; 2Rheumatology, National Resource Centre for Rehabilitation in Rheumatology, Diakonhjemmet Hospital; 3Medicine, Diakonhjemmet Hospital, Oslo, Norway

Background: The Assessment of SpondyloArthritis international Society Health Index (ASAS HI), is a unidimensional questionnaire, that includes 17 items, measuring functioning and health in patients with spondyloarthritis (SpA) (1). At the beginning of this project, only an English version of the instrument existed.

Objectives: The aim of this study was to conduct the cross-cultural adaptation of the ASAS HI into European Portuguese language and investigate its reliability and validity in a sample of Portuguese patients with SpA.

Methods: The ASAS HI has a range from 0 (best health state) to 17 (worst health state). The questionnaire was first translated and then back translated following published guidelines. Patients fulfilling ASAS classification criteria for either axial (axSpA) or peripheral SpA (pSpA) were included. Reliability was assessed through internal consistency coefficient, and internal consistency was assessed using Cronbach’s alpha.

Concluding remarks: The findings of this study showed that the Portuguese version of the ASAS HI is a comprehensive questionnaire that is reliable and valid. Therefore, its use can be recommended, both for clinical practice and research purposes, to assess the state of health and functioning in Portuguese SpA patients. Future research is needed to evaluate the responsiveness of the ASAS HI in SpA patients.

THU0686 HEART RATE VARIABILITY IN INFLAMMATORY JOINT DISEASE. A META-ANALYSIS

S.A. Provao1, D.S. Olstd2, E.E. Solberg2, G. Smedslund2, H. Dagfinrud2

1Rheumatology, Diakonhjemmet Hospital; 2Rheumatology, National Resource Centre for Rehabilitation in Rheumatology, Diakonhjemmet Hospital; 3Medicine, Diakonhjemmet Hospital, Oslo, Norway

Background: Autonomic dysfunction is an established predictor of all-cause mortality and post-myocardial infarction mortality. It has been suggested to be a pathogenic factor for the development of cardiovascular disease (CVD) in the general population, possibly acting through the impact of the autonomic nervous system on inflammation (1). Heart rate variability (HRV) is a marker of cardiac autonomic function and is increased in many conditions including chronic widespread pain. HRV is responsive to physical exercise. Inflammatory joint diseases (IJD) are characterized by joint inflammation and symptoms include pain, functional decline and restricted movement. Patients with IJD have an increased risk of premature death due to CVD.

Objectives: To compare HRV between adult patients with IJD and healthy controls, using the “Preferred Reporting Items for Systematic Reviews and Meta-Analyses” (PRISMA) methodology, and to describe the associations between IJD disease activity, pain and physical activity, and HRV.

Methods: A research librarian conducted systematic searches in Medline, Embase and Amed from earliest date until August 2016. Inclusion criteria were adult human case-control studies published in English or a Scandinavian language, presenting data on HRV in patients with JD (Rheumatoid Arthritis (RA) or Spondyloarthritis (SpA)). Included under the SpA diagnosis were patients with psoriatic arthritis or ankylosing spondylitis. Six established measures of HRV were selected: the Square root of mean squared difference of successive R-R interval (rMSSD), high frequency (HF), total power (TP), Ewing protocol standing (E-S), breathing (E-B) and Valsalva (E-V). Patients with RA, SpA and healthy controls were compared separately using random-effects meta-analyses of standardized mean differences (SMD).

Results: 847 titles and abstracts were reviewed, 36 papers were eligible for inclusion (Figure 1). For rMSSD the pooled SMD (95% CI) RA vs. controls was -0.90 (-1.35 to -0.44), for SpA vs. controls -0.34 (-0.73 to 0.06). For HF, the pooled SMD RA vs. controls was -0.78 (-0.99 to -0.57), for SpA vs. controls -0.04 (-0.22 to 0.13). For TP the pooled SMD RA vs. controls was -0.60 (1.26 to 0.06), SpA vs. controls -0.27 (-0.51 to 0.03). All pooled Ewing parameters were significantly lower in cases compared to controls, except for E-V which was comparable between cases and controls in patients with RA. 18/36 papers examined the relationship of JD disease activity to HRV, of which the majority, 13, describe an inverse association between the parameters. The impact of pain on HRV was not explored in any study, and only one study explored the impact of physical activity on HRV, finding no cross-sectional association. Conclusions: Patients with JD have lower cardiac parasympathetic modulation compared to healthy controls and this may be a risk factor for CVD. There is an inverse relationship between JD disease activity and HRV. The relationship between pain, physical activity and HRV should be further explored.

the worker's performance whilst at work due to ill health (i.e. presenteeism). A number of global measures have been developed to assess presenteeism in clinical studies. However, limited information is available on the correlation between these measures and the construct validity of these measures.

**Objectives:** To determine the correlation between four global measures of presenteeism and to evaluate the construct validity of these measures.

**Methods:** The main aim of this international observational study (7 countries in Europe and Canada), recruiting patients with IA (RA, PsA or AS) or OA in paid employment, was to investigate content and construct validity of global presenteeism measures. Patients completed 4 global measures (Work Productivity Scale – Arthritis (WPS-A), Work Productivity and Activity Impairment Questionnaire (WPAI), Work Ability Index (WAI), and both the Quality and Quantity scales of the QQ questionnaire) (see table legend for descriptions individual scales). Spearman correlations were applied to test the correlation between individual presenteeism scales and to test construct validity with the 11-item Workplace Activity Limitation presenteeism Scale (WALS) and several health related patient reported outcome measures. Interpretation of correlation coefficients: (very) weak (r range=0.0–0.39), moderate (r range=0.40–0.59) to strong (r range=0.60–1.0).

**Results:** 468 patients with a median disease duration of 10 [IQR 5–18] yrs were included; 62% were female. Median [IQR] presenteeism scores were, respectively: 2 [0.5–5] for WPS-A, 3 [1–5] for WPAI, 8 [6–9] for WAI, 81 [49–100] QQ-total, with WAI and QQ having reversed scales (Legend table). Correlations between the 4 global measures were moderate to strong, ranging from 0.49 for the correlation between WPS-RPA and QQ-Quality to 0.83 between WPS-RPA and WPS-RPA. The multi-item presenteeism scales WALS, measuring difficulty at work, strongly correlated with both WPSI (r=0.65, p<0.05) and WPS-RPA (r=0.64, p<0.05), both measures capturing the affect of interference of illness on work productivity. Moderate correlations were achieved between all six global presenteeism measures and health outcomes (r range=0.36–0.54; 0.37 to 0.54; and 0.40 to 0.58).

**Conclusions:** Global measures of presenteeism show good to moderate construct validity, with the WAI and WPS-IA/OA showing slightly better construct validity compared to the WAI and QQ. The information obtained in this study will further tailor the treatment strategy of various rheumatic diseases. Traditionally used measures to assess disease activity and treatment response in spondyloarthritis (SpA) are ESR, CRP and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS). Serum amyloid A (SAA) is an acute-phase reactant predominantly synthesized in the liver by hepatocytes in response to proinflammatory cytokines. Some studies have shown that SAA can be a valuable indicator of disease activity, damage and functional impairment, however it has not been extensively used in clinical practice.

**Objectives:** To study the association between SAA levels and its variation with other biomarkers and disease activity/functional parameters in a cohort of PsA patients under biologic therapy.

**Methods:** Observational retrospective study was conducted including PsA patients (according to CASPAP criteria) followed at our Rheumatology department with at least one measurement of SAA levels from January 2015 until December 2016. Demographic and clinical data were obtained by consulting the national database (Reuma.pt). The disease activity/functional scores from at least one visit and corresponding measurements of SAA, ESR and CRP levels were collected. The difference (Δ) between 2 evaluations separated by a median time of 6 months [5–18] was calculated for all variables. Agreement between biomarkers was calculated using kappa coefficients. Correlations were studied using Pearson and Spearman coefficient analysis. Significance level was set as 0.05.

**Results:** 53 PsA patients were included. 31 (58%) patients were females with a mean (SD) age of 50 (11.2) years and a median disease duration of 9 years [1–43]. 28% had axial involvement, 34% peripheral involvement and 38% had both types. All patients were under biologic DMARD. 100 SAA measurements were collected. Median SAA and ESR levels were significantly superior in female patients (23 vs 6mm/1st and 8.6 vs 4.4mg/l, respectively, p<0.05) and only ESR levels correlated with age (r=0.20, p<0.05). The three biomarkers showed a weak association with serum creatinine levels, with greater correlation for SAA (r=0.46, p<0.001) and SAA had a stronger correlation with CRP (r=0.75, p<0.001) than with ESR levels (r=0.26, p<0.01). SAA and CRP (dichotomized as negative/positive) had a greater level of agreement (k=0.40) compared to ESR (k=0.26 and k=0.32, respectively). No significant correlations were found between the biomarkers and the tender/swollen joint count or the pain/global disease activity VAS. SAA levels correlated with ASDAS CRP (r=0.43, p<0.001) and no significant associations between SAA and ESR or DAS28 CRP (r=0.20 and r=0.24, respectively, p>0.05). Only ESR had a very weak correlation with both ASDAI, MASES and SPARCRC scores (r=0.25, r=0.21, r=0.35; p<0.05). All the biomarkers had weak correlations with BASFI and HAQ scores. SAA levels had a weak correlation with ΔCRP (r=0.32, p=0.03; n=47) and no significant association was found with ESR, SAA correlated significantly with ASDAS CRP and ΔBASMI (r=0.32, r=0.39; p<0.05).

**Conclusions:** This study showed that SAA levels and its variation had a significant correlation with CRP levels and its variation, respectively. Significant association with ASDAS CRP variations suggests that serial measurements of SAA may represent an additional marker for monitoring disease activity over time in PsA patients.

**THU0691** IS SERUM AMYLOID A PROTEIN AN USEFUL BIOMARKER TO MONITOR TREATMENT WITH ANTI-TUMOUR NECROSIS FACTOR-ALPHA AGENTS IN SPONDYLOARTHROPATHIES PATIENTS?

**Background:** Quantitating the degree of inflammation has become essential to tailor the treatment strategy of various rheumatic diseases. Traditionally used measures to assess disease activity and treatment response in spondyloarthritides (SpA) are ESR, CRP and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS). Serum amyloid A (SAA) is an acute-phase reactant predominantly synthesized in the liver by hepatocytes in response to proinflammatory cytokines. Some studies have shown that SAA can be a valuable indicator of disease activity, damage and functional impairment, however it has not been extensively used in clinical practice.

**Objectives:** To determine if SAA levels have better correlation with conventional biomarkers than CRP and ESR.

**Methods:** Prospective study, including SpA patients under anti-TNFα treatment at a Rheumatology Department of a Portuguese University Hospital. The following parameters were collected and registered in two different evaluations 6 months apart from each other: SAA, CRP and ESR levels, BASDAI, ASDAS-PCR, ASDAS-VA, BASFI, BASMI, swollen and tender joints counts (SJC and TJC), MASES, SPARCRC, and patient global assessment (PGA); physician global assessment (PGA), full back pain (TBP), nocturnal back pain (NBP) measured in a visual analogue scale (VAS). The variation of each parameter was calculated as the difference between the levels registered at each evaluation (baseline and 6 months) and presented as Δ (parameter). We compared the correlation between ΔSAA, ΔCRP and ΔESR levels with ΔBASDAI, ΔASDAS-PCR, ΔASDAS-VA, ΔBASFI, ΔBASMI, ΔSJC, ΔTJC, ΔMASES, ΔSPARCRC, ΔPGA-VA, ΔPGA-VAS, ΔTBP-VAS, ΔNBP-VAS. The statistical analysis was performed using SPSS 21.0 software, and p<0.05 was taken to indicate statistical significance. Correlation was calculated using the Spearman rank correlation (r).

**Results:** 89 patients were included, 58.4% (n=52) were male. On baseline the median age was 44.0 years (range 21.0–74.6) and median disease duration was 18.8 years (2–51.6). ΔSAA was moderately correlated with ΔCRP (r=0.65, p<0.05), both measures
p < 0.001) and had lower correlation with ΔESR (r = 0.28, p = 0.009). ΔSAA correlated with ΔNBV-VAS (r = 0.260, p = 0.016), but ESR and CRP did not correlate with this parameter. We also found statistically significant correlation between ΔSAA and ΔASDAS-VS (r = 0.257, p = 0.017), ΔASDAS-CRP (r = 0.387, p < 0.001), ΔBASFI (r = 0.301, p < 0.005). ΔCRP also showed significant correlation with ΔNBV-VAS, but it was lower than the observed with ΔSAA (r = 0.230, p = 0.033). There was no statistically significant correlation between ΔSAA levels and ΔMASES, although ΔCRP had a weak correlation (r = 0.217, p = 0.041). There was no significant correlation between either ΔSAA, ΔCRP or ΔESR and the following parameters: ΔTP-VAS, ΔPICA-VAS, ΔPQGA-VAS ΔBASDAl, ΔBASMI. ΔSPARCC, ΔTJC or ΔJJC.

Conclusions: This study suggests that SAA can be a useful tool in monitoring treatment with anti-TNFα and that could be introduced in clinical practice. However more studies, with larger sample sizes, should be undertaken to better assess this subject.

THU0692 THE TURKISH VALIDATION AND RELIABILITY OF DISEASE-SPECIFIC, PATIENT REPORTED OUTCOME MEASURE IN RHEUMATOID ARTHRITIS: TR AIMS2-SF
T. Duruoz 1, C. Unal Ertekin 2, C. Sanal Top 3, 1PM&R Department, Rheumatology Division, 2PM&R Department, Marmara University, School of Medicine, Istanbul, Turkey

Background: Rheumatoid arthritis (RA) can have a major impact on health related quality of life (HRQoL). The revised AIMS-2 is the main outcome measure that has been used for measuring HRQoL in patients with rheumatic diseases. Guillen et al. developed a short form of AIMS-2 (AIMS-2 SF) (1) which is more practical and less time consuming compared to AIMS-2.

Objectives: The purpose of this study was to investigate validity and reliability of the Turkish version of AIMS2-SF (TR AIMS2-SF).

Methods: Turkish AIMS2-SF was developed after translation and back-translation method. Culturally adapted version preserved 5 component-structure (upper limb function, lower limb function, affect, pain and social interaction) with 26 items according to the original article (1). Subjects fulfilling ACR/EULAR 2010 classification criteria for RA were consecutively enrolled into the study. Patients with malignancy, fibromyalgia syndrome and other systemic inflammatory diseases were excluded. Demographic data, the body mass index (BMI), severity of pain (VAS), disease duration (month) and other clinical features was evaluated. Reliability was investigated with test-retest reliability (intra-class correlation coefficient-ICC) and internal consistency (Cronbach’s alpha). Spearman’s rank correlation coefficient was used to evaluate the relation between quantitative parameters and the validity. Construct validity was assessed by the correlation of TR AIMS2-SF with other clinical parameters (age, disease duration, VAS pain, DAS-28) and functional parameters such as Nottingham Health Profile (NHP), Health Assessment Questionnaire (HAQ), Beck Depression Inventory (BDI), Duruoz Hand Index (DHI).

Results: Sixty patients (6 males) were recruited into the study. The mean ± standard deviation (SD) of age (years) and disease duration (months) were 51.8±12.5 and 71.4±69.3, respectively. Mean scores of TR AIMS2-SF were; upper limb function 7.3±6.9, lower limb function 7.7±4.7, affect 7.4±3.2, pain 6.3±1.1, social interaction 4±2.3 and total score 35.5±16.6. The floor and ceiling effects were 0% and 0% with mean scores 3.5±0.3 and 35.5±16.6, respectively. Both Cronbach’s alpha and ICC were 0.83 indicating good reliability. There was significant correlation (rho, p value) with parameters that were directly related to HRQol which were NHP subscales (energy level: 0.46, pain: 0.63, emotional reaction: 0.55, sleep 0.33, social interaction: 0.60, physical activity: 0.63, p < 0.001), HAQ (0.30, p < 0.0001), BDI (0.54, p < 0.0001), DHI (0.60, p < 0.0001). Poor or no significant correlation was found with parameters that were not directly related to HRQol such as age (r = 0.04, p = 0.97), disease duration (0.21, p = 0.09), pain (0.37, p = 0.05); on the other hand, disease activity (DAS-28) correlated moderate (0.49, p < 0.0001).

Conclusions: Turkish version of AIMS2-SF is a reliable and valid tool that can be used to evaluate the quality of life in RA. This is a feasible measure that can be used in daily practice easily.

THU0694 EFFECTS OF ANTI-TNF THERAPY ON SOLUBLE UROKINASE PLASMINOGEN ACTIVATOR RECEPTOR (sPAR) LEVELS IN ARTHRITIS
Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

Background: The urokinase plasminogen activator receptor (uPAR) is expressed mainly on immune cells, smooth muscle cells and endothelial cells, favoring extracellular matrix degradation, cell adhesion, cell proliferation and regulates cell migration. The suPAR is the soluble form of the cell membrane-bound protein...
uPAR, elevated levels may reflect increased activation of immune system which observed in the autoimmune diseases.

**Objectives:** The aim of this study was to assess the effects of anti-TNF therapy on uPAR production in rheumatoid arthritis (RA) and ankylosing spondylitis (AS). We also wished to correlate uPAR levels with various autoimmune-inflammatory biomarkers.

**Methods:** Altogether 33 arthritis patients including 22 RA patients treated with either etanercept (ETN) or certolizumab pegol (CZP) and 11 AS patients treated with ETN were included in a 12- month follow-up study. Circulating suPAR levels were assessed by suPARnostic Quick Test Reader. In addition, disease activity (DAS28 or BASDAI), CRP for inflammatory biomarker at V2 were measured. Assessment were performed at baseline, as well as 6 and 12 months after treatment initiation.

**Results:** Anti-TNF treatment was highly effective in both disease, as the mean DAS28 decreased from 3.25 to 2.5 at V1, mean BASDAI decreased in AS. There was no significant change in the suPAR levels after 12 months of anti-TNF therapy, although resulted non-significant decrease (p=0.18) in RA patients with critical suPAR levels (>9ng/ml). Baseline suPAR levels positively correlated with anti-CCP (p=0.001) and rheumatoid factor (p=0.024) in RA patients. Circulating suPAR levels did not correlate with DAS28, BASDAI or CRP.

**Conclusions:** In a mixed cohort of RA and AS patients, anti-TNF therapy did not affect the suPAR levels after 12 months. suPAR levels correlated with rheumatoid factor and anti-CCP. Based on these results suPAR may be a marker of autoimmunity rather than that of disease activity.

**DOI:** 10.1136/annrheumdis-2017-eular.3428
Background: Clinical trials in juvenile spondylarthropathy (JSpA) and axial disease are lacking. To assess the effectiveness of medications, we need measures to evaluate structural progression in the pediatric sacroiliac joint (SIJ).

Objectives: To evaluate the reliability of the SPARCC sacroiliac joint structural score (SSS) in children with suspected or confirmed JSpA.

Methods: The SSS assesses a spectrum of structural lesions of the SIJ on MRI including fat metaplasia, erosion, backfill, and ankylosis on 5 consecutive slices through the cartilaginous part of the joint. These components are scored 0–20 (backfill and ankylosis) or 0–40 (fat metaplasia, erosion). We developed a pediatric training module that included a detailed description of each SSS component plus sclerosis (0–40), scoring methodology, and numerous examples.

Poster 2

Results: Correlation (ICC).

A second training module based on DICOM images and scored an additional component plus sclerosis (0–40), scoring methodology, and numerous examples. A pediatric training module that included a detailed description of each SSS component plus sclerosis (0–40), scoring methodology, and numerous examples.

Poster 3

Analysis of the item level revealed a strong floor effect (WALS: 16% ± 56%; WLQ: 27% ± 81% of answers for all items except one) but no ceiling effect, likely reflecting the relatively low limitation expected in a working sample. Correlations with disease (fatigue, pain, physical function, depression) and job characteristics (job demand, autonomy, social support at work, commuting difficulty) with time, difficulty, or combined scores of the WALS and WLQ met the a priori hypothesized correlation levels.

Disclosure of Interest: None declared

THU0698 MEASUREMENT PROPERTIES OF PRESENTEEISM MEASURES WITH DUAL ANSWER KEYS IN INFLAMMATORY ARTHRITIS

M. Donaldson 1, A. Kobza 2, D.E. Beaton 2, M.A. Gignac 2, D. Lacaille 1,3

1Arthritis Research Canada, Richmond; 2Institute for Work and Health, Toronto; 3University of British Columbia, Vancouver, Canada

Background: Employment studies in arthritis have emphasised the importance of decreased productivity at work, or presenteeism. Yet, how to best measure presenteeism remains challenging. The “Work Limitations Questionnaire” (WLQ) is frequently used. A drawback is that it measures the amount of time people are limited, but not the degree to which they are limited. In contrast, the “Workplace Activity Limitations Scale” (WALS) measures the degree of limitation, but not the time it modifies the response key. We compared the WLQ and WALS to measure both degree of productivity and amount of time with productivity suffering.

Objectives: Our objective was to evaluate measurement properties, i.e. internal consistency and construct validity, of the WLQ and WALS with combined scores from dual answer keys.

Methods: A cross-sectional study used baseline data from the RCT of an employment intervention, the “Making It Work” Program. Participants were recruited from BC, Alberta and Ontario. Inclusion criteria included: having inflammatory arthritis, currently employed, age 19–59, and having concerns about work productivity. Participants were included (RA:195, PsA:54, SLE:46, AS:69; 77% female, mean (SD) age: 45.9 (9.8) yrs). Combined scores were obtained by i) multiplying, and ii) adding, the scores of difficulty and time answer keys at the item level. No significant differences were observed between the additive and multiplicative models. Hence, we report on the multiplicative model, which reflects consumers’ preference. Internal consistency was analyzed using Cronbach’s alphas; construct validity by measuring correlation (Spearman coefficients) between WALS or WLQ subscales and constructs such as work productivity activity impairment (WPAI), risk of impending work loss (work instability, RA-WIS), disease measures, and job characteristics.

Results: Analyses at the item level revealed a strong floor effect (WALS: 16% ± 56%; WLQ: 27% ± 81% of answers for all items except one) but no ceiling effect, likely reflecting the relatively low limitation expected in a working sample. Correlations with disease (fatigue, pain, physical function, depression) and job characteristics (job demand, autonomy, social support at work, commuting difficulty) with time, difficulty, or combined scores of the WALS and WLQ met the a priori hypothesized correlation levels.

among participants using observed variables, was used to differentiate "pain phenotypes" considering sex, body mass index (BMI), emotional problems, comorbidities, number of painful sites and knee structural damage on MRI.

**Results:** Three pain phenotypes were identified: Class 1: high levels of emotional problems and low levels of structural damage (24%); Class 2: high levels of structural damage and low levels of emotional problems (20%); Class 3: relatively low levels of emotional problems and low levels of structural damage (56%). People within Class 1 were more likely to be female, had greater BMI, lower education level, more comorbidities, more severe knee pain and more painful sites as compared to Class 2 and Class 3. Furthermore, WOMAC pain scores and number of pain sites were consistently greater at baseline, 2.6, 5.1 and 10.7 years in Class 1 than Class 2 and Class 3 (all P < 0.05).

**Conclusions:** Psychological and structural factors interact with each other to influence pain perception.

**THU0700 IMMUNOGENICITY IN PATIENTS SWITCHING FROM STABLE ORIGINATOR INFLIXIMAB TREATMENT TO CT-P13: ANALYSES ACROSS SIX DISEASES FROM THE 52-WEEK RANDOMIZED NOR-SWITCH STUDY**

G.L. Goll 1, I.C. Olsen 1, K.E.A. Lundin 2, K.K. Jørgensen 3, M. Lorentzen 4, R.A. Klaassen 5, D.J. Warren 5, C. Mark 6, J. Jahnsson 7, E.A. Haavardsholm 1, T.K. Kvien 1, N. Bolstad 8 on behalf of The NOR-SWITCH study group, 1Dept of Rheumatology, Oslo University Hospital, Oslo; 2Gastroenterology, Akershus University Hospital, Lørenskog; 3Dermatology; 4Biochemistry DNR, Oslo University Hospital, Oslo; 5Dermatology, St Olav University Hospital, Trondheim, Norway

**Background:** TNF-inhibitors (TNFi) have improved treatment of Crohn’s disease (CD), ulcerative colitis (UC), spondyloarthritis (SpA), rheumatoid arthritis (RA), psoriatic arthritis (PsA) and chronic plaque psoriasis (Ps). The NOR-SWITCH study was funded by the Norwegian government to investigate if switching from originator infliximab (Remicade®, INX) to biosimilar CT-P13 (Remsimä®), is safe. Previously, the primary analyses of the pooled indications have been published. Immunoegenicity is associated with treatment failure and has been of particular concern in switching.

**Objectives:** The NOR-SWITCH study aimed to assess if immunogenicity to infliximab differed between patients treated with continuous INX vs patients switched to CT-P13.

**Methods:** The study was designed as a 52-week randomized, double-blind, non-inferiority phase IV trial. Adult patients with a diagnosis of CD, UC, SpA, RA, PsA or Ps on stable treatment with the originator infliximab were eligible. Patients were randomized 1:1 to either continued INX or switch to CT-P13 treatment, using an unchanged dosing regimen. Trough drug levels and neutralizing anti-drug antibodies (ADAb) measurements were done prior to every infusion, but results were not reported during the study. Assays for drug serum levels and ADAb are fully automated on the AutoDELFI® (PerkinElmer, Waltham, MA) immunoassay platform.

**Results:** Twenty patients entered the study with detectable ADAb (9 in INX arm, 11 in CT-P13 arm). 36 additional patients developed detectable ADAb during the 52-week study period (17 in INX arm, 19 in CT-P13 arm). Incident ADAb in each disease are shown in the table. Patients with detectable ADAb at any time during the study period were more likely to discontinue study drug treatment (7/26 (26.9%) in INX arm, 5/30 (16.7%) in CT-P13 arm) than patients without detectable ADAb (17/214 (7.9%) in INX arm, 13/210 (6.2%) in CT-P13 arm) (p<0.001).

**Conclusions:** The NOR-SWITCH study demonstrated similar immunogenicity in patients switched to CT-P13 vs those who continued INX treatment, supporting that switch does not influence ADAb formation. Presence of ADAb was associated with termination of study treatment.

**THU0701 THE EFFECTS OF STRUCTURAL DAMAGE ON FUNCTIONAL DISABILITY IN PSORIATIC ARTHRITIS**

A. Kerschbaumer, F. Alasti, J.S. Smolen, D. Aletaha. Department of Medicine III (Chairman: Prof Josef Smolen, MD), Medical University of Vienna, Vienna, Austria

**Background:** Functional outcomes are central in patients with chronic inflammatory musculoskeletal diseases. It has been shown in rheumatoid arthritis that functional outcomes are impaired in the presence of structural damage, a finding that has not yet been investigated in psoriatic arthritis (PsA), which has a more complex phenotype than rheumatoid arthritis (RA).

**Objectives:** To quantify the association of radiographic damage with physical function in PsA patients.

**Methods:** We analysed patients enrolled in the GO-REVEAL study 1 who had received golimumab. We obtained modified Sharp-van-der-Heijde scores (mSvDHS) from X-rays, performed at week 0, 24, 52 and week 104 (n=262). In longitudinal data analysis, we then used generalized estimating equations (GEE) on all patients in DAPSA remission (n=96), utilising all their remission visits, whereby the health assessment questionnaire (HAQ) disability index of each patients visit was used as dependent variable and mSvDHS, joint space narrowing (JSN) and erosion (ERO) scores, respectively, were used as independent variables in separate models. To analyse effects of structural damage on changeability of functional limitations, we identified a subgroup of patients who had functional limitations at baseline (HAQ≥1) and who showed a major response of DAPSA (improvement of ≥85% from baseline). In this model we assess the effect of mSvDHS on changes in HAQ, while adjusting for HAQ at baseline (n=54).

As validation cohort, we analysed a routine clinic PsA cohort with complete HAQ, while adjusting for HAQ at baseline (n=32).

**Results:** As shown in table 1 and visualised in figure 1A, for patients in DAPSA remission, significant effects were seen for both DAPSA and mSvDHS, whereas no effects were seen for either for patients in DAPSA major response (n=96) and in patients with limited/intermediate activity (n=96).

In the second analysis, looking at patients achieving DAPSA major response, again, results were significant for the association total mSvDHS and JSN. Additionally, higher estimates of JSN, compared to mSvDHS could be observed, with relative HAQ change as outcome parameter (see table 1 and figure 1B).

Table 1. Association of radiographic damage and HAQ in separate GEE models

*Adjusted for HAQ at baseline.

**Conclusion:** Our results suggest that in JSN is functionally more important than...
erations. Functional outcomes have an irreversible component that is strongly related to the amount of structural damage. This needs to be considered when targeting functional outcomes in clinical practice.

THU0702 ARE MRI-DETECTED EROSIONS SPECIFIC FOR RA? A LARGE EXPLORATIVE CROSS-SECTIONAL STUDY
D. Boeters1, W. Nieuwenhuis1, H. van Steenbergen1, R. Landewé2, M. Reijniers3, A. van der Helm-van Mil1, 1Department of Rheumatology, LUMC, Leiden; 2Department of Clinical Rheumatology and Immunology, AMC and Anium MC, Amsterdam and Heerlen; 3Department of Radiology, LUMC, Leiden, Netherlands

Background: Magnetic resonance imaging (MRI) is recommended in the diagnostic process of rheumatoid arthritis (RA), as it can detect damage at an earlier time point than conventional radiographs. However, MRI-detected erosions as defined by EULAR and included in RAMRIS are also observed in symptom-free controls, especially at older age. It is unclear how RA-specific erosions on MRI can be distinguished from physiological erosions in symptom-free individuals. Therefore this study compared MRI-detected erosions between RA-patients and healthy controls, including evaluation of the effect of age.

Objectives: To compare characteristics of MRI-detected erosions (total erosion score, location and severity of erosions and simultaneous presence of MRI-detected edema) found in metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints between RA-patients and healthy controls.

Methods: 422 subjects (229 newly presenting patients with a clinical diagnosis of RA and fulfilling the 2010-criteria and 193 symptom-free controls) underwent contrast enhanced 1.5T MRI of unilateral MCP and MTP joints. The readers were blind to the clinical information. Total erosion score according to the RAMRIS method (hence a combination of number and severity), location and severity of erosions and simultaneous presence of MRI-detected inflammation (synovitis and/or bone marrow edema) were compared between groups, also in relation to age.

Results: First total erosion scores were analyzed. Both in RA-patients and in controls this score was associated with age (p<0.001 in both groups). In addition, at all ages and on group level, RA-patients had 1.2 (95% CI 1.1–1.3) times higher erosion scores than controls. Despite this difference, total erosion scores could not differentiate RA-patients from controls on the individual level, as there was large overlap (Figure). Next different characteristics of erosions were explored within age groups (<40, 40–59, ≥60) to search for RA-specific features. With respect to location, erosions found in MTP5 were specific for RA (spec 90–98% for different age groups). Erosions found in MTP1 were specific for RA if subjects were aged <40 (spec 98%), but specificity decreased by increasing age (spec 86% if aged 40–59 and 63% if aged ≥60). Evaluating the severity revealed that “severe erosions” (scores ≥2) were infrequent in all subjects, but almost exclusively present in RA (spec 98–100%). Finally the simultaneous presence of erosions with inflammation was studied. In the age group <40 years, the simultaneous presence was exclusively observed in RA-patients (specificity 100%); but specificity decreased by age since the combined presence was also seen in symptom-free controls (spec 91% if aged 40–59 and 71% if aged ≥60 years).

Conclusions: Whilst the group of RA-patients at disease presentation had significantly higher erosion-scores than healthy controls, scores of individuals subjects were largely overlapping. Some erosion characteristics were specific for RA, but these were present in only a minority of all RA-patients (22%).

THU0703 SYSTEMATIC REVIEW OF RHEUMATOID ARTHRITIS CLINICAL STUDIES: SUBOPTIMAL STATISTICAL ANALYSIS OF RADIOLOGICAL DATA
S. Mahmood1, L. van Tuy1, L. Schoonmade2, R. Landewé1, D. van der Heijde1, J. Twisk1, M. Boers1, 1Amsterdam Rheumatology and immunology Center; 2VUmc, Amsterdam; 3LUMC, Leiden, Netherlands

Background: Radiography is an inexpensive, reliable and reproducible method to detect and quantify progression of damage, an important outcome in rheumatoid arthritis (RA) trials and observational studies. However, the distribution of progression scores is skewed with many low or small readings. Analysis of such data is challenging, and the choice of analysis technique may influence the result. Current analysis practice is unknown.

Objectives: We systematically searched the literature to identify current practice for the analysis of radiographic progression in clinical trials and observational studies of RA.

Methods: PubMed Embase and Cochrane databases were searched (2006–2016) to identify studies that described analysis techniques to compare radiographic progression in at least two groups. Studies in animals, children as well as conference abstracts and studies not written in English were excluded. Titles and abstracts were screened by one researcher (SM); a second investigator (LvT) evaluated the included cases, doubtful cases and a random sample of the excluded cases.

Results: On study design, sample size, assessment methods and analysis technique was extracted by one researcher (SM), in consultation with 3 others (LvT; MB and JT).

Results: Of 5980 identified papers, 252 were eligible. 228 of these reports were on a single study while 26 were on multiple studies in one paper. Of the 226 eligible studies, 75 studies used parametric techniques (hence a combination of number and severity), location and severity of erosions and simultaneous presence of MRI-detected edema were compared between groups, also in relation to age.

Results: First total erosion scores were analyzed. Both in RA-patients and in controls this score was associated with age (p<0.001 in both groups). In addition, at all ages and on group level, RA-patients had 1.2 (95% CI 1.1–1.3) times higher erosion scores than controls. Despite this difference, total erosion scores could not differentiate RA-patients from controls on the individual level, as there was large overlap (Figure). Next different characteristics of erosions were explored within age groups (<40, 40–59, ≥60) to search for RA-specific features. With respect to location, erosions found in MTP5 were specific for RA (spec 90–98% for different age groups). Erosions found in MTP1 were specific for RA if subjects were aged <40 (spec 98%), but specificity decreased by increasing age (spec 86% if aged 40–59 and 63% if aged ≥60). THU0704 EVALUATION OF THE ACCURACY OF HAND AND FOOT MRI IN THE EARLY IDENTIFICATION OF RA: USING THE PREVALENCE OF LOW-GRADED INFLAMMATION IN THE SYMPTOM-FREE POPULATION AS REFERENCE REDUCES FALSE-POSITIVE MRI RESULTS
A.C. Boer1, L.E. Burgers1, L. Mangrus1, R.M. Ten Brink1, W.P. Nieuwenhuis1, H.W. Van Steenbergen1, M. Reijniers4, T.W. Huizinga1, A.H. van der Helm van Mil1, 1Rheumatology; 2Radiology, LUMC, Leiden, Netherlands

Background: Early identification of rheumatoid arthritis (RA) is important, because it allows early treatment initiation and is associated with better disease outcomes. In this perspective, the use of hand and foot MRI in the diagnostic process of rheumatoid arthritis (RA) has been advocated. Recent studies showed that MRI is helpful in predicting progression from clinically apparent arthritis (CAA) to clinical arthritis, and from undifferentiated arthritis (UA) to RA. However, the diagnostic value of MRI is still undetermined. Most studies focussed on the sensitivity rather than the specificity of inflammation detected on MRI. It is known that symptom-free persons can also show inflammation on MRI. Consequently, it has been questioned if MRI-findings in symptom-free volunteers are relevant to consider as a reference when defining a “positive MRI”.

Objectives: To determine the value of considering MRI-findings in a control group for the predictive accuracy of MRI when defining a positive MRI.

Methods: 225 patients with CSA and 201 patients with UA underwent MRI of MCP-, wrist- and MTP-joints at baseline and were followed for 1 year on progression to arthritis and RA respectively. MRI was considered positive either if ≥1 joint showed inflammation (called “uncorrected definition”), or if ≥1 joint had inflammation that was present in <5% of persons of the same age-category and location in a symptom-free reference population (called “5% corrected definition”). MRI scans were scored according to RAMRIS method. Test characteristics were compared for both definitions, hence with and without the incorporation of a reference population when defining a “positive MRI”.

Results: By using MRI-data of symptom-free volunteers as reference, the
specificity of MRI-detected inflammation increased from 22% to 56% in CSA-patients, and from 10% to 36% in UA-patients. The sensitivity was not affected; it was 88% and 85% in CSA-patients and 93% and 93% in UA-patients. The accuracy also increased, from 32% to 60% in CSA-patients and 22% to 44% in UA-patients.

Conclusions: The use of a reference population resulted in a substantial reduction of false-positive results, without affecting the sensitivity. This is of high importance because of the potential risks of false-positive MRI-results, for example in the setting of UA as a positive MRI-result may influence the decision to initiate disease modifying medication. Although a reference population is generally used in medicine for other tests to derive a definition of a positive test result, this is the first study demonstrating the value of a reference population to define a “positive MRI”.

**THU0705 EXPERIMENTAL USE OF 3D PRINTING TECHNOLOGY FOR THE CONSTRUCTION OF DEVICES AS INTEGRATION OF OCCUPATIONAL THERAPY INTERVENTION WITH RHEUMATOID ARTHRITIS PATIENTS (RA)**

G. Sandri 1, A. Bottini 2, F. Franchi 3, M.T. Mascia 2, 1 Department of Clinical, Diagnostic and Public Health, Service of Rheumatology; 2 Department of Clinical, Diagnostic and Public Health, Occupational Therapy Unit; 3 Orthopedic, Hand Rehabilitation, Modena, Italy

Background: RA is a chronic inflammatory disease that can interfere with the ability to perform activities of daily living. The adoption of aid devices allows to maintain and/or improve employment performance, reducing the pain preventing further joint damage. However, it is known that the abandonment rate of such devices is quite high, resulting in failure of the rehabilitation project, and waste of resources. The reasons people give for abandoning support technology are that they have not been involved in the process of provision, and that the devices do not have the intended effect (1).

Objectives: technology may allow customization of 3D printing devices agreed together with patients, utilizing materials which are cheap, fast and easily adjustable.

Methods: The study was organized into the following phases: recruitment of RA patients for the “joint protection laboratories”; sessions of the “joint protection laboratories”; recruitment of patients for the identification of needs for customized aid devices; co-design of customized aid devices; printing of customized aid devices; delivery of customized aid devices; detection using customized aid devices. We have collected a list of needs to be able to develop such customized aid devices at the end of a course to educate on joint protection covering: ergonomic gestures, management of fatigue and pain, environmental adaptations and aid devices.

18 patients (17 women and 1 man), age between 30 and 75 years old, were organized into small groups for the “joint protection laboratories”. 9 patients expressed their specific needs regarding the aid devices and therefore subsequent meetings were organized that have allowed us to produce and deliver customized objects. Autodesk® Fusion360 for object modeling; Ultimaker Care for slicing; 3D printing laboratories”; recruitment of patients for the identification of needs for customized aid devices; co-design of customized aid devices; printing of customized aid devices; delivery of customized aid devices; detection using customized aid devices. We have collected a list of needs to be able to develop such customized aid devices at the end of a course to educate on joint protection covering: ergonomic gestures, management of fatigue and pain, environmental adaptations and aid devices.

Results: 6 aid devices were customized: hand grip holder for chalk, toothbrush, ignition key, tablespoon, iron, as well as a handle to open the moka coffee machine.

The psychosocial assessment of 6 delivered aid devices, collected through PIADS, showed an overall positive outcome (mean competence +1,488; adaptability: +1,690; self-esteem: +1,375). The assessment of patient satisfaction through QUEST, was good overall (scale 1–5: satisfaction aid: 4,75; service satisfaction: 4,68).

Conclusions: This work also demonstrated, over a range of small numbers, that the path of co-design and production of customized aid devices via rapid manufacturing with 3D printing technology is feasible and fulfilling.

**THU0706 LOW DISEASE ACTIVITY AFTER A SHORT COURSE OF DRUG THERAPY AND REHABILITATION IS ASSOCIATED TO A GREATER IMPROVEMENT IN FUNCTIONAL CAPACITY IN RHEUMATOID ARTHRITIS**

B. Cunha, B. Ferreira, L. Moreira, C. Barros, A. Gushikem, J. Kauer, T. Ferreira on behalf of SARAR 2 cohort. Rheumatology, SARAF Network of Rehabilitation Hospitals, Brusia, Brazil

Background: Patients with rheumatoid arthritis (RA) have lower functional capacity than general population (1). Studies have shown that patients are able to improve their functional capacity after adequate treatment with disease-modifying antirheumatic drugs (DMARDs) (1–2), but it is unclear which other factors are involved in rehabilitation settings.

Objectives: To investigate which clinical factors are associated to improvement in functional capacity in patients with RA in the context of DMARD therapy and rehabilitation.

Methods: It was a case-control study. Patients with RA admitted between June 2014 and July 2016 were included. Assessments were carried out just before and after completion of rehabilitation program. Functional capacity was assessed with Health Assessment Questionnaire-Disability Index (HAQ-DI). Disease activity was evaluated with Clinical Disease Activity Index (CDAI). It was allowed to change DMARD treatment or dose during the follow-up period. Interventions were carried out at the discretion of the rehabilitation team and could include joint injections, exercises, orthoses, insoles, educational interventions and assistive devices. Patients that were operated in the follow-up period were excluded. An improvement in HAQ-DI was defined as a difference of -0,22. Patients that improved after treatment were compared with those who did not, regarding clinical characteristics and modalities of treatment that were employed. Chi-square or Fisher exact test analyses were employed.

Results: Forty-six women and two men were included, with average age of 56 (11) years old and 10,8 years of diagnosis, Rheumatoid factor was positive in 58% (mean title 2423 U/L); anti-CCP was positive in 48% (mean title 283,8 U/L). Patients were followed for 6–12 months.

HAQ-DI improved 0,51 (0,3–0,71; p<0,001) and CDAI improved 12,8 (7,6–17,9). Patients that were able to improve HAQ-DI had a better average CDAI in the second assessment (16 vs. 7; p<0,011). There was no association between improvement of HAQ-DI and other clinical and laboratory variables, including drug and rehabilitation modalities.

Conclusions: Low disease activity after a short course of drug therapy and rehabilitation is related to a greater improvement of functional capacity in patients with RA. Therefore, patients with RA may have better outcomes in rehabilitation if disease activity is controlled.

**THU0707 RACE & REHABILITATION DESTINATION AFTER TOTAL HIP REPLACEMENT**

E.R. Vina 1, M. Kallan 2, A. Collier 2, C. Nelson 2, S. Ibrahim 2, 1 University of Arizona, Tucson; 2University of Pennsylvania, Philadelphia, United States

Background: There are marked racial/ethnic disparities in the utilization of hip joint replacement in the US. Differences in post-surgical rehabilitation care may influence this disparity. There is relatively little research on racial variations in post-hip joint replacement surgery care processes.

Objectives: The main objective of this analysis was to examine racial differences in where patients go for post-acute care rehabilitation after elective hip replacement surgery. We also assessed whether or not where patients go for post-surgery rehabilitation care impacts quality of care markers such as 90-day hospital readmission.

Methods: A retrospective, large regional dataset analysis using the Pennsylvania Health Care Cost Containment Council database was performed. Patients who underwent elective hip replacement surgery and discharged from Pennsylvania hospitals between fiscal years 2008–2012 were selected. Post-surgery rehabilitation destination options included: home with self-care, home with health (HH) care; skilled nursing facility (SNF) and in-patient rehab facility (IRF).

We used multinomial logistic regression models to estimate unadjusted and adjusted relative risk ratios (aRRRs) of being discharged home with HH care, to a SNF or to an IRF (vs. home with self-care) after surgery, comparing African-American (AA) to white patients. Multivariable models adjusted for patient-level and facility-level variables associated (p<0,10) with post-surgical discharge destination based on bivariate analyses. Unadjusted and adjusted odds ratios (aORs) of 90-day hospital readmission were estimated using binary logistic regression models. Multivariable models adjusted for patient-level and facility-level variables associated
Among patients <65 years of age, compared to whites, AAs had higher risk of discharge to an IRF (aRRR 1.96, 95% CI, 1.39–2.76) and a SNF (aRRR 1.60, 95% CI, 1.15–2.23). Among those ≥65 years of age, compared to whites, AA patients who underwent hip replacement were more likely to rely on Medicare or Medicaid (47.5% vs. 17.3%) (both p<0.001), compared to whites (p<0.001, all comparisons, both age groups).

The Figure summarizes the unadjusted (UN) and adjusted (ADJ) RRRs of referral within 90 days.

Comparing to whites, AA patients who underwent hip replacement were more likely to receive total knee arthroplasty (3).

Background: Knee osteoarthritis affects mobility leading to substantial loss of perceived health and quality of life. Our previous study showed that aged persons with various comorbidities may profit from comprehensive rehabilitation in the short-term by corrected effect sizes up to 0.62 in pain, 0.51 in physical function, and 0.32 in psychosocial health (1).

Objectives: To follow-up those patients to 5 years by 1) quantifying observed effects in pain, function, and psychosocial health and 2) associating risk factors to total knee arthroplasty during the observation period.

Conclusions: Compared to whites, AA patients who underwent hip replacement were more likely to be discharged to an IRF or SNF. Furthermore, discharge to either IRF or SNF was associated with higher risk of hospital readmission.

THU0708 LONG-TERM OUTCOME AND RISK FOR TOTAL ARTHROPLASTY OF KNEE OSTEOARTHRITIS AFTER COMPREHENSIVE REHABILITATION

F. Angst1, T. Benz1, A. Aeschlimann1, S. Lehmann1, B. Winteler2, M.L. Verra3,1 Research, Rehabilitation Clinic "REHACLINIC" Bad Zurzach;2 Physiotherapy, Bern University Hospital, Bern, Switzerland

Background: Knee osteoarthritis affects mobility leading to substantial loss of perceived health and quality of life. Our previous study showed that aged persons with various comorbidities may profit from comprehensive rehabilitation in the short-term by corrected effect sizes up to 0.62 in pain, 0.51 in physical function, and 0.32 in psychosocial health (1).

Objectives: To follow-up those patients to 5 years by 1) quantifying observed effects in pain, function, and psychosocial health and 2) associating risk factors to total knee arthroplasty during the observation period.

Methods: Prospective cohort study with assessments at baseline (start of rehabilitation) and 1, 2, 3, 4, 5 years after. Comprehensive rehabilitation lasted 2–3 weeks for inpatients and 6 weeks for outpatients. Changes between baseline and the follow-ups were measured by the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and the Short Form 36 Health Survey (SF-36). They were expressed as raw scores (RS) according to Kazis (2). Multivariate logistic regression included various sociodemographic and disease-modifying confounders and provided adjusted odds ratios (OR) for the risk of getting total knee arthroplasty.

Results: At baseline, n=205 knee osteoarthritis patients were included: 77.1% were women; mean age 65.7 years (sd=10.3y), 81.5% having 3 or more comorbidities. Up to the 5 year follow-up, n=83 (40.5%) remained with complete data, 48 (23.4%) received arthroplasty. At 5 years, ES were 0.13 to 0.79 for pain, −0.12 (worsening) to 0.42 (improvement) for function, and −0.25 to 0.21 for psychosocial health. At the last follow-up before surgery, WOMAC pain had worsened by ES=−0.42 (p<0.001) and WOMAC function by ES=−0.54 (p=0.002) in the total knee arthroplasty group. Getting total knee arthroplasty was statistically significantly associated with female sex (OR=3.30), educated at university (OR=3.54), minus 1 commodity less (OR=1.14), and 10 (of 100 possible) points worsening on the WOMAC factor ascending-descending (OR=1.60).

Conclusions: Moderate to small improvements on pain, function, and psychosocial health were observed up to 5 years after comprehensive rehabilitation of knee osteoarthritis. Nevertheless, almost one quarter of the participants were referred to total knee arthroplasty suffering from significant deterioration in pain and function. The WOMAC seems to be sensitive to predict the need for arthroplasty. Highly educated women with low number of comorbidities and high disability to manage stairs were more likely to receive total knee arthroplasty (3).

THU0709 DOES THE USE OF ANALGESIC CURRENT THERAPIES INCREASE THE EFFECTIVENESS OF NECK STABILIZATION EXERCISES FOR IMPROVING PAIN, DISABILITY, MOOD, AND QUALITY OF LIFE IN CHRONIC NECK PAIN? A RANDOMIZED, CONTROLLED, SINGLE-BLIND STUDY (A PILOT STUDY)

H. Yesil1, S. Hepguler2, U. Dundar1, S. Taravati3, B. Isleten2, 1Physical Medicine and Rehabilitation, Akyon Kocatepe University, Faculty of Medicine, Akyonkarahisar;2Physical Medicine and Rehabilitation, Ege University Faculty of Medicine, Izmir;3Physical Medicine and Rehabilitation, Yalova Akit Hastanesi, Yalova, Turkey

Background: Analogics; such as intercurrent pain (IFC) and transcutaneous electrical nerve stimulation (TENS) have been applied solo or combined with exercise for management of neck pain (NP), however, the efficacy of these combinations are unclear.

Objectives: To determine if TENS or IFC increase the effectiveness of neck stabilization exercises on pain, disability, mood, and quality of life for chronic NP.

Methods: 60 patients with chronic NP were included in the study. Patients were randomly assigned into 3 groups; Group I: neck stabilization exercise, Group II: TENS+ neck stabilization exercise and Group III: IFC+ neck stabilization exercise. Patients’ pain levels (visual analogue scale (VAS)), quality of life (short form-36), mood (Beck depression inventory (BDI)), levels of disability (Neck Pain and Disability Index) and the need for analgesics were evaluated prior to treatment, at 6th and 12th week follow-up. All participants had group exercise accompanied by a physiotherapist for 3 weeks and an additional 3 weeks of home exercise program.

Results: All three groups had statistically significant improvement regarding their VAS, neck disability index and most sub-scores of short form-36 (p<0.05). At 12th-week follow-up, no difference was found between groups regarding pain, disability, and quality of life (p>0.05). On the other hand, analyses indicated significantly lower scores of neck disability index (p=0.004) and less need for paracetamol (p=0.036) in TENS group 6th-week follow-up when compared to exercise and IFC groups.

Conclusions: All treatment modalities improved pain, disability, mood and quality of life in patients with chronic NP. Besides, results suggest TENS enhanced the efficacy of exercise therapy on pain, disability and need for analgesics in acute phase but not in long term, since there was no difference at 12th week follow-up. To conclude, we think exercise protocols can be of choice since they are inexpensive, easy and effective in the management of chronic NP.

Conclusions: Disease activity changed from moderate to low in the NinJa cohorts and the scoring system was validated for the years 2009 and 2014. The weighted scoring system appears useful to predict functional disability in a simpler way by examining each joint rather than changes in disease activity among patients with RA.

THU0712 DUTCH NORM SCORES FOR FOUR DUTCH-FLEMISH PROMIS ITEM BANKS IMPORTANT FOR PATIENTS WITH RHEUMATOID ARTHRITIS

M.H. Crins1, L.D. Roorda1, H.C. de Vet1, R. Westhovens2,6, M. Boers2,6, J. Dekker1, C.B. Terwee2,1, Amsterdam Rehabilitation Research Center, Reade; 2Department of Epidemiology and Biostatistics, The EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands; 3Rheumatology, University Hospitals; 4Department of Development and Regeneration, Skulltal Biological and Engineering Research Center, KU Leuven, Leuven, Belgium; 5Amsterdam Rheumatology and immunology center; 6Department of Rehabilitation Medicine and Department of Psychiatry, VU University Medical Center, Amsterdam, Netherlands.

Background: In the assessment of patients with rheumatoid arthritis (RA), it is important to measure physical function, fatigue, pain behavior and pain interference. The Patient-Reported Outcomes Measurement Information System (PROMIS) initiative developed item banks for measuring these concepts. These item banks were translated into Dutch-Flemish language.

Objectives: To facilitate interpretation and implementation of PROMIS in the Netherlands, we aimed to calibrate and validate the Dutch-Flemish PROMIS Physical Function (DF-PROMIS-PF), Fatigue (DF-PROMIS-PA), Pain Behavior (DF-PROMIS-PBP) and Pain Interference (DF-PROMIS-PI) Item Banks in the general Dutch population, to obtain Dutch norm scores for these item banks.

Methods: 3568 persons of the general Dutch population completed a web-based survey, of which 1309 persons completed the full DF-PROMIS-PF (121 items), 1007 persons completed the full DF-PROMIS-PA (95 items), and 1049 persons completed the full DF-PROMIS-PBP (39 items) and the full DF-PROMIS-PI (40 items). The sample was stratified for gender, age, education, and ethnicity according to the distribution of the Dutch census of the 2015 census of the general Dutch population. A one-factor confirmatory factor analysis (CFA) was performed per item bank to assess unidimensionality. A graded item response model (GRM) was fitted per item bank to evaluate the item characteristics of the item banks and to facilitate future development of computer adaptive tests (CATs). Ordinal regression models were used to evaluate Differential Item Functioning (DIF) for language (Dutch vs. English) as a measure of cross-cultural validity.

Results: All four item banks showed good fit to the GRM: they showed good fit indices for CFA and high percentages of explained variance by first factor. The item banks showed only little local dependency and the scalability coefficients suggested strong scalability for all four item banks. The item characteristics
HOW THE VARIATION IN THE LUMBOPELVIC PATTERNS OF MOVEMENT AFFECTS THE NEUROMOTOR CONTROL OF THE BICEPS FEMORIS DURING TRUNK FORWARD BENDING

M. Sarli1, R. Expositor-Rodriguez2, R. Borona-Carvajal1, M. Vázquez-García3, M. Fuster-Ortí1,1 Human Anatomy and Embryology, University of Valencia (UVET), 2 Inst, for Research on Musculoskeletal Disorders, Catholic University of Valencia; 3 Rheumatology Section, Pesset Hospital; 4 Department of Statistics and Operations Research, Universidad de Valencia (UVET), Valencia, Spain

Background: Trunk forward bending is one of the most common activities in daily living; it is a two-part movement involving the lumbar spine flexion and pelvis rotation at hip joint. The pattern of movement during forward bending was defined as the relative contribution of the lumbar spine to pelvis motion, and was expressed as the ratio between the ranges of lumbar spine motion to pelvis motion (L/P), which, calculated at certain degrees of trunk flexion during the entire movement, provides the lumbo-pelvic rhythm. This is associated with a specific pattern of activation for back and hip extensor muscles which was coined as flexion relaxation phenomenon, observed either in the erector spinae and biceps femoris. This paper aims to have described the whole lumbo-pelvic pattern of movement for entire flexion range, showing both lumbar spine dominant and pelvis dominant-patterns of movement.

Objectives: To find out whether the variation in the lumbo-pelvic pattern of movement (lumbar spine or pelvis dominant) affects the appearance of the respective “range of motion” of trunk forward bending.

Methods: Surface electrodes were applied to the skin on right BF, midway between ischial tuberosity and head of fibula to record EMG during trunk flexion (from the upright position). Trunk flexion EMG signal was full-wave rectified and averaged (40ms) to produce a linear envelope. An electrogoniometer measured the differential lumbar spine - pelvis sagittal angular displacement during trunk flexion in asymptomatic subjects. Both signals (EMG and degrees) were synchronized and continuously captured during the movement. Ranges of flexion (RF) for the lumbar spine, pelvis and trunk motion were calculated for the entire movement. The subjects (both sexes) were assigned to group-L (n=11) and group-P (n=15) according to exhibiting lumbar spine and pelvis dominant-patterns of movement (average age, 24.5±3.3 years).

The mean age was found 21.69±2.13 years old for the control group and 20.09±2.85 years old for the HMG group. Body Mass Index was found 22.13±2.54 kg/m² in the control group and 21.54±3.50 kg/m² in the HMG group. HMG group showed significantly wider step width in tandem walking (p=0.001), significantly longer reaction time (p=0.23, p=0.030), significantly higher end-point excursion (p=0.003, p=0.026, p=0.049), significant higher maximum mean excursions (p=0.018) (Table 1).

Table 1. Comparison of Groups About Balance Variables

Conclusions: In this study it was found that hypermobility has significant effects on the stability limits test and tandem walking. In previous studies it was found that hypermobility affects the static balance assessment variables (1, 2), but in this study dynamic balance assessment variables were affected.

Background: Over 85% of rheumatoid arthritis (RA) patients experience foot and ankle problems during the course of the disease. Persistent foot and ankle problems still occur even after clinical remission is reached [1]. In RA, synovitis, effusion, and eventually erosive arthritis are thought to cause clinically recognized planovalgus or valgus heel [1]. With the intention to stabilize and align the foot, patient-specific foot orthotics (FO) are commonly prescribed to this patient group. A limitation of the previous literature on FO to treat RA and related diseases is that it has focused on clinical outcomes of FO such as pain and physical function, while overlooking the biomechanical principles on which the rationales for FO is based [2].

Objectives: The aim of this study was to investigate the effect of patient-specific FO on hip loading during gait. This was accomplished by developing patient-specific (PS) musculoskeletal models (MS) capable of estimating joint mechanics with and without the FO.

Methods: Four early stage RA patients were recruited for this study. A pair of FO was developed for each patient using a weight bearing casting technique. PS bone geometry was obtained from magnetic resonance imaging (MRI) images and segmented in an image analysis package (Mimics 19, Materialise, Belgium). Motion capture was performed with an eight-camera setup (Qualysis, Sweden) with reflective markers together with three force plates (AMTI, USA) sampling at 100 and 1000 Hz, respectively. The gait trials consisted of two conditions: one with PS FO and one with control insole (C). Three force plates of each patient were developed using the AnyBody Modeling System (AnyBody Technology, Denmark), Figure 1A. Muscle attachments were made PS based on the Twente Lower Extremity Model version 2.0 dataset using advanced morphing to customize a generic cadaver-based model with respect to PS morphology.
acquired from MRI [3]. Accurate joint centers and axes were calculated with analytical surface fits to the segmented MRI bones for the hip, knee and ankle. **Results:** Peak hip force for medio-lateral (ML) proximo-distal (PD) and antero-posterior (AP) is presented in Figure 1B for the C and FO with values for each subject. **Conclusions:** The results of this study indicate that FO can change the load distribution in the hip joint. A reduction or similar values for ML, DP and AP force was found for all but one participant. These changes may potentially contribute to the reduction in pain. Further studies are needed to investigate if there is a relationship between changed loading and pain for RA patients. This knowledge can potentially be used for design of better FO and clinical guidelines for use of FO. **References:** [1] Hennessy K. et al, Arthritis Care Res, 64: 311–320, 2012. **THU0716** Longitudinal outcome of aerobic fitness in adolescents and young adults with JIA

P.V. Peit 1,2, T. Takken 3, M.V. Brussel 1, R. Dolhaun 1, J. Hazes 1, J. Bijlsma 5, N. Wulfhart 2, A. Kruize 5. 1Department of Rheumatology, Erasmus MC, University Medical Center Rotterdam, Rotterdam; 2Department of Pediatric Immunology, Wilhelmina Children’s Hospital, University Medical Center Utrecht; 3Child Development and Exercise Center, Wilhelmina Children’s Hospital, University Medical Center Utrecht; 4Child Development and Exercise Center, Wilhelmina Children’s Hospital, University Medical Center Utrecht; 5Department of Rheumatology and Immunology, University Medical Center Utrecht; 6Department of Pediatric Immunology, Wilhelmina Children’s Hospital, University Medical Center Utrecht, Utrecht, Netherlands

**Background:** Aerobic fitness may serve as an important health-related outcome measure in JIA. A reduced aerobic fitness is associated with cardiovascular morbidity, mortality and osteoporosis in adult patients with chronic diseases. However, in adolescents and young adults, long-term outcome data of aerobic fitness are unknown. Reduced aerobic fitness was described in cross-sectional studies in children and adolescents with JIA, and was more impaired in active disease.

**Objectives:** Our objectives are to describe course of the aerobic fitness in a longitudinal cohort of adolescents and young adult JIA-patients who are intensively treated including the possibility of biologics and to identify the association of clinical variables with aerobic fitness.

**Methods:** In a longitudinal cohort, all consecutive JIA patients aged 10–24 years were included after informed consent. Annual examinations were obtained from demographic and disease-related items. At baseline and end of the study, aerobic fitness (VO2peak) test was assessed using a graded cardiological exercise test (CPET) to volitional exhaustion performed on an electronically braked cycle ergometer. Absolute and relative VO2peak values were measured and related to healthy controls (Z-scores), using one-sample T-tests. Non-parametric tests were used to evaluate results.

**Results:** Paired Z-scores were available from 27 patients. 44% were male, median age at baseline was 13.0yrs (IQR 4.3), disease duration 7.6yrs (6.7), JADAS27 4.0 (5.9), DAS28 2.2 (1.2). 76% of the patients were in DAS28-remission. 11% had systemic JIA. 7% persistent oligoarticular and 82% had a polyarticular course. Baseline and end Z-scores were reduced compared to healthy controls (ZAbs_base -0.68, IQR2.3 p<0.01; Zrel_base -1.33, IQR 2.0, p<0.01; Zabs_end -0.23, IQR 1.7, p<0.06; Zrel_end -0.87, IQR 2.2, p<0.01) and did not change significantly over time (change Zabs_change 0.45, p=0.34; Zrel_change 0.46, p=0.31). At baseline, MTX-use (p<0.04) and a higher DAS28 (p<0.015) and ESR (p<0.013) are associated with a worse outcome of aerobic fitness. The greatest improvement of aerobic fitness over time was seen in patients with a higher ESR (p<0.01) and thrombocytes (p=0.01) at baseline. Multivariate analysis showed that a higher DAS28 and male gender were the most important variables for worse aerobic fitness at baseline, a higher ESR at baseline was the most important predictor for improving aerobic fitness over time.

**Conclusions:** Aerobic fitness is significantly reduced in adolescents and young adults with JIA and does not improve over time, despite intensive treatment. Be aware of a reduced quality of life due to a persistent reduced aerobic fitness during disease course of JIA, despite low disease activity.

**THU0717** Mirror visual feedback therapy improves clinical outcomes and the activity of daily living in patients with hand complex regional pain syndrome

S. Patru 1, I.R. Marcu 2, D. Matel 1, A.M. Bumbea 1, A.C. Bighea 1. 1Physical Medicine and Rehabilitation; 2University of Medicine and Pharmacy of Craiova, Craiova, Romania

**Background:** Wrist osteoporotic fractures may be as disabling as vertebral or hip fractures and the functional decline attributed to them is similar to that seen for arthritis and diabetes mellitus. Sometimes these fractures will lead to a painful, debilitating condition with sensory and motor disturbances, changes in vascular tone, temperature and edema complex regional pain syndrome (CRPS). We found in clinical trials and case reports which conclude that mirror visual feedback therapy (MVFT) improves clinical outcomes and the activity of daily living to patients with hand neurological disorders, including CRPS.

**Objectives:** In this controlled randomized clinical study we tried to investigate the effects of (MVFT) in CRPS type I following osteoporotic wrist fracture.

**Methods:** We included 21 subjects with osteoporotic wrist fracture and early CRPS (duration of 3–4 weeks), with a single hand affected by aloldynia, stiffness and vasomotor disturbances, from Physical Medicine and Rehabilitation outpatient clinic. They are randomly assigned into two groups: MVFT group (n=11), simply place a mirror between their two hands and train the patient by asking them to move both hands while watching the reflection of the non-affected hand in the mirror, 10 minutes for each session, four times a day) and Control group (n=10, moved both hands separated by an opaque partition between the arms). All subjects also received conventional therapy. On presentation and after 4 weeks of rehabilitation programme we assessed the wrist flexion and extension with a goniometer and the Patient-Rated Wrist Evaluation (PRWE) a 15-items questionnaire designed to measure wrist pain and disability in activities of daily living.

**Results:** Subjects in the mirror therapy group showed significant improvement in range of motion: extension increased with 50.4% vs. 41.7% and for flexion MVFT achieved 33.2% and Control group 16.8% (P<0.001). The rehabilitation programme also increased hand function with better results to 4 weeks PRWE for MVFT group (40.4 vs. 51.8, P=0.003).

**Conclusions:** MVF is a simple, inexpensive, without adverse events treatment option that significantly reduces pain and stiffness and improves hand mobility in early CRPS after osteoporotic wrist fracture.

**Disclosure of Interest:** None declared DOI: 10.1136/annrheumdis-2017-eular.2339

**THU0718** Differences in the course of Italian- and German-speaking patients’ outcome after interdisciplinary pain program

T. Benz 1,2, S. Lehmann 2, R. Brioschi 2, A. Effering 1, A. Aeschlimann 2, F. Angst 3. 1Institute of Psychology, University of Bern, Bern; 2Research Department, RehaClinic, Bad Zurzach, Switzerland

**Background:** Available evidence shows that the experience and perception of pain varies among different populations. Further, inequalities are reported in pain treatment across various types of pain and in different settings (1). In particular, it is unknown how much immigrants in Western European countries profit from pain management programs.

**Objectives:** The aim of this study was to detect differences in the course of Italian- and German-speaking patient’s state of health and quality of life after a 4-week interdisciplinary pain management program for chronic pain patients in Italian.

**Methods:** The prospective cohort study with 61 Italian-speaking and 63 German-speaking patients with fibromyalgia or chronic back pain measured health-related quality of life, pain, anxiety and depression comparing at baseline, after 4 weeks of pain program and at 1 year follow-up. Differences between the two groups...
were tested on significance by generalized estimation equations (GEE) (2). This method modeled changes of health by multivariate logistic regression adjusting for sex, education, number of comorbidities and the baseline score over both follow-ups for each scale.

Results: Italian-speaking patients (n=61) showed higher proportions of males, lower educated and less burdened by comorbidities than German-speaking patients (n=63). At baseline, physical and psychosocial health, depression and anxiety of the Italian-speaking patients were worse than German-speaking patients, with the exception of less pain in the Italian-speaking patients on the SF-36. Changes of health showed more improvement in German- than in Italian-speaking patients on all scales and at both follow-ups. In GEE, the highest differences were observed in SF-36 physical functioning (p<0.035), HADS anxiety (p<0.038) and HADS depression (p<0.023). On SF-36 bodily pain, the difference was not significant (p=0.166).

Conclusions: This study detected that short- and mid-term outcome of Italian-speaking patients was worse than that of German-speaking patients, even after adjustment for baseline differences. The reasons for this study’s results remain unclear, but may have consequences for future management of Italian-speaking patients in interdisciplinary pain management programs. Considering language as a proxy for acculturation, this supports the hypothesis that patients with lower level of acculturation may have special needs in therapeutic management. A cultural sensitive approach in a multidisciplinary pain program might enhance the positive outcome in the short- and mid-term (3).

Median working capacity improved from 0 at entry to 21 at 6 months and to 30 hours/week at 5 years.

Conclusions: Moderate to large long-term effects were observed. Substantial improvements still occurred between 6 and 60 months after start of the pain program, especially in pain, catastrophizing, and physical role performance. Improvements observed after the inpatient pain program can be maintained and expanded in the long-term at home (3).

ALL STAGES OF SYNOVIAL MESENCHYMAL STEM CELL (SF-MSC) FCS expanded cells (p=0.3429, n=4). Interestingly, replacing TGF
staining Ca++ assay and Nile Red showed no significant difference compared to
FCS-expanded cells (n=4). In osteogenic and adipogenic induction, Alizarin red
up to 21 days on p-TCP. Osteogenic differentiation was performed in the presence of
osteogenic supplements under normoxic conditions (37 °C, 18% O2). Adhesion
and proliferation of hMSCs on p-TCP were evaluated by immunofluorescence and histochemical
analysis. To confirm cell attachment and biocompatibility of p-TCP
particles cellular release of LDH was assessed. Osteogenic differentiation was
analyzed on gene expression level using qRT-PCR. The chondrogenic model, a
scaffold-free 3D cartilage construct (Fitz & Breyer) was generated using hMSCs.
Chondrogenic differentiation was performed under hypoxia (37 °C, 1% O2) with
intermittent mechanical stimulation and analyzed by histology.

Results: We developed an in vitro 3D trabecular bone model by seeding hMSCs
on p-TCP scaffold after pre-incubation for 24 hours. The analysis of cell viability
via LDH detection showed no toxic effects on the cells seeded as compared to
the corresponding control. Furthermore, we assessed cell attachment and
proliferation by measurement of LDH activity after scaffold crushing. As a result,
samples showed higher LDH activity compared to the controls. Histological and
immunofluorescence analysis based on DNA and actin staining demonstrated
cell attachment until day 21. After 21 days, cells were located more inside the
scaffold compared to day 1. qRT-PCR expression of bone-related genes such as
RUNX2, SPPI and COL1A1 confirmed the phenotypic change during osteogenic
differentiation on the scaffold. Furthermore, the scaffold-free 3D chondrogenic
structure was confirmed by HE staining representing the different zones. Cartilage
phenotype was confirmed by the reduced expression of Col1A1, an abundant
expression of Col1A1 and Aggrecan.

Conclusions: The initial results from our in vitro 3D osteogenic and chondrogenic
model confirm good cell vitality which indicates successful progression. To confirm
the exchange of p-TCP through cellular matrix, we will now extend the assay
co-culture time for up to 6 weeks. This 3D multi-component joint model enabled us
to simulate arthritis and to study the efficacy of drug treatment in vitro.

and PRO-C2), aggrecanase degraded aggrecan (AGNvi) and MMP degraded aggrecan (exFFGV). C1M and C3M are synovial membrane biomarkers and C2M, AGNvi and exFFGV are cartilage biomarkers.

**Results:** Explants were viable throughout the experiments, albeit the bSME lost some viability with time. bSME treated with O+T showed increased C1M and C3M (450% 0 day 10, compared to w/o), whereas in bCC O+T increased C1M from day 21 and C3M from day 14 (>400%, >1900%), O+T treatment increased C2M was increased from day 21 (>400% and >1000%) in both BEX and BC. The release was blocked by the generic MMP inhibitor GM6001 which also decreased the C1M and C3M compared to w/o. O+T treatment increased AGNvi at day 7 and 10 (>600%) and exFFGV from day 21 (>650%) in both BEX and BCC. In bSME, TGF-b1 continuously and dose-dependently increased P1NP from day 7 compared to w/o (250%). O+T pre-treatment for 10 days followed by TGF-b1 stimulation increased P1NP after 7 days of TNF-b1 treatment (150%, figure). IGF-1 did not affect the P1NP level at any time point in bSME. In bCC both TGF-b1 (dose-dependently) and IGF-1 sustained the PRO-C2 level at the level of baseline throughout the study periods (figure), whereas O+T decreased PRO-C2 compared to w/o. The PRO-C2 level in BEX with TGF-b1 was unaltered compared to w/o.

**Conclusions:** We here show that bovine synovium can be anabolic and catabolic stimulated, both alone and in co-culture with cartilage. Anabolic stimulation was achieved with TGF-b1 in both bSME and bCC, while IGF-1 only showed an anabolic effect in the bCC. Previous human explant models using human tissue have lacked the anabolic capacity. These translational explant models may be applied in the early development of anabolic drugs for cartilage degenerative diseases.

**FRI0004 14-3-3 ETA AS A NOVEL INVADOSOME REGULATORY MOLECULE IN RHEUMATOID ARTHRITIS**

C. Lalanne1, R.R. Laviole1, M. Charbonneau1, J. Savill2, A. Marotta3, C. Dubois1

1University of Sherbrooke, Sherbrooke; 2Augurex Life Sciences Corp., Vancouver, Canada

**Background:** Progressive cartilage destruction, mostly mediated by invasive fibroblast-like synoviocytes (FLS), is a central feature in the pathogenesis of rheumatoid arthritis (RA). We have reported that the ability of arthritic FLS to degrade the extracellular matrix depends on the formation of actin-rich plasma membrane invadosomal structures detected in cells strategically located at the cartilage-synovial membrane interface. Interference with the formation of invadosomes in RA FLS impeded matrix degradation in vitro and cartilage at the cartilage-synovial membrane interface. Interference with the formation of invadosomal structures detected in cells strategically located fibroblast-like synoviocytes (FLS), is a central feature in the pathogenesis of patients (N=5) was extracted and the relative level of 14–3-3 isoforms and MMP degrade the ECM.

**Objectives:** To evaluate the role of 14–3-3η in inflammatory processes and the ability of synoviocyte cell lines to form invadosomes was observed (r=2.8299). Knockdown of 14–3–3η decreased the ability of arthritic synoviocytes to form invadosomes indicating a role of 14–3–3η in extracellular matrix degrading ability. Confocal microscopy revealed that 14–3–3η staining was mostly found in small punctated structures in the cytoplasm and at the cell periphery of arthritic synoviocytes where they colocalized with leading edge F-actin and discrete patches of the exocyst component, Exo70.

**Conclusions:** The findings propose that the role of 14–3–3η in invadosome formation points to a previously unappreciated facet of how 14–3–3η influences joint ECM remodelling and reinforces its role as a marker of RA progression and joint damage. How 14–3–3η is involved in the regulation of MMP production/secretion and the possible role it plays in remodelling of actin-rich subcellular structures is the subject of ongoing studies.

**FRI0005 TARGETING CARTILAGE AGING AS OSTEOARTHRITIS THERAPEUTICS BY DRUG REPURPOSING**

B. Caramés1, U. Nogueira-Recalde1, M. Loza2, F.J. Blanco1, E. Dominguez2

1Rheumatology Division, Cartilage Biology Group, The Institute of Biomedical Research of A Coruña (INIBIC), A Coruña; 2Biofarma Research Group, Center for Research in Molecular Medicine and Chronic Diseases (CIMUS), University of Santiago de Compostela, Santiago de Compostela, Spain

**Background:** Effective treatments for Osteoarthritis (OA) are not available. In aging-related diseases, including OA, failure of cellular homeostasis mechanisms, such as autophagy can cause extracellular matrix destruction and cell death (1). With aging, chondrocyte function is diminished, contributing to a cellular senescence phenotype often observed in OA chondrocytes. In addition, a defect in autophagy is observed in both aging and cartilage degeneration (2,3).

**Objectives:** The objective of this study was to identify anti-senescence and pro-autophagy molecules by a cell-based high-throughput screening (HTS) in human chondrocytes.

**Methods:** To induce cellular senescence or reduced autophagy, immortalized human chondrocytes (TC28a2) were seeded (2500 cells/well) in 384 well plates, and treated with IL-6 (20 ng/ml) for 72 hours or 18 hours, respectively. Then, chondrocytes were incubated with Prestwick Chemical Library (1120 approved drugs with chemical and pharmaceutical diversity, as well as bioavailability and safety in humans) at 10 μM for 72 hours. To identify anti-senescence hits, nuclei were stained with Hoechst 33342 (2.5μg/ml), while β-galactosidase subcellular structure was stained by using Imagene Green C12FDG substrate (30 μM). To evaluate autophagic flux, a reporter cell line was generated by retrovirus transfection of pBABE-mCherry-EGFP-LC3 plasmid in TC28a2 chondrocytes. Plates were imaged by using Operetta® High Content Screening (HCS) system in non-continuous mode using the 20x WD objective. For each well, 4 fields and 4 planes of bright field, Hoechst and fluorescein channels were obtained. Relative intensity of C12FDG in cytoplasm and number of autophagosomes/autolysosomes per area of cytoplasm were determined to quantify β-galactosidase activity and autophagy flux respectively. Compound validation was performed in TC28a2 chondrocytes and in primary human chondrocytes by evaluating cell senescence, autophagy pathway and cell death by apoptosis.

**Results:** A primary screening was performed to identify anti-senescence compounds by measurement of senescence-associated β-galactosidase activity. 283 compounds with both anti-senescence and anti-autophagy effects were identified. The anti-senescence hits were analyzed by monitoring autophagic flux. 29 compounds with both anti-senescence and pro-autophagy effects were selected. Then, one compound was selected for further validation. The compound reduced chondrocyte senescence, increased autophagy (p<0.0001) and protected against inflammation and cell death by apoptosis in human chondrocytes (p<0.05) in response to IL-6. Interestingly, this protective effect was partially mediated by mTOR inhibition, a proposed mechanism to prevent cartilage aging.

**Conclusions:** Our screening methodology provides a unique opportunity to use drugs and mechanisms to prevent cartilage aging. Autophagy activation and protection against senescence by 14-3-3η may be potential targets for delaying cartilage degeneration.

**Objectives:** Immature dendritic cells (DCs) are able to trans-differentiate into osteoclasts (OCs) although the mechanisms regulating this process are little understood. We have recently described an important role for protein citrullination and peptidylarginine deiminase (PAD) enzyme activity in the regulation of OC development (1).

**Background:** Immature dendritic cells (DCs) are able to trans-differentiate into osteoclasts (OCs) although the mechanisms regulating this process are little understood. We have recently described an important role for protein citrullination and peptidylarginine deiminase (PAD) enzyme activity in the regulation of OC development (1).

**Methods:** We studied the molecular bases of DC-OC trans-differentiation and aimed at understanding the role of protein citrullination in this process.

**Dosage:** Three groups of mice were treated with either hIL4–10FP (n=3), PBS (n=3) or LPS (n=3).

Conclusions: Therefore, we confirmed that protein citrullination, most likely through a PAD enzyme mechanism, was important for OC development. In conclusion, our results strongly indicate that the regulation of protein citrullination could be a potential therapeutic target for the treatment of RA.

**EFFECTS OF THE HUMAN IL4-10 FUSION PROTEIN IN THE CANINE GROOVE MODEL OF OSTEOARTHRITIS**

E.M. Van Helvoort 1, J. Popov-Celeletic 1, K. Coeleveld 1, M.A. Tryfonidou 2, F.P. Lafeber 1, S.C. Mastbergen 1, 1Rheumatology and Clinical Immunology, University Medical Centre Utrecht; 2Clinical Sciences of Companion Animals, Faculty of Veterinary Medicine, University Utrecht, Utrecht, Netherlands

**Objectives:** Ideally a disease modifying osteoarthritis drug (DMOAD) combines treatment for pain, tissue damage and inflammation, all in one molecule. Intra-articular application of a DMOAD brings additional value to treatment for two reasons, (i) lower risk of systemic side effects and (ii) higher drug concentration and potentially improved penetration of non-vascularized articular cartilage. Interleukin-4 (IL-4) and Interleukin-10 (IL-10) have been shown to prevent joint degeneration and can work synergistically. The aim of this study was to evaluate whether hIL4–10FP could be a useful substance for development of plant-based anti-inflammatory and anti-arthritic therapies.

**Background:** hIL4–10FP was approved for treatment of RA patients and was shown to be efficacious in two studies. We further demonstrated that hIL4–10FP can prevent bone loss in vivo. The objectives of this study were to evaluate the effects of hIL4–10FP on osteoarthritis in a canine model.

**Methods:** Through surgical procedures we treated dogs with either hIL4–10FP or PBS. The treated and control dogs were sacrificed after 6 weeks and their tibiae were harvested. Tissue samples were analyzed for bone mineral density (BMD), histology, and quantitative RT-PCR.

Conclusions: Consequently, the overall data strongly indicated that methyl gallate could be a useful substance for development of plant-based anti-osteoarthritic therapies.

**METHYL GALLATE INHIBITS OSTEOCLAST FORMATION AND FUNCTION THROUGH SUPPPRESSING THE AKT AND BTK-PLCγ2-Ca2+ SIGNALING, AND PREVENTS LPS-INDUCED BONE LOSS**

1Internal Medicine, Wonkwang University Hospital; 2Anatomy, School of Medicine, Wonkwang University, Iksan; 3Internal Medicine, Chonbuk National University Medical School, Jeonju; 4Internal Medicine, Kyung Hee University School of Medicine, Seoul, Korea, Republic Of

**Background:** Methyl gallate, a plant-derived phenolic constituent has been known to possess numerous pharmacological features against inflammation, oxidation, and cancer. But so far, there have been no evidences to describe relationship between methyl gallate and bone metabolism.

**Objective:** In order to propose a promising candidate for osteoporosis, we performed experiments in this study by using methyl gallate.

**Methods:** We performed screening of methyl gallate utilizing TRAP staining and revealed intracellular mechanisms responsible for methyl gallate-mediated regulation of osteoclastogenesis through western blotting and quantitative RT-PCR. Also, we assessed the role of methyl gallate on characteristics of mature osteoclasts. We used LPS-induced bone loss mice as a model of osteoporosis and analyzed using micro-CT system and the right femurs were stained with TRAP and H&E.

**Results:** We observed that methyl gallate significantly suppressed osteoclast formation through Akt and BTK-PLCγ2-Ca2+ signaling. The blockade of these pathways was reconfirmed through transduction of CA-Akt retrovirus and evaluation of Ca2+ influx intensity stained with Fluor-3/AM. Indeed, methyl gallate down-regulated the formation of actin ring-positive osteoclasts and resorption pit areas. In agreement with in vitro results, we found that the administration of methyl gallate restored osteoporotic phenotype stimulated by acute systemic injection of LPS in vivo through micro-CT and histology.

DOI: 10.1136/annrheumdis-2017-eular.2141
in hIL4–10FP group there was no enhanced cartilage degeneration detected compared to the PBS group (fig 3).

Conclusions: Repetitive intra-articular injection of human IL4–10FP led to antibody formation in a non-inflammatory canine model of OA. Despite the immune response, proteoglycan turnover parameters were comparable between the two treatment groups, suggesting a beneficial effect of hIL4–10FP. This study also shows that it is not evident to use a human protein in a (canine) animal model, although this is often done. Instead, a species specific protein is warranted. Therefore a canine version of IL4–10FP will be developed to study its DMOAD activity in this model.

FR0009 ACCELERATED DEVELOPMENT OF AGING-ASSOCIATED AND INSTABILITY-INDUCED OSTEOARTHRITIS IN 12/15-LIPOXYGENASE DEFICIENT MICE

L. Habouri, F. El Mansouri, Y. Ouhaddi, J.-P. Pelletier, J. Martel-Pelletier, M. Benderdour, H. Fahmi, Medicine, CRCHUM, Montreal, Canada

Background: 12/15-Lipoxygenase (12/15-LOX) catalyzes the generation of various anti-inflammatory lipid mediators, and has been implicated in several inflammatory and degenerative diseases. However, there is currently no evidence that 12/15-LOX has a role in osteoarthritis (OA).

Objectives: The aim of this study was to investigate the role of 12/15-LOX in the pathogenesis of OA.

Methods: The development of aging-associated and destabilization of the medial meniscus (DMM)-induced OA were compared in 12/15-LOX-deficient (12/15-LOX-/-) and wild-type (WT) mice. The extent of cartilage damage was evaluated by histology. The expression of OA markers was evaluated by immunohistochemistry and RT-PCR. Cartilage explants were stimulated with IL-1β in the absence or presence of the 12/15-LOX metabolites, 15-HETE, 13-HODE or LXA4, and the levels of MMP-13, NO and PGE2 were determined. The effect of LXA4 on the progression of OA was evaluated in WT mice.

Results: The expression of 12/15-LOX in cartilage increased during the progression of DMM-induced OA and with aging in WT mice. Cartilage degeneration was more severe in 12/15-LOX-/- mice compared to WT mice in both models of OA, and this was associated with increased expression of MMP-13, ADAMTSS, INOS, and mPGES-1. Treatment of cartilage explants with 12/15-LOX metabolites, suppressed IL-1β-induced production of MMP-13, NO and PGE2, with LXA4 being the most potent. Intra-peritoneal injection of LXA4 reduced the severity of DMM-induced cartilage degradation.

Conclusions: These data demonstrate an important role of 12/15-LOX in OA and suggest that activation of this pathway may provide a novel strategy for prevention and treatment of OA.

FR0010 METABOLIC DYSREGULATION ACCELERATES JOINT DEGENERATION UPON MECHANICALLY INDUCED CARTILAGE DAMAGE, DRIVEN BY LOCAL INFLAMMATION; AN IN VIVO RAT STUDY

H.D. Visser 1,2, S. Mastbergen 2, A. Kozijn 2, M.V. Rijen 1, H. Weennis 1,2,3, F. Lafeber 2, Orthopaedics; 2Reumatologie & Clinical Immunology, UMC Utrecht, Utrecht; 3Biomechanical Engineering, Delft University of Technology, Delft, Netherlands

Background: Obesity is a well-known and important risk factor for osteoarthritis (OA). Moreover, obesity is highly associated with the metabolic syndrome (MetS). Growing evidence indicates that both OA and MetS are low-grade inflammatory conditions with elevation in systemic inflammatory markers. Nonetheless, it is unclear whether MetS low-grade inflammation induces OA, or contributes to the disease.

Objectives: To determine the contribution of metabolic alterations, induced by a High-Fat Diet (HFD), on the onset or progression of OA in a rat model of local cartilage damage.

Methods: Forty Wistar rats (12 weeks old, male), were randomly divided over two groups: twenty rats were fed a HFD (60% of the kcal contained fat; D12492i, Research Diets Inc.) while the other animals received a standard diet. After 12 weeks, local articular cartilage damage was induced on the femoral condyles, in one knee joint according to the groove model in 14 rats of each diet group. Remaining animals served as a control group in each arm. At week 24, serum was collected, subchondral bone was assessed by μCT scan (Quantum FX, PerkinElmer,USA), OA severity was evaluated by rat OARSI histopathology score and macrophage presence with CD68 immunostaining from histological sections was assessed.

Results: HFD feeding resulted in metabolic dysregulation as indicated by significantly increased metabolic parameters (weight, fasting insulin and total cholesterol) compared to the standard fed rats. HFD feeding alone resulted in mild cartilage degeneration (2±1.1 vs 0.58 ±0.7; p=0.06) and synovial membrane inflammation (1.0±0.6 vs 0.3±0.3; p=0.07) but both subscores of the rat OARSI histopathology score. However, when HFD feeding is combined with the surgical model of local cartilage damage, OA severity is statistically significant increased compared to the local cartilage damage group on a standard diet (6.2±2.1 vs 3.4±1.4; p=0.001). Synovial membrane inflammation (1.3±2.9 vs 0.5±0.5; p=0.011) and multiple large osteophyte formation, demonstrated by histology (0.9±1 vs 0.2±0.4; p=0.04) and quantified on μCT (328±349 μm3 vs 7±14 μm3; p=0.0001), contributes most to this increased OA severity. Immunohistochemical CD68 expression as observed on both the synovial membrane as well as in the subchondral bone and around the formed osteophytes can explain the increase in selected inflammatory parameters when groove surgery is combined with a HFD (Figure 1).

Conclusions: This study shows that a HFD induces metabolic alterations and increases the inflammatory state of the joint. This by itself does not result in severe OA. However, when adding a HFD to a mild cartilage damage model of OA, joint degeneration is significantly increased. This progression of joint degeneration appears to be driven mainly by inflammatory responses as demonstrated by an increased CD68 expression in both the subchondral bone and synovium membrane with increased osteophytosis. Hence, our findings indicate that systemic metabolic and subsequent inflammatory factors need an additional trigger to contribute to the progression of the OA.

FR0011 TARGETING NEUTROPHIL MICROVESICLES TO DAMAGED CARTILAGE USING ANTIBODIES TO POST TRANSLATIONALLY MODIFIED COLLAGEN II

L.M. Topping, H. Rhys, L. Norling, A. Nissim. Biochemical Pharmacology, William Harvey Research Institute, Queen Mary University of London, London, United Kingdom

Background: Microvesicles (MV) are double membrane-bound extracellular vesicles released from the plasma membrane of cells. MV derived from polymorphonuclear neutrophils (PMN) promote tissue protection, and have been demonstrated to penetrate cartilage during inflammatory arthritis and provide protection to the tissue.}

Figure 1: Immunohistochemical CD68 expression in subchondral bone, synovium, and cartilage. The red staining represents CD68 expression. (A) CD68 expression in the subchondral bone and synovium membrane of control animals fed a standard diet. (B) CD68 expression in the subchondral bone and synovium membrane of control animals fed a high-fat diet. (C) CD68 expression in the subchondral bone and synovium membrane of OA animals fed a standard diet. (D) CD68 expression in the subchondral bone and synovium membrane of OA animals fed a high-fat diet.
Collagen type II (CII) is the most abundant protein found in cartilage. We have produced a single chain variable fragment (scFv) antibodies specific to CII modified by reactive oxygen species (ROS), namely anti-ROS-CII-scFv. Previously, we have demonstrated the ability of anti-ROS-CII-scFv to localise exclusively and deliver payload drugs to the arthritic joint in mice models of rheumatoid arthritis.

Objectives: To test a new association technology: i) target delivery of MV to inflamed joint and/or ii) enhance the avidity of the scFv (several scFv can be loaded in each MV) and may thus increase localisation and enhance therapeutic efficacy.

Methods: Cy5.5 labeled Anti-ROS-CII-scFv were loaded on fluorescently labelled microvesicles (MV) and delivered to arthritic joints using a biocompatible matrix. MV loaded with Cy5.5 Anti-ROS-CII-scFv were observed by flow cytometry analysis.

Results: Positive incorporation of Anti-ROS-CII-scFv upon MV was observed by flow cytometry analysis. ELISA demonstrated the ability of the anti-ROS-CII scFv loaded MV to bind strongly to ROS-CII following incorporation into MV.

Conclusions: In this study, we have demonstrated a simple, efficient and cost effective way of antibody targeting that retains antibody function. Such technology has the potential to improve efficacy of existing therapies by ensuring specific targeting. Future in vivo studies will assess the ability of the Anti-ROS-CII-scFv MV to localise to arthritic joints.

FRI0012 ROLE OF VOLATILE COMPOUNDS RELEASED BY SYNOVIAL FLUID IN THE DIAGNOSIS OF OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS OF THE KNEE JOINT

R. Capuano1, M.S. Chimenti2, F. Dini1, A.C. Domakioski3, E. Martinelli1, P. Conigliaro1, R. Paollesse1, C. Di Natale1, R. Perricone2, A. Bergamini2, 1Department of Electronic Engineering; 2Department of system medicine, Rheumatology, Allergology and Clinical Immunology; 3Department of Chemical Sciences, University of Rome Tor Vergata, Rome, Italy

Background: Synovial fluid (SF) receives protein contribution from the tissue around; cartilages, synovial membranes and bones. The presence of inflammation and oxidative stress alters the its chemical composition. In particular, inflammation modulates the release of volatile organic compounds (VOCs) that are the product of reactive oxygen species and free radicals excreted by mithocondria during oxidative stress (1). Articular inflammation plays a major role both in Osteoarthritis (OA) and Rheumatoid arthritis (RA), thus, the identification of specifics VOCs associated with inflammation in the SF may represent a suitable procedure to facilitate a diagnosis and a better characterization of these diseases. E-noses are versatile instruments based on arrays of partially selective gas sensors system that do not provide specific information about the individual molecules but can detect a large spectrum of VOCs to provide a discrimination among samples classified according to their chemical composition (VOC pattern) (2).

Objectives: Aim of this study was to prospectively investigate whether analysis of VOCs profile emitted from SFs can identify differences between osteoarthritis (OA) and rheumatoid arthritis (RA).

Methods: VOCs Profile emitted from SFs was performed using a gas sensor array (electronic nose). The results were evaluated using statistical analyses.

Results: The analysis of the relative abundance indicated five VOCs significantly different between OA and RA. The abundance of five compounds allowed to identify OA with respect to RA with an accuracy of 82% (sensitivity: 0.90, specificity: 0.80, AUROC=0.92, 99.7% CI). The signals of the electronic nose sensors allowed to classify the studied subjects in OA or RA. In particular, OA patients could be distinguished from that of RA patients with an accuracy of 100% (sensitivity: 1, specificity: 1, AUROC=1, 99.9% CI) (Figure 1). However, no single VOC was specific for OA or RA.

Conclusions: This study shows that OA and RA patients exhibit qualitative and quantitative differences in the chemical compositions of knee synovial fluid. These differences may be attributed to five volatile compounds and can be detected by an electronic nose which may represent a suitable diagnostic tool for diagnosis and characterization of OA vs. RA.

FRI0013 ACFA-INDUCED MOBILITY OF PRIMED SYNOVIAL FIBROBLASTS: THE MISSING LINK BETWEEN ACFA-INDUCED BONE LOSS AND SYNOVIAL CHANGES

M. Sun1, V. Joshua2, A. Krishnamurthy2, A.H. Hensvold3, Y. Liu4, S.B. Caterina3, J. Steen1, M. Engstom1, H. Wahanna3, B. Reith3, A.I. Background: Anti-citrullinated proteins antibodies (ACPAs) injected in mice induce IL-8 dependent bone loss and arthralgia, but no synovial changes. We hypothesized that additional stimuli, sensitizing the synovial compartment to ACPA effects, is needed for the transition from bone to synovial pathology.

Methods: Synovial fibroblasts (SFs) were isolated from synovial tissue of RA patients by enzymatic digestion. Polyclonal ACPAs and other non-ACPA IgGs were separated from peripheral blood of RA patients by affinity purification on a fibrinogen-Sepharose column. Polyclonal ACPA and other non-ACPA IgGs were mixed with SFs and incubated for 72 hours in the absence or presence of IL-8. The results were evaluated by NIH ImageJ software.

Results: Serum starvation of SFs increased citrullinated proteins and PAD expression and protein citrullination were evaluated by immunohistochemistry. The role of signaling pathways in the ACPA-mediated SF modulation was analyzed by using specific signal inhibitors and by monitoring protein phosphorylations using western blot.

in starved SF indicated an important role for PI3K-mediated signals in the ACAP-induced increase of SF mobility.

Conclusions: We demonstrated that additional stimuli (such as stress-induced citrullination and cytokine priming) were needed for SF to react upon ACAP stimulation. This is an indirect proof supporting the idea that a synovial insult that would normally resolve unobserved, might be essential for the transition towards chronic synovial changes in the presence of ACAP.

FR00104 ANTIOXIDANT ROLE OF MICROVESICLES FROM ADIPOSE TISSUE-DERIVED MESENCHYLMAL STEM CELLS IN HUMAN OSTEARTHRITIC CHONDROCYTES

M. Tofiño-Vian 1, I. Guillen 1,2, M.D. Perez del Caz 1, A. Silvestre 4, M.J. Alcaraz 1

1Pharmacy and IMD, University of Valencia, Burjassot, Valencia; 2Dpt. Pharmacy, CEU-Cardenal Herrera; 3Department of Burn and Plastic Surgery, la Fe University Hospital; *Orthopaedic Surgery and Traumatology, Clinical University Hospital, Valencia, Spain

Background: Oxidative stress results in the disruption of normal physiological signaling leading to inflammatory changes, cartilage degradation and osteoarthritis (OA) progression (1). Recent advances have revealed the role of cell-derived microvesicles (MV) as a new mechanism of cell-to-cell communication with paracrine therapy potential (2). We have shown previously the antiinflammatory effects of human adipose tissue-derived mesenchymal stem cells (AD-MSC) conditioned medium in OA chondrocytes (2).

Objectives: We have isolated the MV fraction from the secretome of AD-MSC to conditioned medium in OA chondrocytes (2).

Methods: We isolated the MV fraction from the secretome of AD-MSC to conditioned medium by differential centrifugation with size filtration. MV size and concentration were determined by resistive pulse sensing. Proteomic analysis was performed by LC-MS/MS, with ProteinPilot and PeakView software and the bioinformatic tools UNIPROT and PANTHER. OA chondrocytes were isolated from knee specimens of advanced OA patients, stimulated with IL-1β (10 ng/mL) and treated with MV (3.6x10⁵ particles/mL) for 24h. Accumulation of 4-hydroxy-2-nonenal (HNE)-modified proteins and cytokines were measured by ELISA, NO production and MMP activity by fluorometry. Expression of specific proteins was evaluated by confocal microscopy or immunostaining. The data were analysed by ANOVA followed by Dunnett’s test.

Results: MV reduced the accumulation of HNE-modified proteins, a biomarker of oxidative stress in these cells. Moreover, we analysed the induction by two inflammatory mediators in vitro. These results are also supported by positive of vanox staining. Additionally, qRT-PCR results yielded higher expression of RUNX2, SP1, RANKL and DLx5. Furthermore, immunohistochemistry showed high ALP-activity and Coll-expression.

Conclusions: Preliminary results of our study focusing at developing a 3D bone-like model displayed a promising trend towards modelling endochondral ossification in vitro by increased mineralization (in vitro μCT analysis and vanox staining), and upregulation of osteogenic-relevant RUNX2 and SP1 expression as well as ALP-activity and Coll-expression. High expression of SP1 and RANKL could refer to osteoblast-like activities, which will be in the focus of further investigations. Finally, the complete 3D model will leave us the opportunity for studying the first phase of fracture healing under in vitro conditions.

FR0016 INVOLVEMENT OF RUNX2 AND β-CATENIN SIGNALING IN THE PRODUCTION OF ADAMTS-7 AND ADAMTS-12 IN OSTEARTHRITIC SYNOVIAL FIBROBLASTS

S. Pérez-García 1, I. Gutiérrez-Cañas 1, R. Villanueva-Romero 1, J. Leceta 1, J. Fernandez 2, I. Gonzalez-Andres G, Y. Juarros 1, R.P. González 2, 1Cell Biology, Faculty of Biology, Complutense University of Madrid; 2Traumatology Service; 3Rheumatology Service, la Princesa University Hospital, Princesa Medical Research Institute, Madrid, Spain

Background: Proteinsases released from synovial membrane of osteoarthritic (OA) patients contribute to cartilage damage. We recently reported in synovial fibroblasts (SF) the expression of ADAMTS (a disintegrin and metalloproteinsase domain with thrombospondin motifs)-7 and -12, involved in the destruction of the cartilage oligomeric matrix protein (COMP) (1). Signaling pathways regulating these ADAMTS are poorly understood. As Runx2 and β-catenin are two transcription factors involved in chondrocytes metabolism and OA pathiology (2-5), we studied whether these factors are implicated in the expression of ADAMTS-7 and 12 in SF. Moreover, we analyzed the induction by two inflammatory mediators present in OA joints: interleukin-1β (IL-1β), and fibronectin fragments (Fn-fs), previously described in ADAMTS expression (1).

Objectives: To elucidate the effects of Runx2/β-catenin pathways involved in the production of ADAMTS-7 and -12 in healthy donors (HD) - and OA-SF.

Methods: ADAMTS-7 and -12 were detected in HD- and OA-SF protein extracts by Western blot. Blockade experiments were performed after stimulation with IL-1β or 45-kDa Fn-fs. We used inhibitors for two mitogen-activated protein kinases (MAPKs), ERK and p38, implicated in the activation of Runx2/β-catenin signaling.

Results: Intra cellular precipitation with ADAMTS-7 and -12 was confirmed in HD- and OA-SF, with higher levels of ADAMTS-7 in OA. After IL-1β or Fn-fs stimulation, DDK decreased ADAMTS-7 transcript in HD and OA-SF that was translated to a protein reduction in OA. Besides, ERK inhibitor decreased ADAMTS-12 mRNA and protein exclusively in OA-SF.

Conclusions: We reported that ADAMTS-7 protein expression is higher in OA-SF compared to HD confirming previous data at mRNA level (1). As DDK decreased ADAMTS-7, Wnt-β-catenin signaling seems to be implicated in its expression. By contrast, the expression of ADAMTS-12 is regulated by ERK, pointing to a possible implication of ERK-Runx2 axis, exclusively in OA-SF.

A NOVEL CONCEPT OF M1 AND M2 MONOCYTES IN RHEUMATOID ARTHRITIS: PRO-INFLAMMATORY MONOCYTE POLARIZATION IMBALANCE, ANTI-CITRULLINATED PROTEIN ANTIBODY AND OSTEOCLASTOGENESIS

S. Fukui1, N. Iwamoto1, R. Masuyama2, K. Kosai3, K. Yanagihara3, A. Kawakami1, 1Immunochemistry and Rheumatology; 2Molecular Bone Biology; 3Laboratory Medicine, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Background: Monocytes can differentiate into either proinflammatory, microbiocidal M1 macrophage or anti-inflammatory M2 macrophage subtypes. In addition to macrophages, regarding monocyte subsets, M1 monocytes and M2 monocytes mirroring the M1/M2 macrophage polarization concept were suggested. Little is known regarding the relationships between osteoclastogenesis and M1/M2 monocyte subsets.

Objectives: We investigated the relationships among M1 monocytes, M2 monocytes, osteoclast differentiation ability and clinical characteristics in patients with rheumatoid arthritis (RA).

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from RA patients and healthy donors, and then we investigated the number of M1 monocytes or M2 monocytes by fluorescence-activated cell sorting. We defined positive CD14, CD68 and CCR2 monocytes as M1 monocytes, and in separate tubes, we defined positive CD14, CX3CR1 and CD163 or CD206 monocytes as M2 monocytes. We also obtained and cultured CD14-positive cells from PBMCs from RA patients and healthy donors, and we then investigated the number of M1 monocytes or M2 monocytes by fluorescence-activated cell sorting. We defined positive CD14, CX3CR1 and CD163 or CD206 monocytes as M2 monocytes.

Results: Forty RA patients and 20 healthy donors were included. Twenty-two patients (55%) were ACPA-positive. The ACPA-positive patients had significantly higher M1/M2 ratio in vivo (p<0.028) (E) and significantly greater numbers of osteoclasts in vitro (p<0.01) (F) than the ACPA-negative patients. We show an ACPA-negative patient’s osteoclasts in vitro (G) and those of an ACPA-positive patient (H).

Conclusions: The M1/M2 ratio is strongly correlated with the in vitro differentiation of osteoclasts in patients with RA. The RA patients with positive ACPA had higher M1/M2 ratio and higher numbers of osteoclasts.

DOI: 10.1136/annrheumdis-2017-eular.5808
ditions, respectively. CTLA-4 expression in MSC was co-cultured with peripheral blood mononuclear cells (PBMC) isolated by density gradient centrifugation from venous blood of healthy donors. The cells were stimulated by anti-CD3 and anti-CD28 (1 μg/ml) and were challenged using IFN-γ (~18% O2) or hypoxic (~1.5% O2) conditions and analyzed by TNFα secretion by suspension assay. Results: The MSC phenotype of bone-marrow derived cells could be verified according to their surface marker expression and their osteogenic and adipogenic differentiation capacity. On transcriptional level, MSC possessed both full-length and - to a higher extent - the soluble CTLA-4 isoforms with a higher mRNA abundance under normoxic as compared to hypoxic conditions. Extra- and intracellular analysis of CTLA-4 expression on protein level, demonstrated a significant decrease of phospho-CTLA-4 (p<0.01) in the soluble CTLA-4 isoforms in MSC from bone marrow. This decrease in CTLA-4 expression by suspension assay. Disclosure of Interest: None declared

Conclusions: We have demonstrated that co-culture of MSC with PBMC significantly reduced the amount of secreted TNFα (p<0.05) which could be reversed by anti-CTLA-4-antibody (p<0.05), under both normoxic and compared to hypoxic conditions, respectively. Conclusions: We clearly demonstrate the existence of CTLA-4 on hMSC and its functionality with regard to the inhibition of PHA-induced TNFα secretion by PBMC. We also demonstrate that the expression of CTLA-4 (l) contributes to the immunomodulatory capacity of hMSC and (ii) supports the ‘immune privileged’ status of these cells.

DOI: 10.1136/annrheumdis-2017-eular.4078
Objectives: We evaluated the role of these metabolic pathways in RA-FLS proliferation and autoimmune arthritis in SKG mice.

Methods: The expression of glycolysis- or glutaminolysis-related enzymes was evaluated by real-time PCR and Western blotting, and the intracellular metabolites were evaluated by metabolic analyses. The effects of glucose or glutamine on RA-FLS proliferation were investigated in glucose- or glutamine-deprived conditions. The growth of RA-FLS was inhibited by GLS1 siRNA transfection or GLS1 inhibitor treatment. Silencing of GLS1 in RA-FLS did not affect IL-6 or MMP-3 production in supernatants. GLS1 expression in RA-FLS was not affected by pro-inflammatory cytokine stimulation. Compound 968 ameliorated the autoimmune arthritis and decreased the number of Ki-67-positive synovial cells in SKG mice.

Conclusions: Our findings suggested that glutamine metabolism plays an important role in regulating RA-FLS proliferation, without being affected by pro-inflammatory cytokine stimulation or affecting cytokine production, and may be a novel therapeutic target for RA.

FR0023 ARTESANTE CAN INHIBIT MIGRATION AND INVASION OF FIBROBLAST-LIKE SYNOVIOCYTES VIA SUPPRESSION OF MATRIX METALLOPROTEINASE 9 IN RHEUMATOID ARTHRITIS PATIENTS

J. Jing1, T. Yan2, J.-D. Ma1, Y.-Q. Mo1, L. Dai

Methods: Synovial tissues were obtained from active RA patients as well as osteoarthritis (OA) and noninflammatory orthopedic arthropathies (Orth.A) patients and immunohistochemical (IHC) staining were performed for MMP9 expression. FLS isolated from these patients were analyzed for MMP9 expression by western blot (WB) and incubated with artesunate at different concentrations (0, 5, 10, and 20 μM) and methotrexate (MTX, 10 nmol/L) or hydroxychloroquine (HCQ, 20 μM) for 24 hours. Effects of artesunate on migration and invasion capacity were detected by transwell and wound healing assays. MMP9 and PI3K/Akt signal transduction protein expression after artesunate treatment was measured by WB. Serum cytokine levels were measured by Elisa.

Results: (1) IHC staining showed that synovial MMP9 expressed in lining and sublining area with intense nuclear and endochylema staining in RA synovium and the percentage of MMP9+ cells was significantly higher in RA (n=32) than that in OA (n=6) or Orth.A (n=6), Figure 1A, B.

(2) Migration and wound healing assays for 12 hours and invasion assay for 24 hours showed that RA-FLS possessed stronger capacity in migration and invasion than OA-FLS or Orth.A-FLS (Figure 1E, F). Artesunate inhibits the migration and invasion capacity of RA-FLS in a dose-dependent manner. MTX also has an inhibition effect on the migration and invasion of RA-FLS, but not HCQ (Figure 2A).

(3) MMP9 expression in RA-FLS was significantly higher than that in OA-FLS or Orth.A-FLS (Figure 1C, D). 40 μM or 60 μM artesunate markedly inhibited the expression of MMP9 in RA-FLS by WB (Figure 2B).

(4) WB analysis showed artesunate suppressed generation of pphospho-Akt in a dose-dependent manner which indicated that Akt activity (phospho-Akt/Akt) in RA was significantly lower than that in untreated group (Figure 1C).

Conclusions: Artesunate could inhibit the migration and invasion capacity of RA-FLS and the expression of MMP9 through suppressing Akt activity.

FR0024 MICRONNA-146A CONTROLS LOCAL BONE DESTRUCTION BY REGULATING FIBROBLAST INDUCED OSTEOCLASTOGENESIS IN INFLAMMATORY ARTHRITIS

V. Saferding1, A. Puchner1, E. Goncalves-Alves1, M. Hofmann1, M. Bonelli1, S. Hayer1, H.P. Kiener1, P. Georgel2, M.I. Koenders3, G. Steiner1, J.S. Smolen1, K. Redlich1, S. Blueml1.

Background: MicroRNA (MiR-) 146a plays an important role in the regulation of the innate immune response and has also been shown to suppress cancer development in myeloid cells. Although in late stages of arthritis elevated expression of miR-146a in synovial tissue of rheumatoid arthritis patients was detected, the level of this miRNA was found to be down regulated in early disease, but its role in the development of inflammatory arthritis is still elusive.

Objectives: The objective of this study is to analyse the role of miR-146a in arthritis by the use of a chronic arthritis disease model. We aim to investigate the regulatory function of this miRNA in the pathogenic stroma, therefore in fibroblasts but also in immune cells.

Methods: To induce arthritis we used the chronic inflammatory hTNFtg disease model, therefore we crossed miR-146a deficient into hTNFtg mice. Disease severity was assessed clinically and histologically. Blood of arthritis animals was analysed by flow cytometry. Serum cytokine levels were measured by ELISA. Synovial fibroblasts were isolated from metatarsal bones and their proliferation
was analysed histologically and by 3[H]thymidine incorporation. RNA expression levels were measured by qPCR.

**Results:** When we crossed mir-146a RANKL−/− onto TNFtg mice, histological examination revealed a significant increase in synovial inflammation and even more striking a more than twofold increase in local bone destruction, due to increased generation of osteoclasts. Moreover, the levels of mir-146a−/−TNFtg mice compared to TNFtg mice. Interestingly, systemic bone loss was comparable in TNFtg compared to mir-146a−/−TNFtg mice, suggesting an important local role of mir-146a. Indeed, we detected increased levels of IL-1, TRAF6, a major target of mir-146a and RANKL, in addition the expression level of OPG was decreased locally in the paws of TNFtg−/− compared to TNFtg mice. By performing bone marrow transplants we could indeed show a pivotal role for mir-146a in mesenchymal cells in controlling local osteoclast generation and bone destruction. Analysis of important mesenchymal cells in arthritis, the synovial fibroblasts exhibited enhanced proliferation if mir-146a was missing, in vitro and in vivo. Moreover, stimulation of these cells with IL-1β, a prominent cytokine in arthritis which was also shown to be negatively regulated by mir-146a, led to increased expression of RANKL and TRAF6 in mir-146a deficient synovial fibroblasts.

**Conclusions:** These data demonstrate an important protecting role of the mir-146a in inflammatory arthritis, most importantly in local bone destruction, by controlling mesenchymal expression of osteoclastogenic factors. This shows an important anti-inflammatory role of mir-146a, which might possibly be exploited for therapeutic purposes.

**FR10026**  IDENTIFICATION OF MICRORNAS CANDIDATES SPECIFICALLY EXRESSED IN MONOCYTES OF UNDIFFERENTIATED ARTHRITIS PATIENTS WHO PROGRESSED TO RHEUMATOID ARTHRITIS

W. Kurowska 1, E. Kuca-Warnawin 1, A. Radzikowska 1, M. Ciechomska 1, U. Skalska 1, M. Jakubaszek 1, B. Kwatikowska 1, W. Maslinski 1, 1 Department of Pathophysiology and Immunology; 2 Early Arthritis Clinic, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland

**Background:** Monocytes are central to the initiation of inflammation and bone erosion in the development of Th17 and T(H)17 arthritis. Therefore, understanding of molecular pathways regulating monocytes, especially at the early stages of RA development, is of crucial importance as it may help to predict the progression to the full-blown disease. However, mechanisms of gene regulation in monocytes, particularly the role of microRNA (miRNA) expression, which can be involved in regulation of several cellular inflammatory pathways, in early phases of RA (i.e. at undifferentiated arthritis-UA stage) are not fully characterized.

**Objectives:** To investigate the pattern of miRNAs expression in monocytes that could serve as new biomarkers for RA development.

**Methods:** Magnetically sorted monocytes from peripheral blood of 19 patients with UA served for total RNA isolation. Total RNA from both sample and reference was labelled with Hy3 and Hy5 fluorescent label, respectively, using the miRCURY LNA microRNA H-Prime Labeling Kit (Exiqon, Denmark). Fluorescent labelled samples and a reference RNA sample were hybridized to the miRCURY LNA microRNA Array Microarray Scanner (Agilent Technologies, USA). The image analysis was carried out using ImageGene 9 Software (Exiqon).

**Results:** Out of 19 patients with UA enrolled in the study, 12 were verified for diagnosis after 4 years of follow-up (7 patients did not respond to the call for re-evaluation). Four patients developed full-blown RA (UA→RA patients), 6 patients remained still in UA phase (UA→UA patients), 1 patient was diagnosed as having Sjögren’s Syndrome, and 1 undifferentiated connective tissue disease. Baseline characteristics of UA→RA vs UA→UA patients were as follows: age (median: 50, range 37–59 years), sex (52.5, range 32–74 years), CRP (median: 9.0, range 1–22 mg/l vs 8.0, range 1–21 mg/l), ESR (median: 37.0, range 4–47 mm/h vs 34.0, range 15–44 mm/h) and swollen joints count (median: 3.0, range 1–9 vs 2.5, range 1–4). Following computational unsupervised analysis we identified 50 miRNAs in monocytes that have the largest variation across all patients samples. From these 50 miRNAs we selected several specific miRNA candidates on the basis of significantly changed expression in monocytes of UA→RA vs UA→UA patients. Predicted specific miRNAs targeting inflammatory genes in monocytes of UA→RA patients are: mir-483–3p (2.7-fold increased, p=0.009), mir-376d (4.1-fold decreased, p=0.0059), mir-3718–5p (52.8-fold increased, p=0.0381) miR-6422b–5p (13.7-fold increased, p=0.0380), and miR-25–3p (1.8-fold decreased, p=0.0317). Additional validation of selected miRNAs candidates will be further performed using qPCR analysis.

**Conclusions:** Our results indicate new miRNA candidates differentially expressed in peripheral blood monocytes from patients with UA who subsequently developed RA, in comparison to patients with UA who did not progress to RA after 4 years follow-up.

**FR10027**  TNF EXPRESSION ON MICROPARTICLES FROM RHEUMATOID ARTHRITIS PATIENTS MEDIATES ENDOTHELIAL CELL FATE IN VITRO

C. Barbati 1, M. Vomero, T. Colasanti, L. Novelli, F.R. Spinelli, F. Miranda, F. Cacchiarllo, A. Finucci, C. Perricone, R. Scirvo, F. Conti, G. Valesini, C. Alessandri. 1 Department of Internal Medicine and Medical Specialties, Arthritis Center, Sapienza University of Rome, Rome, Italy. 2 University of Rome, Sapienza University of Rome. 3 University of Rome, Sapienza University of Rome.

**Background:** Microparticles (MPs) are small membrane vesicles released by activated platelets or monocytes under physiological and pathological conditions. MPs have increased levels of MPs have been reported in patients with autoimmune diseases, such as Rheumatoid Arthritis (RA) which is characterized by an accelerated atherosclerosis. TNF, a key cytokine involved in the pathogenesis of RA, has been associated to RA atherosclerosis (2). Moreover, MPs could also have a role in endothelial dysfunction contributing to atherosclerosis in RA patients.

**Objectives:** The aim of this study was: 1) to evaluate TNF expression on RA-MPs. 2) to estimate the effects of serum RA-MPs on endothelial apoptosis and 3) to evaluate the effects of TNF on endothelial cell apoptosis in vitro and in vivo treatment with Etanercept.

**Methods:** 15 RA patients were recruited from the Department of Rheumatology Sapienza University of Rome at baseline (T0) and after three months of therapy (T3) with Etanercept. A fasting blood sample was collected and centrifuged twice to obtain platelet-poor plasma rich in MPs. The resulting plasma was stained with anti-TNF and analysed by flow cytometry. In vivo, MP samples from RA patients on endothelium were evaluated using human umbilical vein cell line EA.hy926. Cells were treated with RA-MPs purified at T0 and T3 and with RA-MPs in vitro treated with Etanercept. At the end of experiments apoptosis and autophagy were evaluated. Apoptosis was analyzed by flow cytometry using a FITC-conjugated
annexin V and propidium iodide apoptosis detection kit; autophagy was analyzed by western blot for the expression level of the autophagic marker LC3-II.

**Results:** Our results showed that MPs purified from RA patients at T0 expressed TNF on their surface and this expression decreased after three months of treatment with Etanercept (p<0.04). Moreover, serum RA-MPs at T0 significantly increased, in a dose-dependent manner, both apoptosis and autophagy levels in the human umbilical vein cell line EA.hy926 (p<0.005 and p<0.02, respectively versus untreated cells). After three months of treatment with Etanercept, RA-MPs were not able to significantly change these parameters. Finally, in vitro studies showed that RA-MPs treated with Etanercept significantly decreased surface expression of TNF and were no longer able to modulate apoptosis and autophagy in EA.hy926 cells.

**Conclusions:** Our data demonstrate that serum RA-MPs express TNF on their surface. Moreover, both in vivo and in vitro treatment with Etanercept interfere with the ability of MPs to significantly modulate apoptosis and autophagy of endothelial cells by decreasing surface expression of TNF.

**FR0028 IN VITRO INHIBITORY EFFECT OF ETANERCEPT ON AUTOPHAGY: A NEW MECHANISM OF ACTION OF TNF INHIBITORS IN RHEUMATOID ARTHRITIS**

**M. Vomero**, 1, A. Capozzi 2, C. Barbati 1, T. Colasanti 1, V. Manganelli 2, F. Cecarelli 1, F.R. Spinelli 1, F. Conti 1, C. Perricone 1, A. Finuic 1, R. Pelliola 1, R. Scivo 1, R. Misasi 1, M. Sorice 1, G. Valesini 1, C. Alessandrini 1

1 Department of Internal Medicine and Medical Specialties, Arthritis Center, Sapienza University of Rome; 2Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy

**Background:** Autophagy has emerged as a key mechanism in the development, survival and function of immune cells and dysregulation of autophagic pathway has been implicated in the pathogenesis of several autoimmune diseases including Rheumatoid Arthritis (RA) (1). In fact, autophagy seems to be involved in the generation of citrullinated peptides, with consequent breakdown of tolerance in RA (2). Moreover, increased autophagy levels and a reduction of apoptosis-related molecules have been found in RA synovial tissues and a role of TNF-induced autophagy in RA development has been proposed (3).

**Objectives:** The aim of the study was to analysed the effect of TNF and anti-TNF inhibitor etanercept on autophagy and apoptosis in cells involved in RA pathogenesis.

**Methods:** Peripheral blood mononuclear cells (PBMCs) and fibroblast-like synoviocytes (FLS) isolated from RA patients were cultured in presence of TNF and in serum deprivation state (starvation) for 4 hours and then etanercept, at concentration of 15 ug/mL, were added to the culture. After 24h cells were analyzed for levels of autophagy marker LC3-II by western blot and for percentage of annexin V-positive apoptotic cells by flow cytometry.

**Results:** As expected, TNF and starvation induced autophagy on RA PBMC and FLS in dose-dependent manner after 24h of culture (p<0.05 in all experimental conditions). Moreover, the adding of etanercept caused a significant reduction of LC3-II levels (p<0.004) and an increase of apoptosis rate (p=0.002) after both pro-autophagic stimuli (p<0.05).

**Conclusions:** We demonstrated for the first time an inhibitory effect of etanercept on autophagy activation of cells involved in RA pathogenesis. In addition, our findings suggest a crucial role of autophagy in RA cells survival.

**FR0029 THE OXYGEN SENSOR PHD1 IS AN INDISPENSABLE REGULATOR OF ARTHRITIS DEVELOPMENT**

**K. De Wilde** 1,2, D. Gauliombme 1,2, J. Coudenys 1,2, F. Windels 1,2, S. Van Welden 1, A. De Muynck 4, D. Elewaut 1,2. 1Department of Rheumatology, Department of Internal Medicine, Ghent University; 2Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center; 3Department of Gastroenterology; 4Department of Physics and Astronomy, Ghent University, Ghent, Belgium

**Background:** Oxygen supply is a fundamental requirement for all living tissues. Some tissues such as articular joints are characterized by a physiological state of hypoxia. Interestingly, under conditions of inflammation such as in arthritic disease, this level of hypoxia is even further enhanced. However, the functional significance of these observations and the molecular mechanisms involved remain poorly characterized to date. Our goal was therefore to examine the role of 3 hypoxia-sensing receptors, particularly PHDs, in inflammation.

**Objectives:** Our goal was to examine the role of oxygen sensors PHD1, PHD2 and PHD3 in preclinical models of rheumatoid arthritis, and to delineate the cellular source involved.

**Methods:** We subjected the collagen antibody induced arthritis (CAIA) model (resembling rheumatoid arthritis) to hypoxic (10% O2) and normoxic conditions (21% O2). Furthermore, the CAIA-model was induced in mice with germeline deficiency of the specific PHD’s and in mice with a myeloid cell-specific PHD1 deficiency versus controls. Arthritis development was assessed by clinical scoring of paw swelling, histopathology of knee joints and μCT.

**Results:** Mice kept in hypoxic conditions during CAIA experiments showed markedly less arthritis (both by clinical and histopathological assessment) compared to mice in normoxic conditions. Furthermore, we demonstrated that PHD1 knockout (KO) mice had significantly less joint inflammation compared to wildtype mice. PHD1 KO mice were also protected against inflammation induced bone loss as evidenced by μCT. By contrast, no difference was found in between PHD2 heterozygous (PHD2 KO mice are not viable) or PHD3 KO mice and littermate controls. Because myeloid cells are considered critical effector cells upon passive transfer of arthrogenic antibodies in the CAIA model we also generated myeloid cell specific ko mice (PHD(−/−)M). Of interest, PHD(−/−)M mice developed less arthritis compared to wildtype mice and were protected against inflammation induced bone loss.

**Conclusions:** Our data are consistent with a new paradigm that the oxygen sensor PHD1 is a critical regulator of myeloid cell function in arthritic disease. Overall, the data suggest that PHD1 is a potential target in the treatment of arthritis.

progression, our work suggests that the analysis of synovial MCs could help to identify patients at high risk of progression in radiographic damage, warranting further investigations to confirm the association of MCs with the development of joint damage and their direct contribution to bone erosion, possibly via a RANKL-mediated activation of osteoclasts.

**FR0033 IMPORTANT ROLE OF CD11C+ DENDRITIC CELLS IN INFLAMMATORY ARTHRITIS**

A. Puchner1, V. Saferding1, M. Bonelli1, H. Leiss1, R. Pfeifer2, G. Kroenke1, M. Koenders3, J. Smolen1, K. Redlich1, S. Blüml1, 1Medizinische Universität Wien, Wien, Austria; 2University Hospital Erlangen, Erlangen, Germany; 3Radboud University Nijmegen Medical Center, Nijmegen, Netherlands

**Background:** Dendritic cells (DCs) are important antigen presenting cells (APCs) and therefore they play an important role in bridging the innate and the adaptive immune response. DCs can be divided in different subsets with specific functions. A powerful APCs, DCs are thought to play an important role in the induction of autoimmune diseases such as rheumatoid arthritis. However, the actual role of DCs in joint inflammation is not known yet.

**Methods:** We analyzed histological sections of K/BxN serum transfer arthritis as well as hTNFtg arthritis for the presence of CD11c+ cells by immunohistochemistry. We also performed synovial biopsies and analyzed the cellular composition of the inflammatory infiltrate with respect to DCs. We used CD11c-diphtheria toxin receptor (DTR) transgenic mice, which express the human diphtheria-toxin receptor under the CD11c promoter, allowing for specific depletion of CD11c+ cells by administration of diphtheria toxin (DT). K/BxN serum transfer arthritis was induced, and mice were given either DT or PBS or in wt and BARF3 deficient mice. In addition CD11c DTR mice were crossed into hTNFtg animals and also received either DT or PBS. The severity of arthritis was determined clinically and histologically.

**Results:** We show that CD11c+ cells are present in significant numbers in the synovia of K/BxN and TNF driven arthritis. Both CD8+CD11c+ and CD11b+CD11c+, can be found in synovial tissue. Upon depletion of CD11c+ cells clinical signs of K/BxN serum transfer arthrits were significantly reduced. Histological analysis found reduced synovial inflammation after the depletion of CD11c+ cells in K/BxN arthritis. In addition, local bone destruction and the number of osteoclasts was also significantly reduced. Analysis of K/BxN arthritis in wt mice and BATF3-/- mice, which lack a subset of DCs, namely CD8+CD11c+ DCs, revealed no difference in arthritis severity between the two groups. In addition to K/BxN arthritis, we found that also in TNF-driven arthritis depletion of CD11c+ cells led to a striking reduction of synovial inflammation and a complete depletion of osteoclasts.

**Conclusions:** These data show that in addition to initiating an adaptive immune response, CD11c+ dendritic cells, are also involved in innate effector mechanisms of inflammatory arthritis. Especially CD11b+CD11c+ and monocyte derived dendritic cell intermediate phenotype, play an important role in inflammatory arthritis, suggesting that they could be an important therapeutic target for patients suffering from inflammatory arthritis.

**FR0034 ADALIMUMAB REDUCES CXCR4 EXPRESSION DURING INFLAMMATORY ARTHRITIS AND IN FIBROBLAST-LIKE SYNOVOCYTES AND OSTEOCLASTS UNDER CHRONIC TNF EXPOSURE**

B.P. Harvey1, L. Li1, M. Konrad2, H. Knight1, S. Westmoreland3, M. Ruzev1, Z. Kaymakcalan1, 1Biology; 2Translational Research; 3Immunology Pharmacology, Abbvie Bioresearch Center, Worcester, United States

**Background:** The CXCL12/CXCR4 chemokine axis has been implicated in the pathogenesis of RA. The expression of this chemokine and receptor has been shown to be increased in RA synovium, and moreover, CXCR4 levels in synovium have been correlated with joint destruction in RA patients.

**Objectives:** Given that high levels of CXCR4 are associated with RA pathogenesis, we sought to determine whether CXCR4 levels are altered by adalimumab (a) both in RA patients, and in the human TNF transgenic mouse model (huTNF Tg197) of arthritis, as well as in vitro with RA fibroblast-like synoviocytes (RA-FLS) and human osteoclast precursors (OCP) following TNF exposure. In addition, we investigated the role of CXCR4 in human osteoclastogenesis (OCogenesis) under chronic TNF exposure.

**Methods:** Public DNA microarray data of synovial tissue from ADA treated RA patients was analyzed for changes in the expression level of various chemokines and their cognate receptors. PBMC populations from ADA treated RA patients taken at baseline, wks. 4 & 12 were assessed by CyTOF for CXCR4. IHC staining was performed on formalin paw sections from wk. 13 placebo control and ADA treated (1 mg/kg i.p.) huTNF Tg197 mice to evaluate CXCR4 expression in various pannus-associated cells. To assess the role of TNF and concomitant ADA treatment on human cultures in vitro, CXCR4 RNA expression was evaluated in RA-FLS stimulated with conditioned media from PBMCs +/-ADA for 6 hrs., and CXCR4 protein on OCP by flow cytometry in response to 72 hr. M-CSF+RANKL +/-TNF +/-ADA. To demonstrate the role of CXCR4 in OCgenesis, OCP were cultured for 6 d. in M-CSF+RANKL+/-TNF+/-ADA. Pretreatment with CXCR4 neutralizing antibody. CC maturation and activity were assessed by measuring TRAP5b activity in the conditioned media of OCP. Additionally, OCP were treated with conditioned media from PBMCs +/-ADA for 6 hrs., and CXCR4 protein on OCP by flow cytometry in response to 72 hr. M-CSF+RANKL+/-TNF+/-ADA. To demonstrate the role of CXCR4 in OCgenesis, OCP were cultured for 6 d. in M-CSF+RANKL+/-TNF+/-ADA. Pretreatment with CXCR4 neutralizing antibody. CC maturation and activity were assessed by measuring TRAP5b activity in the conditioned media of OCP.

**Results:** Preliminary microarray data analysis of synovial tissue demonstrated that active RA patients over-expressed CXCR4 while CXCR4 was significantly normalized (two-fold reduction) in the responders to ADA therapy. In addition, CyTOF analysis of PBMC from ADA treated RA patients indicated a significant 2-fold reduction from baseline in CXCR4 expression on B cells with a modest trend of reduction on CD4+ T cells by wk. 4. In huTNF Tg197 mice, CXCR4 expression in the inflamed pannus (most notably in FLs, lymphocytes and OC) was also decreased by ADA therapy. In vitro human cultures of similar cell types including RA-FLS and OCP were subjected to conditioned media or TNF, respectively, and found to express lower levels of CXCR4 that were reduced with concomitant ADA treatment. Finally, antibody-mediated blockade of CXCR4 on human OCP decreased both TNF-enhanced OC maturation and activity.

**Conclusions:** Our findings demonstrate that ADA therapy reduces CXCR4 expression in vivo both in RA patient PBMCs and in the pannus of huTNF Tg mice with inflammatory arthritis expression in FLs, lymphocytes, OCPs and OC. Similar results were also observed with our in vitro human cultures of equivalent cell types. More importantly, we’ve shown that inhibition of CXCR4 can reduce TNF-enhanced OCgenesis in vitro, suggesting that CXCR4 may be a contributing factor to TNF-enhanced osteolysis.

FRI0036  ASSOCIATION BETWEEN THE 18FDG-PET IMAGING AND THE PATHOLOGICAL FINDINGS OF RHEUMATOID SYNOVITIS

C. Okura, Y. Yonemoto, K. Okamura, T. Suto, M. Tachibana, H. Chikuda. Orthopaedic Surgery, Gunma University Graduate School of Medicine, Maebashi, Japan

Background: It has been reported that 18FDG-PET (PET) is useful in the evaluation of RA and for monitoring the effects of treatment on the disease activity, so its utility for the evaluation of arthritis is expected. However, the mechanism underlying the uptake of FDG into the inflamed joint is still unclear.

Objectives: The aim of this study was to investigate the associations among the amount of FDG uptake in RA joints, the inflammatory findings with regard to the pathology of the synovium and the clinical findings.

Methods: We performed PET in 18 RA patients who underwent Total Kne Pisaoplasty surgery in our hospital just prior to surgery. We calculated the FDG uptake as the standardized uptake value (SUVmax) and scored it using the Rooney score, with the degree of inflammation of the synovial tissues used for the pathological evaluation. We evaluated the associations among the SUVmax, Rooney score, CRP level, ESR and MMP-3 level just before surgery.

Results: The subjects were 18 cases with 20 joints, which were in four females and 14 males. At the time of surgery, the average age of the patients was 66.7±7.9 years old, and the mean disease duration was 20.8±14.0 years. Significant correlation was not observed between SUVmax and total Rooney score (r=0.056, p=0.814). But there were strong correlations between SUVmax and some of the individual items in Rooney score, including the “Synoviocyte hyperplasia”, and also between SUV max and “Diffuse infiltrates of lymphocytes” (r=0.512, p=0.021 and r=0.581, p=0.007, respectively).

Conclusions: The accumulation of FDG was associated with the extent of “synoviocyte hyperplasia” and “diffuse infiltrates of lymphocytes”. It is estimated that accumulation of FDG is associated with relatively early stage of active inflammation of RA.

FRI0037  MER-MEDIATED EFFECOTOMY TEMPS ARTHRITIS BY PREVENTING NEUTROPHILS TO GO INTO SECONDARY NECROSIS AND SPILL THEIR INFLAMMATORY CONTENT IN THE JOINT

Background: Rheumatoid arthritis is characterized by an inflammatory response in synovial joints, showing a predominant influx of neutrophils. These cells are cytotoxic and contribute to matrix degradation. In addition, they are implicated as a source of citrullinated auto-antigens, leading to the production of anti-citrullinated protein antibodies (Acpa). Neutrophils have a relative short life span and many of them undergo apoptosis. If they are not cleared, they undergo secondary necrosis and release their cell content. A key mediator in the resolution of inflammation and the uptake of apoptotic cells, or efferocytosis, is the receptor tyrosine kinase Mer.

Objectives: To elucidate the local role of Mer during gonarthritis.

Methods: Macrophages were transduced by adenoviruses encoding the Mer ligand Pros1 or Luciferase. One day after the collagen booster injection in mice, Mer-specific antibodies or IgG antibodies, or adenoviruses overexpressing Pros1 or Luciferase were injected intravenously. Mice were euthanized at day 30 and joint homogenates were assessed.

Results: Adenoviral overexpression of the Mer ligand Pros1 resulted in reduced production of pro-inflammatory cytokines and chemokines by macrophages, compared to Luciferase. In addition, local Pros1 overexpression resulted in reduced expression of pro-inflammatory and pro-destructive mediators by synovial cells of arthritic mice. Systemic and local Pros1 overexpression diminished joint pathology, reduced the number of cleaved Caspase 3-positive apoptotic cells and secondary necrotic neutrophils. Conversely, inhibiting Mer-mediated efferocytosis by Mer-specific antibodies or Merther gene ablation resulted in aggravation of arthritis compared to controls, as evidenced by increased inflammation and tissue destruction. Additionally, Mer-inhibited mice had increased numbers of apoptotic cells in their knee joints, and higher serum levels of IL-16C, a cytokine released by secondary necrotic neutrophils.

Conclusions: Together, these results demonstrate that Mur locally plays a unique protective role in knee joint disease by enhancing resolution of arthritis. Our data suggest that promoting and/or restoring Mer-mediated uptake of apoptotic cells in the arthritic joint might be therapeutically beneficial.

FRI0038  RELEASE OF PEPTIDYLARGININE DEIMINASE 2 FROM ACTIVATED NEUTROPHILS

M.A. Steffensen, D. Damgaard, M. Bassi, C.H. Nielsen. Institute for Inflammation Research, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark

Background: Extracellular citrullination catalyzed by peptidylarginine deiminase (PAD) is thought to play a central role in the pathogenesis of rheumatoid arthritis. Neutrophils are a major reservoir of PAD2 and PAD4. Cellular release of PAD2 and PAD4 is usually considered a consequence of cell death.

Objectives: We aimed to determine if PAD2 can be released from live, activated neutrophils as an active process.

Methods: Whole blood cells were purified from healthy blood were stimulated with phorbol 12-myristate 13-acetate (PMA). To capture PAD2 released from neutrophils and detect it by flow cytometry, we used biotinylated anti-CD15 and anti-PAD2 antibody (mAb D59). In addition, intracellular PAD2 was quantified by intracellular staining with PE-anti-PAD2. PAD2 released from leucocytes and subcellular fractions of human granulocytes were assessed for content of PAD2 using an in-house lumixen-based assay.

Results: On incubation of whole blood cells with PMA, PAD2 was detectable in the supernatant 30 minutes, and levels increased thereafter in parallel with increasing cell death. However, using PAD2 catch reagent, we found that live neutrophils released PAD2 in the 30 minutes after stimulation. Intracellular staining for PAD2 showed that the content of PAD2 in live neutrophils decreased correspondingly. Upon subcellular fractioning of granulocytes, the majority of PAD2 was found in cytosol and, in 25 times lower quantities, in the fraction containing plasma membranes and secretory vesicles. Sparse amounts of PAD2 were also observed in gelatinase granules.

Conclusions: In conclusion, PAD2 can be released from live, activated neutrophils, which may contribute to extracellular citrullination and thereby play a role in driving inflammatory processes in RA patients with immune responses to citrullinated proteins.

FRI0039  ENDOTHELIAL DYSFUNCTION IN RHEUMATOID ARTHRITIS: WHICH EFFECT OF METHOTREXATE? A STUDY IN ADJUVANT INDUCED ARTHRITIS MODEL

R. Bordy1, P. Potosin1, F. Verhoeven2, C. Prati1,2, J. Moretto1, M. Tournier-Nappey1, C. Demougeot1. Peptide Ed4267, Université de Franche-Comté; 1Rhumatologie, CHRU Besançon, Besançon, France

Background: Rheumatoid arthritis (RA) is associated with increased cardio-vascular risk [1]. The mechanism of this increased CV risk [1] seems to be endothelial dysfunction (EDHF). EDHF is involved in the regulation of peripheral resistance arterioles. EDHF is mainly generated by NO, produced by nitric oxide synthase (NOS) [2]. Inhibition of NOS reduces the production of EDHF [3]. This supports the hypothesis that RA is associated with increased CV risk due to impaired EDHF generation. In this study we aimed to investigate the effect of MTX on EDHF generation in the RA model.

Objectives: The aim of this study was to determine the effect of MTX on endothelial function in arthritis and to investigate its effect on endothelial pathway.

Methods: Experiments were conducted in the adjuvant-induced arthritis (AIA) model in Lewis rat. At onset of arthritis, rats were treated by a sub-cutaneous injection of MTX (1 mg/kg/wk) or phosphate buffer saline (vehicle) for 3 weeks. Arterial score was daily recorded. At the end of treatment, thoracic aorta was harvested to measure the relaxation to acetylcholine on pre-constricted aortic rings in the presence or not of inhibitor of nitric oxide (NO) synthase (L-NAME), arginine (nor-NOHA), EDHF (Apamin/Charybdotoxin), or a superoxide dismutase analog (Tempol). The effect of norepinephrine (NE) and sodium nitroprusside (SNP) was also measured. We used an in-house luminex-based assay.

Results: MTX treatment induced a marked impairment of EDHF generation in AIA-induced arthritis. The effect of MTX on EDHF generation was significantly different between the two treatment conditions.

Conclusions: The results of this study suggest that MTX treatment may reduce the severity of EDHF generation in RA.

CHARACTERIZATION OF ANTI-CARBAMYLATED SYNOVIAL IN VIVO MONITORING OF ANTI-FOLATE THERAPY IN ARTHRITIC RATS USING [18F]FLUORO-PEG-FOLATE AND PET

1Amsterdam Rheumatology and Immunology Centre – location Amsterdam, Netherlands; 2Department of Chemistry, Purdue University, West Lafayette, United States

Background: Macrophages play a key role in the pathophysiology of rheumatoid arthritis (RA). The folate receptor (FR) is expressed on these macrophages and [18F]fluoro-PEG-folate PET can be used to visualize arthritis in vivo. In addition, [18F]fluoro-PEG-folate PET could be a highly interesting tool for therapeutic monitoring of MTX therapy, the corner stone for RA therapy.

Objectives: To study the potential of [18F]fluoro-PEG-folate PET for monitoring response to MTX in a rat model of RA.

Methods: Arthritic rats [3] (n=3–6 per group) received interventions with either MTX (1 mg/kg; 2 times [group A] or 4 times [group B]) or PBS (control group) with a time interval of 3–4 days. Healthy rats didn’t receive any arthritic induction or therapy. [18F]fluoro-PEG-folate PET-CT were acquired for one hour after tracer injection [2]. Scans were analysed using the region of interest method and standardized uptake values (SUVs) were determined (50–60 min time frame). Sixty minutes after the PET scan, ex-vivo tissue distribution was performed and the amount of radioactivity measured in a gamma counter (expressed as percentage of the injected dose/gram tissue (%ID/g)) [2]. For histopathology (Hematoxylin-Eosin (HE) and immunohistochemistry with macrophage specific antibodies ED1 and ED2) were applied. Synovial macrophages were counted in predefined areas of the knees [3].

Results: PET scans clearly visualized significantly lower SUVs (1.5-fold, p<0.01) in arthritic knees of both MTX-treated groups, approximating the levels observed in healthy rats. Corroborating [18F]fluoro-PEG-folate PET, ex vivo tissue distribution ([18F]fluoro-PEG-folate demonstrating a 2- and 4-fold decrease (group A and B, respectively) in tracer uptake in arthritic knees after MTX therapy (0.12 and 0.06 for groups A and B, and 0.22 and 0.14 for controls, respectively) (Figure). This reduction in uptake of [18F]fluoro-PEG-folate in arthritic knees was also associated with a significant decrease in ED1 and ED2 positive synovial macrophages in arthritic knees (4-fold) for both treated groups compared with control rats knees (p<0.01).

Conclusions: This study in arthritic rats underscores the potential and usefulness of [18F]fluoro-PEG-folate PET as tool to monitor of MTX therapy and potentially other anti-folate treatments of RA.

BAFF-R EXPRESSION IN NAIVE CD5+IGM+ B CELLS IN RHEUMATOID ARTHRITIS PATIENTS REPOPULATING AFTER RITUXIMAB

E. Becerra1,2, I. de la Torre2, M.J. Leandro2, G. Cambridge2. 1Rheumatology, Hospital universitario de Torrevieja, Alicante, Spain; 2Rheumatology, University College London, London, United Kingdom

Background: Serum levels of B cell activating factor (BAFF) rise following Rituximab (RTX) therapy in patients with Rheumatoid arthritis (RA). CD5+IgM+B cells are present within transitional and naïve B cell subsets and their increased production or accumulation is associated with some autoimmune diseases. Previous studies have shown that BAFF does not enhance their survival compared with CD5- naïve B cells, suggesting that signalling pathways are important in promoting their survival.

Objectives: To determine serum BAFF levels and BAFF-receptor (BAFF-R) expression in CD5+IgM+B cells in healthy controls (HC), RTX-naïve RA patients (pre-RTX), and relapsing at different time points after peripheral B cell repopulation post-RTX treatment, divided into 2 groups: early relapsers (0–3 months post-B cell return) and later relapers (~4 months post-B cell return).

Methods: Immunophenotyping of peripheral blood mononuclear cells was used to determine %CD5+IgM+B cells and BAFF-R (% and expression, mean fluorescence intensity (MFI)) in 5 HC, 13 pre-RTX and 12 post-RTX RA patients. Results were analyzed with respect to timing of relapse after peripheral B cell return

Table 1

<table>
<thead>
<tr>
<th>Group</th>
<th>%BAFF-R+ve</th>
<th>BAFF-R MFI</th>
<th>BAFF levels (ng/ml)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pre-RTX</td>
<td>98.7 (97.9–99.5)</td>
<td>62.5 (50.5–82.4)</td>
<td>1.1 (0.9–1.2)</td>
</tr>
<tr>
<td>Post-RTX early</td>
<td>97.3 (85.8–100)</td>
<td>58 (34.3–129)</td>
<td>1.4 (0.9–1.7)</td>
</tr>
<tr>
<td>Post-RTX late</td>
<td>60.6 (12.9–71.2)</td>
<td>15.6 (11.8–17.5)</td>
<td>2.4 (2–6.4)</td>
</tr>
</tbody>
</table>

Results: %CD5+IgM+B cells, but not absolute numbers, were significantly higher in post-RTX early relapers compared to HC (p<0.01), pre-RTX patients (p<0.001) and post-RTX later relapers (p<0.01). There was a strong inverse correlation between %CD5+IgM+B cells and time after B cell return (r²=0.88, p<0.0001). BAFF-R expression was significantly lower in both post-RTX groups compared to HC and pre-RTX patients; early relapers showed the lowest % and MFI BAFF-R+ expression, compared with later relapers (p<0.01). BAFF-R+ expression increased with time after B cell return, both % (r²=0.47, p=0.002) and MFI (r²=0.76, p=0.0004). BAFF levels were significantly higher in both post-RTX groups compared to HC and pre-RTX patients, with the highest BAFF levels in early relapers (p<0.05 compared to later relapers). There was a significant inverse correlation between BAFF levels and % (r²=0.51, p<0.01) and MFI (r²=0.4, p<0.05) BAFF-R+ expression.

Conclusions: Early relapers show increased %CD5+IgM+ naïve B cells, and decreased BAFF-R expression, similar to ontogeny and what is seen in cord blood B cells. Whether the increased numbers of CD5+ naïve cells were contributing to relapse was not determined but they have the capacity to rapidly mature into autoantibody producing plasma cells, independent of the BAFF/BAFFR system. The aim of this study was to evaluate the radiological outcomes after an early treatment during 21 days by Etanercept, or Naproxene, or Celecoxib, or Prednisone, or Diclofenac or Methotrexate in adjuvant induced arthritis in rats.

Methods: Adjuvant-induced arthritis (AIA) was induced in 6 weeks old male Lewis rats by injection of Mycobacterium butyricum in adjuvant at the basis of the tail. At the onset of arthritis, rats were daily treated with Naproxene (10 mg/kg/d), or Diclofenac (5mg/kg/d), or Celecoxib (3 mg/kg/d), or Prednisone (10 mg/kg/d), or Etanercept (10 mg/kg/3 days, s.c.), or Methotrexate (1mg/kg/3 days, s.c.), or saline solution (Vehicle), for 21 days. Arthritic score was daily monitored. At the end of treatment, paws’ radiological exam was performed with a BMA High Resolution Digital X Ray (40mV, 10mA). A score of 0 to 20 was determined for each paw using a grading scale modified from Ackerman et al (1979).

*** p<0.0001 compared with HC, ** p<0.01, * p<0.05 compared with pre-RTX.
Results: Compared to the Vehicle, all treatments significantly reduced (p < 0.001) arthritic score with a reduction of the arthritic score evaluated between 40% (for methotrexate) and 70% (for diconfexan) (figure 1. Compared to the vehicle, the radiographic score was improved by Naproxene, Diconfexan, Celcoxib, Glucocorticoids, Etanercept (p < 0.001) but not by methotrexate. Compared to Etanercept, Naproxene and diconfexan showed less radiological structural changes (p < 0.01) (figure 2).

Conclusions: Our study demonstrates for the first time that an early treatment with NSAIDs, excluding COX2 selective inhibitor, is more beneficial than Etanercept on the radiological damages in adjuvant induced arthritis. The close efficiency of all drugs on the arthritis suggests that the beneficial impact of NSAIDs is not only driven by their impact on the systemic inflammation. NSAIDs should be used during the window of opportunity.

DOI: 10.1136/annrheumdis-2017-eular.2611
Conclusions: The persistence of 14–3-3-η levels ≥0.50 ng/ml appears to be associated with a lower probability of reaching remission in polyarthritis patients. 14–3-3-η levels >0.50 ng/ml in patients in clinical remission appear to be associated with more rapid radiographic (especially erosive) progression over the following year. A larger study is required to validate these findings, especially with the most stringent criterion of Boolean remission.

THE ANTI-CD20 ANTIBODY RITUXIMAB REDUCES THE INFLAMMATORY AND PROTHROMBOTIC PROFILE OF LEUKOCYTES FROM RHEUMATOID ARTHRITIS PATIENTS AND MODULATES THE ACTIVITY OF ENDOTHELIAL CELLS
I. Cecchi 1, C. Perez-Sanchez 2, P. Ruiz-Limon 2, I. Arias de la Rosa 2, M.C. Abalos-Aguilera 2, Y. Jimenez-Gomez 2, R. Ortega 2, E. Collantes-Estevez 2, A. Escudero 2, N. Barbarosa 2, S. Sciascia 2, C. Lopez-Pedrera 2. 1 Department of Clinical and Biological Sciences, Center of Research of Immunopathology and Rheumatic Diseases · Coordinating Center of Piemonte and Valle d’Aosta Network for Rare Diseases, Turin, Italy; 2 GC-5/Rheumatology, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain

Background: Rituximab (RTX) has been shown to be successful in the treatment of rheumatoid arthritis (RA), indicating that B cells have an important role in this disease.

Objectives: The present study was undertaken to investigate the mechanisms of action of RTX on the immune and endothelial cells (EC) of the vascular system in the setting of RA.

Methods: Purified lymphocytes from five RA patients with high disease activity were treated with RTX (1μg/mL) for 24 hours. Then, the depletion of B cells was assessed by flow cytometry, and the changes occurred in the inflammatory profile of T-lymphocytes was analysed by RT-PCR. In a second set of experiments, to evaluate the influence of B-cell depletion on the inflammatory/prothrombotic profile of cells belonging to the vascular system, supernatants from cultured lymphocytes of RA patients in the presence or in the absence of RTX were added to isolated monocytes from AR patients and to cultured endothelial cells. The response to RTX was then examined.

Results: As expected, RTX promoted a significant depletion of B-cells. In parallel, the inflammatory profile of T lymphocytes from RA patients was downregulated, as shown by a significant drop of IL-1, IL-6, IL-17, IFN and TNF expression levels, thus suggesting that the anti-inflammatory effects of RTX might be related to B cell depletion. Supernatants from RTX-treated lymphocytes further abridged the prothrombotic profile of RA-monocytes, promoting a significant inhibition of TF, MASP-1 and VEGF-A gene expression. Moreover, endothelial cells, activated after treatment with supernatants from cultured RA-lymphocytes, showed reduced expression of cell-adhesion molecules (i.e. VCAM, ICAM, E-Selectin) and pro-thrombotic factors (i.e. TF, VEGF, IL-8) after treatment with supernatants from cultured RA-lymphocytes in the presence of RTX.

Conclusions: Overall, these results reveal that depletion of B-cells by RTX in RA influences the inflammatory profile of T lymphocytes, as well as their interaction with monocytes and ECs, thus modulating the inflammatory and prothrombotic shape of vascular cells in the setting of RA.

FRI0049 | FC GAMMA RECEPTOR IV ENHANCES BONE EROSION IN EXPERIMENTAL ARTHRITIS BY PROMOTING INFUX OF PMNS
I. Di Ceccio 1, G. Ascone 1, M. van den Bosch 1, J.S. Verbeek 2, P. van der Kraan 3, P. van Lent 1. 1 Experimental Rheumatology, Radboud University Medical Center, Nijmegen; 2Leiden University Medical Center, Leiden, Netherlands

Background: FCγ-Rs are involved in regulation of synovial activation and bone destruction during immune complex (IC)-mediated arthritis. The balance between activating FCγ-Rs (FCγRII,III and IV) and inhibiting FCγ-Rs determines synovial activation. Here we investigated the particular role of activating FCγ-RIV in bone erosion in IC-mediated osteoarthritis (OA) by comparing FCγRI,II,III,IV-/- mice with their WT controls. This observation suggests that the anti-inflammatory effects of RTX might be related to bone erosion in the knee joints of FcγRI,II,III,IV-/- mice to differentiate into osteoclasts in vitro was comparable to the one of WT controls. Moreover, we observed comparable numbers of TRAP+ osteoclasts on the bone surface of FCγRII/III,IV-/- and WT arthritic mice, suggesting that the observed decrease in bone erosion is mainly caused by a reduced osteoclast activity, rather than decreased osteoclast number. However, in contrast to FCγRII/III,IV-/-, AIA induction in knee joints of FCγRII/III,IV-/- resulted in increased bone erosion and inflammatory cytokines compared to WT mice. AIA induction in knee joints of FCγRII/III,IV-/- resulted increased, whereas it was decreased in the knee joints of FCγRII/III,IV-/- compared to their WT controls. This observation suggests that particularly FCγ-RIV is involved in regulating influx of PMNs. PMNs are potent producers of alarmins S100A8/A9 which are described to promote osteoclast activity. In line the number of S100A8/A9 positive cells in synovium was increased in FCγRII/III,IV-/- while decreased in FCγRII/III,IV-/-, compared to their WT control.

Conclusions: FCγ-RIV promotes bone erosion in AIA by enhancing influx of PMNs within the synovium. PMNs are potent producers of S100A8/A9 which has been described to induce osteoclast activity.

FRI0050 | TYPE II COLLAGEN SECRETED FROM ARTICULAR CHONDROCYTES IS MAINLY DESTROYED BY CATHEPSIN S IN RA MICE
J. Zhao 1, Q. Huang, H. Ren, M. Yang. Department of Rheumatology, Nanfang Hospital, Southern Medical University, Guangzhou, China

Background: Mast cells have long been recognized to increase strikingly in number in the synovial membrane of rheumatoid arthritis (RA), accounting for 5% of the surface synovial membrane cells. Type II collagen has the longest half-life in cartilage matrix. The main cells which might affect articular cartilage in RA are synovial fibroblasts, synovial macrophages and mast cells. The latter two could express cathepsin S.

Objectives: We aimed to find the cells which have the biggest influence on type II collagen secreted from articular chondrocytes and the possible mechanisms in RA mice.

Methods: Four types of cells from collagen-induced arthritis model-established C57BL/6 mice were primary cultured, including synovial fibroblasts, peritoneal...
macrophages, bone marrow-derived mast cells and articular chondrocytes. The first three were co-cultured with articular chondrocytes separately. LHV5, a specific inhibitor of caspase 8 and 9, a broad-spectrum inhibitor of cytotoxic proteins, were added into the cocultures of macrophages and articular chondrocytes separately. Also, C48/80, an activator of mast cells, LHV5, and E64 were added into the cocultures of articular chondrocytes. When articular chondrocytes were co-cultured with mast cells, the type II collagen could be restrained by C48/80 (9.82±0.42ng/ml), compared with the control group (17.75±7.84ng/ml). The secretion of type II collagen could return to normal by the inhibitors of caspase 8, both LHV5 (16.15±5.05 ng/ml) and E64 (12.55±6.64 ng/ml). When articular chondrocytes were co-cultured with mast cells, the type II collagen could be restrained by C48/80 (9.82±0.42ng/ml), compared with the control group (26.09±5.34ng/ml). Similarly, the secretion of type II collagen could return to normal by the inhibitors of caspase 8, both LHV5 (16.15±5.05 ng/ml) and E64 (12.55±6.64 ng/ml), respectively. There was no significant difference in the expression of type II collagen mRNA between different groups. It showed that the type II collagen was not suppressed at the transcription level, but was mainly destroyed by cathepsin S and cathepsin K.

Conclusions: Macrophages and mast cells are the major sources of caspase 8, which might be the main factor that destroys type II collagen secreted from articular chondrocytes in RA mice.

FRI0051 EARLY ARTHRITIS INDUCES DISTURBANCES AT BONE NANOARCHITECTURAL LEVEL REFLECTED IN DECREASED TISSUE HARDNESS

B. Vidal 1, R. Casco 1, M. Finnili 2,3, I. Lopes 1, S. Saarakkala 2,4,5, P. Ziopeos 6, H. Canhão 7, J. Fonseca 3,6,8, 1 Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal; 2 Research Unit of Medical Imaging, Physics and Technology, Faculty of Medicine, University of Oulu, Oulu; 3 Department of Applied Physics, University of Eastern Finland, Kuopio; 4 Medical Research Center, Kuopio University Hospital; 5 Department of Diagnostic Radiology, Oulu University Hospital, Oulu, Finland; 6 Biomechanics Labs, Cranfield Forensic Institute, Cranfield University, Swindon, United Kingdom; 7 EpilepToC Unit, CEDOC, NOVA Medical School, NOVA University; 8 Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisboa, Portugal

Background: Arthritis induces joint erosions and skeletal bone fragility.

Objectives: The main goal of this work was to analyze the early arthritis induced events at bone tissue level.

Methods: Eighty-eight female-type Cotswold rats were randomly housed in experimental groups, as follows: adjuvant induced arthritis (N=47) and a control healthy group (N=41). Rats were monitored during 22 days for the inflammatory score, ankle perimeter and body weight and sacrificed at different time points (11 and 22 days post disease induction). Bone samples were collected for histology, micro-CT, 3-point bending, nanointerdenraland and Fourier transformed infrared spectroscopy (FTIR) analysis. Blood samples were also collected for bone turnover markers and systemic cytokine quantification.

Results: At bone tissue level, measured by FTIR analysis and nanointerdenraland, there was a reduction of the mineral and collagen content and of hardness in the arthritic group, associated with an increase of the ratio of bone concentric to parallel lamellae and of the area of the osteocyte lacuna. In addition, increased bone turnover and changes in the microstructure and mechanical properties were observed in articularhritis, since the early phase of arthritis, when compared with healthy controls.

Conclusions: Arthritis induces very early changes at bone tissue level characterized by decreased tissue hardness and of collagen and mineral content. These results highlight the pertinence of immediate control of inflammation in the initial stages of arthritis.

FRI0053 ANTIBODIES TO A SUBSET OF CITRULLINATED PEPTIDE ANTIGENS CORRELATE WITH NEUTROPHEL EXTRACELLULAR TRAP LEVELS IN THE SPUTUM OF SUBJECTS AT-RISK FOR FUTURE RA

K.D. Deane 1, M. Murpialek 2, N.L. Seto 2, E. Bowers 1, J.M. Norris 2, VM. Hölers 1, W. Robinson 3, M. Kaplan 4, M.K. Demorouelle 5, 1 Division of Rheumatology, University of Colorado Denver, Aurora; 2 Systematic Autoimmunity Research Center, National Institutes of Health/NIAIMS, Bethesda; 3 Epidemiology, Colorado School of Public Health, Aurora; 4 Division of Immunology and Rheumatology, Stanford University, Palo Alto, United States

Background: Prior data suggest that anti-citrullinated protein/peptide antibodies (ACPA) may originate in the lung prior to the onset of synovitis in rheumatoid arthritis (RA) (1). Neutrophil extracellular trap (NET) formation is one potential mechanism that could trigger or be associated with local ACPA generation because NETs externalize citrullinated proteins and release peptidylarginine deiminase that could citrullinate nearby proteins (2-4).

Objectives: Using induced sputum, we recently identified a significant correlation between NETs and anti-cyclic citrullinated peptide antibodies (CCP) antibodies in subjects at-risk for future RA. Herein, we sought to explore associations of individual ACPAs and NETs in these subjects.

Methods: From the Studies of the Etiology of RA (SERA) cohort, we included 24 RA-free subjects at-risk for future RA based on familial (i.e. first-degree relative of RA patient) or serologic (i.e. serum anti-CCP positive identified at health fairs) risk. Induced sputum was tested using a bead-based ACPA array for IgG and IgA titters. Levels of NET complexes in sputum were measured using a deoxyribonucleic acid (DNA)-myeloperoxidase (MPO) and DNA-neutrophil elastase (NE) sandwich ELISA. Analyses included Spearman’s correlation and linear regression. Using Bonferroni’s correction, results were considered significant if both DNA-MPO and DNA-NE assays had a p<0.05.

Results: Subjects had a median age of 51 years, were 67% female and 38% ever-smokers. Increasing sputum NET levels significantly correlated with increasing ACPA levels for 27/29 ACPAs, including proteins/peptides of cit-vimentin, cit-fibrogen, cit-fibroactin, cit-apolipoproteins and cit-alpha-enolase. After adjusting for ever-smoking, sputum NET levels remained significantly associated with 17/29 ACPAs. The strongest associations (p<0.001 and 4.4 (1.2–10.9), p<0.05). Comparing PAD activity in saliva samples of RA patients we found significant differences between the low (2.3±0.5), moderate (3.4±0.8) and high (4.3±0.3) disease activity subgroups (p<0.01%), whereas patients in remission demonstrated a PAD activity similar to the low disease activity group (1.9±0.39). Additionally, we found a significant correlation between oral PAD activity and RA activity, but not with autoantibody titers.

Conclusions: These results show that RA activity is associated with severe periodontitis, high oral PAD activity and the presence of T. forsythia and P. gingivalis, suggesting that both bacteria equally participate in PAD activity present in the oral microenvironment.

A NOVEL PHARMACOLOGICAL ACTION OF MTX THROUGH CIRCADIAN CLOCK GENES IN RA FIBROBLAST-LIKE SYNOVIAL CELLS

K. Suzuki1, K. Yoshida1, T. Hashimoto2, K. Kaneshiro3, A. Nakai4, N. Hashimoto1, Y. Kawasaki1, N. Shibanuma4, N. Nakagawa5, Y. Sakai6, A. Hashimarto1, T. Biophysics, Kobe University Graduate School of Health Sciences;2Rheumatology;3Kobe Kaisei Hospital, Kobe, Japan;4Orthopaedic Surgery, Kobe Kaisei Hospital, Kobe;5KonanKakogawa Hospital, Kakogawa;6Kobe University Graduate School of Medicine, Kobe, Japan

Background: Methotrexate inhibits the proliferation of RA fibroblast-like synovial cells (RA-FLS) by folic acid metabolism. We previously reported that disruption of circadian clock genes was involved in the pathogenesis of inflammatory arthritis (1,2).

Objectives: To explore pharmacological effects of MTX on circadian clock genes of RA-FLS.

Methods: Under treatments of MTX on RA-FLS, cell viabilities were determined of RA-FLS.

Results: MTX (1,10 nM) treatment significantly decreased the cell viabilities. MTX (10nM) increased mRNA expression of Per2, BIK and CYTOCHROME C and morphological changes of the nucleus were observed by fluorescent immunostaining. RA-FLS were transfected with Per2 and BIK siRNAs and successively treated with MTX to determine cell viabilities.

Conclusions: The transcriptional factor PAR bZip binds to the D-box elements of Per2 and BIK promoters (3,4). Here, we propose a novel action of MTX that up-regulates the expressions of Per2 and BIK via PAR bZip to induce apoptosis in RA-FLS.

FRIO0554

INCREASED EXPRESSION OF THE COLLAGEN INTERNALIZATION RECEPTOR ENDO180 IN FIBROBLAST-LIKE SYNOVIOCYTES OF PATIENTS WITH RHEUMATOID ARTHRITIS

L. Yan1, Y. Wen. Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Hyperproliferative and invasion are the characteristics of fibroblast-like synoviocytes in rheumatoid arthritis (RA-FLSs), which contribute mainly to RA disease progression and ultimately to joint destruction. Endo180 is a recycling endocytic receptor that has functions to regulate cell migration and bind and internalize collagen. However, the expression of Endo180 in RA-FLSs and its underlying mechanisms remain unclear.

Objectives: To examine the expression of Endo180 in RA-FLSs and the role it played in RA.

Methods: Tissues were collected from RA patients with joint replacement surgery or arthroscopy and RA-FLSs were obtained by tissue culture; Western blot was used to measure the expression of Endo180 in RA-FLSs. Chemically synthesized small interference RNA (siRNA) specifically targeting Endo180 gene was transfected into RA-FLSs by cationic liposome; The interference efficiency of Endo180-siRNA on the production of Endo180 mRNA and protein was determined by RT-qPCR and Western blot respectively; The proliferative inhibition rate was examined by CCK8 assay and the migration of RA-FLSs were examined by Transwell assay.

Results: Expression of Endo180 was obviously higher in fibroblast-like synoviocytes in RA than OA and the traumatic patients. And its expression level has positive correlation with disease activity. The proliferative inhibition rate was obviously higher in the Endo180-siRNA group than the control groups (P<0.05) after transfection for 48h (83.11±1.17%), 72h (15.93±2.12%), 96h (18.01%±2.78%); Transwell migration assay demonstrated the RA-FLSs through the transwell membrane in Endo180-siRNA group (21.27±6.35) were lesser than the NC-siRNA group (80.20±11.12) (P<0.05) and the blank control group (82.17±10.36) (P<0.05).

Conclusions: Endo180 may play a role in the regulation of proliferation and migration of RA-FLSs, which may provide beneficial therapeutic effects in RA.

HISTONE DEACETYLASE 1 (HDAC1): A NOVEL THERAPEUTIC TARGET IN RHEUMATOID ARTHRITIS

L. Göschl1, M. Bonelli1, V. Saferding1, T. Pregel2, C. Seiser2, S. Knapp3, J. Backlünd3, C. Bock4, P. Mathias5, K. Hirahara6, C. Scheinecker4, G. Steiner7, W. Ellmeier8, Division of Rheumatology, Medical University of Vienna;3Division of Immunobiology, Medical University of Vienna;4Department of Medical Biochemistry, Medical University of Vienna;5Research Center for Molecular Medicine (CeMM), Austrian Academy of Sciences, Vienna, Austria;6Division of Rheumatology, Medical University of Vienna;7Division of Immunobiology, Medical University of Vienna;8Division of Medical Biochemistry, Medical University of Vienna;9Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden;10Research Center for Molecular Medicine (CeMM), Austrian Academy of Sciences, Vienna, Austria;11Friedrich Miescher Institute for Biomedical Research, Basel, Switzerland;12Department for Cell Biology, Chiba University, Chiba, Japan;13Internal Medicine III, Division of Rheumatology,14Division of Immunobiology, Medical University of Vienna, Vienna, Austria

Background: Autoactive T cells have been shown to play a major role in Rheumatoid Arthritis, which drive the inflammatory process leading to an important destruction of the joints. Gene transcription and regulation of proinflammatory cytokone production in T cells is regulated by epigenetic mechanisms. Histone deacetylases (HDACs) modify the epigenetic landscape by removing acetyl groups of lysine residues of histones, resulting in chromatin condensation and repression of transcription. The application of pan-HDAC inhibitors has been shown to be a potential therapeutic strategy. However, major side effects limited the clinical use and underline the need of more specific HDAC inhibitors.

Objectives: Our aim was to to investigate whether HDAC1 is linked with the development of autoimmune diseases. Therefore we were using the collagen-induced arthritis model (CIA) and the experimental autoimmune encephalomyelitis model (EAE).

Methods: Mice with a T cell specific deletion of HDAC1 (HDAC1cKO) were generated by using the CD4Cre/LoxP system. The clinical and the histological phenotype were assessed in the CIA and the EAE. Anti-collagen antibody levels were determined by ELISA. Qualitative and quantitative analysis of T cell subsets of the spleen and draining LN were assessed using flow cytometry. Additionally comparative RNA-sequencing of CD4+ T cells from wild type (WT) and HDAC1cKO mice was performed.

Results: To address whether HDAC1 is involved in the pathogenesis of autoimmune diseases we induced the CIA and the EAE in WT and HDAC1cKO mice. Unexpectedly, HDAC1cKO mice did not develop any clinical or histological signs of inflammation, despite the presence of serum anti-CII antibodies. A similar protection against disease development was also observed in the context of EAE. A molecular analysis of HDAC1cKO CD4+ T cells revealed increased STAT1 phosphorylation in activated HDAC1cKO CD4+ T cells in comparison to WT cells. This was accompanied with an impaired expression of CCR6 in activated HDAC1cKO CD4+ T cells, which is an essential chemokine receptor for the development of arthritids and EAE. In line with this finding we observed increased expression of CCR6 in STAT1−/− CD4+ T cells. This indicates a negative role of STAT1 in the regulation of CCR6 expression.

Conclusions: Our data show the importance of HDAC1 as a key immune regulator in the pathogenesis of collagen induced arthritis. Therefore it might be considered as an interesting novel therapeutic target in RA.

**FR10057** EVALUATION OF THE IMMUNODOMINANCE OF A HISTONE H4 PEPTIDE IN ANTI-CCP ANTIBODIES FROM RHEUMATOID ARTHRITIS PATIENTS

L. Rodríguez-Martinez 1, C. Regueiro 1, A. Montes 1, E. Perez-Pampin 2, A. Mera-Varela 1, A. Gonzalez 1. 1Experimental and Observational Rheumatology; 2Rheumatology Unit, Instituto Investigacion Sanitaria- H. Clinico Universitario de Santiago. Santiago de Compostela, Spain

**Background:** The anti-CCP assay identifies antibodies against endogenous citrullinated proteins that are not completely characterized. The histone H4 seems to be a prominent one according to a recent study (1), which found this protein specifically in the immune complexes from synovial fluid of anti-CCP positive RA patients. Only vimentin, among the previously proposed autoantigens, was present in those immune complexes, but its abundance was much lower than that of histone H4. Consequently, a citrullinated H4-derived peptide, H4-c39/40, showed marked immunodominance since antibodies directed against this peptide were present in 100% of synovial fluid samples and in 92–94% of anti-CCP positive sera. These frequencies are much larger than the reported with other autoantigens.

**Objectives:** To confirm the immunodominance of the H4-c39/40 peptide in anti-CCP antibodies from RA patients by direct comparison with citrullinated peptides of two other potential autoantigens.

**Methods:** Five hundred and thirteen patients with established RA and 273 healthy controls were included. Antibodies against H4-c39/40, rFibB36–52 and rMIF 7C were evaluated using indirect ELISA. Concordance between positives and negatives was analyzed with the Goodman and Kruskal’s gamma coefficient (γ).

**Results:** In contrast to the previous report (1), only 68.5% of the anti-CCP positive patients carried anti-H4-c39/40 antibodies. However, this frequency was higher than the observed with the other two peptides, 50.5% of anti-FibB36–52 and 28.8% of anti-rMIF60–75 positive patients. Consequently, a high concordance was found between anti-CCP and anti-H4-c39/40 antibodies (γ = 0.95), which was moderately larger than that observed between anti-CCP and anti-rFibB36–52 antibodies (γ = 0.86). In addition, anti-H4-c39/40 antibody titers were correlated with anti-CCP titers, but this correlation was similar to the observed between anti-rFibB36–52 and anti-CCP titers (r = 0.34 and 0.33, respectively). The anti-rMIF60–75 antibodies, in turn, showed notably low concordance and low correlation with the anti-CCP antibodies.

**Conclusions:** Our results confirm that anti-H4-c39/40 antibodies are a significant component of the antibodies detected with the anti-CCP assay. However, immunodominance of this peptide was not as marked in our patients as the described in the original study.

**FR10058** EFFECT OF MIF GENE HAPLOTYPES ON RHTNF-A AND RHMIH RESPONSE IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF RHEUMATOID ARTHRITIS PATIENTS

L.A. Hernandez-Palma 1, S. Garcia-Arellano 1, S. Cerpa-Cruz 2, J.F. Muñoz-Valle 1. 1Research Institute in Biomedical Sciences, University of Guadalajara; 2Division of Rheumatology, Guadalajara Civil Hospital “Fray Antonio Alcalde”, Guadalajara, Mexico

**Background:** Macrophage migration inhibitory factor (MIF) is a pro-inflammatory cytokine that plays important role in the development and pathogenesis of rheumatoid arthritis (RA). MIF promotes the expression of cytokines related to RA development, as tumor necrosis factor alpha (TNF-α) and interleukin (IL)-6 and IL-17. Two polymorphisms in the promoter of the MIF gene have been associated with increased production of protein and it has been shown that TNF-α is involved in the regulation of MIF mRNA expression and protein secretion in a dose-dependent manner.

**Objectives:** To evaluate the effect of MIF gene haplotypes on rHTNF-α and rHMIH response in peripheral blood mononuclear cells (PBMC) of RA patients.

**Methods:** Genotyping was performed for MIF gene haplotypes in 230 RA patients. Cell culture of PBMC from two patients per homozygous haplotype (5G, 6G and 7C) was performed and stimulated with rHTNF-α and rHMIH. Cytokine levels were analyzed by a microsphere-based ELISA method (Bio-Plex® MAGPIX™).

**Results:** rHTNF-α and rMIF-induced IL-6, IL-17A and IL-17F secretion in PBMC of RA patients. We observed that PBMC extracted from patients with MIF 7C haplotypes stimulated with rHTNF showed higher secretion of IL-17A and IL-17F than patients with 5G and 6G haplotypes. IL-6 production with rMIF stimulation was more pronounced in the 5G haplotype group than 6G or 7C haplotype groups. Conversely, in a MIF responsive model, rhTNF promote chronic inflammatory joint and intestinal diseases.

**Conclusions:** Similarly to human RA patients, TNF-driven arthritis models develop multiple RA-associated comorbidities, offering novel insights into potential molecular and cellular mechanisms commonly underlying these complex pathologies.

MONOCYTE-DERIVED MICROPARTICLES IN CIRCULATION OF PATIENTS WITH RHEUMATOID ARTHRITIS: A NOVEL BIOMARKER FOR THE DISEASE ACTIVITY

M. Koseki, H. Yasuoka, K. Sakata, K. Yoshimoto, K. Yamaoka, T. Takeuchi. Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

Background: Rheumatoid arthritis (RA) is a systemic connective tissue disease and characterized by inflammation of synovium of multiple joints, however, its pathogenesis is still unclear (1). Physiologically, microparticle (MP) is categorized as a membrane microvesicle which contains various humoral factors such as cytokines or growth factors and 0.1–1 μm in size (2). And MPs can distribute systemically through circulation. MP is released from almost all cell types and induced by stimulation, stress or apoptosis (3). Thus, we hypothesized that MPs derived from various cells contribute to the lesion of RA and be associated with systemic disease process of RA.

Objectives: To clarify the source of MPs in circulation of RA and elucidate their role in the pathogenesis and the possibility for application as a novel disease marker.

Methods: Twenty patients with RA and 13 healthy controls were involved. Using gradient centrifugation, platelet-rich plasma was isolated from whole blood and applied to flow cytometry. MP is defined as a vesicle less than 1 mm in diameter and Megamix® was used to set a gating condition to detect microparticles (4). Subsequently, MPs were identified by the expression of cell-specific markers using flow cytometry with fluorescently labeled antibodies as follows: platelets: CD41+CD62P+; monocytes MP: CD45+CD41- MP, MP derived from other cells: CD41-CD31-CD45- MP. U-test with Bonferroni correction. Significant difference was defined as corrected p-value ≤ 0.01

Results: Mean age of 20 patients with RA was 56±14 years, 95% was female, disease duration was 6.5±3.0 years, and DAS28-ESR was 2.0±1.1. Methotrexate was administered to 15 patients, average dose was 8.0±2.4 mg/week. Platelet-derived MP covered the largest proportion in all groups. Interestingly, proportion of immune-cell-derived MP was higher (P<0.001) in patients with RA compared to controls. Proportion of immune-cell-derived MP was positively correlated with inflammatory markers such as CRP and composite disease activity markers such as DAS28-ESR. Furthermore, when stratified by monocyte fraction and non-monocyte fraction based on CD14 expression, proportion of immune-derived MP showed higher (P<0.01) in patients with RA compared to controls, but non-monocytes MP did not, and that of monocyte-derived MPs was also correlated with disease markers for activity of RA.

Conclusions: Proportion of circulating immune-cell-derived MPs, especially monocyte-derived MPs, increased in RA and correlate with disease activity. These results suggest that monocyte-derived MPs can be measured as a novel biomarker and involved in the disease process of RA.

RESVERATROL ATTENUATES SYNOVIAL HYPERPLASIA IN AN ACUTE ANTIGEN-INDUCED ARTHRITIS MODEL BY AUGMENTING AUTOAPOTHEXY AND DECREASING ANGIGENESIS

M. Almonte-Becerril 1, J.A. Fernandez-Rodriguez 1, O. Ramil-Gomez1, R.R. Riveiro-Naveira1, L. Hermida-Carballo 1, A. Concha 2, M. Almonte-Becerril 1, J.A. Fernandez-Rodriguez 1, O. Ramil-Gomez1, R.R. Riveiro-Naveira1, L. Hermida-Carballo 1, A. Concha 2

Background: Previously, we have demonstrated that dietary supplementation with resveratrol lowers synovial hyperplasia, inflammatory markers and oxidative damage in an acute antigen-induced arthritis (AIA) model.

Objectives: In this work, we investigated whether resveratrol can also regulate this abnormal proliferation of synovial tissue in an acute AIA model by inducing cell death pathways and by modifying angiogenesis in the synovial membrane.

Methods: Animals were randomly divided into 3 groups: control, AIA, and resveratrol-treated AIA group. Resveratrol (12.5 mg/kg/day) was given orally 8 weeks before AIA induction until sacrifice day (48 h after intra-articular injection). Control and AIA animals were administered 100 μl of water. Resveratrol effects on apoptosis and angiogenesis were evaluated by LC3 and active caspase-3 expression (confocal and immunohistochemistry, respectively). Angiopoietin 1 (Ang-1) and vascular endothelial growth factor (VEGF), and the mouse factor NF-kappa-B p65 subunit (p65) were also determined by immunohistochemistry and cartilage degradation with Safranin-O.

Results: Resveratrol significantly reduced the histological score of synovial tissue. Results showed a significant higher expression of LC3 signals in the synovial membranes, compared with control samples, in which the presence of vesicles was easily observed. Interestingly, the synovial tissues from the resveratrol group showed a significantly higher signal for LC3, compared with the AIA samples. Active caspase-3 expression was up-regulated at the same level in the synovial membranes of AIA group than in resveratrol-treated AIA group; however, in resveratrol-treated AIA group active caspase-3 signal was mainly located in the inflammatory cells. Resveratrol consumption significantly attenuated Ang-1 signal, whereas expression of VEGF showed a non significant reduction. Resveratrol administration also mitigated, even not significantly, p65 expression that was significantly higher in the AIA animals than those from the control animals. In addition, resveratrol decreased articular cartilage degradation.

Conclusions: These data suggest that resveratrol is able to modulate synovial hyperplasia by increasing apoptotic cell death and limiting angiogenic response in an acute AIA model, which could also modulate the inflammatory and destructive processes for rheumatoid arthritis.

CHEMOKINE RECEPTOR 6 MODULATES ARTHRITIS IN A T CELL DEPENDENT MANNER

M. Bonelli, A. Puchner, L. Goeschi, S. Hayer, B. Niederreiter, J.S. Smolen, G. Scheinecker, S. Blueml. Division of Rheumatology, Medical University of Vienna, Vienna, Austria

Background: Rheumatoid arthritis (RA) is an inflammatory autoimmune disease, characterized by synovial infiltration of various cells. Chemokines are involved in the recruitment of different cell types into the synovial membrane. Accumulation of CCR6 expressing mononuclear cells can be found in joints of RA patients. CCR6 expression has also been reported on CD4+ T cells, in particular regulatory as well as Th17 cells. In addition, a subset of regulatory T cells, namely CD25+Foxp3+ T cells, can upregulate CCR6 and RANKL and thereby can promote osteoclastogenesis.

Objectives: In this study, we investigated the role of CCR6 in the pathogenesis of arthritis using different arthritis models.

Methods: Clinical as well as histological signs of arthritis were investigated in the collagen-induced arthritis (CIA), K/BxN serum transfer arthritis and in the human tumor necrosis factor (TNFα-)/- mice model. We analyzed the phenotype of lymph node cells by flow cytometry and cytokine concentrations in serum. Anti-collagen antibodies and cytokines were measured by enzyme-linked immunosorbent assay.

Results: The K/BxN serum transfer arthritis and hTNFtg arthritis model are known to be T cell independent. Since CCR6 is an important component of the innate immune system we compared the development of arthritis in both models. We did not detect any significant differences in clinical signs of inflammation or histological severity of arthritis between wt and CCR6-/-mice. In addition, bone volume was similar between wt and CCR6-/- mice. To investigate the role of CCR6 as part of the adaptive immune system in the development of arthritis we induced CIA in wt and CCR6-/- mice, which is known to be T cell dependent. CCR6-/- mice were almost completely protected from CIA. Indeed, analyses of T cell subsets by flow cytometry revealed a significant reduction of CD25 Foxp3+ T cells in CCR6-/- mice.

Conclusions: CCR6 is necessary for the generation of pathogenic CD25 Foxp3+ T cells in CIA, suggesting an important function of CCR6 on T cells in the development of autoimmune arthritis.

MICRONA PROFILING OF MTX-TREATED FIBROBLAST-LIKE SYNOVIAL CELLS IN RHEUMATOID ARTHRITIS REVEALED A POSSIBILITY OF MICRONA-887-3P AS NOVEL THERAPEUTIC TARGET OF RA

N. Iwamoto, S. Fukui, T. Koga, S.-Y. Kawashita, K. Ichinose, M. Tamai, H. Nakamura, T. Oriaguchi, A. Kawakami. Department of Immunology and Rheumatology, Unit of Advanced Preventive Medical Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

Background: The hallmarks of rheumatoid arthritis (RA) is the expansive of fibroblast-like synovial cells (FLS) in affected joints, causing joint destruction. FLSs are resistant to programmed cell death resulting in aggressive, invasive phenotype like a cancer invades and the hyperplastic synovial tissue destroys cartilage and bone. Therefore inhibition of FLS proliferation is one of the therapeutic targets of RA. MicroRNAs (miRNAs), a group of small non-coding RNAs, have been shown to regulate cell differentiation through regulation of gene expression post-transcriptionally. Recently, several studies reported anti-cancer drugs modulate miRNA expression and that have been considered as one of important mechanism of cellular action to drug.

Objectives: To investigate the changes in microRNA expression profiles in response to MTX.

Methods: RA-FLS were treated with MTX with 1nM 48 hours, that could inhibit IL-6 production from RA-FLS. To investigate differentially expressed miRNAs in response to MTX, we performed miRNA array analysis. Expression of miR-887–3p in response to MTX of RA-FLS was analyzed by quantitative real-time PCR. To investigate the functional role of miR-887–3p, RA-FLS was transfected with synthetic precursor miR8–3p (anti-miR) of miR-887–3p using Lipofectamine and then gene expression microarray was performed. The cytokine/chemokine production was screened by Multiplex cytokine/chemokine bead assays and confirmed by ELISA. Finally, we analysed migratory activities of RA-FLS by scratch assay.

Results: After 48 h of treatment with MTX, 7 miRNAs were up-regulated and 6 miRNAs were down-regulated as compared with that of untreated control. Among them quantitative real-time PCR with additional samples confirmed that miR-887–3p was up-regulated in response to MTX treatment of RA-FLS. 1.7±0.46-fold, p<0.05, n=7). To elucidate the functional consequence of the deregulation of miR-887–3p of RA-FLS, we performed gain-and-loss of function assays with miR-887–3p. Microarray analysis with gene ontology analysis revealed several genes correlated with cell signalling was modulated by miR-887–3p. Multiplex bead assay showed that overexpression of miR-887–3p decreased cytokine/chemokine production of RA-FLS such as TNF-a, GM-CSF, CCL4. Among these candidates, the secretion of GM-CSF was consistently and strongly decreased from RA-FLS transfected with pre-miR-887–3p. Furthermore overexpression of miR-887–3p reduced migratory activity of RA-FLS in scratch assay.

Conclusions: Our result revealed that miRNA expression profiles in RA-FLS. MiR-887–3p might be downstream effector of MTX in suppression of its cytokine production and invasive phenotype. This knowledge may also be useful for the development of novel therapeutic strategies for RA based on other treatments able to boost the cellular reservoir of miR-887–3p.

REDUCTION OF PROLIFERATION, MIGRATION AND INVASION OF RHEUMATOID SYNOVIOCYTES BY ALL-TRANS RETINOIC ACID

N. Mosquera 1, A. Rodriguez-Trillo 2, S.B. Bravo 3, A. Mera 1, C. Conde 1.
1Experimental and Observational Rheumatology; 2Proteomic Unit, IDIS, CHUS, Santiago de Compostela, Spain

Background: Fibroblast-like synovial cells (FLS) are pivotal in inflammatory and joint destruction of rheumatoid arthritis (RA). These cells proliferate, become resistant to apoptosis, migrate and invade, contributing to perpetuate synovial inflammation and destruction of cartilage and bone. Current treatments of RA are focused against inflammatory factors and immune cells, however, a significant percentage of patients do not successfully respond. Combined treatments with drugs that control inflammation and with others that reverse the pathogenic phenotype of FLS could improve the prognosis of these patients. An unexplored area includes vitamin A and its metabolites. These compounds modulate differentiation, development, apoptosis and proliferation. Indeed, retinoids are being successfully used in the treatment of several cancers for their anti-proliferative and pro-differentiative actions. In addition, several studies have shown a notable reduction of cell migration and invasion in different cell types after treatment with all-trans retinoic acid (ATRA). However, it is not known if ATRA could modify the migratory and invasive ability of rheumatoid synoviocytes.

Objectives: To analyse the effect of treatment with the retinoid all-trans retinoic acid in proliferation, migration and invasion of rheumatoid synoviocytes.

Methods: FLS were obtained from 8 RA patients. Cellular proliferation was determined using the CellTiter-Blue luminescent viability assay (Promega). Migration was analysed by wound healing assay, using ibidi inserts. Percentage of migrating cells was determined by Image J. Invasion was tested by the Boyden chamber method using inserts (Millicell) coated with Matrigel (BD Biosciences). Invasion was determined by quantification of Giemsa stained cells on the bottom side of the inserts under the microscope. Proteome analysis was performed using LC-MALDI-TOF/TOF and 1D- and 2D-gels. MS and MS/MS data was searched against the UniProt/Swiss-Prot database of protein sequences.

Results: We analysed the effect of ATRA in the spontaneous proliferation of FLS from 8 RA patients. ATRA treatment significantly inhibited proliferation at 48, 72 and 96 h (p<0.005; p<0.002; p<0.04; respectively). Next, we analysed the effect of ATRA on RA FLS migration and invasion. Migration of RA FLS treated with ATRA for 96 h was reduced by 46% when compared with cells treated with vehicle control (p<0.002). In addition, in wound healing assay showed that ATRA treatment, as the invaded area was 31% lower than in controls (p=0.018). To elucidate the mechanisms underlying the effects of ATRA on RA FLS a proteomic analysis was performed. We compared the proteome of FLS from 5 RA patients treated with ATRA or with vehicle using LC-MALDI analysis. The differentially identified proteins in ATRA-treated FLS vs control FLS were Septin, Rho GTPase activating protein (ARHGAP1) and actin related protein 2 (ARPP2). Validation experiments using 1-DE and 2-DE gels were performed.

Conclusions: Overall these results reveal that retinoid treatment reduces the proliferative, migratory and invasive capacity of RA FLS, indicating that this treatment could decrease joint damage and loss of function in RA patients.

Background: MicroRNAs (miRNA) are a new class of modulators of gene expression, regulating inflammation, degradation of extracellular matrix and invasive behavior of the resident cells in rheumatoid arthritis (RA).

Objectives: 1) To investigate the miRNA expression profile in synovial and blood neutrophils in RA and its role in the pathogenesis of this disorder. 2) To study the effects of biological therapies on the miRNA profile in neutrophils.

Methods: Neutrophils were isolated from peripheral blood (PB) of 25 healthy donors (HD) and 25 RA patients. Neutrophils were isolated from paired synovial fluid (SF) of 15 RA patients. nCounter miRNA Assay was used to detect 800 human microRNAs simultaneously. Altered miRNAs were analyzed for potential miRNA targets using Ingenuity pathways analysis (IPA) software. miRNA targets and genes involved in miRNA biogenesis were evaluated. RA neutrophils were treated in vitro with tocilizumab and infliximab. Healthy neutrophils were treated in vitro with anti-CCPs isolated from RA patients alone or combined with tocilizumab or infliximab. RA neutrophils were cotransfected with the pre-miRNA 126 and 148.

Results: 94 miRNAs were downregulated and 3 upregulated in PB neutrophils from RA patients compared to HD. Among the miRNAs deregulated in blood, 34 miRNAs were also downregulated in SF neutrophils from RA patients. Accordingly, RA neutrophils showed a downregulation of the proteins participating in miRNA biogenesis and upregulation of its mRNA targets. Altered miRNAs were mainly involved in immunological disease and inflammatory response, suggesting the abnormal activation of this cell subtype in RA. In vitro treatment of RA neutrophils with tocilizumab and infliximab increased the expression of miRNAs, genes involved in their biogenesis and reduced the inflammatory profile in these cells. In addition, treatment of healthy neutrophils with IgG anti-CCPs isolated from RA patients decreased the expression of the miRNAs proteins, involved in the biogenesis machinery and increased its inflammatory targets. Finally, cotransfection of RA neutrophils with the pre-miRNAs 126 and 148 reduced the levels of their target proteins.

Conclusions: 1) RA neutrophils exhibit a defect in the miRNAs processing, showed by a decrease in most of the detected miRNAs and the downregulation of proteins involved in their biogenesis. This defect seems to be modulated by anti-CCPs antibodies. 2) miRNA downregulation is even more pronounced in synovial neutrophils isolated from RA patients compared to HD. Among the miRNAs deregulated in blood, 34 miRNAs were also downregulated in SF neutrophils from RA patients. Accordingly, RA neutrophils showed a downregulation of the proteins participating in miRNA biogenesis and upregulation of its mRNA targets. Altered miRNAs were mainly involved in immunological disease and inflammatory response, suggesting the abnormal activation of this cell subtype in RA. In vitro treatment of RA neutrophils with tocilizumab and infliximab increased the expression of miRNAs, genes involved in their biogenesis and reduced the inflammatory profile in these cells. In addition, treatment of healthy neutrophils with IgG anti-CCPs isolated from RA patients decreased the expression of the miRNAs proteins, involved in the biogenesis machinery and increased its inflammatory targets. Finally, cotransfection of RA neutrophils with the pre-miRNAs 126 and 148 reduced the levels of their target proteins.
the development of arthritis or are rather a consequence of the inflammatory processes. Furthermore, while both germ-free condition and administration of oral antibiotics prevent arthritis in mice, it is unclear whether modulation of the intestinal microbiota after the onset of arthritis may still suppress the disease.

Objectives: We aimed to assess potential alterations of the intestinal microbiome in the preclinical phase of inflammatory arthritis in mice, and to determine the efficacy of microbiota modulations in the treatment of established disease in mice.

Methods: We sequenced fecal bacterial 16S rRNA to define the intestinal microbiome in mice before immunization with collagen and 21 days later before the booster injection for the induction of collagen-induced arthritis (CIA). To assess the efficacy of microbiota modulation during arthritis, mice with ongoing CIA were treated orally by a broad-spectrum antibiotic cocktail for one week to partially eliminate the intestinal microbiota. T cell differentiation and production of cytokines in intestinal lamina propria and joint-draining lymph nodes were assessed by flow cytometry. Immunohistochemistry and confocal microscopy were used to assess macroscopically and by histology. Serum-transfer arthritis induced by intraperitoneal injections of arthrogenic K/BxN mouse serum was used as a control. T cell-independent, model.

Results: The preclinical phase of inflammatory arthritis in mice was characterized by marked changes in the intestinal microbiome, represented by a significant increase of the phylum Bacteroidetes and a decrease of Firmicutes and Proteobacteria. Among the most abundant bacterial families, S24–7 and Staphylococcaceae were expanded, whereas Lachnospiraceae were reduced during the immune priming phase of CIA. Several operational taxonomic units associated with CIA were expanded, whereas those assigned to Lachnospiraceae and Ruminococcaceae were expanded in the intestinal microbiota before the clinical onset of arthritis. The abundance of intestinal lamina propria Th1 cells significantly correlated with the severity of CIA; however, intestinal Th1 cells were not correlated with the disease. Elimination of intestinal microbiota in mice with ongoing CIA significantly reduced intestinal Th1 cell differentiation without affecting Th1 and Treg cells. Importantly, elimination of intestinal microbiota suppressed Th1 cell differentiation and IL-17 production in joint-draining lymph nodes, and reduced the severity of established CIA. In contrast, the T cell-independent serum-transfer arthritis induced by T cell-independent arthritis (T CIA) was not affected by this strategy.

Conclusions: These observations suggest that perturbations of the intestinal microbiome may precede the development of inflammatory arthritis. Similar studies are warranted in human pre-RA or at-risk individuals to shed light on the functional role of the microbiome in the development of RA. Our studies also suggest that modulation of the intestinal microbiota after the onset arthritis may still provide opportunities to treat inflammatory arthritis.

FR0074 | ANTI-INFLAMMATORY EFFECT OF RESVERATROL IN VITRO; POTENTIAL ROLE IN MANAGING LOW DISEASE ACTIVITY IN ARTHRITIS?
1Aarhus University, Aarhus C, Denmark; 2Department of Biomedicine, Aarhus University; 3Department of Endocrinology and Internal Medicine; 4Department of Rheumatology, Aarhus University Hospital, Aarhus C, Denmark.

Background: Resveratrol (RSV), a non-toxic polyphenol found in grapes, certain nuts, roots etc., has received increased attention in the last decade due to its anti-inflammatory potential. Perturbations of the intestinal microbiota may precede the development of inflammatory arthritis. Similar studies are warranted in human pre-RA or at-risk individuals to shed light on the functional role of the microbiome in the development of RA. Our studies also suggest that modulation of the intestinal microbiota after the onset arthritis may still provide opportunities to treat inflammatory arthritis. The preclinical phase of inflammatory arthritis in mice was characterized by marked changes in the intestinal microbiome, represented by a significant increase of the phylum Bacteroidetes and a decrease of Firmicutes and Proteobacteria. Figure: Histological morphological deterioration of bone quality in RA patients receiving GCCs. (A-D) Representative photomicrographs of H&E stained sections of the specimens. Images show sections from Control (A, C) and RA groups (B, D). Boxed areas in B and D are shown at higher magnification in the indicated images. (E, F) Representative micrographs focused on osteoclasts of Control (E) and RA groups (F) with toluidine blue staining. Osteoclastic lacunae (red arrows) are out of shape and eminuous in RA patients. (G) Representative micrographs of Control (H) and RA groups (I) with immunostaining of sclerostin (black arrow). (J, K) Representative micrographs of Control (J) and RA group (K) with von Kossa staining. (L) Representative micrographs of Control (L) and RA groups (M) with immunostaining of sclerostin. (N) Representative micrographs of Control (P) and RA group (Q) with TRAP staining. Osteoclasts are stained red. Values shown are means ± SD (p < 0.05).

Conclusions: Our findings showed that RA patients receiving glucocorticoid treatment have severe bone fragility regardless of increased bone quantity by using bisphosphonate. The functional deteriorations of the osteocyte system and the abnormalities of bone quality might induce bone fragility fracture. Therefore, management of osteoporosis associated with RA should be targeted about bone quality as well as bone quantity.

aeroaciens had a complete opposite effect. Suppression of arthritis by P. histiola was dependent on an increase in the numbers of CD103+ dendritic cells, myeloid suppressors, CD11b+Gr-1, and T regulatory cells, CD4+CD25+FoxP3+, in the gut as well as systemically. This led to reduction in TH17 response while increasing IL-10. On the other hand, C. aeroaciens gavage increased expression of IL-17 and regulatory chemokines as compared to controls. DO11.10 mice gavaged with intestinal microbes of arthritis-resistant mice developed arthritis with lower incidence and had skewed Th17/Th2 response.

**Conclusions:** Our studies suggest that gut commensals influence immune response in and away from the gut. Commensals and their products may provide novel targets for therapeutic strategies in arthritis.

**FR10078** ADENOSINMONOFOSFAT-AKTIVATING PROTEIN KINASE (AMFK) – THE BIOPOWER REGULATOR OF AN AUTOPHAGY IN RHEUMATOID ARTHRITIS (RA)

V.I. Shihkin, G.V. Kudriavtseva, V.V. Shishkin, Y.A. Malenkov. Saint Petersburg state University, Saint Petersburg, Russian Federation

**Background:** Rheumatoid arthritis is an autoimmune disease characterized by altered cellular homeostasis. A great role of an autophagy is expected in the pathogenesis of these changes.

**Objectives:** To assess the functional activity of AMFK as a strategic biower regulator of an autophagy and specific indicator of red-ox potential of cells in the synovial fluid (SF) of patients with rheumatoid arthritis (RA)

**Methods:** SF of knee joints of 7 RA patients with active synovitis and 5 donors were investigated. Activity of enzymes was measured in cytosol of SF cells after ultracentrifugation. Activity of AMFK was estimated with the Western blotting method. The consumption speed of oxygen by SF cells was recorded polarographically using as the substrate glumatic acid (5 μmol/ml in incubation fluid). Registration of the active forms of oxygen was carried out by EPR (electron paramagnetic resonance). Levels of adenyl nucleotides were determined chromatographically.

**Results:** In RA SF we noted activation of AMFK (on average by 2.5 times) at the considerable increase of the AMP level and decrease in ADP and ATP.

**Conclusions:** These data demonstrate transition of cells of SF in RA to the energy saving mode of functioning that is followed by strengthening of oxidizing processes, deep dissociation of respiration with oxidizing phosphorylation and sharp increase of oxygen consumption spectated by SF cells glucose acid (5 μmol/ml in incubation fluid). Registration of the active forms of oxygen was carried out by EPR (electronic paramagnetic resonance). Levels of adenyl nucleotides were determined chromatographically.

**FR10079** TASS315, A NOVEL BRUTON’S TYROSINE KINASE INHIBITOR, IMPROVE BONE MINERAL DENSITY (BMD) AND BONE EROSION VIA INHIBITION OF OSTEOCLAST ACTIVATION IN MURINE MODEL FOR RHEUMATOID ARTHRITIS

**Background:** The erosions of bone and cartilage are a cardinal feature of rheumatoid arthritis (RA) and associated with disease severity and poor functional outcome. Although several anti-inflammatory drugs improve symptoms of articular inflammation, they are less effective against bone erosion. The bone erosions in RA are associated with aberrant activations of osteoclasts induced by pro-inflammatory cytokines and receptor activator of nuclear factor-κ B ligand (RANKL). Bruton’s tyrosine kinase (BTK), which is expressed in immune cells and mature osteoclast, is reported to be a key molecule in inflammatory response and bone resorption. Thus, targeting BTK may be efficacious against not only inflammation but also bone erosion through direct regulation of activation of effectors such as B cells, macrophages and osteoclasts in RA.

**Objectives:** In this study, we evaluated the effect of TASS315, a novel BTK inhibitor, on in vitro and in vivo bone erosion in mouse collagen-induced arthritis

**Methods:** Kinase selectivity of TASS315 was assessed by available kinase assay panels. The effects of TASS315 on macrophages and osteoclasts were assessed by examining phosphorylation of BTK, cytokine productions, osteoclast differentiation and bone resorptions. The effects of TASS315 were investigated in mouse collagen-induced arthritis (CIA). Disease severity was evaluated by clinical score of paw swelling. Changes in bone mineral density (BMD) and bone erosion were assessed using microCT. TNF blocker was used as a control drug.

**Results:** TASS315 selectively inhibited the enzyme activity of BTK and had less off target inhibition against other kinases. TASS315 dose-dependently inhibited cytokine productions by macrophages, phosphorylation of BTK, osteoclastogenesis and bone resorbing activity in osteoclasts. In established mouse CIA, TASS315 significantly ameliorated paw swelling in a dose dependent manner and the anti-inflammatory effect of TASS315 (0.3 mg/kg, once daily) was comparable to that of TNF blocker. Most importantly, improvement of BMD and bone erosion were observed in TASS315 treated mice at a doses of higher than 0.1 mg/kg within 13 days from treatment initiation, but not in TNF blocker-treated mice. The onset of action of TASS315 on BMD and bone erosion was earlier and stronger compared with that of TNF blocker. These data suggest that TASS315 had direct effect against osteoclasts function and led to improvement of bone erosion in murine model for RA.

**Conclusions:** Our study demonstrates that TASS315, a novel BTK inhibitor, would be an ideal RA therapeutic agent that could inhibit bone destruction as well as inflammation.

**FR10080** CD11b+Gr1dim TOLEROGENIC DENDRITIC CELL-LIKE CELLS ARE EXPANDED IN INTERSTITIAL LUNG DISEASE IN SKG MICE

S. Sendo, J. Saegusa, Y. Ichise, H. Yamada, I. Naka, T. Okano, S. Takahashi, Y. Ueda, K. Akashi, A. Onishi, A. Morinobu. Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe City, Japan

**Background:** SKG mice develop interstitial lung disease (ILD) resembling human rheumatoid arthritis (RA)–associated ILD. We identified a unique cell population of CD11b+Gr1dim cells in the severely inflamed lungs in SKG mice.

**Objectives:** The aims of this study is to clarify the mechanism behind the ILD pathology, and to elucidate the phenotype and function of CD11b+Gr1dim cells in ILD-induced SKG mice.

**Methods:** We assessed the severity of zymosan A-induced ILD in SKG mice histologically, and examined lung-infiltrating cells by Giemsa stain and flow cytometry. Total lung cells and isolated monocytic myeloid-derived suppressor cells (M-MDSCs) were cultured in vitro with GM-CSF (and IL-4). The proliferation of CSFE-labeled naïve T cells co-cultured with isolated CD11b+Gr1dim cells and M-MDSCs was evaluated by flow cytometry.

**Results:** MDSCs, Th17 cells, and group 1 and 3 innate lymphoid cells (ILC1s and ILC3s) were increased in the lungs; the proportion of these cells varied with ILD severity. In this process, we found that a unique cell population, CD11b+Gr1dim cells, were expanded in the severely inflamed lungs (Figure). About half of the CD11b+Gr1dim cells expressed CD11c and Giemsa stain revealed that they were morphologically dendritic cell (DC)-like. The CD11b+Gr1dim cells were induced from M-MDSCs with GM-CSF in vitro and were considered tolerogenic because they expressed high levels of PD-L1 and suppressed T-cell proliferation. The CD11b+Gr1dim cells have never described previously and termed CD11b+Gr1dim tolerogenic DC-like cells. (CD11b+Gr1dimDC-LCs). Th17 cells, ILC1s and ILC3s in the inflamed lung produced GM-CSF, which in turn could induce CD11b+Gr1dimDC-LCs to reduce inflammation.

**Conclusions:** We identified a unique cell population, termed CD11b+Gr1dimDC-LCs, in ILD-induced lungs in SKG mice.

A MACAQUE MODEL OF RHEUMATOID ARTHRITIS BY IMMUNIZATION WITH CITRULLINATED PEPTIDES: LESSONS FOR THE HUMAN DISEASE

S. Bitoun1, P. Roques2, T. Larcher3, G. Nocturne1, C. Serguera4, P. Chretien5, G. Serre6, R. Le Grand7, X. Mariette1, 1Université Paris-Sud, Hôpitaux Universitaires Paris-Sud, INSERM U1184, le Kremlin Bicêtre; 2 Immunology Core Laboratory, Chaim Sheba Academic Medical Center, Ramat Gan; 3 Medicine, Sackler Faculty of Medicine, Tel Aviv University; 4 Faculty of Life Sciences, Tel Aviv University, Tel Aviv; 5 Rheumatology, Chaim Sheba Academic Medical Center, Ramat Gan, Israel

Background: Recent evolution in the understanding of rheumatoid arthritis (RA) mechanisms is the role of antibodies directed against citrullinated (cit) proteins (ACPAs). The shared epitope (SE) on the MHC class II is the main genetic risk factor of RA and favors presence of ACPAs. Mouse models dependent on cit peptides immunization require transgenic expression of the SE and are controversial. Non-human primates are ideal to study the interaction between ACPA and RA since 8% carry, similarly to humans, the SE called the H6 haplotype.

Objectives: The goal of this study was to develop a new animal model of RA based on immunization of genetically predisposed macaques against cit peptides to generate an ACPA-mediated model of arthritis.

Methods: Six macaques were intra dermally (ID) immunized with 4 peptides: vimentin (59–71) and (66–78), α-lilogenin (79–91) and aggrecan (89–103). H6 animals were immunized with either cit (n=2) or arginine (arg) (n=2) containing peptides. Two non H6 animals were immunized with cit peptides. These peptides are known to induce a T cell response in RA patients carrying the SE. T-cell response was assessed with Interferon γ ELISPOT and B-cell response by ELISA. An intra articular (IA) boost was done 30 weeks after initial immunization with either incomplete Freund’s adjuvant (IFA) alone, IFA and cit peptides and IFA plus non relevant peptides.

Results: In the macaques, the T-cell response was specific to cit or arg peptides (depending on the peptides used for immunization). Surprisingly, the presence of the H6 epitope did not influence the response. Conversely the antibodies generated in response to the peptides were cross-reactive between the cit and arg peptides. Since no clinical response was observed, an IA boost was performed with the same 4 cit peptides and IFA adjuvant. This led to a prolonged neutrophil-rich mono-arthritis preferentially in H6 animals (Figure). Conversely, animals boosted with IFA alone only or with IFA plus myelin oligodendrocyte glycoprotein (MOG) peptides and previously immunized with MOG peptides presented with a transient mono-arthritis. Histological analysis revealed a local mononuclear infiltrate in one of the two animals that had prolonged knee monoarthritis. There was no clinical polyarthritis but 2 animals displayed synovial proliferation in 1 MCP and 1 MTP, respectively.

Conclusions: Immunization of macaques with cit peptides, then IA boost with the same cit peptides plus IFA, induced a prolonged monoarthritis. Shared epitope bearing did not restrict the T-cell response but seemed to favor the prolonged swelling after the IA boost. Neutrophil infiltration of the joint occurred similarly to what is seen in RA. Further use of neutrophil chemo-attractant might lead to a poly-articular disease. This macaque model of RA appears unique to study the events occurring during the pre-clinical phase of RA.

FR0082 RAS SIGNALING INHIBITORS ATTENUATE ARTHRITIS IN ANIMAL MODELS OF RHEUMATOID ARTHRITIS BY DOWN MODULATING THE PATHOGENIC TH17 CELL RESPONSE

M. Zayoud1, 2, E. Vax1, G. Elad Stadla3, V. Marcu-Malina4, Y. Kloo5, C. Serguera4, P. Chretien5, I. Goldstein1, 2, 4, 1 Immunology Core Laboratory, Chaim Sheba Academic Medical Center, Ramat Gan; 2 Medicine, Sackler Faculty of Medicine, Tel Aviv University; 3 Faculty of Life Sciences, Tel Aviv University, Tel Aviv; 4 Rheumatology, Chaim Sheba Academic Medical Center, Ramat Gan, Israel

Background: Ras-GTPases are vital for normal T cell activation, and downstream effectors of Ras include the MEK/ERK, PI3 kinase/AKT, mTOR/p70S6-kinase, and NF-kB pathways. Somatic mutations in NRAS cause an autoimmune lymphoproliferative disorder and T cells from Rheumatoid Arthritis (RA) patients exhibit perturbation of the Ras/MEK/ERK pathway. The small molecule Farne-synthiosalicylic acid (FTS) inhibits the interaction between Ras-GTPases and prenyl-binding chaperones vital for proper plasma membrane localization and downstream signaling [1]. Previous pre-clinical studies suggested that FTS has an immunomodulatory effect in various animal models of autoimmunity [2].

Objectives: To test in the Lewis rat adjuvant induced arthritis (AIA) and in the DBA/1 mouse collagen type-II induced arthritis (CIA) models the therapeutic immunomodulatory effect of FTS alone or combined with methotrexate (MTX).

Methods: Arthritis was induced in 8–12 week old male Lewis rats by complete Freund’s adjuvant (CFA) injection and in male DBA/1 mice by collagen type-II (CII) immunization. Animals were treated prophylactically with once daily oral FTS (100 mg/kg); weekly i.p injection of MTX (0.5 mg/kg), oral FTS combined with MTX, or daily oral vehicle solution (0.5% carboxy methyl cellulose: CMC). Arthritis severity was scored daily from disease onset until study termination. In addition, we measured multiple disease- and drug-related immunological/molecular biomarkers.

Results: AIA severity was significantly reduced by FTS treatment compared to CMC controls (Figure 1A, P<0.001). Combining FTS and low dose MTX significantly increased its therapeutic efficacy compared to each drug alone (Figure 1A, P<0.05). FTS or FTS+MTX treatment also suppressed the upsurge in serum IL-17 and CRP compared to ailing controls. Global gene expression analysis of relevant splenic CD4+ T cells revealed that FTS is a potent inhibitor of pro-inflammatory and TH17 related gene networks. Next, our data from the mouse CIA model show that the therapeutic efficacy of FTS was non inferior to MTX and it significantly reduced arthritis severity compared to controls (Figure 2, P<0.001). Importantly, FTS significantly inhibited the production of pathogenic anti-IgG autoantibodies and upregulation of serum IL-6 and IL-17A compared to control arthritic mice. The in depth, multiplex, analysis of the effect of FTS on the T cell cytokine response to CII, revealed strong suppression of IL-22, IL-17, IL-9, GM-CSF and TNF production. Noteworthy, FTS therapy positively correlated with reduced Ras-GTP, p-ERK and p-AKT levels in splenic lymphocytes (drug related biomarkers).

Conclusion: FTS, a first-in-class oral selective Ras-GTPases inhibitor, exhibits a potent immunomodulatory effect in two classical murine model of arthritis, coupled with the inhibition of the TH17 response to relevant arthritogenic-antigens. Thus, Ras-signaling-blockade is a promising novel therapeutic approach for RA.

REDUCED INCREASE OF ACPA IGG-FC GALACTOSYLATION DURING PREGNANCY IN COMPARISON TO TOTAL IGG: AN EXPLANATION WHY AUTOANTIBODY POSITIVE RA-PATIENTS IMPROVE LESS DURING PREGNANCY?

A. Bondt1,2,3, L. Hafkenscheid1, D. Falck4, T.M. Kuiper5, Y. Rombouts5, J.M. Hizse1, M. Wuherer4, R.J. Dolhain1, A. Ronnet2,4, M. Cornillet5, A. Bondt1,2,3

Background: Rheumatoid arthritis (RA) disease activity (DAS28- CRP) improves less during pregnancy in autoantibody positive patients.1 The most specific autoantibodies for RA are anti-citrullinated protein antibodies (ACPA), which mainly occur as the immunoglobulin (Ig) G isotype. An association with DAS28- CRP and the pregnancy-associated improvement is well established for the Fc glycosylation of total IgG, in particular for galactosylation (Gal) and sialylation (SA).2 The Fc glycosylation of ACPAs – mainly present as IgG – has been reported to be different from the total IgG Fc glycosylation.3

Methods: ACPA positive patient sera (n=152) were obtained within the framework of the PARA cohort, a prospective study designed to investigate pregnancy-associated improvement of RA. ACPA IgG was isolated using microscale affinity chromatography. Trypsin digested ACPA IgG was measured using nano-liquid chromatography mass spectrometry, and compared to total IgG.

Results: Pregnancy-associated changes in the levels of glycosylation were observed for all ACPA IgG subclasses. Pregnancy-associated glycosylation changes were less pronounced during pregnancy and after delivery in ACPA IgG (Gal +5%; SA +0.5%) compared to total IgG (Gal +11%; SA +2.5%; Figure 1), but – for total IgG – not different between ACPA+ and ACPA- patients. No association of the change in DAS28-CRP with the change in ACPA IgG or total IgG galactosylation was observed for ACPA- patients, whereas a strong association of total IgG galactosylation was observed for ACPA+ patients.

Conclusions: During pregnancy the increase in galactosylation of ACPA IgG was less pronounced than that of total IgG, whereas the increase in the galactosylation of total IgG was not different between ACPA+ and ACPA- patients. Since it is known that changes in IgG galactosylation are associated with improvement of RA during pregnancy and since ACPA is thought to be of pathogenic significance in RA, our data might provide an explanation why ACPA+ RA patients are less likely to improve during pregnancy.

of antibodies against individual citrullinated peptides (ACPAs; Hansson M et al. Arthritis Res Ther 2012;14:R201). We have also developed a method for the quantification of autoantibodies in immune complexes (IC; Sobhian et al. Ann Rheum Dis 2015;74(Suppl 1):A74). Here we have combined these techniques to determine ACPA profiles in RA IC.

Objectives: To investigate measurement of specific ACPA in synovial fluids (SF) and in IC from sera and SF can provide more prognostic information than conventional measurement of total ACPA and rheumatoid factor (RF) in serum.

Methods: Seventy-seven RA patients with knee synovitis were treated with intra-articular trimethiconel hexaconeotide, and followed until relapse. DAS28 and radiographic joint damage according to Larson-Dale were recorded. Anti-CCP2, IgM and IgA RF and circulating C1q-binding immune complexes (CIC) were determined in paired sera and SF. IC were purified from sera and SF by binding to C1q-coated beads, and thereafter eluted with a procedure developed in our laboratory. Antibodies against 19 citrullinated peptides were investigated with a custom-made microarray assay based on the ImmunoCAP ISAC system (Phadia AB, Sweden) in sera and SF as well as in IC from sera and SF. The target peptides were filaggrin 307–324 (CCP1), vimentin peptides 60–75 and 2–17, fibrinogen β563–583, α563–583, α560–600, δ21–75, δ26–74, δ26–81 (with citrullination in positions 72 and 74, respectively), ε-enolase 5–21 (CEP-1), peptides 1, 5, 21, 22 and Bla26 from hnRNPs, and histone 4 peptides 31–34 and 31–50. Cutoffs were established in relation to healthy controls. Backward stepwise regression was used to investigate what factors determined Larsen Dale index, DAS28, and steroid treatment. Independent factors with anti-CCP2-CPCP, IgM RF, IgA RF, CIC, number of ACPA peptide reactivities, and number of ACPA reactivities in IC, all measured both in serum and paired SF.

Results: A considerable proportion of anti-CCP2 negative patients had multiple ACPA in SF, and in IC fractions. High DAS28 associated with reactivity against 7/19 peptides in serum and 9/19 in SF. High Larsen score associated with number of specific ACPA in SF and IC with CIC in SF, DAS28 levels associated with IgM RF in SF and with CIC in SF, and steroid response duration with number of specific ACPA in serum and in IC.

Conclusions: We found that reactivity to ACPAs in SF, and especially in the IC fraction of SF, offers additional information beyond anti-CCP2 levels and allows radiological destruction and length of remission after intra-articular steroid therapy. Our data do not support a role for any unique ACPA specificity in RA pathogenesis. Instead, the number of individual ACPA specificities may be important.

FR00086] EFFICACY AND SAFETY DATA BASED ON HISTORICAL OR PRE-EXISTING CONDITIONS AT BASELINE FOR PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS WHO WERE TREATED WITH BARICITINIB

B. Combe1, A. Balsa2, P. Sarzi-Puttini3, H.-P. Tony1, I. de Torre5, V. Rogaï6, F. Durand2, A. Jahangir3, S. Witt3, J. Zhong3, M. Dougados4, Hospital Lariboisière-Necker, Montrouge, France; 2Hospital Puerta de Hierro la Paz, Madrid, Spain; 3Sacco Hospital, Milano, Italy; 4University Hospital of Würzburg, Würzburg, Germany; 5Elly Lilly and Company, Indianapolis; 6Elly Lilly and Company, Madrid; 7QuintilesIMS, Morrisville, United States; 8Hene Descartes Univ/ Cochin Hospital, Paris, France.

Background: Patients (pts) with rheumatoid arthritis (RA) often experience comorbidities that may affect efficacy and safety when treated with different drugs. Baricitinib (BARI) is a selective inhibitor of Janus kinase 1 and 2 that improves disease activity in pts with RA with an acceptable safety profile.1-4,6 Objectives: To investigate the effect of selected comorbidities on safety and efficacy outcomes in pts treated with BARI.

Methods: Pts were selected for this post hoc analysis on the basis of historical or ongoing conditions defined by Medical Dictionary for Regulatory Activities and divided by the following comorbidity subgroups: depression, osteoporosis, hepatic disorders, and previous cardiovascular events. Efficacy outcomes included 20% disease activity score for 28 joints improvement (DAS28, ≤3.2) at 12 weeks, and ≥50% improvement in American College of Rheumatology 20 Response (ACR20) and American College of Rheumatology 50 Response (ACR50) criteria, respectively; the proportion of pts who achieved a Disease Activity Score for 28 joints (DAS28) ≤3.2; and change from baseline in Health Assessment Questionnaire-Disability Index (HAQ-DI) at week 12. Pts who had an inadequate response (IR) to conventional disease-modifying antirheumatic drugs (cDMARDs) from 5 studies with BARI 4 mg and placebo (PBO) were included in efficacy analyses (N=1684) and safety analyses (N=1684). The interaction of comorbidity by treatment was analysed using logistic regression or analysis of variance modelling. Interaction tests were performed within each comorbidity subgroup for increased risk of events after treatment with BARI 4 mg compared with PBO.

FR00087] LOW RATES OF RADIOGRAPHIC PROGRESSION OF STRUCTURAL JOINT DAMAGE OVER 2 YEARS OF BARICITINIB TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. van der Heide1, M. Schiff2, Y. Tanaka3, R. Klair4, L. Xia5, G. Meszaros5, E. Iatsenko1, M. Casillas5, R. Ortmann5, P. Emery5,1, Leiden University Medical Center, Leiden, Netherlands; 2University of Colorado, Denver, United States; 3School of Medicine, Kitakyushu, Japan; 4Quintiles IMS Holdings, Inc, Durham; 5Elly Lilly and Company, Indianapolis, United States; 6University of Leeds, Leeds, United Kingdom

Background: In p3 studies, baricitinib (bari) inhibited progression of radiographic joint damage up to 1 year in pts with active rheumatoid arthritis (RA) who were DMARD-naïve or who had an inadequate response to conventional synthetic DMARDs (csDMARD-IR).

Objectives: To evaluate radiographic progression of structural joint damage in pts with RA over 2 years of treatment.

Methods: Upon completion of a bari p3 study, pts could enter a long-term extension (LTE) study, in which they continued to receive the same bari dose as in the original p3 study. At 52 wks, DMARD-naïve pts receiving methotrexate (MTX) or combination therapy (bari 4 mg + MTX) were switched to bari 4 mg monotherapy; LTE-IR pts receiving adalimumab (ADA) were switched to bari monotherapy subgroup for ACR20, ACR50, DAS28-50CRP ≤3.2, response, and HAQ-DI was higher for BARI 4 mg compared with PBO. Within each comorbidity subgroup, BARI responses compared with PBO were similar (interaction P ≥ 0.1) (Table 2).

Table 1: Adverse Events Reported by Selected Comorbidity up to Week 10

Table 2: Effect of comorbidity subgroup for increased risk of events after treatment with BARI 4 mg compared with PBO.
4mg on background MTX. At 24 wks, csDMARD-IR pts receiving placebo (PBO) were switched to 4mg on background csDMARD. Radiographs at baseline, year 1 and year 2 were scored using the van der Heijde modified total sharp score (mTSS). Data are least squares mean change from baseline using mixed model repeated measures on observed data.

Results: Of all pts randomised, 82.6% entered the LTE, and 87.6% of those could be entered in this analysis. At year 2, progression was significantly lower with initial bari (including monotherapy) vs. initital MTX in DMARD-naive pts. In MTX/csDMARD-IR pts, progression with initial bari was significantly lower than initial PBO, and similar to initial ADA.

Conclusions: Treatment with once-daily oral bari resulted in low rates of radiographic progression for up to 2 years. Pts starting with bari showed progression that was significantly less than those starting with PBO or MTX, and comparable to those starting with ADA. The most robust benefit was seen with the 4mg dose.

DOI: 10.1136/annrheumdis-2017-eular.1324

FR0089 | EFFECT OF STARTING DOSE OF BARICITINIB IN ACHIEVING SUSTAINED LOW DISEASE ACTIVITY

J.R. Curtis¹, A. Kavaughan², D. van der Heijde³, D. Muram¹, J. Alam⁴, S. Beattie⁵, J.S. Smolen⁶, ¹ Univ of Alabama at Birmingham, Birmingham, ² UC San Diego School of Medicine, La Jolla, United States; ³ Leiden University Medical Centre, Leiden, Netherlands; ⁴ Eli Lilly and Company, Indianapolis, United States; ⁵ Medical University of Vienna, Vienna, Austria

Background: In Phase 3 studies, baricitinib (bari) treatment with 2 different doses (2 mg and 4 mg once daily) demonstrated significant improvements across multiple measures of disease activity in patients (pts) with active RA and an inadequate response (IR) to conventional synthetic (cs) DMARDs (RA-BUILD1) or biologic (b) DMARDs (RA-BEACON2).

Objectives: To determine the effect of starting dose of bari on achieving and sustaining low disease activity (LDA).

Methods: RA-BUILD and RA-BEACON trials were 24 week (wk), placebo (PBO) controlled studies. Pts completing the studies on bari treatment could enter a long-term extension (LTE) study, RA-BEYOND, continuing blinded treatment with the same dose, while pts on PBO switched to bari 2 mg. This post hoc analysis assessed disease activity in pts who achieved CDAI ≤10 at ≥1 visit (LDA) or at ≥2 consecutive visits (sustained LDA) within the originating study (24 wks) and continued into the LTE. The length of time required by pts to achieve LDA was determined by the incidence rate (percent pts responding per month) for each group.

Results: Treatment with bari 2 mg and 4 mg, when compared to PBO, resulted in higher rates of LDA and sustained LDA, as well as higher incidence rates (shorter time to achieve LDA/sustained LDA) within 24 wks of each originating study. Analysis of treatment with bari 4 mg demonstrated higher incidence rates when compared to bari 2 mg, both in achieving LDA and sustained LDA, indicating that these pts reached the desired LDA state faster. Incidence rates were lower in all treatment groups in bDMARD-IR pts compared with csDMARD-IR pts.

Conclusions: The most robust benefit in terms of achieving LDA and sustained LDA was observed with bari 4 mg treatment, which required shorter time to response, than treatment with 2 mg. This was observed in both the short (24 wks) and in the long-term in pts with IR to csDMARDs or bDMARDs.

ANALYSIS OF NEUTROPHILS, LYMPHOCYTES, AND PATIENT-PROVIDER DISCORDANCE MAY BE ASSOCIATED WITH SLIGHTLY HIGHER RATE OF INFECTIONS (Table 1).

Mean platelet counts increased to peak at wk 2, returned towards baseline, stabilized over time, and returned to baseline after treatment discontinuation (Figure 1). Permanent study drug discontinuations from thrombocytosis occurred in 2 bari-treated pts (0.1%). No clear association between platelet increase and thromboembolic events was observed.

Conclusions: Treatment with bari was associated with a decrease in ANC and an increase in ALC and platelets, which stabilized over time and returned to baseline with prolonged treatment (ALC) or treatment discontinuation (ANC and platelets). No associations between ANC decrease and infections or between thrombocytosis and thromboembolic events were observed.

DOI: 10.1136/annrheumdis-2017-eular.1339
Objectives: We aimed to assess the occurrence and severity of patient-reported flares of RA in patients who had discordant estimates of RA disease activity with their provider at baseline compared to those who had concordant estimates.

Methods: Patients with RA (age ≥18 years; 2010 ACR criteria) participating in an ongoing prospective study underwent clinical evaluation by a rheumatologist (MD/NI/PD) at baseline with assessment of tender (TJC28) and swollen joint counts (SJOC28), C-reactive protein (CRP), patient and provider GA of RA disease activity, disease activity score (DAS28-CRP), clinical disease activity index (CDAI), completion of Health Assessment Questionnaire-II (HAQ-II), visual analogue scales (0–100 mm) for pain (VAS-pain) and the flare-assessment in RA (FLARE) questionnaire. Patient-provider discordance was defined as ≥25 mm difference in GA between the patient and provider. Occurrence of patient-reported RA flares was compared between patients with and without discordance in GA. Flare was defined based on patient report when answered “Yes” to the question “Are you having a flare of your RA at this time?” or a predefined cut-off ≥2.5 on FLARE questionnaire (1,2).

Results: The study included 55 patients with RA (mean age 60.7 years; 65% female), of whom 40 had GA concordant with their provider and 15 had higher GA than their provider. Table 1 summarizes patient characteristics depending on GA discordance at baseline. Patients with discordance were similar in age, sex, duration of follow-up, had similar TJC28 and SJOC28, but had significantly higher HAQ-II, VAS-pain, CRP, DAS28, CDAI, provider GA and FLARE scores at baseline vs patients with concordant GA. During the follow up, patients with discordance had significantly higher number of visits and number of flares, and tended to have more visits with discordant GA compared to patients who had concordant GA with their provider at baseline.

Conclusions: Patients with patient-provider discordance at baseline were more likely to report flares of RA during follow-up. Patient-provider discordance tended to persist at follow-up visits. Disease activity assessments with patient-reported component (i.e., HAQ-II, VAS-pain, DAS28, CDAI, FLARE score), as well as CRP and provider GA, but not joint counts, were higher at baseline in patients with discordance. Consideration of the results of clinical and laboratory assessment in combination with patient-reported measures of RA disease activity may be important to inform future risk of flares in patients with RA and help improve patient-provider communication and shared decision making.

CAROTID ATHEROSCLEROSIS IS ASSOCIATED WITH DISEASE ACTIVITY AND BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS

J.W. Kang, E.S. Lee, J.S. Eun, J.H. Kim, J.Y. Kang, G.B. Bae, N.R. Kim, S.J. Lee, E.J. Nam, Y.M. Kang. Kyungpook National University School of Medicine, Daegu, Korea, Republic Of

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease which causes joint-articular and generalized bone loss. Several studies revealed that bone mineral density (BMD) is associated with atherosclerosis.

Objectives: In the present study, we investigated the association between BMD and RA disease activity and the carotid atherosclerosis in RA patients based on Kyungpook National University Hospital Atherosclerosis Risk in Rheumatoid Arthritis (KARRA) cohort study.

Methods: A total of 323 patients with RA, who performed dual-photon x-ray absorptiometry and carotid ultrasound, were included. We assessed RA disease activity, risk factors for atherosclerosis including hypertension, diabetes mellitus and dyslipidemia, presence of carotid plaque, carotid intima-media thickness (IMT), and BMD. BMD was measured at the lumbar spine (L-spine, L1-L4), femur (total femur neck) and distal forearm (total radius), and low BMD was defined as a T score of -1.0 or less.

Results: The BMD in the L-spine, femur, and radius was significantly lower in patients with carotid plaques (n=152) compared to patients without plaques (n=171) (1.014 g/cm² ± 0.21 vs. 1.066 g/cm² ± 0.18, p < 0.001 for L-spine; 0.816 g/cm² ± 0.16 vs. 0.863 g/cm² ± 0.13, p < 0.001 for femur; 0.542 g/cm² ± 0.13 vs. 0.603 g/cm² ± 0.12, p < 0.001 for radius). The frequency of low BMD in these areas was also higher in patients with carotid plaques, compared to patients without plaques (52.7% vs. 47.5%, p = 0.045 for L-spine; 56.0% vs. 44.0%, p = 0.003 for femur; and 59.5% vs. 57.9%, p = 0.036 for radius). In subgroup analysis, patients with the highest IMT quartile had a significantly lower BMD in all the regions than those with the lowest IMT quartile (61.2% vs. 37.7%, p = 0.004 for L-spine; 59.5% vs. 35.1%, p = 0.003 for femur; and 71.4% vs. 28.6%, p = 0.004 for radius). Multivariate logistic regression analysis demonstrated that BMD at radius (OR 1.906, 95% CI [1.067–10.276], p < 0.001), DAS28-ESR (OR 2.334, 95% CI [1.164–4.730], p < 0.02) and dyslipidemia (OR 4.995, 95% CI [1.067–10.276], p < 0.001) were risk factors for presence of carotid plaques.

Conclusions: The present study showed that carotid atherosclerosis was influenced by both disease activity and impaired bone health.

TIME TO AND FACTORS ASSOCIATED WITH INITIATION OF BIOLOGICAL THERAPY WITH DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN COLOMBIA

J.E. Machado-Alba, L.F. Calvo-Torres, A.M. Bañol-Giraldo, S. Garcia-Betancurt on behalf of Grupo de Investigación en Farmacoepidemiología y Farmacovigilancia. Universidad Tecnológica de Pereira- Audifarma S.A. Grupo de Investigación en Farmacoepidemiología y Farmacovigilancia, Universidad Tecnológica de Pereira-Audifarma S.A. Pereira, Colombia

Background: Rheumatoid arthritis (RA) treatment is usually done with non-biological disease-modifying antirheumatic drugs (DMARDs), but the addition of a biological DMARD can be necessary. Biological drug therapy is usually prescribed following failure to achieve remission of the morbidity with one or more non-biological DMARDs. However, there is the possibility of using them as a first line in the initial phase, which there is the possibility of potentially altering its course or even reverting it to normality.

Objectives: To determine the time Colombian patients with rheumatoid arthritis (RA) are treated with non-biological disease-modifying antirheumatic drugs (DMARDs) before changing to biological therapy.

Methods: A retrospective cohort study that collected information about the start of antirheumatic treatment in patients of all ages with a diagnosis of RA until the change to biological DMARD therapy. Survival analysis using Kaplan–Meier curves, from 1 January 2007 until 31 December 2013 by SPSS 23.0 for Windows, was made.

Results: A total of 3880 patients (75.3%) women with a mean age of 51.3 years started non-biological DMARDs. After 5 years, 234 patients (6.0%) initiated biological DMARD therapy in 17.5±13.9 months. Differences in the socio-demographic and pharmacological characteristics between the two groups of treatment are shown in the table. The use of glucocorticoids was associated with a greater risk of biological DMARD initiation (OR: 2.49; 95% CI: 1.658–3.732; p < 0.001), while the use of methotrexate (OR: 0.04; 95% CI: 0.014–0.108; p < 0.001) and chloroquine (OR: 0.13; 95% CI: 0.092–0.187; p < 0.001) reduced the risk of initiation.

Conclusions: After 5 years of non-biological DMARD therapy, 6.0% of people with RA started biological DMARDs. Receiving glucocorticoids, having any comedication, being treated in Bogota City or cities of the Colombian Atlantic coast affected the probability of switching to biological therapy in these patients.

**PILOT STUDY OF THE EARLY RHEUMATOID ARTHRITIS DIAGNOSIS PROGRAM WITH A STRUCTURED REFERRAL FORMAT**

1. Rheumatology Department, ISSEYM Toluca Medical Center, Toluca, State of Mexico; 2. Rheumatology Department, ISSEYM Toluca, Toluca; 3. Rheumatology, Mexican College of Rheumatology, Mexico City, Mexico.

**Background:** The delay in referral of patients with suspicion of Undifferentiated Inflammatory Arthritis (UIA) is especially the Rheumatoid Arthritis (RA), from the primary care physician (PCP) to the Rheumatologist prevents diagnosing and treatment in a timely manner. Early diagnosis and treatment decreases progression and permanent joint damage. Several strategies have been proposed to improve the time to referral of patients with UIA, however there is none for early RA in specific.

**Objectives:** We present a pilot study for the use of a weighted construct format for the improvement of the time to referral of patients with suspicion of early RA.

**Methods:** Since June 2005, in clinics and hospitals, PCPs were trained for the use of the weighted construct format tool. Adult patients with less than 1 year of symptoms were considered for the referral. The criteria for reference of suspicion of early RA are shown in Table 1. The patient referral was made through the counter-reference system, including the complete format and laboratory results. The patient’s appointment was given within 15 business days. Once the patients were evaluated and studied in the Department of Rheumatology, they were classified with RA according to 2010 ACR/EULAR criteria when was available this criteria classification. For the demographic variables, we used descriptive and inferential statistics and for the format validation we verified the reliability, and validity of the construct and criterion tool.

**Results:** Between July 2005 and July 2015, 298 patients were referred to our clinic. The average referral time in the first year (2005–2006) was 34.3±20.4 days, maintaining an average of 32.1±16.8 days until 2015. There was a reduction of 74% of referral time compared to a historical reference (mean time of referral was 127.4±51.8 days; in 122 patients). 182 (62%) patients filled out the 2010 ACR/EULAR criteria classification. For the demographic variables, we used descriptive and inferential statistics and for the format validation we verified the reliability, and validity of the construct and criterion tool.

**Conclusions:** In this pilot study, we observed that the construct had a suitable sensitivity, specificity and PPV for a referral format. Therefore, on suspicion of early RA the referral format could be used as a simple clinical tool for the timely referral to the Rheumatologist. On the other hand, the program implementation allowed the reduction in the referral time substantially. To implement the use of this tool in the daily clinical practice it needs to be validated with an open population and an adequate sample size.

**DURABILITY AND MAINTENANCE OF EFFICACY FOLLOWING PROLONGED TREATMENT WITH BARICITINIB**

**Background:** Baricitinib (bari) demonstrated clinical efficacy in Phase 3 trials in RA patients (pts) naïve to DMARDs (RA-BEIGIN1); and in RA pts with inadequate response to conventional synthetic DMARDs (RA-BEAM2 and RA-BUILD3) or biologic DMARDs (RA-BEACON4).

**Objectives:** To evaluate durability and maintenance of efficacy over an additional 96 weeks (wks) of bari treatment.

**Methods:** Pts included were those randomised to bari in an originating study (OS), completed that study without rescue (52 wks in RA-BEigin or RA-BEAM; 24 wks in RA-BUILD or RA-BEACON), and entered the long-term extension (LTE) study ≥96 wks prior to data cut-off. Durability of response was evaluated as pts achieving low disease activity (LDA) of SDAI ≤11 and minimal clinically important difference (MCID) of HAQ-DI improvement ≥0.22. Maintenance of response was evaluated as proportion of pts who had responded to bari at entry into LTE and maintained response at wk 96. Data are also provided for pts who had not responded to bari at entry into LTE who achieved response.

**Results:** Approximately half the pts in the durability analyses were categorised as LDA by wk 24 and the proportion of pts in the LDA category were similar or higher at wk 96. Three quarters of pts across groups demonstrated HAQ-DI improvement by wk 12 and more than half achieved MCID at wk 96. Most responders at entry into LTE maintained their response through wk 96. More than 25% of SDAI and HAQ-DI nonresponders at entry into LTE achieved response after 96 wks of treatment.

**Conclusions:** These data provide further evidence of the effectiveness of bari treatment in achievement of meaningful clinical control of disease activity long term.

**FR0097 REPAIR OF JOINT DAMAGE IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS PATIENTS OCCURS BUT DOES NOT RELATE TO PREVIOUS SUPPRESSION OF INFLAMMATION; AN 8-YEARS SUB ANALYSIS IN THE BEST-COHORT**

J.A. van der Pol 1, G. Akederm 1, M. van den Broek 1, L. Dirven 1, P. Kerstens 2, W.F. Lems 3, I.M. Markusse 1, T.W. Huizinga 1, C.F. Allaart 1. 1Department of Rheumatology, Leiden University Medical Center, Leiden; 2Department of Rheumatology, Westhies Gasthus, Hoorn; 3Department of Rheumatology, VU Medical Center, Amsterdam, Netherlands

**Background:** Joint damage in rheumatoid arthritis (RA) is thought to be irreparable. We hypothesized that in patients where inflammation is well suppressed for a long time, repair may be possible.

**Objectives:** To investigate whether reversal of erosions and joint space narrowing (JSN) in RA occurs and whether clinical variables predict repair.

**Methods:** In the BeSt study, patients with active early RA (ACR 1987 criteria, and symptoms <2 years) were randomized to 4 treatment strategies, each with the aim to ensure and maintain suppression of disease activity by adjusting medication based on three-monthly calculations of the 44-joint Disease Activity Score (DAS), target ≤24. Radiographic joint damage was assessed yearly, using the Sharp/van der Heijde score (SHS). In this analysis, 8-years data of the study were used. Repair of erosions or JSN was defined as the individual joint level as a reduction of ≥3 SHS point compared to the previous available X-ray, present in ≥2 consecutive visits and with ≥3 out of 4 independent scorers agreeing. Radiographs were scored in random order per patient, blind for patient identity and treatment arm. Multiple logistic regressions were applied at the patient level for associations between achieving repair and maximum duration of previous remission, mean DAS until repair, gender, presence of ACPA, or previous exposure to prednisone or infliximab use, anti-citrullinated protein antibody (ACPA), age, and randomization arm. All models were adjusted for mean joint damage over time in the group with repair. In the group without repair, the models were corrected for mean damage over time until mean time point of repair in the group with repair.

**Results:** Seven out of 508 patients did not have any X-ray images taken in the study. Of the remaining 501 patients, 329 had damage in at least 1 joint and thus could potentially show repair. In total, 2385 X-ray images were available, on average 7.5 per patient (range 2–9). Median SHS after 8 years in these patients was 10 (IQR 4–21, range 0–234), and mean (SD) DAS from month 3 was 2.00 (0.67). In 3 patients repair was seen in 2 joints (same time point). Mean (SD) time to repair was 44.1 (20.1) months. Ten of 17 patients (59%) had previously achieved DAS-remission, compared to 100% of the patients who at a matching time point showed no repair. Adjusted for mean SHS until repair, we found no associations with remission for duration of remission, mean DAS until repair, gender, age, presence of ACPA, or previous exposure to prednisone or infliximab (table 1). Apart from a trend towards fewer patients with repair in the initial infliximab study arm, there were no differences in any of the groups in any of the regression analyses.

**Conclusions:** In this early RA cohort, during 8 years treated to target DAS ≤2.4, repair of JSN and erosions was seen in 17 patients (3.3%), which supports that repair occurs in early RA. However, repair is a rare phenomenon, and does not seem to relate to previous inflammation or other predictors in this cohort.

RA patients with low MBDA scores (N=6 of 16; 37%) but high in those with moderate/high scores (N=10 of 13; 77%) (chi square p=0.015) (Figure; right graph).

**Conclusions:** These data show that the majority of RA patients in sustained clinical remission with low MBDA scores can successfully taper TNFi. In contrast, tapering cannot be recommended in patients with moderate to high MBDA scores, as relapse rates are high in these patients.

**DETERMINING MINIMUM CLINICALLY IMPORTANT CHANGE IN MULTI BIOMARKER DISEASE ACTIVITY SCORE ASSOCIATED WITH CLINICAL IMPROVEMENT IN METHOTREXATE NAIVE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS**

K. Chatzidionysiou 1, A.H. Hensvold 1, S. Saevarsdottir 1, R.J. Boice 2, D. Chernoff 2, C.C. Hwang 2, X. Wang 2, A.I. Catrina 1.

1Karolinska University and Institute, Stockholm, Sweden; 2Crescendo Bioscience Inc., South San Francisco, United States.

**Background:** The Multi-Biomarker Disease Activity (MBDA) score is a validated tool that quantifies 12 biomarkers to assess disease activity in rheumatoid arthritis (RA) patients. Many studies have demonstrated usefulness of the score for assessing RA disease activity.

**Objectives:** To determine minimum clinically important change in MBDA score (ΔMBDA) from baseline (BL) to Month 3 (M3) associated with clinical improvement (decrease in DAS-ESR >1.2) in early RA patients after initiating methotrexate (MTX).

**Methods:** We evaluated the MBDA test in patients from one of the sites participating in the Solna Epidemiological Investigation of RA (EIRA) cohort. EIRA patients were eligible if they were ≥18 years; RA diagnosis within 12 months of symptom duration; had serum and clinical assessments at BL and M3; and clinical follow-up data in the Swedish Rheumatology Quality Register. Patients naïve to disease modifying anti-arthritic drugs who received MTX were included. Krukas-Wallis was used to test the null hypothesis that medians of ΔMBDA scores of 3 EULAR response groups are equal. Receiver operating characteristic (ROC) analysis was performed. The optimal threshold of ΔMBDA associated with DAS28-ESR improvement (decrease in DAS-ESR >1.2 at M3) was determined by Youden criterion maximizing sum of sensitivity and specificity.

**Results:** 176 patients were included: 72% women, mean age 51 (SD: 11.7) years, mean DAS28-ESR score 5.6 (SD: 0.99); 51% had ESR ≤28 mm/hr, 66% were anti-CCP2+; and 22% received prednisone. Mean BL MBDA score was 56.8 (SD: 14.7) with 8 (5%) patients in low (<30), 29 (16%) patients in moderate (30–44) and 179 (79%) patients in high MBDA disease activity categories. Median MBDA scores for patients with no EULAR response worsened by 2 points and for patients with moderate and good response improved by 12 and 16 points, respectively (p<0.0001 across groups, Fig 1A). Median MBDA scores improved by 10 points for all patients and 15 points in patients with a DAS28-ESR decrease >1.2. The best combination of sensitivity and specificity to achieve a DAS28-ESR decrease >1.2 was provided by a >8 point MBDA score improvement (Fig 1B). A similar result was obtained using the bootstrap method. AUROC was 0.77 (95% CI: 0.71, 0.84). 125 patients (71%) had concordance between DAS28-ESR improvement and ΔMBDA improvement at the optimal threshold (Table 1).

**Conclusions:** The optimal threshold of ΔMBDA score associated with a clinically relevant decrease of DAS28 was 8 points. Using this threshold, the MBDA test is informative to detect clinical improvement. Thus, based on these results improvement in MBDA score >8 points at M3 after initiating MTX is indicative of meaningful clinical improvement.

RA IN MALE CARPENTERS: OCCUPATIONAL WOOD DUST EXPOSURE INCREASES ACPA AND RF SEROPOSITIVITY AND SIGNIFICANTLY RAISES RF TITRES

K. Bellis, M. Whallette, D. Murphy, D. Hutchinson
1Rheumatology, Royal Cornwall Hospital; 2University of Exeter Medical School, Cornwall Campus, Truro, Cornwall, United Kingdom

Background: Wood dust has been hypothesised as a trigger in RA. Exposure may activate peptidyl arginine deaminase through exposure to silica and carbon nanoparticles, stimulating RF autoantibody production. Though non-silica dusts have shown increased RA risk in construction workers, wood dust exposed individuals were excluded from analysis in a recent large registry study.

Objectives: To analyse the autoantibody status of male RA woodworkers in Cornwall, UK, compared to matched RA controls with no occupational dust or fume exposure.

Methods: All male RA patients were sent an occupational questionnaire, detailing current occupation, last occupation (if retired) and other occupations for >1 year. A control cohort was recruited using local employment data. Each patient was matched to 102 RA controls with no dust or fume exposure for age ±/– 5 years, sex and index date. RF and ACPA seropositivity was compared using a Z test of 2 proportions. Mann Whitney U test, and ACPA seropositivity was compared using a Z test of 2 proportions.

Results: No significant differences were seen in median age between woodworker cases (median 59 years IQR 50–63), and controls (median 58 years IQR 48–65).

Conclusions: Wood dust exposed RA patients are more likely to be seropositive. Sequential environmental insults of smoking and wood dust exposure have an additive effect on rheumatoid factor levels, conferring increased disease severity. Further studies are needed to determine if occupational wood dust exposure causes RA.

ULTRASOUND AND MRI DURING FLARES OF PALINDROMIC RHEUMATISM REVEAL A DISTINCT PHENOTYPE EVEN IN IMPIMIENT RA

1Instituto de Rheumatic and Musculoskeletal Medicine and Nhr Leeds Musculoskeletal Biomedical Research Unit; 2Radiology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Palindromic rheumatism (PR) is a recurrent, self-abORTive arthritis and peri-arthritis which progresses to RA in up to 50% of patients, especially those that are anti-CCP positive (1). Whether PR is truly a prodrome of RA or a distinct syndrome is unclear; the pathological phenotype of PR flare, and whether this changes when RA is imminent, remains unknown

Objectives: To describe the clinical and imaging (US and MRI) phenotype during PR flares and to determine whether this changes in PR patients with imminent RA. We hypothesised PR patients with imminent RA would have a RA phenotype during flare.

Methods: Patients were recruited from a prospective PR cohort. PR flares were defined as ≥ 2 of pain, swelling, erythema or in around ≥ 1 joint, that joint was later normalised. Clinical details were recorded during flares. Blinded US assessment (wrists, MCPs, PIPs, elbows, knees, MTPs, ECUs and 2nd-5th finger flexor tendons) was performed during and between flares. Synovitis, tenosynovitis, subcutaneous oedema, peri-articular inflammation and peri-tendinous oedema were reported at each joint. Where possible, MRI was also performed on the most symptomatic region during flare. Patients were followed for progression to RA.

Results: US was performed in 22 patients during flare. 19 patients also had non-flare US. Mean age was 49 yrs. 16/22 (73%) were anti-CCP+ and 6/22 (27%) anti-CCP-. Six (27%) patients developed RA (mean 23 weeks post flare); these patients had higher frequencies of flares and absence of flare trigger (figure) but no difference in distribution of flaring joints. The flare US showed grey scale (GS) synovitis in 13/22 (59%) patients, power Doppler (PD) synovitis in 4/22 (18%) and no erosions. 12/22 (55%) patients had peri-articular inflammation and/or subcutaneous oedema; in 6 patients this was without synovitis/tenosynovitis. Tenosynovitis and/or peri-tendinous oedema were present in 6/22 (27%) patients. Non-flare US demonstrated fewer erosions with improvement post flare. In 6 patients multiple flares were imaged with variable US abnormalities identified. The US flare phenotype did not differ (from non-progressors) in patients who progressed to RA, with PD synovitis present in only 17% (table 1) contrasting with our early RA cohort where PD synovitis occurred in 73% of patients (2). MRI was performed on 8 patients (2 flares imaged in 1 patient) and detected more pathology than US. Bone marrow oedema (BME) was found in only 1 patient. No erosions were seen.

Table 1: Proportion of flares with US abnormalities

<table>
<thead>
<tr>
<th>US abnormality</th>
<th>Progressed to RA (n=6)</th>
<th>Not progressed to RA (n=16)</th>
</tr>
</thead>
<tbody>
<tr>
<td>PD synovitis</td>

<td>3 (50%)</td>
<td>4 (25%)</td>
</tr>
</tbody>
</table>

Conclusions: PR flares have a distinct imaging phenotype characterised by peri-articular inflammation and subcutaneous oedema, often without synovitis. The low prevalence of PD synovitis, BME and erosions distinguishes PR from RA. PR patients with imminent RA have no triggers and more frequent flares, but retain the distinct PR phenotype. This suggests distinct pathological mechanisms in PR and should be of value for potential therapeutic interventions.

DOI: 10.1136/annrheumdis-2017-eular.6237
Methods: A total of 426 newly diagnosed RA patients treated from August 2011 to December 2014 were included. The DAS28-P score (the subjective components of the DAS28 relative to the total components) was calculated as DAS28-P = 0.56*sqrt(TJC28) + 0.014*(VAS-GH) / 0.56*sqrt(TJC28) + 0.28*sqrt(SJC28) + 0.78*(ESR) + 0.014*(VAS-GH). The EULAR response was assessed after 6 months of treatment. Of those who failed to attain good EULAR responses, those for whom the objective measures (the ESR, the CRP peak, and swollen joints) were normalized were defined as having failed treatment because of subjective measures.

Results: The mean age of all patients was 54 years and 79% were female. The median (IQR) DAS28 score at baseline was 4.8 (4.0–5.4) and that after 6 months of treatment 3.21 (2.4–3.95). Good responders (according to the EULAR criteria) numbered 180 (38.9%), moderate responders 150 (32.4%), and non-responders 96 (20.7%). The DAS28-P score fell significantly from baseline to 6 months in good (0.43 versus 0.28, p<0.001) and moderate responders (0.44 versus 0.4, p=0.003), but not in non-responders (0.43 versus 0.45, p=0.727). Younger age, a lower DAS28 score, and a lower DAS28-P score at baseline were related to a good EULAR response. Subjects who failed to respond because of subjective measures tended to have higher DAS28-P scores at baseline.

Conclusions: We found that RA patients with high DAS28-P scores, reflecting subjective measures, were less likely to achieve good EULAR responses 6 months after treatment initiation and tended not to be classified as good responders despite normalization of objective measures.

FRIO105 FFLUCTUATING, UNPREDICTABLE AND CHALLENGING: HOW PAIN, FATIGUE AND SLEEP DISTURBANCE IMPACT QUALITY OF LIFE IN PEOPLE WITH RHEUMATOID ARTHRITIS

V. Shorth 1, J. McBeth 1, K.L. Druce 1, S. Moore 1, W. Dixon 1, S. Kyle 1, M. Lunt 1, U. Langton-Hewer 2,3,4, 1Arthritis Research UK Centre for Epidemiology, University of Manchester, 2Research User Group, NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust, Manchester; 3Sleep & Circadian Neuroscience Institute, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford; 4Division of Musculoskeletal & Dermatological Sciences, University of Manchester, Manchester, United Kingdom

Background: Qualitative studies of patient experiences have provided useful insights into how rheumatoid arthritis (RA) affects quality of life (QoL). RA threatens self-image and feelings of independence, reduces personal control, and is associated with difficulty in juggling self-management alongside pre-existing demands of work, home and family life. Pain, fatigue, sleep problems and low mood are commonly reported by patients and perceived as particularly troublesome aspects of RA. We wanted to know whether these symptoms of RA were viewed as the key drivers of reported changes to QoL.

Objectives: To explore RA patients’ perceptions of RA-related pain, fatigue, sleep problems and mood, and their impact on QoL.

Methods: Participants, recruited through RA charities across England, were purposively sampled to include a broad range of current ages and ages at onset of RA. Eleven individuals with RA were interviewed either in a group interview (three participants) or individual semi-structured interviews (eight participants). The interview topic guide was developed in consultation with patient representatives. Interviews were audio-recorded and transcribed in full. Interview data were analysed using inductive latent thematic analysis.

Results: All participants were female, aged 36–75 years. Disease duration ranged from five months to 31 years. Pain, fatigue, poor sleep and low mood were all attributed to RA, and viewed as having wide-ranging impacts on QoL. Participants saw the bidirectional nature of relationships between these four symptoms as particularly challenging. For example, reduced sleep led to increased pain and vice versa. Themes included: “Fluctuating symptoms” referring to the impact of the significant changes in mood, fatigue or pain which can occur within a single 24 hour period “an RA flare”; “The unpredictability of symptoms” was viewed as emotionally draining, anxiety-provoking and undermined both short and long-term plans; “Challenging” described both the symptoms and the need to anticipate potential daily challenges in the context of current levels of symptoms. Most were able to articulate the attitudinal, practical and emotional strategies which could facilitate adaptation to living with RA such as the need to maintain focus on what could realistically be achieved, day-to-day cognitive flexibility and practical support. Pain, fatigue and changes to sleep patterns were viewed as affecting the following aspects of QoL; ability to work effectively, family and social relationships, self-worth, ability to feel “in control”, threats to future plans and appearance. The appearance theme included a desire not to be viewed as ill or “disabled”, weight-gain and self-consciousness.

Conclusions: Daily and hourly variations in pain, fatigue and low mood are challenging for individuals with RA. The unpredictable nature of RA often was associated with anticipatory anxiety and mood fluctuations within the day. However, despite this the importance of positivity and acceptance were identified as mitigating some of the impact RA was having on QoL.

RESULTS OF A SYSTEMATIC LITERATURE REVIEW OF PROGNOSTIC FACTORS IN RHEUMATOID ARTHRITIS AS A BASIS FOR A PROSPECTIVE RHEUMATOLOGISTS SURVEY

L. Carmona1, T. Otón1, A. Royo2, J.L. Baquero3, S. Luján2, S. Muñoz-Fernández4, 1Instituto de Salud Musculoesquelética; 2Medical Dpt., Bristol-Myers Squibb; 3Departamento Científico, Scintia Salus; 4Rheumatology, Hospital Universitario Infanta Sofía, Universidad Europea, Madrid, Spain

Background: Selecting the most appropriate therapy for each patient with rheumatoid arthritis (RA) is crucial in order to prevent joint damage, particularly in patients with rapidly progressing disease. The literature on prognostic factors is tremendous, being practical to summarize which factors are most strongly associated with a particular outcome and what is the utility that rheumatologists assign to these factors.

Objectives: To identify well established factors predicting long-term outcomes in RA, as the basis for a survey.

Methods: The identification of the factors was performed via an overview of systematic reviews studying prognostic factors in RA, followed by scoping reviews for individual factors. All searches were conducted in PubMed. In order to be included in the overview, the study had to have a systematic review of prognostic factors of any of the following outcomes: disability, mortality, remission, response to treatment, or radiological damage. All factors identified, in positive or negative association with the selected outcomes, were compiled in a matrix of factors * outcomes. Subsequent scoping literature reviews were performed for each combination of the matrix.

Results: The overview of systematic reviews allowed the identification of 36 prognostic factors (see Table 1).

Conclusions: We have analyzed and compiled a summary of prognostic factors published in RA and their predictability of long-term outcomes. This may act as a reference for cross-factor comparison and evidence-based risk assimilation and serve as a basis of surveying the value of such factors.

DEVELOPMENT OF A PREDICTIVE MODEL FOR RHEUMATOID ARTHRITIS MORTALITY USING RANDOM SURVIVAL FOREST

L. Rodríguez-Rodríguez1,2, J.M. Lezcano1, E. Soudah1, J.A. Jover1, I. González-Alvarez2, F. Salazar1, L. Abásolo1,2, 1Rheumatology, Hospital Clínico San Carlos; 2San Carlos Health Research Institute, Madrid, Spain

Background: Different machine learning methods have been used to develop predictive models of high quality and precision [1]. Among them, Random Survival Forests (RSF) has been proposed as an alternative to traditional survival models [2], being able to overcome most of the limitation of traditional survival techniques, such as Cox proportional hazards models.

Objectives: Our objective was to develop and internally validate a predictive model for rheumatoid arthritis (RA) mortality using Random Survival Forests (RSF).

Methods: Retrospective longitudinal study involving 1,461 patients diagnosed with RA between January 1994 and August 2011, and followed at the outpatient clinic of the Rheumatology Department of the Hospital Clínico San Carlos (Madrid, Spain) until death or September 2013. Demographic and clinical-related variables collected during the first two years after disease diagnosis were used. RSF models were developed, based on 1,000 trees. 100 iterations of each model were performed to measure the mean and standard deviation (SD) of the predictive error and the integrated Brier score (IBS). Missing values were imputed using the function implemented by the randomForestSRC package [3]. The predictive capacity of the variables was assessed using the “variable importance” (VIMP).

Results: 148 patients died (10.1%). M LG showed the lowest prediction error. All variables exhibited a positive VIMP. Final model showed a mean (SD) prediction error and IBS of 0.187 (0.002) and 0.150 (0.003) respectively. The most important predictor variables were age at diagnosis, median erythrocyte sedimentation rate and number of hospital admissions in the first 2 years after RA diagnosis.

Conclusions: We developed an accurate and precise model for RA mortality using RSF. Age and disease activity showed the highest influence in mortality.

TIME TO FIRST TREATMENT IS ASSOCIATED WITH A REFRACtORY COURSE OF RHEUMATOID ARTHRITIS

M. Bécédé1, F. Alasti1, L. Haupt2, A. Kirschbaumer1, U. Landesmann1, G. Supp1, J. Smolen1, D. Aletaha1, 1Department of Internal Medicine 3, Division of Rheumatology, Medical University of Vienna; 2Hietzing Hospital, Vienna, Austria

Background: It is an ongoing matter of research, whether the natural course of rheumatoid arthritis (RA) can be altered by an early intervention, a concept historically referred to as the “window of opportunity” [1]. So far, only short-term disease activity outcomes have been investigated, which are, however, inherently affected by the unknown rate of underlying rate self-limiting disease. It is unclear, whether among those, who eventually develop RA, the disease course is really affected by the timing of their initial treatment.

Objectives: To explore whether the long-term course of RA is different according to the delay of initial treatment.

Methods: Based on a longitudinal observational dataset, we initially identified a group of patients with an observed refractory disease, we defined presenting with ongoing moderate or high disease activity (by the Simplified Disease Activity Index, SDAI), despite at least three courses of DMARDs, of which at least on course was a biological compound. To ensure that sufficient time had been allowed for the previous treatments to be exert their non-effects, we also required these patients to have total treatment time of at least 18 months in accordance with treat to target strategy (3 x 6 months). We identified 399 patients with a treatment time of at least 18 months. 48 patients were excluded despite fulfilling the disease activity criteria, because they haven’t experienced enough treatment courses, or had received a biological compound yet, to claim refractory disease as per our criteria above. We could include 69 refractory and 262 non-refractory patients in our analyses and then performed
logistic regression analysis to assess the effects of different characteristics at baseline, including disease duration, on becoming refractory.

Results: By comparing patient characteristics (Table 1), more of the patients, who later will become refractory, are female (94.2% vs 73.4%, p<0.001), have higher baseline disease activity (SDAI of 25.5 vs 17.7, p<0.001), and longer delay of the initial treatment from symptom onset (3.17 vs 1.34 years, p<0.001). The multivariable logistic regression model confirmed that a longer delay of first treatment is independently affiliated with a higher probability of a refractory disease course at a later stage. This model was adjusted for disease activity at baseline, including disease duration, on becoming refractory.

The multivariable logistic regression model confirmed that a longer delay of first treatment from symptom onset (3.17 vs 1.34 years, p=0.001).

Our data suggest that delay to initial treatment in RA affects the chance of a dire disease course rises by approximately 1% every 6 months.

**FR01010 METHOTREXATE MONOTHERAPY IN REAL LIFE: A DRUG SURVIVAL ANALYSIS INCLUDING VERY EARLY ARTHRITIS AND EARLY ARTHRITIS COHORTS**

M.G. Anelli 1, C. Rotondo 2, G. Righetti 3, A. Rinaldi 2, S. Perniola 2, M. Nivuori 2, C. Scioscia 1, F. Cacciapaglia 2, C. Scioscia 3

Background: Methotrexate (MTX) is the first line drug suggested in the ACR/EULAR guidelines to treat the rheumatoid arthritis (RA) (1) and spondyloarthritides (SpA). Although MTX efficacy is demonstrated by high levels of evidences, maximum benefit might require interventions even earlier. For this reason, it is suggested to identify the patients (pts) with symptom onset of less than 12 weeks, that is very early arthritis, to obtain better outcomes. Few data are available by the clinical practice on MTX monotherapy (MTXm) survival in very early or early arthritis pts.

Objectives: We aim to evaluate the presence of different outcomes in MTXm drug survival and MTXm efficacy between Very Early Arthritis (VEA) pts (less than 12 weeks from symptom onset) and Early Arthritis (EA) pts (12–52 weeks from symptom onset), and between early RA pts and early SpA pts.

Methods: On 305 pts, we selected 219 pts (30 pts diagnosed as VEA (4.2 (4) weeks from symptom onset) and 185 pts as EA (25.7 (25) wks from symptoms onset) in which MTXm could be started. The RA pts were 93 and SpA pts were 126. To assess the MTXm survival we used the Kaplan-Meier survival curve analysis. Although MTX efficacy is demonstrated by high levels of evidences, maximum benefit might require interventions even earlier. For this reason, it is suggested to identify the patients (pts) with symptom onset of less than 12 weeks, that is very early arthritis, to obtain better outcomes. Few data are available by the clinical practice on MTX monotherapy (MTXm) survival in very early or early arthritis pts.

Conclusions: A single intra-articular corticosteroid injection, performed under US guidance, is a very fast treatment to reduce synovitis of the injected joint. In the hours next to the injection is common to reveal a rise of joint space enlargement together with that of PD signal score.

DOI: 10.1136/annrheumdis-2017-eular.3537
earlier diagnosis from symptom onset (p<0.0001), higher tier of rheumatoid factor (p=0.037) and female gender (p=0.019). In early SpA pts the only predictor of shorter MTXm survival was younger age at diagnosis (p=0.037). VEA and EA diagnosis did not influence the MTXm survival.

Conclusions: The MTXm survival is not influenced by VEA or EA diagnosis. The presence of ACPA is associated with radiographic progression in RA, and it has been suggested that ACPAs with different reactivities may be associated with different phenotypes of RA.

Objectives: To assess the prevalence of baseline ACPA reactivities in an inception cohort of early RA patients, including subgroups based on anti-CCP/RF status, and to compare the findings to healthy controls.

Methods: 217 DMARD-naïve early RA patients from the ARCTIC trial (1) were analysed. Radiographs were scored according to van der Heijde Sharp (vdHS) score. Anti-CCP status was analysed by FEIA (pos. if ≥10 U/mL) and RF by ELISA (pos. if ≥25 U/mL). ACPA titres (AU/ml) were considered positive if above the 98-thec. of values in 619 non-RA subjects. Analysis of 13 ACPA reactivities targeting citrullinated peptides from fibrinogen, alpha-1 enolase, vimentin, fillagrin and above the histone were performed at baseline in patients and 94 controls (blood donors matched for age/gender/smoking), using a multiplex chip-based assay (2).

### Conclusions

The prevalence of ACPA reactivities differed in subgroups of DMARD-naïve early RA patients according to anti-CCP status and RF status. All RA subgroups, including RF- and anti-CCP- patients, had higher prevalence of ACPA reactivities compared to healthy controls.

## FRIO112 SERUM LEVELS OF IL-33 AND SST2 ARE ASSOCIATED WITH FUNCTIONAL DISABILITY IN RHEUMATOID ARTHRITIS

M.R. Pinto1, A. Kakehashi2, M.V. Andrade3, 1Rheumatology, Hospital das Clínicas da UFMG; 2Aparelho Locomotor; 3Faculdade de Medicina, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Interleukin 33 (IL-33) is a cytokine related to amplification of the articular inflammation in rheumatoid arthritis (RA) animal models. Elevated IL-33 serum levels have been described in RA patients, suggesting a possible participation of this cytokine in the physiopathology of the disease. IL-33 soluble receptor (sST2) is a decoy receptor that functions as an inhibitor of the interaction of the transmembrane receptor with IL-33.

Objectives: To identify the association between serum levels of IL-33 and its soluble receptor (sST2) with clinical and laboratory characteristics of RA.

Methods: Cross-sectional observational study in which RA patients were submitted to clinical and laboratory evaluation. IL-33 and sST2 serum levels were measured by ELISA (R&D System Inc, Minneapolis, MN, USA).

Results: 102 RA patients were included, 92.5% women, mean age of 55.5±10 years and mean disease duration of 10 years. Eighty-four (82.4%) patients had seropositive RA. The median (interquartile range) IL-33 serum level was 69.1 pg/ml (31.6 - 114.5). Higher scores on the visual analogue scale (VAS) of disease activity assessed by the examiner were associated with higher IL-33 values (C195%; 0.01–0.65). In the group of patients with high titres of rheumatoid factor (RF), IL-33 levels were higher, compared to the group with negative RF (95% CI: 0.05 - 2.34). In 34 (33.3%) patients, IL-33 was undetectable and the presence of metabolic syndrome represented a 63% lower chance (OR =0.37, 95% CI: 0.15–0.90) of having IL-33 detected. In addition, 1-unit increase in HAQ-DI increased by 2.43 times the chance of detecting IL-33 (95% CI: 1.23 - 4.80). The median sST2 serum level was 469.8 pg/ml (336.3–651). sST2 was associated with worse functional capacity by the classification of Steinkroger (IC95%: 0.01–0.05). In the group of patients with negative RF (95% CI: 0.02 - 0.53) use (current or in the past) of tobacco was associated with IL-33 and sST2 serum levels.

Conclusions: These findings may suggest that both IL-33 and its soluble receptor play a role as a marker of RA severity and functional disability. The negative association of IL-33 with metabolic syndrome is in agreement with the possible protective role of this cytokine in relation to lipid metabolism.

FR0113 VALIDATION AND RESULTS OF THE SYMPTOMS IN PERSONS AT RISK OF RHEUMATOID ARTHRITIS (SPARRA) QUESTIONNAIRE

M.V. Beers-Tas 1, M. Ter Wee 1, B. Maat 1, W. Hoogland 1, A. Hensvold 3, A. Catrina 4, E. Mosor 4, A. Finch 1, D. Courvoisier 1, K. Raza 1.

Background: A range of symptoms can be present in persons at risk of rheumatoid arthritis (RA). However, information on the nature, location, timing, severity and predictive value of these symptoms is largely lacking. The Symptoms of At Risk of Rheumatoid Arthritis (SPARRA) questionnaire has been developed with support from EULAR, informed by data from a qualitative study.

Methods: The SPARRA questionnaire contains questions about presence, severity, impact and location of 13 symptoms. 240 individuals (69% rheumatoid factor and/or ACPA positive, 23% seronegative with clinically suspect arthralgia and 8% first degree family members of patients with RA) completed the questionnaire in the Netherlands (N=125), United Kingdom (N=70), Sweden (N=15), Austria (N=11) and Switzerland (N=19). Individuals had no history or presence of clinically diagnosed arthritis at the time of first physical examination. Reliability (test-retest) and validity (face, content and construct validity) were tested.

Results: Face validity was tested by a group of experts on the at-risk phase of RA and feedback on the questionnaire was asked and received from 30 arthralgia patients, leading to only minor comments. The test-retest within 7–14 days (N=51) showed moderate to good agreement (kappa mean 0.565, range 0.309–1. agreement mean 71%, range 59–100%). The content validity was high, in line with the fact that the items were derived from a qualitative study in seropositive arthralgia patients. In contrast, the construct validity (relation to visual analog scale scores (VAS) for pain and well-being) was low (R-square 0.040–0.199), suggesting that the questions measure different elements in different time frames and grasp symptom content not captured with regular VAS pain/well-being. Most symptoms were present in a high percentage of individuals, with pain, stiffness and fatigue as the most common ones. When a symptom was present, it was usually experienced as moderate to severe, and with moderate impact. ACPA positive individuals reported lower presence of symptoms than ACPA negative individuals (mean 47% for ACPA-positive (N=118), 41% for only RF positives (N=53) and 59% in seronegative individuals (N=69)), but functional impact was higher in ACPA positive individuals (51%, versus 42% in seronegatives, NS). Note that the inclusion criteria for the seronegative individuals was presence of symptoms.

Conclusions: This study provides evidence of good psychometric properties of the SPARRA questionnaire, except for low construct validity. This means the questionnaire adds information to currently available clinical measures in persons at risk of RA. Future studies are needed to evaluate whether SPARRA data can help to improve the prediction of RA.

FR0114 ALLOGRAFT INFLAMMATORY FACTOR 1 (AIF1) POLYMORPHISMS RS4711274 (G/A) AND RS2269475 (C/T) MAY PREDICT ETANERCEPT PLUS METHOTREXATE RESPONSE IN FRENCH CAUSATIVE PATIENTS WITH RHEUMATOID ARTHRITIS

D.F. Azzouz 1, M. El Haddad 1, S. Kanaan 1, N. Blandraud 2, M. Martin 2, C. Picard 2, J. Rouder 2, 3, T. Auger 2, N.C. Lambert 2.

INSERM UMR1097; 2Rheumatology, AP-HM; 3HILA Laboratory, Etablissement Français du Sang, Marseille, France

Background: Several risk loci for Rheumatoid Arthritis (RA) have been identified by Genome Wide Association Studies (GWAS), but they do not include Allograft Inflammatory Factor 1 (AIF1). Nevertheless, a few studies have shown that AIF1 rs2269475 (C/T) is associated with RA.

Objective: We propose to analyze Allogeneic associations in French Caucasian patients with RA, of the seven most described AIF1 SNPs; 2 To study their linkage disequilibrium with HLA-DRB1 alleles; 3 To evaluate whether AIF1 single nucleotide polymorphisms (SNPs) could predict first line treatment responses in RA.

Methods: We amplified the AIF1 gene region containing the 7 SNPs and sequenced PCR products on a total of 469 individuals, including 95 Anti-Citrullinated Protein Antibody (ACPA) positive RA patients, 146, patients with scleroderma, 132 healthy controls and 69 additional healthy controls selected from a large database of volunteers bone marrow donors (VMD) for carrying at least one RA associated SNP. Patients and controls were HLA-DRB1 genotyped. Patients with RA were divided into 2 groups, a first group called “non responders” was defined as patients who did not respond to first-line methotrexate (MTX) combined with Etanercept and a second group called “good responders” was defined as patients who did respond to methotrexate combined with Etanercept.

Results: Two SNPs were associated with RA: rs4711274 (G/A) and rs2269475 (C/T). The frequency of minor allele carriers was respectively 37% (A) and 36% (T) in patients with RA versus 18% among controls (p=0.0014 and p=0.001). Furthermore, patients with RA-associated HLA-DRB1 alleles carried more often minor alleles for both SNPs (p=0.0005). Preliminary clinical data show that 56% of non-responders (N=16) carried the minor alleles of both rs4711274 and rs2269475 compared to only 21% of good responders (N=24, p=0.02).

Conclusions: AIF is an inflammation-responsive protein encoded within the HLA class III region on chromosome 6 (6p21.3). As already described in British and Polish Caucasians, we found a significant AIF1 Rs2269475 association with RA. We also found an association with Rs4711274 in linkage disequilibrium with the former. The increased frequency of minor AIF1 alleles in RA was not associated with a particular HLA-DRB1 allele, but to any HLA-DRB1 allele carrying the C minor allele.

Finally, patients who failed to respond to Etanercept and MTX carried more often minor alleles of the 2 described AIF1 SNPs.

Further analysis on a larger groups of patients is required to confirm whether AIF1 SNPs can predict response to therapy with Etanercept and Methotrexate.

FR0115 EVER-SMOKING IS ASSOCIATED WITH DISEASE SEVERITY AND OPIOID USE IN RHEUMATOID ARTHRITIS

A. Karellis 1, E. Rampakakis 1, J.-S. Sampalis 1, M. Cohen 3, M. Starr 2, P. Ste-Marie 1, Y. Shi 1, Y. Mare 4, M.-A. Fitzcharles 2, 3, 4USS Medical Research, St-Laurent; 2Jewish General Hospital; 3Rheumatology, AP-HM; 4Alan Edwards Pain Management Unit, McGill University Health Centre, Montreal, Canada

Background: Cigarette smoking, both current and past, is a risk for incident rheumatoid arthritis (RA), even for those with low exposure rates of 1–10 pack years. Current smoking is also associated with severity of disease and poorer response to treatments. It is however not known whether any exposure to cigarettes impacts disease expression, especially for those who have discontinued smoking.

Objectives: To assess the disease severity in RA according to smoking status (ever-, past-, current-, non-smoker).

Methods: As part of a study to examine cigarette and marijuana smoking in rheumatic disease patients, consecutively attending rheumatology patients completed an anonymous self-administered questionnaire including: pain severity on visual analog scale (VAS), patient global assessment (PGA) and cigarette or marijuana smoking status. Concomitant physician recorded information included: sociodemographics, co-morbidities, treatments for RA, physician global assessment (PGA). Patients were categorized according to smoking status. Categorical variables were compared between groups with the Chi-Square test and continuous variables with the Student’s t-test. Variables showing a statistical trend (p<0.15) in univariate analysis were considered in multivariable logistic regression.
Results: Over a 2-month period (April-May 2014), there were 248 (25%) RA attendees of 1000 participants. Significant differences were observed between current, past and non-smokers in regard to age [mean (SD): 59.5 (10.0) vs. 65.2 (10.6) vs. 61.0 (18.2) years; p<0.034], gender (male: 23.9% vs. 30.3% vs. 14.6%; p=0.027), unemployment due to disability (13.3% vs. 3.1% vs. 4.9%; p=0.044), number of RA medications (mean (SD): 2.3 (1.1) vs. 2.1 (1.1) vs. 1.8 (1.1); p=0.019), DMARD use (78.3% vs. 82.8% vs. 64.1%; p=0.008), opioid use (19.6% vs. 10.1% vs. 3.9%; p=0.009), pain [mean (SD): 5.0 (3.3) vs. 4.0 (2.9) vs. 3.7 (2.6) cm; p=0.040] and PGA [mean (SD): 3.8 (2.8) vs. 3.1 (2.8) vs. 3.0 (2.4); p=0.039]. Recreational marijuana was used by 3 non cigarette smokers only, with 1 also reporting medicinal marijuana use. Ever smokers vs. non-smokers used a greater number of RA medications [mean (SD): 4.3 (3.0) vs. 3.7 (2.6); p=0.081], were more likely to use DMARDs (81.4% vs. 64.1%; p=0.003) and opioids (13.1% vs. 3.9%; p=0.014), and showed a trend towards more pain [mean (SD): 4.3 (3.0) vs. 3.7 (2.6); p=0.081]. In multivariate analysis, male gender (OR=2.193; p=0.025) and DMARD use (OR=2.376; p=0.010) were significantly associated with ever smoking while opioid use (OR=2.784, p=0.103 for ever smoking; OR=3.561, p=0.040 for current smoking) showed a statistical trend.

Conclusions: Current, but also ever cigarette use, was associated with worse RA disease as indicated by the use of more drug categories, and more likely use of DMARDs to treat RA, and a trend to more pain and opioids. The combination of opioids and cigarettes may be a manifestation of a patient "chemical coping" strategy in RA patients.

Clinical Utility of Area-Under-Curve (AUC) of a Proposal for a SDAI, CDAI, and RAPID3-Based Definition of Minimal Disease Activity for Use in Routine Care of Rheumatoid Arthritis: Results from a Japanese National Database

M. H. A. Leung1, E. Choy2, C. S. Lau3.

1. Department of Medicine, Queen Elizabeth Hospital, Kowloon, Hong Kong; 2. Arthritis Research UK, Health and Care Research Wales CREATE Centre, Institute of Infection and Immunity, Cardiff University, Cardiff, United Kingdom; 3. Department of Medicine, LKS Faculty of Medicine, University of Hong Kong, Hong Kong

Background: The standard of care in RA is treat-to-target of remission or low disease activity state (LDA). Integral to this is the regular assessment of disease activity. Patient-derived Disease Activity Score 2 (PDAS2) was developed to allow RA patients to self-assess. Validation, corresponding disease activity statuses cut-points and response criteria had been published. PDAS2 scores >3.8, 3.8–4.5, 4.6–5.0, >5.0 correspond to remission, LDA, moderate and high disease activities respectively. PDAS2 can be recorded by patients in-between clinic visits.

Objectives: To explore the clinical utility of PDAS2 on remission, flare and need of drug adjustment

Methods: A cohort of 100 consecutive RA patients was recruited to complete PDAS2 score at home fortnightly in between two consecutive rheumatology clinic visits. Patients would return the forms when they attended the second clinic. Rheumatologists adjusted treatment according to disease activity while blinded to the scores of PDAS2 recorded at home. AUC of PDAS2 was calculated from the mean of (PDAS2 score multiplied by the time interval between scores). They were compared with disease activity at the first and second visits. The change of PDAS2 score for those patients having SDAI flare-up (from remission/LDA to moderate/high disease activity) was compared to those didn’t flare-up using unpaired T-test. Receiver Operator Characteristic curve was used to determine the cut-point for AUC-PDAS2 increment to predict flare-up and the cut-point of PDAS2 score for rheumatologists to escalate anti-rheumatic drugs.

Results: Mean age of the cohort was 60 years, mean RA duration 14 years. 90% female, 71% sero-positive and 48% in remission/low disease activity. 89 patients (89%) returned written questionnaires which were done 7.8±3.5 times on average (mean±standard deviation) (range 1–16) for a follow-up interval of 17.5±9.4 weeks (range 3–35.2) weeks. Disease activities in first and second visits are shown in Table 1. Remission: For the 14 patients in SDAI remission in both visits, 13/14 were in AUC-PDAS2 remission, and 1/14 in LDA. There were 47, 45 and 37 out of 89 patients in SDAI, CDAI and DAS28 remission/LDAS respectively – they were all in AUC-PDAS2 remission/LDA. Flare-up: There were 10/89 patients in SDAI remission/LDAS in first visit and moderate/high disease activity in second visit. Their AUC-PDAS2 score rose by 0.33±0.35 points compared to 0.01±0.32 who had no flare-up (p=0.002). ROC curve AUC was 0.80 (95% CI: 0.64, 0.95) (p=0.002), with optimal cut-point at increment of AUC-PDAS2 score by 0.11 to predict flare, sensitivity and specificity being 80%. Moreover, rheumatologists decided to escalate anti-rheumatic drugs in 15/89 patients. ROC curve AUC was 0.71 (95% CI: 0.56, 0.86) (p<0.01), with optimal cut-point at PDAS2 score 4.33 to predict the need of escalating anti-rheumatic drugs, sensitivity being 60% and specificity 77%.

Conclusions: PDAS2 scoring by patients in-between follow-up is feasible and useful in reassessing RA patients kept in remission/LDAS, informing a potential flare from previous remission/LDAS state, and predicting rheumatologists’ decision to escalate anti-rheumatic drugs. AUC-PDAS2 concept is useful in development of smartphone application for patient use.

DOI: 10.1136/annrheumdis-2017-eular.1902
Conclusion: Serum calprotectin is not predictive for successful TNFi dose reduction or discontinuation in the context of RA patients with low disease activity, and calprotectin was only weakly correlated to CRP levels. These results might be caused by the lack of variability in calprotectin levels at baseline as all patients were in low disease activity state.

FRI0122 PREDICTING FACTORS FOR DISAPPEARANCE OF ANTI-MUTATED CITRULLINATED VIMENTIN ANTIBODIES IN SERA FROM PATIENTS WITH RHEUMATOID ARTHRITIS

N. Ishigooka, T. Fujii, S. Kondo-Ishikawa, M. Hashimoto, M. Furui, M. Tanaka, H. Itô, R. Nakashima, K. Murakami, Y. Imura, H. Yoshitani, K. Ohmura, T. Mimori. Department of Rheumatology and Clinical Immunology, Kyoto University Graduate School of medicine, Kyoto; 2Department of Rheumatology and Clinical Immunology, Wakayama Medical University, Wakayama; 3Department of the Control for Rheumatic Diseases, 4Department of Orthopaedic Surgery, Kyoto University Graduate School of medicine, Kyoto, Japan

Background: Mutated citrullinated vimentin (MCV) is one of the important targets of anti-citrullinated protein/peptide antibodies (ACPA) and is found in synovial fluid in rheumatoid arthritis (RA). The disappearance of anti-MCV antibody (anti-MCV titer) may be better correlated with RA disease activity and radiographic progression than anti-cyclic citrullinated peptide antibody (anti-CCP) titer.

Objectives: In the present study, we tried to determine the predicting factor of anti-MCV disappearance in sera from RA patients.

Methods: Both anti-MCV (ORGENTEC Diagnostika, Germany) and anti-CCP (MESACUP(TM)-2 test CCP, MBL, Japan) in sera from 280 RA patients who met 2010 ACR/EULAR classification criteria in Kyoto University RA Management Alliance (KURAMA) cohort 2013 and 2014 were measured by ELISA. Then, we determined retrospectively the predicting factors of anti-MCV disappearance using a multivariate logistic regression analysis.

Results: In 2013 cohort, anti-MCV and anti-CCP positiveitivities were 64.6 and 84.6%, respectively. The majority (97.8%) of anti-MCV-positive patients was also anti-CCP-positive and there was significant correlation between anti-MCV and anti-CCP positivities (p<0.001). In 2013 baseline, there was no difference in patients’ age, gender and disease duration between anti-MCV-positive (n=181, 64.6%) and -negative (n=99, 35.4%) groups. DAS28, however, was higher in anti-MCV-positive group than in -negative group (3.08±1.22 vs. 2.68±1.07, p=0.011), while anti-CCP-positive (n=237, 94.9%) and -negative (n=43, 15.4%) groups had no significant difference of DAS28. Of note, while decrease of DAS28 positivity rate did not change during 2013 and 2014, anti-MCV changed to positive and to negative were recognized in 20 (7.2%) and 41 (14.6%, disappeared group) patients. So we next compared anti-MCV disappeared and sustained-positive groups (n=140, 50.0%). There was no difference in patients’ age, gender, disease duration and DAS28 in 2013. While decrease of DAS28 from 2013 to 2014 (△DAS28) in disappeared group was more apparent than that in sustained-positive group (-0.58±1.1 vs. -0.02±0.34, p=0.028). Methotrexate monotherapy was rarer in disappeared group than in sustained-positive group (26.8% vs. 53.8%, p=0.015), while continuous use of biological disease modifying antirheumatic drug (bDMARD) was more frequent in disappeared than sustained-positive group (64.7% vs. 25.2%, p<0.0001). Also serum levels of KL-6, a serum marker of intestinal lung disease, were lower in disappeared than in sustained-positive group (255±146 vs. 315±183, p=0.006). To clear the most effective factor in anti-MCV disappearance, we choose variables including anti-MCV titers in baseline, KL-6 levels, △DAS28 and bDMARD use, and performed multivariable analysis. Analysis showed that anti-MCV titers and bDMARD use, especially TNF inhibitor (Odds Ratio =7.2, p<0.001) were significantly associated with anti-MCV titer disappearance. These analyses aimed to characterize temporary interruptions of study drug during the BARCITINIB PHASE 3 RHEUMATOID ARTHRITIS PROGRAM

P. Emery, Y. Tanaka, T.E. Cardillo, D.E. Schlichting, S. Beattie, L. Chen, T.P. Rooney, J.S. Smolen. 1Leeds MSK Biomed/Chapel Allerton Hosp, Leeds, United Kingdom; 2University of Nottingham & Environmental Health, Kitakyushu, Japan; 3Eli Lilly and Company, Indianapolis, United States; 4Medical University of Vienna, Vienna, Austria

Background: Temporary interruption of RA therapy is common in clinical practice; therefore, rapid clearance and low immunogenicity may be useful DMARD attributes. Baricitinib (bari) is a non-biologic Janus kinase (JAK) 1/2 JAK2 selective inhibitor with a pharmacokinetic half-life in RA patients of approximately 19 hours. It has demonstrated improved clinical efficacy compared to MTX, adalimumab and placebo (pbo) with a satisfactory safety profile when administered once daily to RA patients in 4 completed Phase 3 studies.

Objectives: These analyses aimed to characterize temporary interruptions of study drug during these studies and explore the kinetics of RA symptoms during and following interruption.

Methods: During bari Phase 3 studies, investigators were required to document temporary interruptions of study drug, including timing, reason and duration, using electronic case report forms. In 2 studies, patients recorded RA symptoms (duration and severity of morning joint stiffness, worst tenderness and worst joint pain) daily for 12 weeks. Post hoc analyses investigated changes in these scores among patients randomized at least 7 days prior to interruption, having an interruption that lasted at least 3 days, and retreated.

Results: Across the 3 pbo-controlled studies, interruptions occurred in a larger proportion of patients with bari than pbo only in the biologic DMARD-inadequate responder (IR) study RA-HEACON. In the 2 active comparator-controlled studies, the lowest rates of interruption were in the bari monotherapy arm of the DMARD-inadequate responder bari responder (IR) study RA-HEACON, and proportions similar for bari and adalimumab in the MTX-IR study. RA-HEAB (Table 1). Adverse events (predominantly non-serious, mild or moderate infections, most commonly of the respiratory tract) were the most frequent reason for interruption. Few patients interrupted for the reason of abnormal laboratory results. Most interruptions lasted for 2 weeks or less; in RA-BEAM, interruptions appeared shorter in duration for bari than for adalimumab. Diary measures indicated modest symptom increases during interruption compared to the last pre-interruption value, with a return to pre-interruption values or better after resumption of study drug (Table 2).

Conclusions: Consistent with its pharmacologic properties, brief temporary interruptions of bari during Phase 3 studies were associated with minor increases in RA symptoms, which resolved following resumption of therapy. A small molecule with a short half-life may offer advantages over injectable biologic therapies with respect to drug interruption for clinical cause in RA patients.

Disclosures of Interest: P: speakers bureau: Abbvie, BMS, JCB, Roche, Novartis, Samsung, Sandoz, Eli Lilly and Company, Y. Tanaka Grant/research support from: Mitsubishi-Tanabe, Takeda, Daiichi-Sankyo, Chugai, Bristol-Myers, MSD, Astellas, Abbvie, Eisai, Speakers bureau: Abbvie, Chugai, Daiichi-Sankyo, Bristol-Myers, Mitsubishi-Tanabe, Astellas, Takeda, Pfizer, Teijin, using specific HLA DRB1 typing kits (Dyonal RELI SSO). The presence of shared epitope (SE) was determined based on this genotyping. The statistical analysis was performed using Stata 12.1. Chi-Square and Kruskal-Wallis tests were used for the bivariate analysis. A multivariate logistic regression was performed to determine which factors may be related to ACPA positivity, including BMI, anti-CCP titers and smoking habit, number of SE alleles and study level as independent variables.

Results: Patients were 54.9 years old [44.2-67.5] (median [p25-p75]); disease duration was 5.3 months [3-8.4]. Table 1 shows the main variables significantly associated to BMI. In addition, we observed less ACPA positivity with increasing BMI (57% low weight vs. 43% in obese [p=0.06]), as well as a lower frequency of SE in patients with a higher BMI. The multivariate analysis confirmed that being smoker (ever or current) and carrying SE alleles is associated with the presence of ACPA. Adjusted by these variables, overweight and obesity were associated with ACPA positivity during an ACPA positive disease (OR 0.49, p=0.027 and OR 0.39, p=0.019 respectively).

Conclusions: In our early arthritis register, patients with a higher BMI have predominantly ACPA negative disease, a more intense perception of pain and higher disability. These findings should be validated in other populations.

DOI: 10.1136/annrheumdis-2017-eular.4456
Anti-acetylated-peptide antibodies (AAPA) have recently been described in rheumatoid arthritis (RA) patients. [1] Patients that show multiple autoantibody positivity have a higher likelihood to flare when stopping biological treatment. The role of AAPA antibodies for response to Tumor-Necrose-Factor-Inhibitor treatment (TNFi) has not been explored.

**Objectives:** To determine the prevalence and serological overlap of AAPA to rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) in a cohort of RA patients starting their TNFi-treatment. Therefore, AAPA might add additional information to estimating the chances of RA patients for responding to TNFi-inhibitors.

**Methods:** Longitudinal data from the METEOR database were used. Fifteen definitions of remission were tested: ACR-EULAR boolean-based; Simplified Disease Activity Index (SDAI); Disease Activity Score (DAS) and 28-joint count DAS (DAS28), both with ESR/CRP, with ≥ 4 variables (3/4/4), and various cut-offs tested. Disability was measured by the Health Assessment Questionnaire (HAQ) and HAQ≤ 0.5 as dependent variable and the various remission criteria as independent variables. Potential confounding factors (age, body mass index, gender, rheumatoid factor positivity, erosions and biologic treatment) were also tested. Sensitivity analyses were performed using first visits only and using patients with no missing data for all definitions of remission.

**Results:** Data from 32,915 patients and 157,899 visits were available. The most stringent definition of remission (table 1) was the ACR-EULAR boolean definition (4.5%). The proportion of patients with HAQ≤ 0.5 among patients in remission was 54.6%. The proportion of patients for responding to TNFi treatment was 57% for ACPA and 61% for RF (for overlap of antibodies see figure). There were no significant differences in baseline characteristics of autoantibody positive and negative patients, and their association with a 50% response by the Simplified disease activity index (SDAI50), and with achieving of SDAI low disease activity or remission at 6 months after starting the first TNFi. Likelihood ratios were calculated from logistic regression analyses. To better determine differences in SDAI change over time General Estimated Equation analyses (GEE) was used.

**Conclusions:** AAPA positivity, in contrast to RF and ACPA positivity, appears to have a tighter association with greater levels of response in patients who are initiating TNFi-treatment. Therefore, AAPA might add additional information to estimate the chances of RA patients responding to TNFi-inhibitors.

was higher for the most stringent definitions. However, this also meant that, for the most stringent criteria, many patients in non-remission had HAQ>0.5. The strongest degree of association between remission and HAQ=0.5 was observed for the SDAI. However, only minor differences were noted between definitions (table 1). Sensitivity analyses yield similar results (not shown).

Conclusions: The remission definitions confirmed their validity in terms of physical function in a large international clinical practice setting. However, many patients in non-remission will still have good functional status and being in clinical remission does not equate to having HAQ<0.5. A multidimensional approach should be taken to help patients achieve this functional goal. Achievement of remission according to any of the indices is more important than the use of a specific index.

FR0127 OUTCOMES OF DISEASE ACTIVITY IN A 5-YEAR LARGE COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED UNDER TREAT TO TARGET RECOMMENDATIONS AND A MULTIDISCIPLINARY CARE MODEL – A REAL-LIFE EXPERIENCE

P. Santoso-Moreno1, D. Gomez1, E. Castillo1, R. Giraldo1, G. Ballesteros1, L. Villarruel1, J. Belo2, D. Buitrago-García3, 1Rheumatology; 2Psychology and processes; 3Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia

Background: Treat to Target (T2T) strategy becomes from the need to develop therapeutic targets and tools to achieve defined outcomes in rheumatoid arthritis (RA). PRISM was easy to use and most patients understood the simple disease activity (ptGbl), assessed at wks 12 and 24, using the sign test.

Methods: A descriptive cohort study was conducted. Medical records of patients from specialized in RA center were reviewed; those patients were followed-up under T2T standards and a multidisciplinary approach. Each patient had a minimum of 6 follow-up visits. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3–5 weeks (DAS28 >5.1), every 7–9 weeks (DAS28 >3.1 and ≤5.1), and every 11–13 weeks (DAS28 ≤3.1). Tender joint count (TJC), swollen joint count (SJC) and DAS28 were measured on each visit. Therapy had to be adjusted with DAS28 >3.2 unless patient’s condition didn’t permit it; we considered this follow-up type as implementation of a T2T strategy in patients with RA. We divided patients in four groups: remission (REM), low disease activity (LDA), moderate disease activity (MDA) and severe disease activity (SDA) patients and the aim of the study was to look at what percentage of patients who were in moderate or severe disease activity reached a low disease activity or remission. Descriptive epidemiology was done, percentages and averages were calculated; the median of each variable was analyzed using t-Student assuming normality for DAS28 distribution and the level activity disease was analyzed using Pearson’s statistics.

Results: 3618 patients meet the inclusion criteria. 72% were receiving conventional DMARDs therapy and 28% were receiving biological therapy. 83% were woman and 17% were men. Mean age was 61 years ±11. Mean DAS28 at beginning was 3.3±1.3 and at the end of five year period was 2.8±0.7. The difference was statistically significant (p

Conclusions: This study show evidence of an improvement in DAS28 and level disease activity in a cohort of RA patients from a Colombian center specialized in RA center.

FR0128 PRISM – PICTORIAL REPRESENTATION OF ILLNESS AND SELF ACTIVITY: THE USE OF A SIMPLE NON-VERBAL TOOL AS A PATIENT-CENTRED OUTCOME MEASURE IN EARLY RHEUMATOID ARTHRITIS COHORTS

P.C. Taylor1, R. Atten2, B. Harauki3, B. Amess1, J. Macdonald1, M. Truchon4, C. Pohl5, C. Swales6, Y. Kanelo7, T. Sensky8, 1University of Oxford, Oxford, United Kingdom; 2Schlosspark-Klinik Charité, University Medicine Berlin, Berlin, Germany; 3Université de Montréal, Montréal, Canada; 4Institut de Rhumatologie de Montréal, Montréal, Canada; 5Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan; 6Centre for Mental Health, Imperial College London, London, United Kingdom

Background: Treatment recommendations in early RA advocate a treat to target approach, the ideal goal being remission. But not all patients attain this goal. There is a need for outcome measures that are meaningful to patients and inform management of which alleviation of suffering is a key aim. PRISM® is a novel, validated, brief method of measuring suffering consistent with Cassell’s seminal conceptualisation.

Objectives: To understand the relationships between a patient’s perception of the totality of the impact of RA and commonly used clinical assessments of disease activity, depression and illness intrusiveness.

Methods: Basic sociodemographic and clinical data were collected from 182 RA patients from 3 international centres, assigned to one of four cohorts (two early RA and two established RA), at baseline, weeks 12 and 24. The two early RA cohorts (diagnosis <2 yr) comprised Group 1 on stable treatment (n=37) and Group 2 requiring csDMARD adjustment (n=34). Using the iPRISM App on a tablet, all patients were asked to complete the basic PRISM task to measure self-illness separation (SIS). The smaller the SIS, the greater the person’s perceived suffering. In the PRISM+ task, patients were asked to identify two valued aspects of their life at the moment (X and Y) which bring pleasure, satisfaction, a sense of achievement, or a sense of purpose. The iPRISM App automatically records the distance between the centres of each of these disks and the Self disk to measure patients’ perceptions of the intrusiveness of their illness on two personally valued aspects of their lives.

For both groups, direction of change in SIS and the PRISM+ measures were compared with direction of change in disease activity measures and patient global disease activity (ptGbl), assessed at wks 12 and 24, using the sign test.

Results: PRISM was easy to use and most patients understood the simple instructions. Of 182 patients at baseline, SIS showed significant correlations with ptGbl (r

Conclusions: PRISM is a novel PRO that quantifies factors salient to each individual with respect to the impact of RA and its treatment while allowing for incorporation of a wide range of such influences. It may have utility as an adjunct to references for disease activity measures in setting agreed personalised therapeutic targets.

FR0129 COMPARATIVE SAFETY OF BIOLOGIC DMARD INITIATION IN RA: A POPULATION-BASED OBSERVATIONAL STUDY OF MALIGNANCY RISK

S. Suitsa1, S. Dell-Ariello2, T. Simon2, 1McGill University, Montreal, Canada; 2Bristol-Myers Squibb, Princeton, United States

Background: Patients (pts) with RA are at increased risk for some malignancies and the use of biologic (b)DMARDs has been reported to further increase this risk. A retrospective cohort study comparing the safety of bDMARDs with other treatment options in RA patients, is not often prescribed as a first-line bDMARD, but long-term effects are unknown.

FRIDAY, 16 JUNE 2017

Rheumatoid arthritis - comorbidity and clinical aspects

FR0129
Objectives: To assess in a real-world, observational study whether treatment with ABA had a similar malignancy risk as other biologics, with or without MTX, when used as the initial bDMARD for RA.

Methods: The Truven MarketScan® Commercial and Supplemental Medicare databases were used to identify adult pts diagnosed with RA who initiated bDMARD treatment with ABA or another bDMARD between Jan 2007 and Dec 2014. Other bDMARDs included adalimumab, anakinra, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab. Pts were required to have ≥ 6 months (M) of continuous health plan enrolment before bDMARD initiation (index date) and deemed to have initiated a treatment if there was no claim for any bDMARD, other bDMARD, or csDMARD within the 6M period before bDMARD initiation. Pts who had a malignancy in the baseline 6M period were excluded. Pts were followed up from the date of the first bDMARD prescription initiation, either ABA or another bDMARD, until occurrence of a malignancy (identified by ICD-9 diagnosis code), end of enrolment, database or end of data collection, whichever occurred first. A 6M latency period was included. Propensity scores of ABA initiation were estimated from the baseline covariates using a logistic regression model, and trimmed to include only pts with ranges common to both ABA-exposed and comparator bDMARD cohorts. The Cox proportional hazard regression model was used to provide an estimate of the hazard ratio (HR) of malignancy associated with ABA initiation compared with initiation of another bDMARD, adjusted for age and deciles of the propensity score after trimming.

Results: A total of 3591 pts were identified as above as having initiated bDMARD therapy with ABA and 17,415 initiated with another bDMARD, with follow-up of > 6 years (median 7.5 yrs). Pts who initiated ABA vs other bDMARDs were older (mean 55 vs 52 yrs), had more comorbidity, used less MTX (49 vs 57%) and more other non-bDMARD (41 vs 36%) at baseline. After trimming on propensity scores, 565 pts developed a malignancy after ABA (incidence rate 5.0 per 100 yr) compared with other bDMARD (incidence rate 3.8 per 100 yr). When adjusted HR (95% CI) of any malignancy with ABA initiation relative to other bDMARDs was 1.18 (1.06, 1.30), while for any malignancy excluding non-melanoma skin cancer it was 1.17 (1.02, 1.34). The risk (HR; 95% CI) was not significantly elevated for lung cancer (1.11; 0.70, 1.76), female breast cancer (1.21; 0.91, 1.62) and lymphoma (1.21; 0.77, 1.90).

Conclusions: In this large, real-world study of pts treated for RA, the incidence of the most common malignancies of breast, lung and lymphoma were not significantly increased in pts using abatacept as first-line bDMARD treatment compared with other bDMARDs, though the confidence intervals were wide. The significantly increased in pts using abatacept as first-line bDMARD treatment was for any malignancy excluding non-melanoma skin cancer. This large, real-world study of pts treated for RA, the incidence of the most common malignancies of breast, lung and lymphoma were not significantly increased in pts using abatacept as first-line bDMARD treatment compared with other bDMARDs, though the confidence intervals were wide. The significantly increased in pts using abatacept as first-line bDMARD treatment was for any malignancy excluding non-melanoma skin cancer.

FRID1301
RATES AND RISK FACTORS OF NEW-ONSET PSORIASIS UNDER DIFFERENT BIOLOGIC AGENTS AND CONVENTIONAL SYNTHETIC DMARD TREATMENT

A. Strangfeld1, L. Baganz2, A. Richter1, B. Manger2, G.-R. Burmester2, C. Eisterhues4, S. Wassenberg3, A. Zink3, J. Listing1, G. German Rheumatism Research Center, Berlin; 2Scientific Advisory Board, Erlangen; 3Charité University Medicine, Berlin; 4Rheumatolog, Braunsweg; 5Rheumatolog, Ratingen, Germany

Background: Psoriatic skin disease is a burdensome, sometimes painful, dermatologic condition which was reported to occur as an adverse event (AE) during the initial treatment with bcsDMARDs and to investigate risk factors.

Objectives: To compare incidence rates of psoriasis in RA under treatment with different biologic and conventional synthetic (b/cs)DMARDs and to investigate risk factors.

Methods: We used data of 12,722 patients (53,585 patient years (py)) enrolled with the start of a b/csDMARD in the German biologics register RABBIT. Patients were required to have psoriasis at baseline and at least one follow-up. All psoriatic events (PsE) reported until 30 April 2016 were selected and assigned to treatments administered within 3 months prior to the event. Crude incidence rates (IR) of PsE were calculated per 1,000py. Cox regression was applied to investigate risk factors for the occurrence of PsE with and without inverse probability weights (IPW) to adjust for confounding by indication.

Results: 98 PsE were reported, with only 6 of them categorized as being serious. The median time between enrollment in the cohort and onset of psoriasis was 19 months (IQR:11–45 months). 21 of all PsE (22%) were palmoplantar manifestations of which 9 were reported as pustular type.

Conclusions: PsE under biologic treatment with the crude IR of 0.44/1,000py (95% CI 0.20;2.9) were not significantly different from csDMARD patients. Across TNFi, the IR varied insignificantly. Adjusted regression analysis showed higher risk for PsE with TNFi, abatacept and rituximab (graph). Female sex (adjusted hazard ratio (HR) 1.8 (1.03;3.3)) and being rheumatoid factor negative (HR 1.6 (1.02;6.2)) were additional significant risk factors. Smoking (HR 1.6 (1.1;2.5)), age (HR 1.0 (0.97;2.01)), glucocorticoids per 5 mg/d increase (HR 1.1 (0.8;3.4)) or tocilizumab (HR 0.7 (0.1;2.0)) IRs for PsE were not significantly associated. Replacing glucocorticoids with DAS28 did not show differing results. Adjustment with IPW attenuated the effect of rheumatoid factor (p=0.4) but smoking was significantly associated with a higher risk (p<0.01).

**FR0132** HIGH DISEASE ACTIVITY IS A PREDICTOR OF DEPRESSION AND PERSISTENT DEPRESSION IN EARLY RHEUMATOID ARTHRITIS: RESULTS FROM THE ONTARIO BEST PRACTICES RESEARCH INITIATIVE (OBRi)

R. Joshi 1, M. Movahedi 2,3, E. Rampakakis 2, A. Cesta 4, X. Li 5, S. Couto 5, J. Sampalis 6, C. Bombardier 6,7, B. Kuriya 2 on behalf of OBRi investigators.

1Departments of Rheumatology, Brampton Civic Hospital, William Osler Health System, Brampton; 2JSS Medical Research, Montreal; 3Ontario Best Practices Research Initiative, Toronto General Hospital, University Health Network; 4Division of Rheumatology, Mount Sinai Hospital; 5Department of Medicine (DOM) and Institute of Health Policy, Management, and Evaluation (IHPEM); 6Sinal Health System, University of Toronto, Toronto, Canada

**Background:** The prevalence of depression among individuals with rheumatoid arthritis (RA) may be as high as 40% but persistence of depression over time is relatively unknown. Uncontrolled inflammation may drive severe disease and, in turn, inflammation and high disease activity are hypothesized to mediate depression and associated symptoms.

**Objectives:** The aims of this analysis were to: (1) describe the prevalence of depression at baseline and determine how often depression persists over time; (2) determine whether there is an association between changes in disease activity and depression over time among individuals with early RA (ERA).

**Methods:** ERA patients enrolled in the Ontario Best Practices Research Initiative (OBRi) with ERA (<1 year disease duration) and >2 years of follow-up were included. Persistent depression was defined as self-reported depression at baseline and at >50% of visits over the first 2 years. The association between baseline disease activity, measured by the Clinical Disease Activity Index (CDAI), and depression at baseline or persistent depression was evaluated with multivariate logistic regression. The General Estimation Equation was also used to explore the association between changes in CDAI disease activity over time and risk of depression.

**Results:** 469 patients with ERA (72.9% female) were included with a mean (SD) age of 56.8 (13.6) years. Mean (SD) disease parameters were: CDAI: 22.9 (14.1); DAS28: 4.6 (1.5); and HAQ disability Index: 1.1 (0.75). At baseline, the prevalence of depression was 26%, and 23% reported persistent depression. Persistent depression was significantly higher in patients with moderate CDAI (19%) and high CDAI (29%) compared to those in CDAI low disease activity (LDA) or remission (16%; p<0.001). After adjusting for potential confounders (sex, rheumatoid factor status, prior use of csDMARDs, current use of bDMARDs, HAQ disability index, number of comorbidities), increased CDAI at baseline was significantly associated with both baseline depression and persistent depression (OR: 1.04; 95% CI: 1.01–1.06, p<0.002). Female gender (OR: 3.17; 95% CI: 1.50–6.80, p=0.002) and greater number of comorbidities at baseline (OR: 1.68; 95% CI: 1.47–1.93, p<0.001) were also associated with persistent depression. Over the course of follow-up, the risk of depression was significantly higher among patients with moderate disease activity compared to those in CDAI LDA or remission (OR: 1.16; 95% CI: 1.04–1.29, p=0.006). The risk of depression was substantially greater for those with high disease activity (OR: 1.32; 95% CI: 1.15–1.52) over time compared to those achieving LDA or remission states.

**Conclusions:** Depression in ERA is common and initial high disease activity increases the risk of depression as well as its persistence. High CDAI during the early years of follow-up was also an independent predictor of depression. This highlights the importance of intervening during the “window of opportunity” to control disease activity and the potential to mitigate adverse health outcomes, including depression.

**FR0133** IS THERE INCREMENTAL MENTAL HEALTH BURDEN ASSOCIATED WITH RHEUMATOID ARTHRITIS?

V. Strand 1, M. Kosinski 2, R. Rendas-Baum 3, D. Brooks 3, R. Ganguly 3

1Stanford University, Palo Alto, CA; 2Optum, Inc., Eden Prairie, MN; 3GlaxoSmithKline, Collegeville, PA, United States

**Background:** Rheumatoid arthritis (RA) patients are more likely to experience depression.1 This comorbidity is associated with increased disability, use of healthcare services, and mortality risk.2 3 The association between RA and other mental health disorders has received limited attention and there remains a need to further demonstrate and understand the impact of RA on mental health.

**Objectives:** Evaluate the mental health burden of RA patients based on the analysis of Short Form-36v2 Health Survey (SF-36v2) mental health (MH) and role emotional (RE) domain scores from two independent general population databases in the US and Europe.

**Methods:** The mental health burden associated with RA was analyzed by comparing mean SF-36v2 MH and RE scores of individuals self-reporting RA (with or without depression) and the scores from 2 benchmark samples (individuals without RA, individuals with depression and no RA) in two large cross-sectional survey studies (QualiMetrix’s 2009 General US Population Norming Study of the SF-36v2 and the 2014 European National Health and Wellness Survey). Multivariate regression methods were used to adjust each benchmark sample to the distribution of the RA sample in terms of age and gender. Differences between groups were interpreted with respect to minimally important differences: 3 points for MH; 4 points for RE.

**Results:** The US (2009) and European (2014) samples included 4,042 and 81,366 individuals, respectively. Compared with individuals without RA or depression, mean RE scores were significantly (P<0.001) lower for RA patients without depression in the US (-7.75 points) and Europe (-5.31 points). Likewise, mean MH scores were significantly (P<0.001) lower among RA patients without depression in the US (-4.85 points) and Europe (-5.03 points) compared with individuals without RA or depression. Compared with individuals with depression and no RA, mean RE and MH scores were 5 to 10 points higher (P<0.001) for RA patients without depression in both the US and Europe. Comparisons of RA and RE/MH scores between RA patients with and without comorbid depression showed that comorbid depression was associated with 2 to 6 points lower scores (P<0.01) in RE and MH domains, in both the US and Europe.

**Conclusions:** RA is associated with significant and clinically meaningful mental health burden as measured by SF-36v2 MH and RE domains. Results comparing scores between RA patients with and without comorbid depression suggest that there is an incremental mental health burden associated with RA, often exceeding minimally important differences among US patients.

**FR0134** CLUSTER ANALYSIS OF PULMONARY LESIONS IN RHEUMATOID ARTHRITIS (RA): AIRWAY DISEASE IS SHARED AND CRITICAL PULMONARY ABNORMALITY IN RA

A. Tanaka, Y. Namiki, R. Yamazaki, H. Okada, S. Arii, T. Owada, R. Maewa, M. Arima, K. Kurasawa. Department of Rheumatology, Dokkyo Medical University, Shimotoga-Gun, Japan

**Background:** Rheumatoid arthritis (RA) is a systemic inflammatory disease that affects joints and various organs including the lung. The pulmonary involvement is critical for prognosis of the patients and decision of the treatment. Moreover, the pulmonary involvement showed various abnormalities such as interstitial pneumonia (ILD) and airway disease (AD). Importantly, a pulmonary abnormality coexists with other ones in RA patients. There have been large numbers of studies on the prevalence of pulmonary abnormalities and clinical features of patients with these lesions. However, it remains to be elucidated what existence pattern of pulmonary abnormalities RA patients have.

**Objectives:** To reveal the existence pattern of the pulmonary abnormalities in RA patients using cluster analysis, and to clarify the clinical features of patients with multiple pulmonary lesions.

**Methods:** Subjects were consecutive 208 RA patients who were treated by bDMARDs as the first one from Feb. 2004 to Sep. 2015 in our department and received HRCT scan before and after the therapy. Pulmonary abnormalities were classified into 4 categories (ILD, nodular lesions, AD and other) and 20 lesions such as ground-glass opacities, consolidation, reticular pattern, bronchiectasis and were examined their existence and distribution. Cluster analysis was conducted according to the existence of the lesions by Ward method. Clinical features were analyzed through reviewing medical records.

**Results:** Subjects were 208 RA cases (M/F: 64/144, mean age 59.2 year-old,
Conclusions: Pulmonary abnormalities were found in 70% in RA. AD was found in 55% of RA patients and coexisted with other pulmonary lesions such as ILD and nodular lesions. Patients with AD frequently showed newly emerging or exacerbation of pulmonary abnormalities developed in AD patients compared to those without pulmonary abnormalities or AD. No significant differences were found in clinical features, among AD alone, AD with ILD and AD with nodules.

A. Emamifar1, R. Hvid Larsen2, R. Asmussen Andersen1, I. M. Jensen Hansen1,2,3,4, A. Hansen1,3,4, R. Dolhain Hansen1,3.

**Background:** Rheumatoid Arthritis (RA) should be treated instantly to prevent further joint destruction. The first few months after treatment initiation are critical for long-term treatment outcome. [1] Patients with RA are at increased risk of thyroid disease with direct effect on initial treatment response. [2]

**Objectives:** To characterize the prevalence of thyroid disease among RA patients as well as to evaluate the correlation between presence of thyroid disease in RA patients and initial treatment response.

**Methods:** All RA patients who were registered in the local part of Danish Danbio registry were included in this study. Patients' demographic data, serology results (IgM Rheumatoid Factor, Anti-CCP, Fibrinogen, C-reactive protein (CRP) at the time of diagnosis and after 4 months (±1–2 months) of treatment (anti-ccp) as well as disease activity score in 28 joints-C-reactive protein (DAS28- CRP) at the time of diagnosis and after 4 months (±1–2 months) of treatment initiation were extracted. DAS28 was calculated as follows: DAS28 at the time of diagnosis – DAS28 after 4 months (±1–2 months) of treatment initiation. Patients' electronic hospital records including laboratory results were reviewed to reveal if they had been diagnosed with thyroid disease.

**Results:** 1035 patients were included in the study (Table 1). Prevalence of thyroid disease was 11.8% (122/1035). Multiple linear regression analysis showed a negative correlation between DAS28 and presence of thyroid disease adjusted for age, gender, disease duration, RF, anti-ccp and DAS28 at the time of diagnosis (Regression coefficient (95% Confidence Interval): -0.157 (-0.312 to -0.002), P = 0.047) (Table 2). RA patients with thyroid disease had significantly poorer initial response to RA treatment compared to patients with isolated RA after 4 months of treatment (P<0.002).

**Conclusions:** Presence of thyroid disease in RA patients worsens initial treatment response and is suggestive of poor long-term prognosis. The authors propose routine measurement of serum thyroid stimulating hormone (TSH) in all RA patients at the time of diagnosis and with yearly interval.

Objectives: To define the prevalence of PHP in patients with RA.

Methods: All RA patients who were registered in the local part of Danish Danbio registry were included in this study. Patients’ demographic data and serology results (rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (anti-ccp)) were extracted from Danbio. Patients’ electronic hospital records including laboratory results (Parathyroid hormone (PTH) and calcium levels) were reviewed to reveal if they had been diagnosed with PHP as well.

Results: 1035 RA patients were included in this study [table 1]. Prevalence of PHP was 2.8% (29/1035). RA Patients with PHP had significant longer disease duration compared to patients with isolated RA (p<0.003). There was no significant difference between RA patients with and without PHP with respect to age, gender, RF and anti-ccp positivity (Table 1).

Conclusions: Clinicians should pay special attention to higher prevalence of PHP among RA patients compared to the general population. Presence of PHP in RA patients may aggravate the effect of RA on bones and joints by means of interaction with cytokines and inflammatory markers involved in RA. Concurrent PHP can be diagnosed at early stage by testing PTH and calcium levels which minimize the future morbidities e.g. fracture due to osteoporosis.

FR10141 | LEFT VENTRICAL CONCENTRIC REMODELING IS MORE PREVALENT IN RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY

D.A. Galarrza-Delgado1, J.R. Azpiri-López2, I.J. Colunga-Pedraza3, F.J. Torres-Quintanilla4, R.E. Ramos-Cázares5, A. Vaidovinos-Bafuelos6, A. Martínez-Moreno7, R.I. Arvizu-Rivera8, R. Vera-Pineda9, A.A. Cárdenas-de la Garza1, M.A. Garza-Elizondo2, M.A. Benavides-González2, J.A. Silva-Ortiz2, R. Hydrology; 2Cardiology; 3Internal Medicine, Hospital Universitario “Dr. José Eleuterio González”, UANL, Monterrey, Mexico

Background: Patients with rheumatoid arthritis (RA) have a higher risk to develop cardiovascular complications than general population (1), leading to a decrease in life expectancy of 3 to 10 years (2). RA is associated to increased left ventricle mass, pericardial effusion and diastolic dysfunction (3).

Objectives: The aim of this study was to assess the structure and function of the left ventricle in patients with RA and compare the results with matched controls.

Methods: We designed an observational cross-section case-control study. Patients diagnosed with RA according to the 1987 ACR and/or 2010 ACR/EULAR classification criteria, 40–75 years old, with no overlap syndromes, atherosclerotic cardiovascular disease or hypertension were included. Subjects for the control group were matched by sex, age and comorbidities. A board-certified cardiologist performed a transthoracic echocardiogram.

Results: We included a total of 44 RA patients and 26 control subjects. Table 1 summarizes the demographic characteristics for each group. Left ventricular concentric remodeling (LVCR), defined as a relative wall thickness (RWT) ≤ 0.42 cm and a left ventricular mass index (LVMI) > 95 g/m² in women and > 115 g/m² in men, was found in 14 patients (32.6%) of the RA group and 2 subjects (8%) of the control group; this difference was statistically significant (p=0.021). When we analyzed general abnormalities of left ventricle (either LVCR or left ventricular concentric hypertrophy [RWT > 0.42 cm and LVMI > 95 g/m² in women, > 115 g/m² in men]) we found 15 RA patients (34.1%) with abnormalities and 3 subjects in the control group (11.5%) (p=0.037). There were no statistically significant differences among the groups in LVMI, diastolic dysfunction, global longitudinal strain or ejection fraction.

Conclusions: Left ventricle concentric remodeling is more prevalent in RA-patients when compared to controls. Further research is needed to determine the impact of these findings in the clinical prognosis of RA-patients.

References:
[1] Solomon DH, Currin GC, Rimm EB, Cunnancio CC, Karlson EW. Cardiovas-
**Background:** Neutropenia is an uncommon finding in the context of rheumatoid arthritis (RA). The incidence and association with RA features is not yet well-defined.

**Objectives:** To determine the incidence and severity of neutropenia in an early RA inception cohort, explore possible association with RA features and describe its impact on patient's management.

**Methods:** The Scottish Early Rheumatoid Arthritis (SERA) inception cohort prospectively recruited newly diagnosed RA patients (ACR-EULAR 2010 criteria), who were followed-up every 6 months. Patients who developed at least one episode of neutropenia (grade 1: <1000/μL, grade 2: <1500/μL, grade 3: <5000/μL, grade 3: <10000/μL) were compared with patients who never developed neutropenia. Binominal logistic regression was performed, exploring the enter model and using the occurrence of neutropenia as dependent variable.

**Results:** 77 episodes of neutropenia were observed in 60 (8.6%) out of 698 RA patients, who were followed-up for a median (range) time of 18 (6–48) months. Neutropenia occurred in 12 (0–120) [median (range)] months after RA diagnosis. The majority had mild neutropenia (grade 1: n=49, grade 2: n=9, grade 3: n=0; grade 4: n=2) and the mean ± SD number of neutrophils/μL was 1.68±0.35. Of the 77 neutropenic episodes recorded, coexistent lymphopenia was found in 11.5%, leukopenia in 70.1%, thrombocytopenia in 1.3% and anaemia in 32.5%. At the time of the neutropenia, most of the patients were in remission (DAS28<2.6: 53%, DAS28>3.2: 15.5%, DAS28<5.1: 22.4%, DAS28>5.1: 8.6%). Neutropenia was a single episode in the majority (76.7%) of the patients and led to treatment discontinuation in 11.7% of them.

Patients who subsequently developed neutropenia, were more likely females (p=0.03) and non-smokers (p=0.009) [Table 1]. Treatment received for RA was comparable between the two groups. Binominal regression analysis confirmed female gender [p=0.017, Exp(B): 2.587] and not smoking [p=0.032, Exp(B): 2.880] as predictors of neutropenia development. During total follow-up time, patients who had at least one episode of neutropenia they also manifested more commonly anaemia (p=0.04) and lymphopenia (p=0.03). The rate of infections/1000 person-months did not differ between patients who developed neutropenia and those who did not [5.75 (2.47–11.33) vs 4.1 (3.13–5.47), p=0.399].

**Conclusions:** Neutropenia was observed in about 9% of patients in this early RA cohort. It was usually mild, transient and not associated with increased infection rates. Interestingly, not-smoking and female gender were associated with neutropenia.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.5623
Methods: A total of 141 patients (103 female, 38 male) who were diagnosed RA according to ACR (American College of Rheumatology) diagnostic criteria were included in the study. Fatigue Symptom Inventory (FSI) was used for evaluation of fatigue. While the disease activity was determined using the Disease Activity Score-28 (DAS28), the Health Assessment Questionnaire (HAQ) was used to determine functional status. The pain intensity was determined using 10 cm Visual Analogue Scale-Pain (VAS-pain).

Results: The mean age of the patients is 54.67±10.70 years and the mean duration of illness is 14.31±10.89 years. When the relationship between fatigue and other factors was examined, a statistically significant relationship was found between FSI fatigue severity scores (maximum, minimum, mean, current), FSI duration scores (number of days felt tired, amount of time felt tired), FSI interference score and HAQ, number of swollen joints, number of tender joints, VAS rest and VAS motion values (p<0.05). There was a statistically significant lower correlation between FSI fatigue scores (at least, mean) and DAS28 (r: 0.216, r: 0.181, respectively). There was no significant relationship between FSI scores and age, duration of illness, steroid use.

Conclusions: Fatigue affects patients independently of disease duration in patients with RA. Fatigue is associated with disease activity, functional status, and pain. For this reason, fatigue in RA patients should be considered as an important symptom that should not be overlooked and should be struggled.

FR0145 | DOES PAIN HAVE INFLUENCE ON HEALTH ASSESSMENT QUESTIONNAIRE DISABILITY INDEX (HAQ-DI) IN RHEUMATOID ARTHRITIS PATIENT? AN ATTEMPT TO EVALUATE EFFECTIVENESS OF PAIN VAS (PS-VAS) ON HAQ-DI IN REAL CLINICAL PRACTICE –

I. Yoshii 1, T. Chijiwa 2, 1 Rheumatology, Yoshii Hospital, Shimanto City; 2 Rheumatology, Kochi Memorial Hospital, Kochi, Japan

Background: Health Assessment Questionnaire Disability Index (HAQ-DI) is the most important index in treatment for rheumatoid arthritis (RA) patient. HAQ-DI expresses patient’s disability in daily life (ADL), and this is influenced by disease activity (ACT-HAQ) and joint structural damage (DAM-HAQ), and aging when patient gets older in senectitude (AGE-HAQ) (1–3). One more factor that possibly makes influence on HAQ-DI is patient’s pain. However, this problem is not discussed in all.

Objectives: We have investigate patient’s pain and its effect on HAQ-DI in our clinical data in order to evaluate whether pain influences on HAQ-DI, and to make assessment existence of pain related HAQ-DI (PAIN-HAQ).

Methods: RA patients who have been treated continuously for more than five years, who had visited later than October 31th, 2016, were picked up in this study. Patients average 28-joints disease activity score with C-reactive protein (DAS28-CRP), modified HAQ (mHAQ), Sharp/van der Heijde Score (SvdHS), age, and pain score calculated by visual analogue scale (VAS-PS) were calculated in five treatment years. Means and operation values of these parameters have been calculated. Relationships among these factors have been investigated statistically using multiple linear regression analysis (MLR). After evaluation of relationship of each pair of these factors, the relationship between HAQ-DI and the other factors had been evaluated from modified data of these patients in minimize the effect of parameters other than PS-VAS and data that minimized effectiveness of PS-VAS with MLR.

Results: 382 patients had been picked up. Their sex distribution was 87 for male and 295 for female, and their average values and standard deviations of age, DAS28-CRP, HAQ-DI, SvdHS, and PS-VAS were 68.99 and 13.47, 1.91 and 0.54, 0.43 and 0.55, 54.97 and 67.30, and 22.96 and 17.85, respectively. HAQ-DI demonstrated significant regression with all of DAS28-CRP, SvdH, age, and PS-VAS (<0.01). DAS28-CRP demonstrated positive correlation with PS-VAS, HAQ-DI, and SvdHS, but negatively correlated significantly with age (<0.01). PS-VAS demonstrated positive correlation with HAQ-DI and DAS28-CRP, but negatively correlated with SvdHS significantly (<0.01), while no significant correlation demonstrated with age. SvdHS demonstrated positive correlation with DAS28-CRP and HAQ-DI, but negative correlation with PS-VAS significantly (<0.01), while no significant significant correlation demonstrated with SvdHS. Age demonstrated positive correlation with HAQ-DI, but negatively correlated with DAS28-CRP and SvdHS (Figure 1).

After minimizing the data effectiveness of DAS28-CRP, Age, and SvdHS on HAQ-DI, HAQ-DI demonstrated significant regression only with PS-VAS. When the effectiveness of PS-VAS was minimized, HAQ-DI demonstrated significant regression with parameters other than PS-VAS. Threshold of PS-VAS was 15mm.

Conclusions: These results suggested that HAQ-DI is influenced PS-VAS when it is no less than 15mm. Therefore, we conclude that HAQ-DI consists with PAIN-HAQ in adding with ACT-HAQ, DAM-HAQ, and AGE-HAQ.

ANTI-MÜLLERIAN HORMONE LEVELS IN FEMALE RHEUMATOID ARTHRITIS PATIENTS TRYING TO CONCEIVE – THE ROLE OF OVArian FUNCTION IN TIME TO PREGNANCY IN A NATIONALWIDE COHORT STUDY

J. Brouwer1,2, J.S. Laven1, J.M. Hazes1, J.A. Visser3, R.J. Dolhain2.
1Division of Reproductive Medicine - Department of Obstetrics & Gynaecology, University of Luebeck, 2Department of Rheumatology, 3Department of Internal Medicine, Eramus MC University Medical Center Rotterdam, Rotterdam, Netherlands

Background: Subfertility, a time to pregnancy (TTP) >12 months, is present in 40% of women with rheumatoid arthritis (RA) actively trying to conceive. Since RA patients appear to reach menopause at a younger age, the reduced fertility may be caused by a lower ovarian reserve (OR). Serum anti-Müllerian hormone (AMH) levels are currently the most reliable way to measure the OR.

Objectives: Our objective was to study preconception AMH levels and their association with TTP in women with RA.

Methods: A post-hoc analysis was performed in patients of the Pregnancy-Induced Amelioration of RA (PARA) cohort who were assessed preconceptionally. Serum AMH levels were measured using the pico AMH ELISA assay (Ansh Labs, Texas, USA), and compared to converted AMH values from a cohort of 554 healthy adult controls.

Results: Preconception serum was available in 209 women aged 32.1±3.9 years, of whom 45% were subfertile. The median AMH level was 2.5 ug/L (IQR 1.5–4.6). Reduced AMH levels were more pronounced in ACPA positive patients, suggesting the OR may be compromised more strongly in patients with a more severe disease. However, since preconception AMH levels were not associated with TTP, the reduced levels do not explain the reduced fertility in women with RA.

Conclusions: Women with RA have lower AMH levels than healthy controls. Reduced AMH levels were more pronounced in ACPSA positive patients, suggesting that the OR may be compromised more strongly in patients with a more severe disease. However, since preconception AMH levels were not associated with TTP, the reduced levels do not explain the reduced fertility in women with RA.

THE EFFECT OF TNF INHIBITORS, METHOTREXATE (MTX), AND THE OTHER DMARDs THERAPIES ON DIABETIC CONTROL IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA): TREATMENT WITH MTX ALONE IMPROVED DIABETES CONTROL MORE THAN TNF INHIBITORS PLUS MTX

K. Fujikoa, M. Tangik, M. Fuwa, I. Mori, T. Ishizuka. Center of General Internal Medicine and Rheumatology, Gifu Municipal Hospital, Gifu City, Japan

Background: It has been shown that inflammation directly influences insulin and glucose metabolism through cytokines such as TNFα and IL-6. It has also been reported that certain RA drugs such as TNF inhibitors, hydroxychloroquine, and MTX were associated with lower diabetes risk among people with RA, but it is still clinically unknown. On the other hand, it has been shown that MTX is involved in activation of intracellular AMP-kinase and promotes glucose uptake in skeletal muscle (Diabetes, 2015).

Objectives: We examined medical records of patients with new RA patients complicated with glucose intolerance to measure HbA1c, body weight, and HbA1c-ESR for 6 and 12 months treated with TNF inhibitors, MTX, and the other DMARDs.

Methods: Newly registered 20 RA patients complicated with glucose intolerance (HbA1c ≥5.6%) at our hospital from May 2013 to December 2015, have treated with as follows: Treatment with infliximab (1 case), golimumab (3 cases), and etanercept (2 cases) in combination with 4–12mg/week of MTX (group A: 6 cases, TNF inhibitors + MTX), MTX (4–10 mg/week) alone (group B: 8 cases MTX alone). The other DMARDs (group C: 6 cases, the other DMARDs including bucillamine (BCL) + sulphasalazine (SASP) + metformin (MTX); 1 case, BCL+SASP; 1 case, BCL alone; 2 cases and SASP alone; 2 cases) had been registered. We have compared the changes of HbA1c levels, body weight, DAS-ESR from the beginning of the treatments and 6 and 12 months later. RA patients treated with glucocorticoid were excluded. Diabetic treatment were diet and exercise in all the groups. Metformin (500 mg) and DPP4 inhibitor were used in 4 cases (Group A and C). However, each patient in Group B did not use anti-diabetic agents. We analyzed these results with paired and unpaired t test using JMP12.2.0.

Results: These registered RA patients with female were 60.0%. The mean age were 62.1, 53.5 and 63.6 for group A, B, and C, respectively. There were significant changes in DAS-ESR after treatment for 6 months in group A and B, respectively (p<0.01 in group A and p<0.05 in group B). Groups A and B showed significant improvement of DAS-ESR after treatment with 12 months (P<0.0001 in group A, p<0.01 in group B), but no significant differences between DAS-ESR-SR mg and DPP4 inhibitor were used in 4 cases in Group A and C. Each patient in Group B did not use anti-diabetic agents. We analyzed these results with paired and unpaired t test using JMP12.2.0.

Conclusions: In this study, MTX was thought to contribute not only to suppress chronic inflammation but also to improve the glucose tolerance as compared with TNF inhibitors plus MTX and the other DMARDs. Further studies concerns about the interrelationship between glucose tolerance and RA treatments may require.

FR0149

DOES THYROID SUBSTITUTION PREDICT NON-RESPONSE TO METHOTREXATE IN EARLY RA?

K. Waldenlin1, S.A. Saevardottir3, C. Bengtsson2, J. Askling1. 1Rheumatology Unit, Department of Medicine, Solna, Karolinska Institute; 2Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden

Background: Response to treatment varies widely between RA-patients. Our means to predict disease course and treatment response is limited, leading to substantial over- as well as under-treatment. Whereas female gender and smoking have been identified as predictors of non-response, the impact of autoimmune co-morbidities remains largely unknown. Autoimmune thyroid disease (AID) is one of the most frequent autoimmune diseases in the population. AID is more prevalent in RA-patients and has also been identified as a risk factor for RA. AID can be readily identified via thyroxin substitution. We aimed at assessing the impact of prevalent AID in relation to 3- and 6-month EULAR response to methotrexate in early RA.

Objectives: To investigate whether thyroid substitution impacts response to methotrexate as the first-line therapy in RA.

Methods: We identified patients with incident RA (symptom duration <1 year), included in the Swedish Rheumatology Quality Register, who were treated with MTX between January 2011 and October 2015 (n=7099). All patients starting treatment with methotrexate and who had a follow-up visit at 3 months (n=4364) and/or at 6 months (n=3148) were included. Prevalent AID was defined as prescription of thyroid substitution before RA-diagnosis (n=347), based on linkage to the Swedish Prescribed Drug register,
and excluding participants with prescriptions for iodine-containing drugs or history of thyroid cancer (e.g. non-autoimmune cause of thyroxin use). We used a case-control design with thyroxin substitution as exposure, cases defined as EULAR DAS28 3- and 6-month non-responders, and controls defined as moderate/good responders at these time-points. Odds Ratios (OR) were calculated adjusted for study center and age. Results: At 3 months, the proportion of thyroxin users did not differ between responders and non-responders 12% vs. 11%, (OR non-response =1.1, 95% CI 0.9–1.4). At 6 months, the corresponding figures were 13% vs. 11%, respectively, (OR non-response =1.3, 95% CI 1.0–1.7). However, a significant difference was observed between RF and/or ACPA positive patients at 6 months, where 15% of non-responders and 10% of responders used thyroxin (OR non-response=1.6, 95% CI 1.1–2.1), while no such difference was observed for seronegative RA. When stratified for gender, thyroxin substitution was significantly associated with non-response in men but not in women.

Table 1. Relative risk of prevalent AITD before RA diagnosis in non-responders compared to moderate and good responders according to EULAR response criteria, at the 6 month follow-up visit among 3148 RA-patients starting methotrexate as first ever DMARD

Values are the number. RA = rheumatoid arthritis; AITD = autoimmune thyroid disease; OR = odds ratio; 95% CI = 95% confidence interval.

Conclusions: This large real-life study of response to methotrexate in early RA suggests that AITD, measured as thyroxin replacement therapy, may be linked to treatment response in seropositive patients (and among males). Exploratory by nature, these findings call for replication.

RHEUMATOLOGISTS’ EXPERIENCES AND VIEWPOINTS TOWARDS MANAGING RHEUMATOID ARTHRITIS IN ELDERLY PATIENTS: A QUALITATIVE STUDY

J. Nawrot 1, A. Boonen 1, R. Peeters 3, M. Stammans 3, M. Van Omme 1,2
1. Department of Internal Medicine, division of Rheumatology, Maastricht University Medical Center +; 2. School for Public Health and Primary Care, Maastricht University, Maastricht; 3. Rheumatology, Zuyderland Hospital, Heerlen, Netherlands

Background: The number of elderly individuals with rheumatoid arthritis (RA) is expanding in Europe mainly due to an increased life expectancy. As a result, management of these patients, e.g. the application of the treat-to-target and tight control principles, shall have to account for frailty and comorbidity. However, knowledge about how rheumatologists perceive and manage RA in the elderly patient population is limited.

Objectives: To explore the viewpoints of rheumatologists on management goals in elderly RA patients and the influence of factors such as age, frailty and comorbidity on these goals. Furthermore, experiences of rheumatologists with regard to outcome instruments to guide management in elderly patients were assessed.

Methods: A qualitative study involving semi-structured interviews with rheumatologists was conducted. Two readers independently annotated the transcripts of the interviews. Important concepts were taxonomically categorized and later combined in overarching themes by using NVivo 11.

Results: Seventeen rheumatologists were purposively sampled from nine medical centres (mean age 44.6 years (SD 7.7 years; 85.3% female)). High levels of frailty and comorbidity frequently influenced management goals of rheumatologists. In these cases, preserving an acceptable functional status prevailed over the treat-to-target and tight control principles. For instance, most rheumatologists accepted the presence of tender and swollen joints when overall functioning and social participation were not or only minimally impaired. In patients >80 years, age instead of frailty and comorbidity was the most prominent factor that steered management. On that line, almost all rheumatologists admitted that their management strategy is less driven by the result of the Disease Activity Score-28 (DAS28), since comorbidity (e.g. osteoarthritis) and an age-related physiological Erythrocyte Sedimentation Rate (ESR)-elevation might distort the DAS28 value. Instead, before adapting anti-rheumatic therapy, rheumatologists weighted the frailty and comorbidity levels of a patient and the functional consequences of these factors such as cognitive and physical decline, dependency and polypharmacy (quote 1, Table 1). This frequently resulted in a less future-oriented management approach that was not aimed at the maximal prevention of joint erosions and deformities (quote 2, Table 1). Rheumatologists reported that a lack of time to evaluate all comorbid conditions, as well as contradictory advices of other medical specialists often complicated the management of elderly RA patients.

Conclusions: Commonly accepted RA treatment paradigms such as treat-to-target and tight control are not automatically adopted in the elderly patient population. Maintaining a patient acceptable functional status prevails. Future RA management recommendations for elderly RA patients are needed and should account for factors such as frailty and comorbidity.

COMPARISON OF CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICS vs METHOTREXATE: RESULTS AT 24-MONTHS OF FOLLOW-UP

M. Khraish1, M. Stutz2, A. Lewis3, C. Mota4, E. Rampakakis2, 2. Rheumatology, Memorial University of Newfoundland, St. John’s; 2. JUS Medical Research, St-Laurent; 3. Epidemiology, Memorial University of Newfoundland, St.John’s, Canada; 4. Rheumatology, MainLine Rheumatology Lankena Medical Center, Philadelphia, United States

Background: Rheumatoid arthritis (RA) is associated with increased risk of atherosclerosis. Cardiovascular (CV) disease. Treatment with conventional systemic disease modifying drugs (csDMARDs) such as methotrexate (MTX), as well as biological DMARDs (bDMARDs), has been shown to decrease CV risk. Although bDMARDs specifically target inflammation common to RA and atherosclerosis, whether or not cardioprotective effects associated with bDMARD use is superior to csDMARD use remains to be determined.

Objectives: To investigate 10-year CV risk, and incidence of new myocardial infarctions (MI), in RA patients treated with either MTX or bDMARD mono/combination therapy, in a Canadian routine clinical care setting

Methods: RA patients were prospectively followed between January 2011-March 2014. Parameters collected were patient demographics, RA disease activity parameters, traditional CV risk factors, lipid parameters, and 10-year CV risk, assessed using the Framingham Risk Score (FRS). Between-group differences in change from baseline to month 24 in FRS, disease activity, and lipid parameters were assessed with the two sample t-test or the Chi-Square statistic; within-group differences were assessed with the paired-sample t-test or the McNemar-Bowker test. Adjusted change in FRS was ascertained using general linear models, and logistic regression identified predictors of MI.

Results: A total of 517 RA patients receiving bDMARDs (n=313) or MTX (n=199), were included. Mean (SD) age was comparable between cohorts [57.57 (11.71) vs. 59.58 (11.0)], N=0.11; bDMARD vs. MTX, respectively], as was female gender [76.7% vs. 73.9%, p=0.268]. Patients receiving bDMARDs had significantly (p<0.05) longer mean (SD) RA duration [12.63 (9.95) vs. 7.86 (6.94) years] and higher total comorbidities [3.96 (2.53) vs. 3.38 (2.32)]. Mean (SD) baseline FRS was 11.84 (9.38) vs. 12.36 (9.19) percent (p=0.564; bDMARDs vs. MTX, respectively), and patient distribution across low (62.3% vs. 54.8%), intermediate (9.9% vs. 12.2%) and high (27.8% vs. 33.2%) FRS risk categories was comparable (p=0.239).

At month 24, FRS category remained stable in bDMARD patients (low: 58.6%; intermediate: 14.2%; high: 27.0%; p=0.380), whereas a shift in FRS category was observed in MTX patients (low: 69.6%; intermediate: 10.1%; high: 27.0%, p=0.006). Within-group changes in FRS were significant for both MTX (p<0.001) and bDMARD patients (p=0.016). Adjusted mean change (SE) in FRS was higher in MTX patients [-1.37 (0.30) vs. -0.72 (0.25)], although not statistically different (p=0.08). Similar between bDMARDs and MTX [OR (95% CI): intermediate: 1.3% vs. 2.7%; p=0.153; MTX vs. bDMARD: 0.3%; p=0.421], and predictors [OR (95% CI)] identified were: higher total comorbidities [1.45 (1.24, 2.20), p<0.001], age [1.07 (1.00, 1.13), p=0.037], and male gender [4.00 (1.38, 11.57), p<0.01].

Conclusion: FRS decreased in significant manner in CV risk at 24 months was observed during treatment with both MTX and bDMARDs. As predictors of MI did not include several established CV risk factors, longer studies, as well as the development of an RA-specific tool, may permit better assessment of CV risk in RA patients.

FR0155 PREVALENCE OF HBV INFECTION AND RISK OF REACTIVATION ON BIOLOGIC TREATMENT: A POPULATION-BASED OBSERVATIONAL STUDY OF RHEUMATOID ARTHRITIS SUBJECTS IN A NORTHERN ITALY AREA
M. Meroni1,2, L. Sangiovanni3, E. Lupi1, S. Fagliolu3, M. Limonta1, T.Rheumatology Unit, ASST Papa Giovanni XXIII, Bergamo; 2Research Laboratory and Academic Division of Clinical Rheumatology, Internal Medicine Dept., University of Genova, Genova; 3Gastroenterology and Transplant Hepatology Unit, ASST Papa Giovanni XXIII, Bergamo, Italy

Background: The introduction of biologic agent’s treatment in rheumatic diseases dramatically changed their outcome, but raised many concerns about infections reoccurrence. Due to the prevalence of hepatitis B virus (HBV) among Italian general population (1.2%) and the possibility of HBV reactivation in case of an immunosuppressive treatment has to be considered.

Objectives: Aim of this prospective, population-based observational study was to assess the prevalence of HBV (both in chronic carriers and reactivated) rheumatoid arthritis (RA) patients in our setting; to verify if these findings were in line to the Italian and European-reported data; finally, to evaluate the final outcome of HBV RA subjects.

Methods: We enrolled the totality of RA patients treated by biologics and, therefore, considering our Unit at least every 12th of November 2015 to January 2017. Acme of action. We collected called FESITEST (FRA) and ASSL) guidelines, every subject was screened for HBV before starting biologic treatment. Descriptive statistics was performed. Acute infection; previous (resolved) infection; inactive and active carrier; and vaccine-immunized subjects were defined according to

Results: A totality of 265 RA patients (female 56.3%; male 43.7%; mean age 36±20 years) underwent biologic treatment after the screening (HBSAg subjects were excluded). The huge majority of them (82%) was treated by TNF-alpha inhibitors (TNFi), since the remaining received biologic agents with different mechanisms of action. We overall detected 33 (12.5%) inactive carriers, for whom HbsAg and HBV DNA periodical monitoring was suggested; in 3 of them (1.1% of the study population), HBV DNA became detectable, with a low viral load (<2000 UI/ml); they prosecute the biologic therapy after the introduction of the standard prophylaxis (lamivudine 100 mg daily) and a more strictly (periodic liver enzymes elevation and liver ETG evaluation) monitoring.

In occasion of the screening, we observed 6 (2.3%) HBV-immunized (due to vaccine) and 6 (2.3%) previously infected (HbcAb+) patients: for the first ones no action is required, since the latter were put on standard prophylaxis before undergoing biologic agent and monitored. One of them (0.38%) developed, after 6 months of treatment, HBV reactivation with high-level (>2000 UI/ml) detectable DNA and liver enzymes elevation (<normality x3). She was therefore stopped from receiving biologic agent and put on entecavir 1 mg daily.

Interpretation of HBV serologic test results

Conclusions: Our prospective, population-based observational study, performed in a first-level referring Hospital in a highly populated area, suggests some considerations. In a way, our data reported a significantly higher prevalence of HBV infection “contact” among our RA population, in comparison to the general one (p<0.05). This issue has previously been reported and could be justified but the generally higher HBV diffusion in certain area (i.e., Italy); by the age/ethnicity of the sample; and, finally, by the bias consisting in an extensive screening of these patients. On the other hand, our experience suggests that a light monitoring of parameters predicting infectious flare should lead to a prompt diagnosis and a lower number of complications for these peculiar patients, as observed in our population.

FR0156 DO CHANGES IN ADIPOCYTOKINES CORRELATE WITH CHANGES TO DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS? FINDINGS FROM THE TOMORROW STUDY
M. Tada1, K. Inoue2, Y. Sugioka3, T. Okano2, K. Mamoto2, T. Koike3, H. Nakamura2, 1Orthopaedic Surgery, Osaka City General Hospital; 2Orthopaedic Surgery; 3Center of Senile Degenerative Disorders, Osaka City University Graduate School of Medicine, Osaka, Japan

Introduction: Cytokines released from mast cells evoke inflammation and correlate with arteriosclerotic lesions and autoimmune disease. The relationship between autoimmune disease activity and lipid metabolism is a notable in research surrounding rheumatoid arthritis (RA). RA patients without disease control reportedly show high titers of leptin or adiponectin as adipocytokines.

Objectives: We analyzed the interaction between changes in disease activity and adipocytokines using data from the TOMORROW (Tomorrow: Risk factors in Rheumatoid arthritis patients to lower morbidity and mortality clinical trial) study, a 10-year prospective study (registration number, UMIN000003876).

Methods: We analyzed data collected from the cohort of the TOMORROW study including 193 patients with RA and age- and sex-matched 194 healthy individuals (controls). We compared changes in leptin and adiponectin (Δleptin and Δadiponectin) in both groups between baseline and after 3 years. Correlations with the change in disease activity (ΔDAS28ESR) during 3 years and changes in Δleptin and Δadiponectin in RA were investigated by univariate analysis.

Results: Leptin levels increased in both groups. No significant differences in Δleptin were seen between RA (0.29 μg/ml) and controls (0.18 μg/ml; p=0.37). On the other hand, adiponectin was significantly decreased in controls (-3.3 μg/ml) compared to RA (-1.8 μg/ml; p=0.01). Negative correlations between Δleptin and Δadiponectin were detected in the RA group (r=-0.29, p<0.01). The correlation between adiponectin and DAS28ESR was positive both at baseline (r=0.22, p=0.01) and after 3 years (r=-0.18, p=0.01). However, no such tendencies were seen for leptin. Table 1 shows details of the correlations with changes in adipocytokine. In terms of the relationship with ΔDAS28ESR, no correlation was seen with Δleptin (r=0.07, p=0.31) or Δadiponectin (r=-0.01, p=0.91). Changes in lipid metabolic markers and fat percentages were detected as predictive factors for Δadiponectines.

Table 1. Correlations with changes in adipocytokine by univariate analysis

FR0157 FERTILITY IN WOMEN WITH RHEUMATOID ARTHRITIS COMPARED TO HEALTHY CONTROLS
M.E.B. Clowse, G. McDaniel, A.M. Eudy, Rheumatology, Duke University Medical Center, Durham, United States

Background: Data suggest infertility is increased in women with rheumatoid arthritis (RA) compared to healthy women. Therefore, it is possible that diminished ovarian reserve and ovulatory dysfunction may be more common among women with RA.

Objectives: To compare differences in ovarian reserve and ovulatory frequency, as well as self-reported infertility, between women with and without RA.

Methods: Women with RA aged 20–40 yrs in a university clinic without a history of ovarian surgery or prior exposure to possible ovary-toxic medications were invited to participate in a cross-sectional survey. Healthy controls were women aged 20–40 without an autoimmune disease, matched for age and current use of hormonal contraceptives. Infertility was defined as a patient reporting physician-diagnosed infertility or being unable to get pregnant after a certain number of attempts of trying. Ovarian reserve was assessed by measuring anti-Müllerian hormone (AMH). In women who were not taking hormonal contraceptives, progesterone level was measured from a serum sample drawn between days 21 and 23 of the menstrual cycle. Anovulation was defined as a progesterone level <3 ng/mL. In
In patients with RA, increased serum levels of vWF and impaired group with thicker IMT (p=0.046), as well as the percentage of men (p=0.030). Patients with RA is divided into two groups according to the value of the IMT, than in controls (0.89±0.13 mm) (P=0.001). FMD% was significantly lower in patients with RA (3). Prothrombotic markers have been shown to be able to have been found to be useful in the assessment of the cardiovascular risk of disease, as a consequence of accelerated atherosclerosis found in this diseases (1). Finding methods for assessing vascular dysfunction during the early stages of the disease is important, particularly in patient groups at high CV risk (2).

Background: In rheumatoid arthritis (RA), higher mortality is mainly due to cardiovascular comorbidities over time. Previous studies have shown that this is attributable to cardiovascular and respiratory disease. Over recent years earlier and more aggressive treatment with higher dosage of methotrexate and the earlier use of biologic drugs has improved disease outcomes. The effect on cause of death is unknown. In this retrospective cohort study we found the major cause of death in RA was infection followed by malignancy and found no correlation with seropositivity or gender.

Objectives: To analyse the causes of death in RA patients treated with aggressive disease modifying anti rheumatic drugs (DMARD) and Biological therapies over a 6 year period.

Methods: Patients with RA who died between 2010 and 2016 were identified using the DAWN software DMARD monitoring database. A cohort of 3106 patients with RA are monitored using DAWN software in Berkshire, UK. The causes of death were identified from medical records, general practice records or the local coroner’s office.

Results: 198 patients on DAWN monitoring died during the 6 year study period. Treatment details and cause of death was identified for 131 RA patients. 71% were seropositive for rheumatoid factor and 61% were female. 91 patients (69%) were treated with methotrexate, 28 hydroxychloroquine (21%), 14 sulphasalazine (21%) and 7 with leflunomide (5%). The majority of patients (81) were on monotherapy (61%), 32 were on 2 DMARDS (24%) and only one was on triple therapy. 4 patients with RA who died were on biologic monotherapy, 10 were treated with biologic and combination DMARD. The most commonly prescribed biologics were etanercept (35%) and rituximab (35%). The leading causes of death in this cohort were pneumonia (39 patients 29%), cerebrovascular disease (16 patients 12%), septicaemia (11 patients 8%) and lung cancer (6 patients 4%). Infection accounted for 57% patients’ deaths (43%) followed by malignancy in 24 patients (18%). Cerebrovascular disease (20 patients, 15%) and cardiovascular disease (13 patients, 9%) were less frequent causes of death in our cohort. Comorbidity data for the cohort was recorded pre-mortem. 49 patients (37%) had cardiovascular disease and 23% had an endocrine comorbidity (predominantly diabetes).

Conclusions: In our large cohort of aggressively treated RA patients, infection followed by malignancy and not cardiovascular disease, was the leading cause of death. Larger prospective studies will be required to see if cumulative drug toxicity of more aggressive early treatment improves outcome from RA but changes mortality from comorbidities over time.

Disclosure of Interest: None declared

FR10159 Infection and malignancy are now the major causes of death in aggressively treated rheumatoid arthritis patients

1. St George’s University of London, London, UK; 2. Rheumatology, Royal Berkshire NHS Foundation Trust, Reading, UK

Background: Patients with rheumatoid arthritis (RA) have an increased mortality compared to the general population. Previous studies have shown that this is attributable to cardiovascular and respiratory disease. Over recent years earlier and more aggressive treatment with higher dosage of methotrexate and the earlier use of biologic drugs has improved disease outcomes. The effect on cause of death is unknown. In this retrospective cohort study we found the major cause of death in RA was infection followed by malignancy and found no correlation with seropositivity or gender.

Objectives: To analyse the causes of death in RA patients treated with aggressive disease modifying anti rheumatic drugs (DMARD) and Biological therapies over a 6 year period.

Methods: Patients with RA who died between 2010 and 2016 were identified using the DAWN software DMARD monitoring database. A cohort of 3106 patients with RA are monitored using DAWN software in Berkshire, UK. The causes of death were identified from medical records, general practice records or the local coroner’s office.

Results: 198 patients on DAWN monitoring died during the 6 year study period. Treatment details and cause of death was identified for 131 RA patients. 71% were seropositive for rheumatoid factor and 61% were female. 91 patients (69%) were treated with methotrexate, 28 hydroxychloroquine (21%), 14 sulphasalazine (21%) and 7 with leflunomide (5%). The majority of patients (81) were on monotherapy (61%), 32 were on 2 DMARDS (24%) and only one was on triple therapy. 4 patients with RA who died were on biologic monotherapy, 10 were treated with biologic and combination DMARD. The most commonly prescribed biologics were etanercept (35%) and rituximab (35%). The leading causes of death in this cohort were pneumonia (39 patients 29%), cerebrovascular disease (16 patients 12%), septicaemia (11 patients 8%) and lung cancer (6 patients 4%). Infection accounted for 57% patients’ deaths (43%) followed by malignancy in 24 patients (18%). FR10158 Evaluation of inflammatory cardiovascular (CV) risk factors in pre- and post-menopausal females with rheumatoid arthritis (RA)

D.O. Garmish, V. Lechencko, V. Kovalenko. NSC “Institute of Cardiology named M.D.Strazhko NAMS of Ukraine”, Kiev, Ukraine

Objectives: To assess inflammatory markers and peripheral vessels involvement as markers of cardiovascular risk in female patients with RA.

Methods: 105 female patients who fulfill ACR/EULAR 2010 criteria were examined. Laboratory assessments consisted of biochemistry and hematological analysis, measuring of CRP level, rheumatoid factor, anti-CCP level, total cholesterol, HDL, LDL, triglycerides, apolipoprotein A1, apolipoprotein B, uric acid, HbA1c, microalbuminuria. DAS28 was used in characterizing RA activity. CV risk was defined per mSCORE. Tibial artery and carotid artery ultrasonography examination included the measurement of IMT in 3 points, detection of focal plaques in the extracranial carotid tree, blood flow velocity and morphology of the extracranial carotid tree.

Results: 83.3% reproductive age patients were without CV risk, 11.1% experienced middle level and 5.6% low level of CV risk on mSCORE. In 96.1% postmenopausal patients moderate, high and very high CV risk was detected. According to multiple logistic regression analysis we identified CV risk factors:
NON-INVASIVE ASSESSMENT OF MYOCARDIAL PERFUSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Anytari1, N. Koletsos1, A. Triantafyllou1, S. Chatzimichailidou2, G. Triantafyllou1, P. Panagopoulos1, E. Oikakiou1, S. Aslanidis1, S. Douma3, 13rd Department of Internal Medicine, Papageorgiou Hospital; 2nd Propedeutic Department of Internal Medicine, Hippokration Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Cardiac involvement among patients with rheumatoid arthritis (RA) is common, potentially life-threatening, but often underdiagnosed at presymptomatic stages. Subendocardial viability ratio (SEVR) reflects microvascular coronary perfusion and it correlates with the ratio of subepicardial to subendocardial blood flow, that can be non-invasively estimated by applanation tonometry. Although it has been studied as a surrogate measure of myocardial perfusion in high-cardiovascular risk populations, it remains unclear whether it is affected in RA patients.

Objectives: The purpose of the study was to compare SEVR between RA patients and healthy controls. We additionally sought predictors of SEVR in RA among a wide range of disease-related parameters, hemodynamic factors, and markers of atherosclerosis, arteriosclerosis, and endothelial dysfunction.

Methods: Consecutive patients with RA and healthy, nontreated volunteers were recruited. SEVR was estimated from applanation tonometry with the Sphygmocor device (AtCor Medical, Sydney, Australia), which was also used to evaluate arterial stiffness (aortic index, Aix; pulse wave velocity, PWV). In the RA group, carotid atherosclerosis was additionally evaluated by ultrasound (carotid intima-media thickness, cIMT); cardiac and hemodynamic parameters by impedance cardiography, and endothelial dysfunction by measurement of asymmetric dimethylarginine (ADMA) in serum samples.

Results: A total of 122 participants, 91 RA patients and 31 controls, were studied. SEVR was significantly lower among RA patients compared to controls (141.4±21.9 vs 153.1±18.7%, p<0.005), and the same was observed when the subgroup of RA patients without cardiovascular comorbidities (n=29) was studied separately (139.7±21.7 vs 153.1±18.7%, p=0.013). In the univariate analysis, SEVR significantly correlated with cardiac and hemodynamic parameters, but not with PWV, Aix, cIMT, ADMA, or disease-related parameters. In the linear regression analysis accounting for sex, statin use, markers of atherosclerosis, carotid, and hemodynamic parameters, female gender (p=0.007), blood pressure (p=0.028), heart rate (p=0.025), cholesterol levels (p=0.008), cardiac index (p<0.001), and left ventricular ejection time (p=0.004) were identified as independent predictors of SEVR among patients with RA.

Conclusions: Patients with RA exhibit lower values of SEVR compared to healthy individuals, suggesting a disturbed balance between oxygen supply and demand that might lead to an additional pathophysiological link for the increased cardiovascular burden in RA. Cardiac and hemodynamic parameters, rather than markers of atherosclerosis, arteriosclerosis, and endothelial dysfunction, may be useful as predictors of impaired myocardial perfusion in RA.

INVESTIGATION OF THE PERIODONTAL CONDITION AMONG RHEUMATOID ARTHRITIS (RA) PATIENTS AND ANALYSIS OF INFAMMATORY MEDIATOR IN THEIR SERUM AND GINGIVAL CREEVICAL FLUID (GCF)

Xiao F, Zhang X, Li Y, Mou H, Chen Z. The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Rheumatoid arthritis (RA) and periodontitis (PD) are common chronic inflammatory diseases with remarkable pathological and clinical similarities. A lot of similarities exist between RA and PD at cellular and molecular levels.

Objectives: To analyse the PD incidence among RA patients, measure the level of tumor necrosis factor-alpha (TNF-α), Interleukin-1 (IL-1) and Interleukin-6 (IL-6) in their serum and gingival crevicular fluid (GCF), and to investigate their correlations.

Methods: The experimental group was composed of 350 patients with RA and the control group consisted of 426 age and gender matched healthy individuals. checks and record periodontal condition by dentist, analyse the PD incidence of the two groups, then select 64 PD patients without systemic diseases and 47 PD patients with a stable condition of RA. Detect and compare their periodontal status and the level of TNF-α, IL-1β and IL-6 in their serum and GCF.

Results: The percentage of PD was 67.7%, which was statistically significant higher than control group (43.6%) (P < 0.001). The periodontal disease index (PDI), Probing depth (PD) and Clinical attachment loss (CAL) in patients with RA and PD are significantly higher than those with simple PD (P < 0.05). But the bleeding on probing (BOP) in the two groups was not statistically significant (P > 0.05). Meanwhile, the level of TNF-α, IL-1β and IL-6 in serum and GCF are significantly higher in all PD patients than oral healthy individuals (P < 0.05). Although those inflammatory mediators in serum are much higher in patients with PD and RA than in those with simple PD (P < 0.01), there is no difference in the two groups about those inflammatory mediators in GCF. The serum level of TNF-α, IL-1β and IL-6 in patients with PD and RA are positively correlated with the corresponding inflammatory mediators in their GCF (r = 0.510.422 and 0.777 respectively, P < 0.01).

Conclusions: Individuals with RA are more likely to experience periodontitis compared to healthy subjects, and the periodontitis is much more serious in patients with RA and PD than those with simple PD. The serum and GCF inflammatory factors' level increased significantly in patients with RA and PD even during their RA stable period. The serum level of inflammatory factors in patients with PD and RA are positively correlated with the corresponding inflammatory mediators in their GCF. There is correlation between periodontitis and RA, and they may be the risk factors for each other. The improvement of the periodontal status of RA patients with RA and PD may help to control systemic inflammatory symptoms.

Differences Between RA Patients With and Without ILD From a United States Tertiary Referral Center

P. Meehan1, J. Solomon1, J. Crooks1, D. Muram1, E. Hoffman1, P. Zelarney1.
1National Jewish Health, Denver; 2Eli Lilly and Company, Indianapolis, United States

Objectives: To describe the characteristics of RA patients with and without ILD and to determine if medication use constitutes a risk factor for the development of ILD.

Methods: The medical records of RA patients with and without ILD treated at one academic center between 2008 and 2016 were analyzed. Data extracted include: patient demographics, serology, medication use, prednisone (mMARDs, biologics or small molecule drugs), and self-reported disease activity as MDHAQ and Rapid3 scores. The subtype of ILD was based upon HRCT imaging, and some patients through histology. Differences between RA-ILD patients and RA patients without ILD were determined by Fisher's exact test, and t-tests with a P < 0.05 were considered statistically significant.

Results: The demographics and clinical data of 1,024 RA non-ILD patients and 96 RA-ILD patients indicate ILD patients were older males, had a higher mortality and were less likely to have been never smokers (Table 1). At the onset of ILD (diagnosis, 31% were on no medication, 35% on monotherapy (MTX 16%, prednisone 13%, Etanercept 7%, Adalimumab or LEF 5%, Rituximab 4%, HCO 3%, and ≤1% on infliximab, SSZ or tocilizumab) and 11% received combination therapy. Twenty percent of the RA-ILD patients developed ILD preceding or coinciding with the diagnosis of RA. After the onset of ILD those patients were more likely to receive prednisonex and less likely to receive MTX than those without ILD (P < 0.05). The predominant types of ILD were as follows: UIP 27%, NSIP 15%, NSIP vs UIP 14%, and unclassifiable 9%.

Conclusions: RA-ILD patients differed from RA patients without ILD in demographic characteristics, but not in self-reported measures of disease activity or serology. Thirty one percent of RA-ILD patients were not on any immunomodulatory medications at the time of ILD diagnosis, and 25% of RA-ILD patients developed ILD preceding, or coinciding with, the onset of active RA. Our results did not identify a specific drug class or biologic agent as a risk factor for developing ILD in RA patients.

SERUM FREE LIGHT CHAINS OF IMMUNOGLOBULINS IN RHEUMATOID ARTHRITIS: CORRELATION WITH INTERSTITIAL LUNG DISEASE

S. Beighl1, S. Lataou1, S. Ferchichi2, K. Baccouche1, N. Elami1, K. Limam2, R. Tegliau1, E. Bouajina1. 1Rheumatology Department; 2Laboratory of Biochemistry, Farhat Hached Hospital, Sousse, Tunisia

Background: Lungs in Rheumatoid arthritis (RA) seem to play an important role, not only as an extra-articular manifestation but also as a site of initiation of the disease and activation for the immune response. B lymphocytes are thought to be involved in the pathophysiology of RA and interstitial lung disease (ILD). The encouraging results of the use of Anti-CD20 treatments to stabilize articular symptoms and lung involvement reinforce this theory. Serum Free immunoglobulin Light Chains (FLC) might represent, in this context, an interesting marker of B lymphocytes activation during this disease.

Objectives: To determine the serum FLC levels in RA patients with and without ILD and to study their possible association with disease characteristics and activity.

Methods: Fifteen RA patients with clinically symptomatic interstitial lung disease, confirmed by computed tomography (RA-ILD) (53.3% females; mean age 61.27±6.48 years) and age matched RA patients (66.7% females) with no evidence of interstitial disease (non-ILD) were studied. Clinical and immunological inflammatory characteristics were assessed for all patients. FLC levels were quantified by turbidimetry (Freelite TM Kappa and Lambda Kits, The Binding Site, UK).

Results: The mean serum FLC-κ levels (RA-ILD: 40.74±16.94 ng/ml vs non-ILD 24.88±8.87 ng/ml, p=0.003) and FLC-λ levels (RA-ILD: 37.34±16.56 ng/ml vs non-ILD 26.28±7.22 ng/ml, p=0.028) were significantly higher in patients with ILD compared to non-ILD, while the serum FLC-κ/λ (RA-ILD: 1.15±0.38 vs non-ILD 1.00±0.43, p=0.304) were comparable.

There was no significant difference for the DAS28 disease activity score between both groups (RA-ILD: 4.6±1.5 vs non-ILD 4.38±1.46, p=0.69). No significant correlations were found between the DAS28-score and FLC-κ, FLC-λ and FLC-κ/λ (p=0.05). FLC-κ levels correlated significantly with ESR and CRP levels (p=0.01), while FLC-λ levels (p=0.005) but not with ESR (p=0.247) and FLC-κ/λ did not correlate with both ESR and CRP levels.

Conclusions: High levels of serum FLC are associated with RA-ILD and with a higher degree of inflammation, supporting the role of B cell activation in the pathophysiology of RA with ILD.

DIFFERENCES BETWEEN RA PATIENTS WITH AND WITHOUT ILD FROM A UNITED STATES TERTIARY REFERRAL CENTER

FR0165

RADIOPHORIC STRUCTURAL DAMAGE IS WORSE IN THE DOMINANT THAN THE NON-DOMINANT UPPER EXTREMIT Y IN PATIENTS WITH RHEUMATOID ARTHRITIS

FR0166

Nakazaki S, Murayama S, Kato S. 1Rheumatology, Johoku Hospital; 2Rheumatology, Kamiyari Clinic, Kanazawa, Japan

Background: The relationship between mechanical stress and radiographic damage in rheumatoid arthritis (RA) has been detected in patients with hemipelgingia or poliomyligitis. In patients without neurological disorder, Kohn reported that radiographic damage was worse and progressed faster in the dominant hand in patients with RA.
individuals with early RA\(^2\). However, few studies have detected the radiographic damage in the whole upper extremity on the mechanical stress. **Objectives:** To examine the relationship between mechanical stress and radiographic damage in RA, we evaluated the joint destruction of the dominant and non-dominant upper extremity.

**Methods:** The joint destruction of the upper extremity (shoulder, elbow, wrist, metacarpophalangeal, interphalangeal, proximal interphalangeal) in 295 patients with RA, who were from 25 years to 91 years (mean age 64 years, mean disease duration 183 months, 86% females and 97% right-handed), was assessed according to the eroded joint, which was defined as ≥ 2 by Larsen scores for radiographic damage. These were divided into the dominant and non-dominant upper extremity. The Wilcoxon signed-rank test was used to examine the difference between the eroded joint count (EJC) in the dominant and the non-dominant upper extremity.

**Results:** The mean EJC in the dominant and the non-dominant upper extremity was 2.4 and 2.05 respectively. The EJC was significantly more in the dominant than the non-dominant upper extremity. And, in regards to every joint of upper extremity, the eroded joint rate was higher in the dominant than the non-dominant extremity.

**Conclusions:** The joint destruction was significantly more in the dominant than the non-dominant one, therefore it was suggested that the mechanical stress influenced the radiographic damage in patients with RA.

**COMPARATIVE CARDIOVASCULAR SAFETY OF ABATACEPT AND TUMOR NECROSIS FACTOR INHIBITORS IN RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT CARDIOVASCULAR DISEASE: A POPULATION-BASED COHORT STUDY**

Y. Jin\(^1\), E.H. Kang\(^2,3\), G. Brill\(^4\), R.J. Desai\(^1\), S.C. Kim\(^4,5\)

\(^1\)Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo; \(^2\)Division of Rheumatology, Saitama Medical Center, Saitama Medical University; \(^3\)Division of Rheumatology, Immunology and Allergy, Brigham and Women’s Hospital, Harvard Medical School, Boston, United States; \(^4\)Division of Rheumatology Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of; \(^5\)Division of Rheumatology, Brigham and Women’s Hospital, Harvard Medical School, Boston, United States

**Background:** Rheumatoid arthritis (RA) patients have an increased risk of cardiovascular disease (CVD). Recent studies suggested that treatment of RA with tumor necrosis inhibitors (TNFi) can reduce the risk of cardiovascular events. However, it is unknown whether a selective costimulation modulator, affects cardiovascular risk among RA patients compared with TNFi.

**Objectives:** To evaluate the comparative cardiovascular safety of abatacept versus TNFi in RA patients with and without underlying CVD.

**Methods:** We identified RA patients aged ≥18 with ≥2 RA ICD-9 codes (714.xx) separated by >7 days but <365 days, from two large insurance claims data across the U.S.: Medicare (2008–2013) and Truven MarketScan (2006–2015). Only new users of abatacept or TNFi (adalimumab, etanercept, certolizumab, golimumab, and infliximab) were included. The primary outcome of interest was a composite endpoint of CVD including myocardial infarction (MI), stroke/transient ischemic stroke, or coronary revascularization. Secondary outcomes were each component of the primary outcome, incident heart failure (HF), and venous thromboembolism (VTE). 1:1 propensity score (PS) matching was performed separately in each database and each subgroup (with or without baseline CVD). Then the PS-matched subgroups were aggregated to form the overall matched cohort. Cox regression model was used to estimate the hazard ratio (HR) and 95% confidence interval (CI) of risk of each outcome. Estimates from two different databases were combined through an inverse variance-weighted fixed-effects model.

**Results:** After 1:1 PS matching, there were 6,102 patient pairs from Medicare and 6,934 pairs from MarketScan. Among them, patients with baseline CVD were 35.3% in Medicare and 14.0% in MarketScan. Baseline characteristics were well balanced between two treatment groups after matching (standardized mean difference <0.1). In Medicare cohort, abatacept consistently showed a decreased risk of composite CVD compared with TNFi in overall and each subgroup (Figure). However, in MarketScan cohort, proportion of patients younger than Medicare cohort, there was no association between abatacept and CVD compared to TNFi. After combining the two databases, abatacept was significantly associated with reduced risk of composite CVD outcome vs. TNFi in overall cohort (HR =0.79, 95% CI=0.67–0.92) and baseline CVD subgroup (HR =0.79, 95% CI=0.64–0.98). We also observed similar trend for secondary outcomes, where abatacept had decreased risk than TNFi.

**Conclusions:** In this large multi-database population-based study of RA patients, abatacept treatment was associated with reduced risk of CVD compared to TNFi, especially among older population and patients with prior CVD conditions.

\(^1\)Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo; \(^2\)Division of Rheumatology, Saitama Medical Center, Saitama Medical University; \(^3\)Division of Hematology, Saitama Medical Center, Saitama Medical University, Saitama, Japan

**Background:** Lympho-proliferative disorder (LPD) is known as a relatively rare but life-threatening complication in RA patients under MTX administration. Spontaneous regression of LPD after MTX withdrawal is regarded as a distinct character of LPD under MTX administration. Previous study from our institution [1] and others [2] reported the link between decreased lymphocyte counts at LPD diagnosis and restoration after MTX cessation and the regression of LPD.

**Objectives:** To investigate the immunological factors including lymphocyte subset which involved in spontaneous regression of LPD following MTX withdrawal.

**Methods:** We studied 35 RA patients complicated with LPD under MTX administration in our institution. Age, sex, RA disease duration matched control MTX-treated patients (N=25) were selected. LPD patients were divided into two groups regarding to the status of LPD after MTX cessation: regressive group (N=22) and persistent group (N=13). Clinical features were compared among 3 groups. Flowcytometric analysis of the whole blood sample and measurement of cytokine core concentration in RA patients under MTX administration. Following MTX cessation, significant increase in proportion and absolute number of these subsets were observed only in the regressive group, but not in persistent group. Regression of Th1 cells and EMCD8+ T cells significantly correlated with increase of serum IFN-γ, and expansion of EMCD8+ T cells inversely correlated with change of serum IL-15.

**Conclusions:** Restoration in proportion and absolute number of Th1 cells, EMCD8+ T cells and EBV specific CD8+ T cells coincided with increase of IFN-γ, and associated with regression of LPD developed under MTX administration. Since changes of those immunological factors were not observed in persistent LPD, this study would be the first report to demonstrate the difference of...
GLOMERULAR FILTRATION RATE IS LOW IN RHEUMATOID ARTHRITIS COMPARED TO HEALTHY POPULATION: ESSENTIAL ROLE OF INFLAMMATION

S. Hanawi, 1 I. AlSalmi 2 1Inflammation, Ministry of Health and Prevention of UAE, Dubai, United Arab Emirates; 2Nephrology, Royal Hospital, Muscat, Oman

Background: Rheumatoid Arthritis is associated with subclinical renal impairment which contributes to increase mortality and morbidity. The role of inflammation on kidney function in inflammatory arthritis is not well studied.

Objectives: To investigate the association between estimated glomerular filtration rates (eGFR), traditional cardiovascular risk factors, and markers of inflammation in rheumatoid arthritis compared to healthy controls.

Methods: RA patient were recruited through a specialized rheumatology clinic at the Ministry of Health and Prevention of UAE, from January 2013 to January 2016. Healthy subjects were recruited from the community through brochure advertisement. The Modification of Diet in Renal Disease Study (MDRD) formula was used to calculate the eGFR, ttest was used to compare the laboratory values and renal function parameters between two groups. Linear regression analysis used to look for the correlation between the eGFR and each of the traditional cardiovascular risk factors and inflammatory markers

Results: 98 RA patients and 82 controls were recruited. None of the patients has history of diabetes, atherosclerosis or renal impairment. The mean age for the total participants was 49±13 years (M±6 – Max 82). The mean eGFR of the inflammatory arthritis patients was 118±30 ml/min (range 60–227) and 128±37 ml/min (range 62–286) for the controls. Patients and control had no significant difference in Systolic and diastolic blood pressure. Inflammatory arthritis patients had lower GFR, albumin (P<0.001), and total protein (P=0.03) levels, and had higher Erythrocyte Sedimentation Rate (ESR) (P<0.001), C-reactive protein (CRP) (P<0.001), and uric acid level (P=0.01). Negative linear relationships were found as follows:

Among RA patients and controls: There was a negative linear relationship between GFR and each of the age of the participants; (p<0.001, CI: -1.24 – 0.40 for the patients and p=0.01, CI: -1.82, -0.26 for the controls), and the systolic blood pressure; (p=0.04, CI: -0.61 for the patients and, -0.0 and p=0.022, CI: -0.61, -0.05 for the controls).

Among RA patients: The GFR had a negative linear relationship with the age of the patients (p<0.001, CI: -1.24, -0.05, diastolic blood pressure; (p=0.02, CI: -0.05, systolic blood pressure; (p=0.04, CI: -0.61, -0.05 for the patients and, -0.0 and p=0.022, CI: -0.61, -0.05 for the controls).

Conclusions: In RA non-traditional cardiovascular risk factors such as inflammatory markers are associated with sub-clinical presence of renal injury. Our data indicate that in RA, inflammation is involved in the early stages of impaired kidney function. Whether anti-inflammatory therapies are effective in slowing down the deterioration of kidney function in the arthritis diseases remain to be established.

FR0169

FR0171 OSTEOPOROSIS CONTRIBUTES TO SUBOPTIMAL PHYSICAL FUNCTION IN RHEUMATOID ARTHRITIS

A. Sirio1, N. Chiariotti1, M. Incer1, M. Jones2, C.O. Bingham III2, S.J. Bartlett1,2
1McGill University, Montreal, Canada; 2Johns Hopkins, Baltimore, United States

Background: Aggressive, early treatment of RA with new therapeutic agents has dramatically improved the management of RA. However, many studies have failed to show greater improvements in function or disability reduction between targeted control vs. less-aggressive care. The prevalence of obesity is increasing dramatically globally, and may be even higher in RA patients.

Objectives: Because obesity is also a risk factor for disability, we evaluated the extent to which excess weight may independently contribute to poorer physical function (PF) in RA.

Methods: RA patients enrolled in an observational study at an academic inflammatory Arthritis Clinic in Baltimore USA completed the patient global, pain VAS, SF 36, SICMS measured oxygen during PF, fatigue, sleep, and depression. RA clinical indicators were also collected at the visit. Outcomes were compared in obese and non-obese patients using t-tests and chi-square. Multiple regression was used to evaluate the effects of pain, fatigue, and BMI on PF, after controlling for age and eGFR. The c-statistics were calculated using the Harrell's C statistic.

Results: Participants were mostly female (82%) and white (83%) with mean (SD) age of 55 (13) years; 24% had < high school; RA duration 12 (9). Mean CDAI was 8.1 (8.1). Most were in CDAI remission (n=57; 32%) or LDA (n=64; 36%); 40 (23%) were in MDA and 16 (9%) in HDA. 49 (28%) was classified as normal weight (BMI 18.5–24.9), 46 (26%) were overweight (BMI 25–29.9) and 82 (46%) were obese (BMI>30). Men had a significantly higher mean BMI than women (33.6 [8.4] vs. 29.5 [7.2], p=0.006). As compared to non-obese participants, obese participants had a significantly higher BMI and HbA1c (6.1 vs. 4.9; p<0.005, respectively) and worse PF, pain, fatigue, sleep, and depression (mean differences -5.0, -4.6, 4.6, 3.8, 2.9, 3.6, and -4.7, respectively). In regression analyses, pain, fatigue, and BMI (but not sleep or depression) were inversely related to PF, after controlling for age and disease activity. In the final model, pain, fatigue and BMI were significantly and inversely related to PF (≤–3.9, -2.4, and -1.53, respectively) after controlling for age and disease activity (F (5, 170) =55.5, p=0.000, adjusted r2=0.61).

Conclusions: Our results suggest that excess weight also contributes to poor PF in addition to pain and fatigue. As the prevalence of obesity continues to

PREVALENCE AND FEATURES OF THE “MASKED” ARTERIAL HYPERTENSION IN WOMEN WITH RHEUMATOID ARTHRITIS IN THE ABSENCE OF CARDIOVASCULAR DISEASES BASED ON AMBULATORY BLOOD PRESSURE MONITORING

T.A. Romanova, N.M. Nikitina, A.P. Rebrow. Hospital Therapy Department, State Medical University of Saratov, Saratov, Russian Federation

Background: Cardiovascular (CV) events are the main reason of increased mortality at patients with rheumatoid arthritis (RA). Arterial hypertension (AH) takes a leading position among CV risk factors in RA. Ambulatory blood pressure monitoring (ABPM) has to be executed for persons with high cardiovascular risk and can be used for evaluation of “masked” arterial hypertension (MAH), according to the current recommendations.

Objectives: To estimate the frequency of identification and peculiarities of the MAH according to ambulatory blood pressure monitoring in women with RA without CV diseases.

Methods: The study included 36 women with RA (ACR 1987 and/or EULAR/ACR 2010 criteria) without CV diseases and AH (according to the anamnesis and 3-fold “office” blood pressure (BP) measurement). Mean age of RA patients was 55.7±15 years; mean duration of RA was 10 [3; 17] years, mean DAS 28 – 5.25 [4.6; 5.7]. As controls were involved 39 women with RA and AH (mean age 58.3±6.8 years; mean duration of RA - 8 [4; 14] years, mean DAS 28- 5.08 [4.04; 5.85]) and 30 women with AH without inflammatory joint diseases (mean age 55.9±6.2). Exclusion criteria were smoking, diabetes mellitus, symptomatic AH (except controls), cardiovascular diseases.

ABPM was measured using the BPlab with the program VASOTENCE® (Russian). Criteria for MAH were out-of-office BP ≥135/85 mmHg and/or average daily out-of-office BP ≥130/80 mmHg according to ABPM and considering optimal office BP.

The anamnesis, laboratory and instrumental methods of inspection were considered. Statistical analysis was performed with STATISTICA 7.0 (State Soft, USA).

Results: According to ABPM 24 of the 36 (66.6%) RA patients had optimal BP, 12 (33.3%) patients had the MAH phenomenon.

The patients with RA+AH and RA patients had the comparable levels of a daily BP [132.1/80.7 and 126.9/78.0 mmHg respectively, P>0.05]. The RA patients with MAH had statistically significant differences of BP in day and night hours [137.5/87 mmHg and 137/84 mmHg, respectively] compared to the RA+AH patients [131.8/80.7 mmHg and 126.3/73.8 mmHg, respectively, P=0.004] and AH patients [126.9/78 and 118/98.5 mmHg, respectively, P=0.001] with what MAH had.

Nocturnal systolic BP correlated with ESR (Spearmen's r=0.64, P<0.05). Daily diastolic BP correlated with SCORE/EULAR (r=0.40, P<0.05) and arterial stiffness index (r=0.86, P<0.05) in RA patients with MAH; nocturnal systolic BP correlated with C-reactive protein (r=-0.36, P<0.05) in RA+AH patients.

More than 60% of the RA+AH patients and RA+MAH patients had high variability of BP. High variability of nocturnal systolic BP occurred at 34.3% and 44.4% of RA+AH and RA+MAH patients, respectively.

In RA patients were found correlations between indices of a BP variability, duration of RA (r=0.33, P<0.05); C-reactive protein (r=-0.36, P<0.05); daily diastolic BP (r=-0.35, P<0.05); pulse BP (r=0.31, P<0.05); and frequency of non-steroidal anti-inflammatory drugs intake (r=-0.42, P<0.05).

Conclusions: In RA patients AH can proceed subclinically. Activity of RA and increased arterial stiffness can predict the masked arterial hypertension's development in RA patients. ABPM measurement can be use full in early evaluation of AH and optimization of RA treatment.

CORRELATION BETWEEN ASYMMETRIC DIMETHYLPARTINE AND HOMOCYSTEINE LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Elizabeth Hospital Birmingham, Mindelsohn Way, Birmingham; 4School of Sport, Health and Exercise Sciences, Bangor University, George Building, Bangor; 5Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom

Background: Rheumatoid Arthritis is a chronic inflammatory condition associated with increased cardiovascular disease (CVD) morbidity and mortality due to high coronary and cerebral atherosclerotic burden. Asymmetric dimethylarginine (ADMA) is the most potent endogenous inhibitor of nitric oxide synthase - is an emerging marker of endothelial dysfunction and CVD in several conditions such as coronary artery disease and diabetes mellitus. ADMA levels are higher in RA patients compared to controls suggesting a role in the development of atherosclerosis. In addition ADMA is involved in the metabolism of homocysteine (Hcy) which is considered a novel, non-traditional CVD risk factor contributing to excess CVD risk in this population.

Objectives: The aim of our study was to determine whether asymmetric dimethylarginine (ADMA) levels are associated with Hcy and methylenetetrahydrofolate reductase (MTHFR) C677T polymorphism in patients with RA.

Methods: Serum ADMA and Hcy levels were measured in 201 RA individuals [155 (77.1%) females, median age 67 years (interquartile range 59–73)]. The MTHFR C677T polymorphism was assessed by using the LightCyclerTM System. Initially, ADMA was compared across the categories of MTHFR using a one-way analysis of variance (ANOVA), followed by a multivariate model, which accounted for Hcy, age, erythrocyte sedimentation rate (ESR), and homeostatic model assessment (HOMA).

Results: In univariable analysis, ADMA differed significantly across the categories of MTHFR C677T (p=0.037). Patients with the MTHFR C677T genotype had the highest ADMA levels, with a median of 0.62 (SE =0.03), significantly higher than either those patients carrying the MTHFR 677CT (0.55, SE =0.01) or the MTHFR 677CC (0.55, SE =0.01) genotype (p=0.042) in both cases. In the multivariable model, Hcy (p=0.023) and ESR (p<0.001) were found to have significant positive associations with ADMA before the relationship between MTHFR gene variants and ADMA was found to be non-significant (p=0.102).

Conclusions: The results of our study indicate an association between ADMA and Hcy in patients with RA without any genetic background as no relationship was established between ADMA and MTHFR gene variants. Abnormal metabolism of Hcy and dimethylarginines may interfere with each other resulting in endothelial dysfunction and accelerated atherosclerosis in RA individuals.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.s512
Conclusions: ILD is a serious complication in RA with a significantly increased mortality compared with a large matched cohort of RA comparisons without ILD.

FR0175 USING SMARTPHONES TO IMPROVE REMOTE MONITORING OF RHEUMATOID ARTHRITIS: COMPLETENESS OF PATIENTS’ SYMPTOM REPORTS

S. Van Der Veer1, L. Austin1,2, C. Sanders2, W. Dixon1, J. Arthritis UK Centre for Epidemiology, Centre for Musculoskeletal Research, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, University of Manchester;2Centre for Primary Care, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom

Background: Clinical decisions about management of rheumatoid arthritis (RA) happen at intermittent clinic visits. In the absence of objective measures of disease severity between visits, understanding fluctuating disease severity largely relies on patients’ symptom reports, and thus on patients’ recall, eloquence, stoicism and willingness to discuss symptoms.

The Remote Monitoring of Rheumatoid Arthritis (REMORA) study aims to improve monitoring of disease severity in RA. Patients, clinicians and researchers co-designed a smartphone app to enable RA patients to report daily symptoms between clinic visits, and integrate these data into a patient electronic health record. The data presented here were collected as part of the REMORA feasibility evaluation.

Objectives: To evaluate the completeness of patient-reported symptom data submitted through the REMORA smartphone app over three months.

Methods: We invited 23 RA patients treated at the outpatient clinic of Salford Royal Foundation Trust (UK) to record their symptoms for three months using the REMORA smartphone app. Participants received notifications to record: daily scores for the seven items of the RA Impact of Disease score, as well as morning stiffness on a scale from 0 to 10; weekly scores for thirteen items of the Health Assessment Questionnaire (HAQ) 20-item disability scale. We calculated the time that participants were in the study as the number of days between the first and last day of submitting daily scores. We then explored patterns of data entry, as well as entry completeness.

Results: Twenty patients accepted the invitation to participate. Eight (40%) were male, all but one were white British, and their mean age was 56.9±11.1 years. The median number of days in the study was 82 (interquartile range [IQR], 80 to 82). Of all 213 weekly entries, fifteen (7%) had missing values, but never more than two. No more than nine (<1%) of the 1325 daily entries were incomplete, with only nine (~1%) having missing values for up to two individual items. Participants submitted weekly scores for a medium of 11 out of 13 weeks (IQR, 10 to 12). Of all 213 weekly entries, fifteen (7%) had missing values, but never more than two. Lastly, 8/20 participants provided monthly HAQ scores only once, while a further 9/20 and 3/20 participants did this for two and all three months, respectively. No monthly entries had any missing values.

Conclusions: Our feasibility study showed that smartphones have the potential to support collection of daily patient reports of symptoms with high levels of completeness over three months. Lengthier monthly question sets were less likely to be completed compared to briefer daily and weekly ones. Future steps include exploring methods of data entry frequency to (fluctuations in) disease severity in order to support sustained symptom reports over longer time periods and in a wider group of patients.

FR0176 | CORRELATION BETWEEN DISEASE ACTIVITY AND MENTAL HEALTH IN CHINESE PATIENTS WITH RHEUMATOID ARTHRITIS: THE ASSESSMENT WITH SYSTEM OF DISEASE MANAGEMENT (SSDM) MOBILES TOOLS

X. Li1, H. Sun2, R. Wu3, H. Wei4, W. Fan5, C. Zhao6, Z. Zhang7, Z. Wu8, Y. Wang9, J. Huang10, F. Xiao11, H. Xiao11, Y. Jia11, M. Zhang12.

1. Arthritis UK Centre for Epidemiology, Centre for Musculoskeletal Research, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, University of Manchester; 2. Centre for Primary Care, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, University of Manchester; 3. Centre for Primary Care, Faculty of Biology, Medicine and Health, University of Manchester; 4. Department of Rheumatology and Immunology, Jiangsu Province Hospital, Nanjing, China

Background: Rheumatoid arthritis (RA) patients can cause joint swelling and tenderness, and affect the patient’s mental health. Previous studies showed that 13–47% of RA patients suffered from anxiety and/or depression. Hospital anxiety and depression scale (HADS) is usually used to evaluate patients’ mental health, which consists of 14 items divided into an anxiety subscale (HADS-A) and a depression subscale (HADS-D). Disease activity score in 28 joints (DAS28) is one of the most used tools to measure disease activity in RA patients. The activity, both HADS and DAS28 assessments were commonly led by health professionals with paper questionnaire. This study applies the mobile platform of Smart System of Disease Management (SSDM) for evaluating DAS28 and HADS by RA patients.

Objectives: The purpose of this study is to describe the morbidity of mental conditions in Chinese patients with RA and analyze the potential association among DAS28 and HADS.

Methods: SSDM is a mobile application includes physicians’ and patients’ interfaces. The patient’s terminal system includes self-assessment (DAS28, HADS), lab test results and medication management. After data entry, patients can synchronize data to the mobile terminal of their authorized rheumatologist. A cohort study was conducted with patients who were diagnosed with RA in tertiary hospital across China. All participants self-assessed both DAS28 and HADS with SSDM at least one time. Descriptive statistics were performed for patient and disease characteristics, assuming normality for DAS28 distribution and the level of disease activity was analyzed using Pearson’s statistics. One-way analysis of variance was employed to explore for difference between sub-groups. Bivariate correlation and linear logistic analysis were employed to explore for potential factors among DAS28 and HADS.

Results: From June 2016 to January 2017, 230 patients (male 66, female 164) from 12 hospitals performed 311 times HADS and 517 times DAS28 self-assessment. The mean (±SD) age was 34.17±13.11 (11–71) years, with the median disease duration of 24.70 (0–572) months. As the standard of HADS score, less than 10, 10 to 11, 12 to 13 and above 13 points, patients could be divided into four levels of anxiety and depression respectively. According to the DAS28 assessment results, the proportion of patients with remission, low disease activity, moderate activity and high activity were 18%, 19%, 46% and 18% respectively. Bivariate correlation showed that DAS28 was positively correlated with HADS, p<0.001. Both HADS-A and HADS-D showed linear regression association with DAS28 score. The regression equation as “HADS-A = 5.962 + 0.435*DAS28” and “HADS-D = 6.379 + 0.694*DAS28” respectively, p<0.001.

Conclusions: DAS28 was positively correlated with HADS. SSDM is an effective mobile interface to serve for RA patients performing self-management of both disease activity and mental health as well as to supply physicians with valuable data.

FR0177 | THE UNDERRATED PREVALENCE OF DEPRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Sruamsiri1, Y. Kaneko2, J. Mahlich1. 1. Health Economics, Janssen Pharmaceutical KK, Tokyo, Japan; 2. Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

Background: Significant evidence in the scholarly literature suggests that depression is a common comorbidity among patients with rheumatoid arthrit (RA) (1) Comorbid depression in RA patients is especially troublesome because it often goes unrecognized and untreated (2) often because rheumatologists and their patients seldom communicate about depression (3). In addition, evidence of depression in RA patients is limited in Asia studies.

Objectives: To determine the prevalence of depression among patients with RA and explore the relationships between depression and an array of variables.

Methods: Cross-sectional online survey (n=500) of RA patients including the Patient Health Questionnaire [PHQ-9] (4) to measure the presence and severity of depressive symptoms were performed. The survey included demographic, clinical characteristics such as functional impairment as assessed using the Japanese version of the Stanford Health Assessment Questionnaire (J-HAQ score), and the participant’s current medical treatment. Ordered logistic regression was used to identify the determinants of depression conditions among survey respondents.

Results: The mean age of the 500 patients with RA was 54.3 years old and 67% were female. While only 25 (5%) of the population studied had been officially diagnosed with depression, 176 (35%) had PHQ-9 scores indicating depression was present. Comorbidity conditions, except for migraine and heart conditions, were not different between patients with depression and those without. Logistic regression analysis revealed a negative correlation between the prevalence of depression and younger age with odds ratio (OR) of 0.96 (95% confidence interval (CI), 0.92–0.99); higher education level (OR, 1.06; 95% CI, 0.96–1.18); and a bachelor’s degree (or higher) and an income level of 0.6–1.6 million yen (OR, 0.45; 95% CI, 0.22–0.91). Positive correlations with depression was found in RA patients with high J-HAQ score (OR, 1.99; 95% CI, 1.47–2.71). Patients treated with biologic monotherapy were significantly less likely have depression compared to those treated with non-biologic anti-rheumatic drugs (OR, 0.36; 95% CI, 0.17–0.75).

Conclusions: It is a potential risk of under-diagnosis and under-reporting of Depression in patients in Asia patients are more likely to experience depression if they are younger, have greater functional impairment, or whose treatment regimen includes pain medications without biologic drugs.
RITUXIMAB IS EFFECTIVE IN THE TREATMENT OF RHEUMATOID ARTHRITIS REGARDLESS OF BODY MASS INDEX

D.H. Yoo¹, W. Park¹, C.H. Suh³, S.C. Shim⁴, S.J. Lee⁵, Y.J. Bae⁵, C. Park⁵, J.H. Koo¹
¹Hanyang University Hospital for Rheumatic Diseases, Seoul; ²In-HA University, School of Medicine, Inchon; ³Apu University School of Medicine, Suwon; ⁴Chungnam National University Hospital, Daejeon; ⁵Celltrion Inc., Incheon, Korea, Republic Of

Background: High body mass index (BMI) is known to be associated with inadequate clinical response to anti-TNF agents in rheumatoid arthritis (RA) patients. However, there are limited data on the effect of high BMI on the response to rituximab in RA patients, who showed an inadequate response or intolerance to anti-TNF agents.

Objectives: To investigate the impact of BMI on clinical response in the post-hoc analysis of randomized controlled trial that demonstrated clinical equivalence between a biosimilar of rituximab, CT-P10 and innovator rituximab, RTX 2

Methods: A total of 332 patients who received two courses of either CT-P10 or RTX were included in this analysis. Patients were classified into 3 groups; normal weight (<30 kg/m²), overweight (≥25 kg/m² – <30 kg/m²) and obesity (≥30 kg/m²) as per WHO BMI category. Improvement in disease activity by the Disease Activity Score using C-reactive protein (DAS28-CRP), remission (≤2.6), low disease activity rate (LDA, <2.2) and ACR response at Week 24 (Week 24 of 1st course) and Week 48 (Week 24 of 2nd course) and duration of sustained LDA (from the 1st LDA observed to the last LDA observed up to Week 48) were analysed by BMI categories in the each and combined group of CT-P10 and RTX.

Results: In the pooled group of CT-P10 and RTX, the mean weights were 59 kg in normal weight, 73kg in overweight and 91kg in obesity. All other baseline characteristics were comparable among BMI groups including baseline disease activity based on DAS28; Moderate disease activity, 22.3% vs. 22.8% vs. 25.7%, respectively; High disease activity, 77.7% vs. 77.2% vs. 74.3%, respectively. There was no statistical difference among BMI groups in terms of DAS28 change from baseline and ACR 20/50/70 response (Table). No particular trend was observed in remission and LDA rate by DAS28 at Week 24 and Week 48 among BMI groups (Figure). Mean duration of sustained LDA (months) were also comparable among the groups (4.5 vs. 4.7 vs. 5.0, respectively). Additionally, similar trends in all analyses were observed in each treatment group; CT-P10 and RTX.

Conclusions: The BMI does not affect the clinical response in RA patients with rituximab treatment. Therefore, this result supports that rituximab could be a reasonable therapeutic option for obese RA patients with inadequate response to anti-TNF agents.

Figure 1. Remission and LDA by DAS28 by BMI group.
safe profile consisting of events occurring in unexposed infants of similar age.

Conclusions: C2P was below the lower limit of quantification in 56% of the milk samples. When detectable, C2P concentrations were less than 3x LLOQ (<1% of expected plasma concentration of a therapeutic dose), indicating no to minimal transfer of C2P from plasma to breast milk. RID was below 0.5% of maternal dose and is thus unlikely to be of clinical concern. C2P absorption in breast milk is unlikely, due to low bioavailability and its Fc-free molecular structure. These findings support continuation of C2P treatment during breastfeeding.

endpoint was disease worsening according to disease-specific composite measures and/or consensus between investigator/patient leading to major treatment change. Exploratory subgroup analyses examined disease worsening and safety in RA. The primary endpoint was analysed using logistic regression, adjusted for diagnosis and disease duration.

**Results:** Demographics, occurrence of disease worsening, change in disease measures and treatment-emergent adverse events (TEAE) were similar (Table). Serum drug levels for INX and CT-P13 were similar throughout the study (Figure).

**Conclusions:** Explorative analyses in the NOR-SWITCH study showed similar efficacy, serum drug levels and safety in RA patients switched to CT-P13 as those on continuous INX. The study was not powered to show non-inferiority within each diagnosis.

**FR0183 ASSESSING ADHERENCE OF RA PATIENTS TREATED WITH ETANERCEPT USING ETANERCEPT SERUM TROUGH CONCENTRATIONS AND PATIENT SELF-REPORT**

E. Vogelzang1, R. Hebing2, M. Nurmohamed3, L. A’Ami1,3, C. Kriekdaert4, G. Wolbink1,2.

1. Rheumatology; 2. Rheumatology, Pharmacy, Amsterdam Rheumatology and immunology Center | Reade; 3. Immunopathology, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands

**Background:** The EULAR recommendations for the management of rheumatoid arthritis (RA) update 2013 contained the following research question: "How good is patient adherence to biological agents and can lack of adherence be related to loss of efficacy?"[1] Limited studies are published in which adherence of RA patients treated with biological disease-modifying antirheumatic drugs (bDMARDs) has been assessed. Previous studies regarding adherence of RA patients treated with etanercept did not take into account that patients are instructed to temporarily discontinue bDMARDs therapy during e.g. a serious infection. In addition, etanercept concentrations have never been utilized in determining adherence to etanercept in RA patients.

**Objectives:** The aim of our study was to determine the percentage of non-adherent RA patients treated with etanercept, using etanercept concentrations and patient self-report, and to assess the relationship between adherence and clinical outcome during 52 weeks.

**Methods:** Non-adherence was defined as an etanercept trough concentration <0.1ug/mL at least once and non valid/medical reason to miss an etanercept dose. In this retrospective cohort study patients visited our clinic at baseline and in 4, 16, 28, 40 and 52 weeks after initiation of etanercept treatment. At baseline and following visits disease activity score of 28 joints (DAS28) was calculated and blood was drawn to measure etanercept concentrations. During each visit patients were asked if they missed an etanercept dose, at which date and for which reason. Remission was defined as DAS28 <2.6 at least for two consecutive visits. Low disease activity (LDA) was defined as DAS28 <3.2 during a minimal of two consecutive visits.

**Results:** In total 292 patients were included. Mean age was 53 years (SD 12.7), 82% were women and median disease duration was 8 years (IQR 3–16). In total 24 patients had an etanercept concentration <0.1ug/mL. Most patients had a medical reason to miss an etanercept dose, see table 1.

Only ten patients (3.4%) were non-adherent during the follow-up of 52 weeks. Of the adherent patients 82 out of 282 (29%) reached LDA versus 1 out of 10 non-adherent patients. A total of 127 of 282 (45%) adherent patients achieved MDA versus 3 out of 10 non-adherent patients.

**Conclusions:** Most patients had a medical reason to miss an etanercept dose. The percentage of patients who are non-adherent to etanercept therapy is very low (3.4%).

**FR0184 THE PROFILES OF PATIENTS WITH RHEUMATOID ARTHRITIS ACCORDING TO THEIR BELIEFS IN THEIR BIOLOGICAL DRUGS. ARCO STUDY**

**Objectives:** To describe profiles of rheumatoid arthritis (RA) patients according to their beliefs in their subcutaneous biological medication (SC).
Methods: ARCO was a study carried out on RA Spanish patients who initiated a SC biological drug 11–18 months prior to the study visit. Patients completed the Beliefs About Medication Questionnaire (BMQ). According to the scores obtained in the necessity (N) and concerns (C) sub-scales, patients were classified into 4 groups: accepting (high N \([-3\) to low C \([\leq 3\) ), ambivalent (N:3 to C:3), indifferent (N:3 to C:3) and skeptical (low N: [3] to high C: [3]). We studied demographic characteristics, expectations and satisfaction with the treatment by group.

Results: 321 patients (77% women) completed the BMQ, 92.8% scored N:3 and 58.9% C:3. A higher % of men than women scored N:3 (13.5% vs. 5.2%, p = 0.031). The % who scored C:3 was higher in those with low satisfaction with symptom control (71.1% vs. 56.7% in satisfied/very satisfied, p = 0.098), or side effects (72.1% vs. 52.0%, p < 0.001), and in those with lower fulfilment of expectations of efficacy and tolerance (p < 0.001). The combination of N and C scores identified 116 accepting (36.1%), 182 ambivalent (57.7%), 16 indifferent (5.0%) and 7 skeptic patients (2.2%). There were no differences in age, gender, or RA duration among the groups, but differences were seen in the satisfaction with the treatment and in the fulfillment of the expectations (table). Ambivalent patients showed less satisfaction and lower fulfillment of expectations with the treatment received than accepting patients.

Conclusions: Patients with RA have strong beliefs about the need of their biological SC medication, but a high % also expresses concerns. Beliefs, and especially concerns, seem to relate to the satisfaction and fulfillment of expectations of efficacy and tolerability of the drug, rather than to demographics or RA characteristics. Discussing expectations may be important when initiating a biological treatment.

FR10186 | INFLUENCE OF IMMUNOGENICITY TO THE FIRST TNF-I THERAPY ON RESPONSE TO THE SECOND BIOLOGIC AGENT IN RA PATIENTS

Background: There is currently no consensus on selecting a therapeutic target in patients (pts) non-responsive to their first TNF-inhibitor (TNF-i). The development of anti-drug antibodies (ADA) is a frequent cause of secondary inefficacy in our pts with TNF-i and there is evidence that those who develop ADA at their 1st TNF-i achieve a higher degree of response to the second, compared to ADA-pts. Thus ADA measurement can help in choosing a therapeutic target in pts who failed to respond to their 1st TNF-i.

Objectives: To assess if development of ADA to the 1st TNF-i determines better response when switching to a 2nd TNF-i versus a non-TNF-i. As secondary objective, analyze whether the presence or absence of ADA to a 1st TNF-i influences the efficacy of a 2nd TNF-i.

Methods: Of a total of 144 pts that switched from infliximab or Adalimumab to a 2nd biologic agent (Etanercept, Rituximab, Tocilizumab, Adalimumab, Abatacept, Certolizumab and Infliximab only, who had measured drug levels (DL/ADA) at discontinuation of the 1st TNF-i, were included. Clinical response was evaluated with DAS28, Delta-DAS28 (ΔDAS28) and EULAR response (E-resp) at 6 (v-6) and 12 (v-12) months after initiating 2nd biologic agent and at the last visit prior to drug discontinuation or ending of the study for those who did not interrupt the biological therapy (v-end). DL/ADA levels were measured by ELISA. Statistical analysis was performed using SPSS version 20.0.

Results: Within the 60 pts who had measured DL/ADA at suspension of the 1st TNF-i, 26 (43%) were ADA- (i.e. DL-). In this ADA-subpopulation, 50% changed to a 2nd TNF-i; at v-end there were no differences between non-changers to a 2nd TNF-i and switchers to a non-TNF-i in DAS28 (3.7±2.1 TNF-i vs 4.2±1.1 non-TNF-i, p = 0.286), ΔDAS28 (1.4±2.1 TNF-i, 1.3±2.1 non-TNF-i, p = 0.374) and resp-E (75% good/moderate resp in TNF-i, 40% in non-TNF-i, p = 0.064). At v-12, switchers to a 2nd TNF-i showed a lower DAS28 (2.5±0.6 TNF-i, 3.9±1.0 non-TNF-i, p = 0.009) and a higher good E-resp rate with a marginally significant difference (80% in TNF-i, 22% in non-TNF-i, p = 0.071). However, at v-end, pts with a 2nd non-TNF-i had better response (ΔDAS28 = −5.1 in 50% of TNF-i pts, 0% of non-TNF-i pts, p = 0.044). Likewise ΔDAS28 at v-end was higher in the non-TNF-i group with trend to significance (0.7±2.7 TNF-i, 1.7±2.8 non-TNF-i, p = 0.06).
good/moderate E-resp rate was higher in switchers to a nonTNF-i (70% in TNF-i, 8.3% in nonTNF-i, p=0.006). In ADA+ subpopulation (n=34), no differences were found in clinical response at v-end in DAS28 (3.7±1.2 TNF-i, 3.9±1.1 nonTNF-i, p=0.564), ΔDAS28 (0.6±1.6 in TNF-i, 1.4±1.4 in nonTNF-i, p=0.35) and good/moderate E-resp rate (30% in TNF-i, 91% in nonTNF-i, p=0.073). In pts who changed to a 2nd TNF-i, those with ADA→1st TNF-i had a higher good response rate than ADA- pts (65% in ADA+ vs. 30% in ADA-, p=0.07).

Conclusions: The development of the ADA to the first TNF-i entails a better response when switching to a 2nd TNF-i, with a similar efficacy to the pts who switched to a nonTNF-i. In those pts who did not develop immunogenicity to the 1st TNF-i, there is a better response when changing therapeutic target. The ADA measurement can help to select the pts who can benefit from a 2nd TNF-i combination therapy.

**Figure 1:**

- **FR0187:** RADIOPHOGIC PROGRESSION BY DISEASE ACTIVITY STATES IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SB2 OR REFERENCE INFLIXIMAB

- **Disclosure of Interest:** None declared.

- **Background:** Based on the totality of evidence, SB2 has shown to be similar with reference infliximab (INF) and has been approved as a biosimilar by the European Medical Agency. It is, however, ethically unknown, if SB2 also shares similar structural efficacy in the different disease activity states when compared with INF.

- **Objectives:** To evaluate the disease activity by simplified disease activity index (SDAI) and clinical disease activity index (CDAI) at weeks 14, 30 and 54 in patients with rheumatoid arthritis (RA) treated with SB2 or INF from a phase III study and to assess the radiographic progression at week 54 in patients by disease activity states (remission, low disease activity [LDA], moderate disease activity [MDA], or high disease activity [HDA]).

- **Methods:** Patients with RA were randomized to receive either SB2 or INF 3 mg/kg at weeks 0, 2, 6, and then every 8 weeks thereafter up to week 46 with background methotrexate. Dose increments were allowed after week 30 by 1.5 mg/kg up to a maximum dose of 7.5 mg/kg. Disease activities by SDAI, and CDAI were compared at weeks 14, 30, and 54. The radiographic progression was measured by modified Total Sharp Score (mTSS) at weeks 0 and 54.

- **Results:** Up to week 54, comparable proportions of patients achieved ACR-EULAR-index remission between SB2 and INF (by SDAI: 13/279 [4.7%] vs. 13/283 [4.6%] at week 14; 24/250 [9.6%] vs. 29/263 [11.0%] at week 30; 34/225 [15.0%] vs. 24/224 [10.7%] at week 54; by CDAI: 12/279 [4.3%] vs. 12/232 [5.2%] at week 14; 22/253 [8.7%] vs. 31/265 [11.7%] at week 30; 33/227 [14.5%] vs. 24/225 [10.7%] at week 54 in SB2 and INF, respectively). The proportions of radiographic non-progressors (defined as change in mTSS ≤ 2.8) at week 54 was 11.7% vs. 22.8% in TNF-i, 6.7% vs. 9.7% in non-TNF-i, p=0.006). In ADA+ subpopulation (n=34), no differences were seen even in LDA and MDA in both treatment arms. These data further confirm the comparability of SB2 and INF.

- **Conclusions:** The proportion of patients achieving remission or LDA was comparable up to week 54 upon treatment with both SB2 and INF. Inhibition of radiographic progression was also comparable in patients in active state. The proportion of radiographic non-progressors was also similarly high in patients achieving remission, and overall very low radiographic progression rates were seen even in LDA and MDA in both treatment arms. These data further confirm the comparability of SB2 and INF.

- **Conclusions:** In this real world study, patients on ADA+MTX had significantly greater improvements in disease activity compared to patients on ADA+nonMTX.
S. Cohen1, A. Alonso-Ruiz2, P.A. Klimiuk3, E. Lee4, N. Peter5, I. Sonderegger5, D. Assudani5, 6Metroplex Clinical Research Center, Dallas, United States; 5Boehringer Ingelheim, Ingelheim a.R., Germany

Background: PK bioequivalence of BI 695501, a biosimilar candidate, and the adalimumab originator was demonstrated previously (VOLTAIRE-PK: Wynne et al., Expert Opin Investig Drugs 2016:25:1381–70) and led to further clinical development.

Objectives: To demonstrate clinical equivalence of BI 695501 with the adalimumab originator by comparing efficacy, safety and immunogenicity using a clinical model sensitive to detect potential differences between the two biologics.

Methods: In this 58-week, multi-national, multicentre, randomised, double-blind, parallel arm Phase III study (NCT02137226), 645 pts (18–80 years) with moderate to severe active RA on stable treatment with methotrexate were randomised to receive US-licensed SC adalimumab originator or BI 695501 40mg Q2W for 24 weeks. At Wk 24, pts on adalimumab originator were re-randomised to continue the adalimumab originator or switch to BI 695501 until Wk 48. Pts on BI 695501 were dummy re-randomised. Co-primary end points were proportions of pts achieving ACR20 at Wks 12 and 24. Equivalence between BI 695501 and the adalimumab originator was demonstrated if the relevant confidence intervals (CI) for differences in ACR20 response rate at Wks 12 and 24 were within the predefined margins (Wk 12: 90% CI −12%, 15%; Wk 24: 95% CI −15%, 15%). This pre-specified secondary end point was powered to detect equivalence, demonstrating clinical equivalence between BI 695501 and the adalimumab originator (Table 1).

The proportion of pts with treatment-emergent adverse events (TEAE) was similar between BI 695501 and the adalimumab originator treatment groups (Table 2).

</tbody>
</table>

Rates of serious AEs and discontinuation due to TEAEs were similar across the groups. No deaths were reported during the study. Similar frequencies of pts tested positive for anti-drug antibodies (BI 695501 43.2%; adalimumab originator 47.8%), and neutralising antibodies (BI 695501 16.0%; adalimumab originator 20.6%) in both groups at Week 24.

Conclusions: This study in pts with RA demonstrated that BI 695501 and the adalimumab originator are highly similar in terms of efficacy, safety and immunogenicity.

FR0190 [FR0109]

CLINICAL OUTCOMES FROM A NATIONWIDE NON-MEDICAL SWITCH FROM ORIGINATOR TO BIOSIMILAR ETA NEUTERCE WITH PATIENTS IN INFAMMATORY ARTHRITIS AFTER 5 MONTHS FOLLOW-UP: RESULTS FROM THE DANBIO REGISTRY

Background: In Denmark, biological drugs are provided free by the hospitals to the patients via a tax-based system. In 2015 a non-medical switch from originator infliximab to CT-P13 was conducted (1). According to national guidelines in April 2016, a non-medical switch from originator (ETA, Enbrel® 50 mg/week) to biosimilar etanercept (SB4, Benepali®) was dictated when SB4 was marketed, including patients with inflammatory arthritis.

Objectives: To investigate 3 months’ disease activity and 5 months’ treatment withdrawal in ETA-treated patients (pts) with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (SpA), who were switched to SB4 and monitored prospectively in the DANBIO registry.

Methods: Pts with RA/PsA/SpA followed in DANBIO since start of first bDMARD were included. Disease activity at 3 months before switch (pre-switch), at the switch and after 3 months (post-switch) and changes over time (pre-switch and post-switch) were calculated. Disease flare was defined as ΔDAS28=1.2 or ΔDASAS=1.3 (SpA). Factors associated with withdrawal.

Results: In total, 1548 pts were identified (919 RA, 335 PsA, 322 SpA). 60% were women, age (median (IQR) 44 (43–46) yrs). Prior ETA treatment duration was 5.2 (3.2–8.0) yrs. ETA was the first biological treatment in 49%, and the second in 33% of pts. Concomitant MTX was given in 60% (RA)/49% (PsA)/15% (SpA). Median follow-up time was 154 (110–178) days.

Disease activity remained largely unchanged 3 months prior to vs. after the switch (Table). The proportion of patients with disease flare pre-/post-switch was 9%/13% (RA), 5%/5% (PsA), 4%/4% (SpA). Higher patient’s global score (HR 1.12/cm, 95% CI (1.05–1.21), p=0.002) and no concomitant methotrexate (HR 2.28 (1.48–3.52), p<0.001) at baseline were associated with withdrawal.

Conclusions: In 1548 patients with inflammatory rheumatic diseases treated with ETA for >5 years, disease activity was largely unaltered in the majority of patients 3 months after non-medical switch to SB4 and comparable to the fluctuations observed in the 3 months prior to the switch. Several patients (>9%)...
stopped treatment during 5 months follow-up. Higher patient's global score and no use of methotrexate were associated with withdrawal. Longer follow-up will offer additional understanding of the potential efficacy and safety consequences of the non-medical switch.

Conclusions: In this prospective longitudinal cohort, patients on long-term innovator IFX therapy show low rates of disease worsening of 2.7% to 11.5% at 1 and 2 years in AS and RA. Additional studies may elucidate the true rate of and reasons for disease worsening in rheumatologic populations.

FR10193 | EFFECT OF VALLENCY OF ANTI-TNFs ON ELIMINATION MEDIATED BY ANTI-DRUG ANTIBODIES

J. Silva, A. Nesbitt
UCB Pharma, Slough, United Kingdom

Background: There are five different anti-TNF biologics: three are bivalent full length (FL) antibodies (adalimumab, golimumab, and infliximab), one a bivalent fusion protein (etanercept), and one a univalent PEGylated Fab’ (PF) (certolizumab pegol, CZP). Administration of such protein biologics can induce anti-drug antibodies (ADAbs), of which the majority are anti-idiotypic antibodies (anti-ID). The potential cross-linking of bivalent anti-IDs with bivalent biologics can decrease in the efficacy of the biologic. Since univalent biologics, such as CZP, only have one binding Fab’ arm, such large cross-linked anti-ID-mediated ICs are unlikely to form. Therefore, anti-IDs may have a different effect on the elimination and bioavailability of univalent and bivalent biologics in vivo.

Objectives: To determine if the valency of a biologic will affect the in vitro size and in vivo elimination from the plasma of ICs formed with an anti-ID following intravenous (IV) administration to BALB/c mice.

Methods: An anti-ID antibody to CZP was generated and used for subsequent studies to mimic an ADA response. Univalent PF CZP was reengineered as a bivalent FL humanized IgG1 antibody (similar to adalimumab) to directly

M.B. Nishishinya, C.A. Pereda, P. Diaz del Campo, A. Balsa on behalf of GUIPCAR, Evidence based Rheumatology Working Group (SER) and GUIPCAR Working Group. 1 Traumatology Institute Quirón, Barcelona; 2 Rheumatology, Hospital Mediterraneo, Alcobaca; 3 Investigation Unit, Spanish Rheumatology Society, 4 Rheumatology, Hospital Universitari de la Paz, Madrid, Spain

Background: Anti TNF therapy, has been used for the treatment of RA patients for several years. Yet, cancer and infections are among the most serious adverse effects described. Unfortunately, little is known about the effect of anti TNF therapy amongst patients with RA and previous cancer, mainly when synthetic DMARDs treatment fails.

Objectives: To review the evidence on the safety of biological therapy in RA patients with previous neoplasia.

Methods: We performed a systematic review through Medline, Cochrane Library, and EMBASE databases. Studies written in English, French and Spanish were considered. Patients 18 years or older, with RA diagnosis (ACR 1987 or ACR/EULAR 2010 criteria), and cancer diagnosis before starting biological therapy were included. While Systematic reviews, clinical trials and observational studies with a minimal follow-up of 6 months were considered; case reports or narratives reviews were excluded.

Results: 1077 studies were potentially identified, and 6 cohort studies were finally included, (Aaltoinen 2015, Dixon 2010, Phillips 2015, Raaschou 2015, Silva-Fernández 2016, Strandfeld 2010). Studies were based on registries of patients with RA treated with DMARDs and biological therapy. Registries evaluated etanercept with adalimumab and 14.16% of patients. The number of patients with documented previous cancer was around 122 to 425 as a whole. Biological therapies evaluated were: IFX, ETN, ADA, RTX, certolizumab pegol, Golimumab, ANAKinRA and synthetic DMARDs. Studies results were organized as anti TNF vs. DMARDs. All studies assessed were cohort trials, SIGN 2+ (Quality Scale). They included solid tumours as breast cancer, lymphoproliferative tumours, skin cancer, neck and brain tumours, as well as in situ uterus cancer. There was no increment in the risk of incidence of previous cancer in patients treated both with synthetic DMARDs and with anti TNF therapy in all studies assessed.

We point out, that 1 SR (LaForest Divonne 2016) evaluated biological therapy safety in patients with RA. It included 124 trials, while in 27 metanalysis was performed. From these 27, only 3 (Dixon 2010, Mercer 2013 and Stranfeld 2010) where the only studies which assessed risk of recurrence of previous cancer in vivo. In RA patients, The RR 0.77 (IC 95% 0.29–2.03), did not exhibit an increment in the risk of cancer in these patients.

Conclusions: Studies showed no differences in the incidence of previous cancer in patients treated either with synthetic DMARDs or with anti TNF. However, we suggest precaution in the use of these therapies, as the real risk in this population is still unknown.

• The final decision of treating or not treating these patients (risk factors, limitations etc.) needs to be performed in accordance with oncologists.
• There is no strong evidence that could identify the real risk of anti TNF therapies in RA patients, with previous cancer.
• The Individual impact of different anti-TNF therapies in this population could not be performed due to incomplete data. Yet, there is not real time schedule considering time since previous cancer and the start of anti TNF therapy.

Well designed studies with long follow-up periods are needed to answer these questions.

compare the effect of valency on IC-mediated clearance. This FL antibody showed very similar TNF neutralization compared to the conventional PF molecule in a bioassay. To generate ICs, the anti-ID was incubated overnight with either IFX or FL CZP, and the size of the resultant ICs determined by an ultrafiltration assay (AU). The anti-ID complexes and FL or PF molecules were then administered IV to the mice, and the elimination of the anti-TNFs from the circulation was monitored by quantitative liquid chromatography-mass spectrometry (LC-MS) in serial plasma samples.

Results: AU analysis of the immune complexes formed between FL CZP and the anti-ID showed the presence of one peak corresponding in size to one anti-ID molecule bound to two PF molecules (~3.5x10^6 Da). In contrast, the FL CZP/anti-ID mixture showed ICs of various sizes up to very large molecular weights (~1x10^6 Da), with the predominant species corresponding to a complex of two anti-IDs bound to two FL CZP molecules (~1x10^6 Da). The in vivo studies showed that the FL CZP/anti-ID ICs were much faster eluted than the FL CZP alone (t1/2=44.5 hours), whereas the PF CZP/anti-ID ICs were eliminated much more slowly (t1/2=60.5 hours) than the PF CZP alone (t1/2=19.7 hours).

Conclusions: The FL CZP molecule formed large ICs with the anti-ID, which led to much faster elimination than the FL molecule alone. This result suggests that an ADAs response to a FL antibody could lead to rapid elimination and loss of efficacy of the drug in patients. In contrast, the FL CZP/anti-ID complex had a longer half-life than the PF CZP alone, presumably because this molecule was not seen as an IC due to the presence of only one Fc. These results showed that an ADA to a univalent biological reagent may not lead to elimination and instead, may actually increase the in vivo half-life of the molecule.

FR01094 USE OF GLORESPONSE™ NF-κB-RE-LUC2P HEK293 CELLS TO MONITOR DRUG AND ANTI-DRUG ANTIBODY LEVELS IN SERUM

Innirumo-Rheumatology research group; 1Immunology, University Hospital la Paz, Madrid, Spain; 2Promega Corporation, Madison (WI), United States; 3Promega Europe Training and Applications Laboratory (PETAL), Promega Corporation, Chatbonnières-les-Bains, France.

Background: Rheumatoid Arthritis (RA) is often treated with anti-TNFα such as infliximab (IFX) which in a long-term treatment can lead to the development of anti-IFX antibodies (ATI), resulting in an interference with the drug activity. The investigation of the bioactivity of the circulating drug and antibodies present in patients sera with inflammatory diseases will allow to harmonize the different published data using both bioassays as well as immunoassays.

Objectives: To compare the bioassay using GloResponse™ NF-κB-RE-LUC2P HEK293 cell line, which responses to TNFα in the quantification of both IFX and ATI in serum from RA patients.

To compare the bioassay performance between capture- and bridging-ELISA.

Results: Serum IFx-trough levels were determined in 50 samples from patients with RA. To measure IFx, the bioassay uses GloResponse™ NF-κB-RE-LUC2P HEK293 cell line, which responses to TNFα in the quantification of both IFX and ATI in serum from RA patients.

Results show an almost perfect agreement between specimens and with the reference ELISA technique. Measurement of anti-drug antibody in serum samples treated with anti-TNFα antibodies. Comparison with ELISA method shows in most of the case the same data.

Disclosure of Interest: No competing interests declared.

DOI: 10.1136/annrheumdis-2017-eular.6352

FR01095 POINT-OF-CARE MONITORING OF ANTI-INFliximAB ANTIBODIES IN PATIENTS TREATED WITH THE REFERENCE INFliximAB OR CT-P13 IN ROUTINE CLINICAL PRACTICE

A. Ametazuza1, N. Rivera2, A. Balsa3, M.P. Areaza4, E. Ruiz2, C. Plasencia2, J. Ortiz2, D. Pascual-Salcedo5, M.C. Muñoz5, C. De Aysa4, M.J. Allande2, N. Torres1, A.M. Hernández1, X. Recalde1, A. Martínez1, D. Nagore1, J.R.D. Progenika-Grifols, Dero1, R.Rheumatology, Basurto University Hospital, Bilbao; 2Nuclear Medicine, la Paz University Hospital, Madrid; 3Rheumatology, Basurto University Hospital, Bilbao; 4Immuno-Rheumatology, la Paz University Hospital, Madrid, Spain.

Background: Loss of clinical response and infusion reactions to infliximab (IFX) are associated to the development of antibodies to IFX (ATI). ATI detection is a key step of patient management. However, current techniques may require additional patient appointments for sample collection, processing and batching in certain facilities. Testing report usually takes several days or weeks impairing effective decision making.

Objectives: To clinically validate the use of a new rapid test to detect ATI in capillary blood in a real-life point-of-care (POC) setting where patients attend the infusion center for the reference IFX (Remicade®, RMC) or CT-P13 (Inflectra®)/IFT, or Remsima®) infusions.

Methods: POQ-EF1 and POQ-EF2 are prospective, observational studies designed to evaluate and compare the performance of a rapid POC test (CE-marked Promonitor®), Quick Anti-IFX, Progenika, Spain) to detect ATI in routine clinical practice. A total of 60 rheumatic and gastroenterology patients treated with IFX or the biosimilar CT-p13 attending the infusion center with the ELISA technique as a reference. The POC test is a qualitative immunochromatographic assay based on lateral flow technology to detect ATI (including biosimilar CT-P13) in either fingerprick or serum or venous whole blood. Consecutive patients (initiating or under maintenance therapy) were recruited and tested in La Paz and Basurto University hospitals with the rapid test in capillary and venous whole blood specimens immediately before the infusion. ATI test results were read visually with the POC test in 30 min, just before the patient started the infusion. Trough sera were also collected for subsequent analysis with the rapid test and benchmarked with Promonitor®-Anti-IFX ELISA (Progenika, Spain). Follow-up time was 6 months. ELISA quantitative results were categorized as positive and negative to allow comparisons with the qualitative rapid test.

Results: Ninety consecutive patients were recruited (a total of 137 visits in the 6 months follow-up) accounting for a total of 137 sera, 137 fingerpricks and 71 venous whole blood samples. Overall, 8 (8.9%) patients developed ATI (5 ankylosing spondylitis, 1 Crohn’s disease, 1 ulcerative colitis and 1 juvenile idiopathic arthritis). ATI were detected in 5 patients treated with Remicade® and 3 treated with Inflectra®. Overall agreements between fingerprick vs venous whole blood and fingerprick vs serum measured with the rapid POC test were 100% and 99%, respectively. Positive (PPA) and negative (NPA) agreements between POC test vs venous and capillary whole blood specimens immediately before the infusion. ATI test results were read visually with the POC test in 30 min, just before the patient started the infusion. Trough sera were also collected for subsequent analysis with the rapid test and benchmarked with Promonitor®-Anti-IFX ELISA (Progenika, Spain). Follow-up time was 6 months. ELISA quantitative results were categorized as positive and negative to allow comparisons with the qualitative rapid test.

Conclusions: ATI can be reliably detected in either venous or capillary circulation. Results show an almost perfect agreement between specimens and with the reference ELISA technique. Measurement with the POC test allows the clinician to detect ATI in a quick and fully decentralised mode facilitating immediate POC decision making.

DOI: 10.1136/annrheumdis-2017-eular.6352
Adherence, satisfaction and fulfillment of expectations on the subcutaneous (SC) biological treatment is better with monthly administration.

Objectives: We further assessed if there are differences in patients expectations and satisfaction with efficacy and tolerance that could contribute to explain such finding.

Methods: ARCO was a retrospective study on RA patients who had been prescribed a SC biological 11–18 months prior to the study. Adherence was calculated with the medication possession ratio (MPR). Satisfaction and expectations were assessed with the Spanish validated Carbonell questionnaire [1].

Results: We included 364 patients (age 54.9 years [SD 12.5], 77.5% women, median duration of RA 7.8 years, period studied for the SC biological 14.8 months). Non-adherence (MPR <80%) was lower in patients with monthly (6.4%) than with weekly (17.4%, p=0.034) or every 2 weeks administration (14.4%, p=0.032). The % of satisfied patients (quite/very satisfied) was 86.2% for efficacy and 64.4% for side effects or tolerance. Non-adherence was similar in satisfied and in neutral/unsatisfied patients (14.7% vs. 8.3%, p=0.399), or in patients satisfied/not satisfied with side effects (13.1% vs. 15.4%, p=0.504). The fulfillment of expectations is shown in the table. With regard to expectations on the effect, non-adherence was 15.5% (higher than expected), 12.6% (as expected) and 10.7% (lower than expected) (p=0.677), and with regard to discomfort/side effects, it was 15.6% (greater than expected), 18.5% (as expected) and 11.1% (lower than expected, or no side effect) (p=0.189). Fulfillment of expectations on efficacy was similar for the 3 dosing schemes, but the % reporting lower than expected discomfort or no discomfort was greater with fewer SC injections (table).

Conclusion: In particular, the % reporting no discomfort/side effects with the administration of 2 or 4 injections was greater than expected. Therefore, the % reporting lower than expected discomfort or no discomfort was greater with fewer SC injections (table). In particular, the % reporting no discomfort/side effects with the administration were 17.8% (weekly), 28.3% (every 2 weeks), and 35.0% (monthly) (p=0.013).

References:

Background: In patients with rheumatoid arthritis (RA), we previously described that adherence to the subcutaneous (SC) biological treatment is better with monthly administration.

Objectives: We further assessed if there are differences in patients expectations and satisfaction with efficacy and tolerance that could contribute to explain such finding.

Methods: ARCO was a retrospective study on RA patients who had been prescribed a SC biological 11–18 months prior to the study. Adherence was calculated with the medication possession ratio (MPR). Satisfaction and expectations were assessed with the Spanish validated Carbonell questionnaire [1].

Results: We included 364 patients (age 54.9 years [SD 12.5], 77.5% women, median duration of RA 7.8 years, period studied for the SC biological 14.8 months). Non-adherence (MPR <80%) was lower in patients with monthly (6.4%) than with weekly (17.4%, p=0.034) or every 2 weeks administration (14.4%, p=0.032). The % of satisfied patients (quite/very satisfied) was 86.2% for efficacy and 64.4% for side effects or tolerance. Non-adherence was similar in satisfied and in neutral/unsatisfied patients (14.7% vs. 8.3%, p=0.399), or in patients satisfied/not satisfied with side effects (13.1% vs. 15.4%, p=0.504). The fulfillment of expectations is shown in the table. With regard to expectations on the effect, non-adherence was 15.5% (higher than expected), 12.6% (as expected) and 10.7% (lower than expected) (p=0.677), and with regard to discomfort/side effects, it was 15.6% (greater than expected), 18.5% (as expected) and 11.1% (lower than expected, or no side effect) (p=0.189). Fulfillment of expectations on efficacy was similar for the 3 dosing schemes, but the % reporting lower than expected discomfort or no discomfort was greater with fewer SC injections (table). In particular, the % reporting no discomfort/side effects with the administration were 17.8% (weekly), 28.3% (every 2 weeks), and 35.0% (monthly) (p=0.013).
Results: A total of 49 patients were enrolled and 48 patients completed the study. The mean injection site pain score was 2.3 in PFS vs 2.0 in PFP immediately post-injection and 0.8 in PFS vs 0.7 in PFP at 15–30 minutes post-injection. At both time points the score was equivalent between PFS and PFP: the 97.5% CI was (0.09, 0.30) and (0.07, 0.25) immediately and 15–30 minutes post-injection, respectively.

The overall impression was also comparable between PFS and PFP. There were no patients who had an overall impression of extremely unfavorable and the proportion of patients who had a favorable impression was higher than that of unfavorable impression in both PFS and PFP. The overall preference for PFP (56.5%) was higher than PFS (30.4%) as presented in the Table. Both PFS and PFP were well tolerated and there were no serious treatment-emergent adverse events. Only one patient after administration of PFS experienced injection site reaction.

Conclusions: The injection site pain score of PFS and PFP was comparable with overall preference rate higher for PFP. Both PFS and PFP were well tolerated with similar safety profiles.

FRIO1099 SYSTEMATIC REVIEW AND META-ANALYSIS ON CERTOLIZUMAB PEGOL FOR RHEUMATOID ARTHRITIS IN ADULTS
J.A. Bernal1, V. Pela1, V. Ruiz García2, A. Burla3, J.B. Cabello4, S. Bort-Martí2.
1Rheumatology, Hospital General Universitario de Alicante, Alicante; 2Hospital at Home Unit, la Fe University Hospital, Valencia, Spain; 3School of Health Sciences, University of London, London, UK; 4Department of Pharmacy, Universitat de Valencia, Spain; 5Academic Unit of Rheumatology, University of Leeds, Leeds, UK

Background: The appearance of tumor necrosis factor-alpha (TNFalpha) inhibitors dramatically changed the prognosis of rheumatoid arthritis. Certolizumab pegol (CZP) is a human Fab fragment of anti-TNFalpha monoclonal antibody which is approved for the treatment of rheumatoid arthritis. We performed a systematic review and meta-analysis, with Cochrane methodology, of the effects of CZP in rheumatoid arthritis.

Objectives: To assess the clinical benefits and harms of CZP in patients with rheumatoid arthritis.

Methods: We performed a search of electronic database (Cochrane Database, MEDLINE, EMBASE, Web of Knowledge and clinicaltrials.gov) until 26th September 2016. We searched for randomized controlled trials of CZP in rheumatoid arthritis compared to any other agent including placebo.

Results: 14 trials were included for the meta-analysis, 12 (5422 patients) in the pooled analysis for benefits and 14 (5499 patients) in the pooled analysis for safety. The overall possibility of bias seemed to be low but the quality of the evidence was low due to the risk of attrition bias.

With the approved dose - CZP 200 mg subcutaneous every other week with the first three doses of 400 mg - CZP showed statistically significant improvements at 24 weeks compared to placebo in: ACR20 improvement 27% (95% CI 20% to 33%); RR 3.8 (95% CI 2.42 to 5.95) and NNT=4 (95% CI 3 to 8); DAS28 <2.6 - original definition of remission - with RR 3.79 (95% CI 1.90 to 7.56); HAQ with 12% absolute improvement (95% CI -9% to -14%); and erosion score with -0.29% (95% CI -0.42% to -0.17%). There are also data available at 12 weeks with -12% absolute improvement (95% CI -9% to -14%); and erosion score with -12% improvement (95% CI -9% to -14%).

Use of an enhanced communication strategy, together with more experience and absence of group think effects, resulted in much higher acceptance and persistence rates after open label shared decision making biosimilar transitioning in patients with a rheumatic disease.

ETANERCEPT RETENTION PATTERNS AND FACTORS ASSOCIATED WITH TREATMENT DISCONTINUATION: A RETROSPECTIVE COHORT STUDY USING CANADIAN CLAIMS-LEVEL DATA

M. Khraishi1, Y. Zhang2, J. Ivanovic2, B. Millson2, M.-J. Brabant2, K. Charland2, E. Singh3, J. Woolcott4, H. Jones3. 1Facility of Medicine, Memorial University of Newfoundland, St. Johns; 2Health Access & Outcomes, QuintilesIMS, Kanata, Canada; 3Inflammation and Immunology, Global Medical Affairs, Pfizer Inc., Collegeville, United States; 4Health Economics and Outcomes Research Pfizer Inc., Kirkland, Canada

Background: Etanercept is a soluble TNF receptor (humanized protein) indicated for the treatment of immune-mediated inflammatory diseases such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), and psoriasis (PsO). Limited data exists on the factors associated with long-term retention and use of etanercept in Canada in a real-world setting.

Objectives: To evaluate the 6-year retention rates of etanercept patients in Canada, and to identify factors associated with discontinuation.

Methods: A retrospective cohort study was conducted using longitudinal pre-prescription drug claims data from QuintilesIMS Private Drug Plan database (PDP), Ontario Public Drug Plan database (OPDP), and Quebec Public Drug Plan database (RAMQ). Between 07/2008 and 06/2010, bio-naïve patients who initiated etanercept were identified and followed for 72 months. 12-month retention rates were evaluated in 1-year increments for all patients retained on therapy at year 1, 2, 3, and beyond. The retention rates in the first year were compared to retention rates in the first year. Covariates associated with time to discontinuation over the entire 72 month period were identified using a Cox proportional hazards regression model.

Results: The study identified 4,528 etanercept patients (61% female, 85% rheumatoid arthritis, and 15% PsO) across Canada who started their therapy in the period 07/2008 - 06/2010. The study identified 4,528 etanercept patients (61% female, 85% rheumatoid arthritis, and 15% PsO) across Canada who started their therapy in the period 07/2008 - 06/2010. Between 07/2008 and 06/2010, bio-naïve patients who initiated etanercept were identified and followed for 72 months. 12-month retention rates were evaluated in 1-year increments for all patients retained on therapy at year 1, 2, 3, and beyond. The retention rates in the first year were compared to retention rates in the first year. Covariates associated with time to discontinuation over the entire 72 month period were identified using a Cox proportional hazards regression model.

Conclusions: Etanercept patient retention likelihood increased the more years a patient was retained on therapy. This pattern was consistent across therapeutic areas, sex, age, and payers. Age, indication, and payer were found to have a significant impact on etanercept retention. With better understanding of factors associated with retention, patient support programs can be designed to address the specific needs of at-risk groups while supporting patients stable on therapy.

FRI0201

GOLIMUMAB IN BIOLOGIC-NAÏVE PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS (RA), PSORIATIC ARTHRITIS (PSA) OR ANKYLOSING SPONDYLITIS (AS) - SUBANALYSIS FROM THE NON-INTERVENTIONAL EVALUATION GO-NICE

K. Krüger1, G.R. Burmester2, S. Wassenberg3, M. Bohl-Bühler4, M.H. Thomas2, 1Rheumatoologisches Praxiszentrum, München; 2Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin, Berlin; 3Rheumafachklinik Potsdam GbR, Potsdam; 4Medical Affairs, MSD Sharp & Dohme GmbH, Haar, Germany

Background: Golimumab (GLM) has demonstrated efficacy and safety in several randomized clinical trials with biologic-naïve patients. However, data from effectiveness and patient-reported outcomes (PROs) parameters in daily clinical practice in Germany are scarce.

Objectives: The aim of this subanalysis is to assess Golimumab on the effectiveness, and PROs in biologic-naïve patients with established RA, PsA or AS.

Methods: This is a subanalysis of the non-interventional, prospective, 24-month study GO-NICE. Biologic-naïve patients with established RA, PsA or AS starting with GLM 50mg Sc once monthly in a real life setting in Germany. Endpoint measures: disease activity DA28S, PsARC and BASD1. PROs included QoL (EQ-5D-3L), functionality (FFbH), fatigue (FACIT-F). Safety data were also collected.

Results: RA patients (n=265): Mean age 54.5 yr, 82.1% of the patients were female, 77.3% (n=204) were rheumatoid factor (RF) positive, and 76.4% (n=201) anti-cyclic citrullinated peptides (anti-CCP) antibodies at BL. The BASDAI at BL was 5.0 and dropped significantly to 2.9 within 24 months (p<0.0001 vs BL). After 3 months of treatment, 45.2% of patients had LDA (DAS28 ≤ 2.6), which increased to 50.8% after 6 months and 64.9% after 24 months. PsA patients (n=247): Mean age 49.7 yr, 53.8% of the patients were female, 42.1% (n=104) had a nail involvement, 25.5% (n=63) dactylitis and 13.8% (n=34) enthesitis at BL. The proportion of patients achieving a response (mod PsARC) was 64%, 72.5% and 77% at 3, 6 and 24 months, respectively. AS patients (n=246): Mean age 41.9 yr, 70.7% of the patients were male, 80.5% (n=198) were HLA-B27 positive. Most common extraarticular manifestations were: enthesitis (12.6%), iritis (12.2%), IBD (3.7%), and dactylitis (2.8%) at BL. The BASDAI at BL was 6.6 and significantly improved to 4.0 (p<0.0001 vs BL) within 24 months. The proportion of patients achieving a response (BASDAI 50) was 62.2%, 66.9% and 76.9% at 3, 6 and 24 months, respectively.

An improvement of quality of life (QoL) by EQ-5D-3L was seen after 6 months and was maintained over 24 months. The patients’ health state today (EQ VAS) improved from 52.3 at BL to 64.9 (RA), from 49.0 to 66.3 (PsA) and from 49.2 to 70.6 (AS). The functional ability (FFbH) improved significantly (p<0.0001 vs BL) from 73.1 to 80.4 points (RA), from 73.0 to 82.2 (PsA) and from 72.8 to 81.2 (AS). The Mean Fatigue score (FACIT-F) increased from BL: 33.3 to 39.5 points (RA), 25.6 to 33.8 (PsA) and 28.4 to 32.9 points (AS) (each p<0.001 vs BL) within 24 months.

No new safety signals were detected.

Conclusions: GLM SC once-monthly showed after 3 months remarkable improvements in clinical effectiveness, patient-reported quality of life, functionality, and fatigue. Functional parameters were maintained over 24 months in biologic-naïve patients with established RA, PsA or AS. At month 24, 64.9% of RA patients achieved LDA status, 77.7% of PsA achieved positive PsARC response and 76.9% of AS patients achieved BASDAI 50. No new safety signals were detected.
FR010204 | COMPARISON THE LONG-TERM CLINICAL OUTCOMES BETWEEN NONTNF-INHIBITORS VERSUS TNF-I IN RA PATIENTS WHO FAILED TO A FIRST TNF-I

P. Bogas 1, C. Plasencia 1, D. Pascual-Salcedo 2, G. Bonilla 1, E. Moral 1, C. Torniero 1, L. Nuño 1, A. Villaña 1, D. Peiteado 1, A. Martínez 2, B. Hernandez 2, A. Balsa 1

1Rheumatology; 2Immunology, Hospital Universitario la Paz, Madrid, Spain

Background: There are many biological therapies for Rheumatoid Arthritis (RA) with different mechanisms of action and good efficacy rate; however, up to 40% of patients (pts) fail to respond to the 1st biologic agent, and it is still not clear what strategy to follow after showing inadequate response to tumor necrosis factor inhibitors (TNF-i).

Objectives: To assess the clinical response and survival (SV), in our cohort of RA pts that discontinued the 1st TNF-i, of a 2nd TNF-i vs a non-TNF-i, both in the global cohort and in the subpopulation that dropped out the 1st TNF-i due to ineffectivity.

Methods: This observational study included 110 pts in the RA-Paz cohort who previously suspended Ifx (68%) or Ada (32%) between 1999–2016. Two groups were established: they switched to a TNF-i or non-TNF-i. Clinical response was evaluated by DAS28, Delta-DAS28 (∆DAS28) and EULAR response (E-resp). The assessments were performed at 6 (v-6) and 12 months (v-12) since initiating 2nd biological agent and during the last visit prior to drug discontinuation or ending of the study for those who did not interrupt the drug (v-end). Statistical analysis was performed using the R program version 3.4.0.

Results: Of the 110 pts who had stopped Ifx or Ada as 1st TNF-i, 65% changed to a 2nd TNF-i. The 84% of the overall pts were women. The mean age was 64±14 years and the mean time of 2nd biologic drug was 3.0±1.3 years. 61% associated methotrexate at the beginning of 2nd biologic agent and 56% at the v-end, without differences between those who switched to TNF-i and those who did to non-TNF-i. At v-6 and v-12, there was no difference in ∆DAS28 [at v-6: 6.3±1.4 in TNF-i and 1.2±1.2 in non-TNF-i (p=0.199), at v-12: 1.3±1.5 in TNF-i and 1.2±1.1 in non-TNF-i (p=0.852)]. In contrast, at v-end, pts with non-TNF-i showed a higher clinical improvement (∆DAS28: 0.68±1.7 in TNF-i, 1.8±1.1 in non-TNF-i, p=0.002). At v-6, the TNF-i group achieved higher good E-resp rate (41% vs 18%, p=0.035), but there was no difference at v-12 (36% in TNF-i vs 23% in non-TNF-i, p=0.435). However, at v-end, the non-TNF-i group achieved better E-resp (good resp: 38% in non-TNF-i vs 25% in TNF-i, no resp 18% in TNF-i vs 56% in non-TNF-i, p=0.01). Likewise, 100% (n=7) of the pts that finished 2nd biologic agent by remission, had changed to a non-TNF-i (p<0.0001).

There were no differences regarding 2nd biologic drug SV (mean SV time of 5.7±0.66 in TNF-i, 4.3±0.59 in non-TNF-i, p=0.197). When analyzing the cohort that discontinued 1st TNF-i because of ineffectivity, at v-6 and v-12 there were no differences between switchers to TNF-I and non-TNF-I in ∆DAS28 [v-6: 1.4±1.4 vs 0.9±1.0 (p=0.164); v-12: 1.5±1.4 vs 1±1, (p=0.192)], but at v-end, the non-TNF-i group reached a higher ∆DAS28 (0.9±1.5 in TNF-i, 1.6±1 in non-TNF-i, p=0.031) between a TNF-i and a non-TNF-i within the 1st year of treatment. However, in the long-term, switching to a non-TNF-I shows enhanced clinical benefits with no impact on survival vis-à-vis a 2nd TNF-I. Despite the efficacy of TNF-I, new therapeautic targets are needed for those who fail to respond to these biological agents.

Disclosure of Interest: None declared

FR010205 | CORRELATION OF PATIENT PREFERENCES TO TREATMENT OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) TREATED WITH ANTI-TNF AGENTS IN GREECE. THE PANORAMA STUDY

P. Sidiroopoulos 1, A. Bounas 2, P. Athanasiou 3, A. Andrianakos 4, E. Petrikou 5, A. Drosos 6, V. Vassilopoulos 7

1Department of Rheumatology, Clinical Immunology and Allergy, University of Crete, Heraklion; 2Private practice, Patras; 3Rheumatology Division, General Hospital of Thessaloniki St. Paul, Thessaloniki; 1ASO General Hospital; 2Medical Affairs, MSD, Athens; 6Rheumatology Clinic, University of Ioannina, Ioannina; 7Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens, Athens, Greece

Background: Route and frequency of administration of treatment options may be an important differentiator between drugs that are used to treat RA and patient preferences may influence adherence to and outcomes of therapy.

Objectives: The objective of this study was to assess the correlation between the fulfillment of patient preferences and clinical and patient reported outcomes.

Methods: PANORAMA was a non-interventional, prospective, multicenter, cohort study. Patients who discontinued a 1st biologic failure or experienced who initiated/switched to anti-TNF at enrollment. Post physician’s anti-TNF choice, patients completed a preferences questionnaire over attributes related to anti-TNF treatment. Satisfaction with treatment was assessed with the TQSM questionnaire and compliance (proportion of full doses/pillaged) was recorded via the use of a patient diary. Persistence was defined as the time period from the last anti-TNF administration. The observational period was 12 months, with study visits every 3 months.

Results: A total of 254 patients were enrolled in the study. The mean patient age was 58.3±13.4 years, 82.7% were female, 65.4% were biologic naive and 66.1% had severe disease (DAS-28 >5.1). The mean DAS-28 and HAQ-DI scores at enrollment were 5.5±1.1 and 1.4±0.6 respectively, while mean disease duration was 67.6±6.2 years with 53.2% of patients being seropositive (RF+) (49.2%, Anti-CCP+) (40.5%). A monthly administration was most preferred by patients (65.7% vs. 20.1% for twice per month, 11.8% for once per week and 3.9% for twice per week), and the large majority of patients (75.2%) preferred the subcutaneous mode of administration. The mean compliance and 12-month persistence rates were 97.0% and 72.3% respectively. At 12 months, good EULAR response rate was achieved by 56.5% of patients and 40.8% were in DAS-28 remission. Univariate analysis demonstrated that fulfillment of patient preferences was correlated to good EULAR response (p<0.001), increased probability of being persistent (p=0.019) and satisfaction with treatment (p=0.063). Multivariate logistic regression analysis revealed that a good EULAR response was associated with satisfaction of patient preferences (OR 5.560, p<0.001), good patient knowledge of the disease (OR 1.327, p=0.006), absence of history of comorbidities (OR 2.42, p=0.014) and lower SJC (OR 1.10, p=0.021), whereas anti-TNF persistence at 12 months was associated (Cox regression analysis) with seropositivity (HR 0.566, p=0.047) and a high baseline ESR (>35 mm/h (HR 0.587, p=0.071)).

Conclusions: In anti-TNF treated RA patients, fulfillment of expressed treatment preferences was independently associated with a good EULAR response and correlated with drug persistence at 12 months, emphasizing the importance of patient preferences in treatment outcomes.

FR010206 | CORRELATION BETWEEN THE SERUM ETANERCEPT LEVEL AND RESPONSE TO ETANERCEPT TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

S.M. Zivojnovic 1, M. Sefik-Bukilica 2, N.S. Damjanov 2

1Clinical IV; 2Laboratory department, Head of Institute of rheumatology, Institute of Rheumatology, Belgrade, Serbia

Background: It is well documented that the blockade of TNF-a significantly reduces disease activity in patients with rheumatoid arthritis (RA). However, at least one third of patients receiving etanercept either do not respond to treatment, or lose initial responsiveness [1]. Recent findings indicate that lack of clinical response may be related with lowering the serum drug levels.

Objectives: To investigate the relationship between serum etanercept levels and response to etanercept treatment in patients with RA.

Methods: The study population consisted of fifty eight patients with rheumatoid arthritis (RA), all treated with etanercept. Disease activity was assessed according to the 28-joint count Disease Activity Score (DAS28) at baseline and 6 months of
therapy. Clinical response was assessed using the European League Against Rheumatism (EULAR) response criteria [2]. Serum etanercept levels were measured by sandwich ELISA based on the ability of etanercept to bind TNF. Antibodies against etanercept were measured by bridging ELISA (Promonitor).

**Results:** The 47 female and 11 male were of a mean age 52±11.2 years (23 yrs–75 yrs), responding with RA for a mean of 13.2±8.2 years (2–24). At baseline the DAS28scores mean score was 6.1±1.0. After six months of etanercept treatment, 20 (34.5%) patients were in remission, 20 (34.5%) were in low disease activity and 18 (31%) were in moderate disease activity. The serum etanercept levels were significantly higher in patients in remission compared with patients in moderate disease activity (p<0.05). According to the EULAR response criteria, RA patients were divided into responders (52pts, 89.7%) and non-responders (6 pts, 10.3%). Median etanercept levels in all patients were 3.937mcg/ml. There were no statistical differences in etanercept levels between responders and non-responders (p=0.41). In addition, we stratified all patients into quartiles according to height of the etanercept level. The percentage of EULAR good responders was significantly different between the highest and the lowest quartiles (p<0.05).

Anti-etanercept antibodies were not found in any of the studied patients (0/58).

**Conclusions:** Patients with RA who did not respond to etanercept treatment achieved lower etanercept levels compared with responding patients. Higher concentrations of the drug were associated with a better response to treatment. Further studies are needed to provide evidence for this approach.

Objectives: This abstract presents results from three clinical trials of infliximab biosimilar, BCD-055, including comparative data on pharmacokinetics (PK), efficacy and safety in a variety of patient populations.

Methods: All three studies were conducted as international multicenter randomized double-blind studies in direct comparison with innovator IFX. ASART-1 study (biosimilar adalimumab vs. innovator adalimumab) was conducted in Russia and Brazil. A total of 200 patients - 119 patients with AS and 81 patients with RA were enrolled in ASART-1 study. 90% (181 out of 200 patients) received concomitant therapy with methotrexate. AUC was calculated for AUC-inf, AUC-0-<inf>∞, AUC-0-tau, Cmax, and Cmax-inf. AUC comparisons were made with 0.80 to 1.25 ratio as non-inferiority margin, for Cmax with 0.75 to 1.33 ratio as non-inferiority margin, and for 2-way ANOVA test for significance.

Results: ASART-1 study demonstrated that the BCD-055 is non-inferior to innovator IFX both in RA and AS patients: AUC <inf>0-τ 0 10.1136/annrheumdis-2017-eular.2357 10.1136/annrheumdis-2017-eular.2357

FR02020 REAL-LIFE SAFETY PROFILE OF BIOSIMILAR ADALIMUMAB IN PATIENTS WITH INFLAMMATORY ARTHRITIC CONDITIONS

V. Kaushik, S. Apparao. Arthritis & Rheumatism Centre, Chennai, Chennai, India

Background: Biologic therapies have dawned a new era in the management of patients with chronic inflammatory arthritis by nudging the goal post from control to induction of remission. Adalimumab, a TNF-α inhibitor, has been proven to be safe and effective in improving the disease activity and quality of life in patients with conditions like rheumatoid arthritis (RA) and ankylosing spondylitis (AS). 1,2 A biosimilar adalimumab (developed by Cadila Healthcare Ltd. India) has been approved for clinical use in 2014 in India. While the initial biosimilarity has been established for physicochemical, functional as well as clinical efficacy and safety aspects, 3,4 ongoing evaluation of safety in real-life patients is crucial for such biosimilar therapies.

Objectives: We share our experience on the real-life safety profile of biosimilar adalimumab following its clinical use in patients with RA and AS.

Methods: Patients with RA or AS treated with biosimilar adalimumab in our outpatient clinic at Arthritis and Rheumatism Centre during the period of 17 months (1 March 2016 to 10 October 2017) were considered for this analysis. Primary outcome was ADR analysis. The patients were prescribed biosimilar adalimumab 40 mg subcutaneously every fortnight for a minimum of 6 months. The patients were followed up till the end of the treatment, and any safety signals or adverse events reported were collected and analysed.

Results: A total of 200 patients - 119 patients with AS and 81 patients with RA - who received biosimilar adalimumab therapy for a period of 6 months were included. The median age for the group was 36 (17–68); and 138 patients were males. The mean BMI was 25.7±4.83; and the median duration of disease for the entire group was 4.5±(0–15.3) years - 4.5±(0–9.5) years for the patients with RA and 4.5±(2.4–15.5) years for the patients with RA. About 90% (181 out of 200 patients) received concomitant therapy with methotrexate. Biosimilar adalimumab therapy was well tolerated by all patients, with no serious adverse events. Adverse events were noted in only 2 patients - one patient had developed pulmonary tuberculosis in the 4th month of treatment, biosimilar adalimumab was discontinued and AKT treatment was started; while another patient experienced rise in transaminases for which, the dose of methotrexate was reduced. Overall assessment of tolerability as “Excellent” was 65.5% by the treating physician and 82% by patients.

Conclusions: To the best of our knowledge, this is the first report on “real-life” use of biosimilar adalimumab in such a large number of patients. The analysis reveals a safety and tolerability profile of biosimilar adalimumab comparable to that of the innovator product.

FR02010 REAL-WORLD HAWK STUDY: LONG-TERM SAFETY AND EFFECTIVENESS OF ADALIMUMAB WITH HIGHER-DOSE METHOTREXATE IN JAPANESE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

Y. Tanaka 1, 2, T. Mimori 2, H. Yamanaka 3, R. Nakajima 4, K. Morita 1, J. Kimura 2, T. Takeuchi 2, 3, 4. The First Department of Internal Medicine, School of Medicine, University of Occupational and Environmental Health, Kitakyushu; 2Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University, Kyoto; 3Institute of Rheumatology, Tokyo Women’s Medical University; 4Abbvie GK; 5Division of Rheumatology, Department of Internal Medicine, School of Medicine, Keio University, Tokyo, Japan

Background: TNF inhibitors are first-line biologic therapy used in combination with MTX for treatment of RA. However, in Japan, limited real-world data exist on this combination with relatively higher doses of MTX (>8 to <16 mg/week).

Objectives: The HAWK study was designed to assess real-world, long-term safety and effectiveness of the TNF inhibitor ADA with MTX (>12 mg/week) in Japan. Week 52 results are presented.

Methods: This multicenter, prospective, observational study, enrolled biologic-naive, early (<2 years) RA patients with DAS28-CRP >3.2 despite MTX therapy or who required Eligible healthcare providers received ADA (12 mg/week at beginning of ADA) for 104 weeks. Primary endpoint was DAS28-CRP <2.6 at week 52. Secondary endpoints included CDAI, SDAI, HAQ-DI and inhibition of structural joint damage using the mTSS. ADRs and dosage of ADA and MTX were recorded.

Results: As of April 15, 2016, 346 patients were enrolled (safety set 301; effectiveness set 293). Effectiveness set comprised 79% women; mean (±SD) age, 54.3 (13.9) years; duration of RA, 12.1 (6.2) months; MTX dosage, 13.4 (1.8) mg/week; DAS28-CRP, 4.5 (0.9); and mTSS, 7.7 (10.0) at baseline. At week 52, DAS28-CRP <2.6 and low disease activity (<3.2) were achieved in 77% and 92% patients, respectively. Remission rates of CDAI (<28), SDAI (<3.3), and HAQ-DI (<0.5) were 49%, 51%, and 82%, respectively. Although average MTX dosage was decreased (<2 mg/week), unchanged, and increased (<2 mg/week) from baseline in 19.6%, 78.9%, and 1.4% patients over 52 weeks, respectively, there was no significant difference in disease activity improvement across these MTX dosage groups at week 52 (p=0.350). Structural remission rate at week 52 was 86% (ΔmTSS <0.5) (Figure). A total 110 ADRs occurred in 80 (26.6%) patients, 23 were serious in 21 (7.0%) patients (Table).

Conclusions: Results show that ADA with MTX (>12 mg/week at the beginning) displayed a consistent safety profile and was effective with a DAS28-CRP remission rate of 77% in routine clinical practice. The ADR rate of 26% was similar to a previous, short-term (28 weeks) postmarketing surveillance report (1).

A DESCRIPTIVE ANALYSIS OF REAL-WORLD TREATMENT PATTERNS OF INNOVATOR INFlixIMAB (REMICADE) AND BIOSIMILAR INFLIXIMAB IN A TREATMENT NAÏVE TURKISH RHEUMATOLOGIC DISEASE POPULATION

Y. Yazici, L. Xie, A. Ogbono, D. Parenti, K. Goyal, A. Teeple, L. Ellis, I. Simsek, NYU Hospital for Joint Diseases, New York; Janssen Scientific Affairs, LLC, Horsham, United States; 2STATinMED Research Inc, Ann Arbor; Janssen Scientific Affairs, LLC, New Jersey, United States; 3Guven Hospital, Ankara, Turkey

Objectives: This retrospective healthcare claims analysis examined treatment patterns of innovator infliximab (IFX) and biosimilar infliximab (CT-P13) in a Turkish rheumatologic disease population after CT-P13 availability in July, 2014. Methods: Adult patients (pts) with ≥1 diagnosis code (ICD-10-CM) for rheumatoid arthritis (RA) were identified in a national Turkish healthcare database during the study period (01DEC2010–01DEC2015). Eligible pts had continuous medical/pharmacy enrollment ≥1 year before and ≥6 months after IFX or CT-P13 initiation (index date). Patients were naïve to IFX or CT-P13 (i.e. had no IFX or CT-P13 within 12 months before the index date). Demographics, comorbid conditions and medications, and treatment patterns, were tested. Confirmed discontinuation was defined as a switch to another biologic medication or the absence of an index biologic claim for ≥120 days without censoring.

Results: Key results are shown in the Table. A total of 1044 patients initiated either medication. The majority (80%; n=831) initiated IFX. The IFX cohort had a larger age, female (58%), and mean age and mean follow up was 12 months. The CT-P13 cohort consisted of 213 pts with mean age of 45 years; 58% women; and mean follow up of 9 months. Approximately one-third of pts in each cohort had a concomitant diagnosis of ankylosing spondylitis (AS; TABLE). Other concomitant disease and medications appeared balanced between cohorts. Pts in the IFX cohort had an average of 5.2 infusions and mean dose of 4.7 vials per infusion approximately every 8 weeks. Pts in the CT-P13 cohort had an average of 3.6 doses and mean dose of 5.8 vials per dispensing approximately 9 weeks apart. A confirmed discontinuation occurred in 55% of the IFX cohort; driven in part by switching, 24% of IFX pts had ≥1 biological switch with 8% initially switching to CT-P13. Time to any discontinuation or censoring of IFX is shown in the Table. In the CT-P13 cohort, a confirmed discontinuation was observed in 63%; 31% switched to another biologic therapy; and 20% initially switched to IFX. Time to any discontinuation or censoring of CT-P13 is shown in the Table.

Conclusions: These findings in a single country indicate that real world utilization patterns may differ between innovator IFX and CT-P13, with predominantly greater overall CT-P13 discontinuation and a higher proportion of patients switching from CT-P13 to IFX. Further studies are needed to understand the reasons for these observed differences.

Compared to monotherapy, combination therapy was associated with a lower drug failure (crude HR 0.75 [95% CI 0.68–0.82]; adjusted HR 0.78 [95% CI 0.70–0.86]; p < 0.0001). In patients in monotherapy, considering ETA as reference and adjusting for the above mentioned clinical characteristics, the HR for bDMARD failure was 1.32 for ADA (95% CI 1.07–1.63) and 2.38 for INF (95% CI 1.85–3.07).

Conclusions: Monotherapy with bDMARDs is consistently associated with lower retention rate in first-line therapy for anti-TNF drugs. Comparing bDMARDs administered in monotherapy, INF and ADA show a higher risk of withdrawal than ETA. Real life data support the currently recommended use of bDMARDs in association to csDMARDs.

FR0214 LONG-TERM EFFICACY AND SAFETY OF SIRUKUMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS DESPITE ANTI-TUMOR NECROSIS FACTOR THERAPY: RESULTS OF THE RANDOMIZED, PHASE 3 SIRROUND-STUDY

Y. Tanaka1,2, D. Aletaha3, P. Agarwal4, R. Kurrausch5, P.P. Tak1,2, S. Popik2. 1Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan; 2Division of Rheumatology, Medical University of Vienna, Vienna, Austria; 3Janssen Research & Development, LLC, Spring House, PA; 4GlaxoSmithKline, Collegeville, PA, United States; 5GlaxoSmithKline, Stevenage, United Kingdom

Background: Sirukumab, a selective, high-affinity human monoclonal antibody to the interleukin-6 (IL-6) cytokine, is under development for rheumatoid arthritis (RA) and other diseases.

Objectives: To evaluate long-term efficacy and safety of sirukumab in patients (pts) with RA refractory or intolerant to anti-tumor necrosis factor (TNF) agents.

Methods: This phase 3 study included pts ≥18 years with moderate to severe active RA, and a lack of benefit to ≥1 anti-TNF or intolerance to ≥2 anti-TNFs. Eligible pts were initially randomized 1:1:1 to sirukumab subcutaneous (SC) 50mg q4w, sirukumab SC 100mg q2w, or placebo SC q2w for 24 wks. Placebo-treated pts with <20% improvement in tender and swollen joints at Wk 18 (early escape [EE]) and those remaining on placebo at Wk 24 (crossover) were re-randomized to sirukumab through Wk 52. Efficacy endpoints included ACR response, HAQ-DI scores, DAS28 (CRP) remission rates, and SF-36 scores. Results are presented for these key endpoints at Week 52.

Results: 678 pts were initially randomized to placebo (n=294), sirukumab 50 mg q4w (n=292), or sirukumab 100 mg q2w (n=292). Of placebo-treated pts, 94 met EE criteria at Wk 18 and 158 crossed over at Wk 24 and were re-randomized to sirukumab. 60% of pts had received ≥2 prior biologics, including non-TNF–targeted biologics. RA signs and symptoms and patient-reported outcomes (PROs [SF-36 scores]) improved significantly with sirukumab versus placebo through Wk 54. Improvements were maintained through Wk 52 with no dose response (Table 1). Through Wk 52 in the combined sirukumab 50mg q4w and 100mg q2w groups, respectively, an adverse event (AE) was reported for 79.6% and 81.3% of pts and a serious AE was reported for 14.2% and 13.2% of pts; injection-site reactions and alanine aminotransferase increases were the most commonly reported AEs.

Conclusions: In this population intolerant or refractory to anti-TNFs/other biologics, sirukumab SC 50mg q4w and 100mg q2w were well tolerated and reduced signs and symptoms of RA and improved PROs through 52 wks of treatment, also among pts who switched from placebo to sirukumab.

Background: Despite a demonstrated superiority of interleukin-6 over tumour necrosis factor (TNF) blockade when used as monotherapy, the choice of the first biologic agent (bDMARD) for treating rheumatoid arthritis (RA) in combination with methotrexate (MTX) is still a challenge for rheumatologist.

Objectives: To retrospectively evaluate in a multicentre observational cohort of Northern Italy (the LORHEN registry) the 6- and 12-month comparative drug survival and remission rate of tocilizumab (TCZ) and TNF inhibitors (TNFi) used as first bDMARD in combination with MTX.

Methods: All RA patients treated with TCZ or a TNFi as first-line bDMARD with at least 12-month follow-up were selected from the LORHEN registry. The analysis was limited to the period from January 2009 to May 2016 and to patients receiving either TCZ or TNFi in combination with MTX, excluding bDMARD monotherapy.

Six- and 12-month clinical remission rate was defined as achievement of disease activity score 28 calculated by using erythrocyte sedimentation rate (DAS28-ESR) <2.6. Drug persistence was calculated by Kaplan-Meier method. The comparison between treatment subgroups was performed by a chi-square test for remission data and by a log-rank test for drug survival. Moreover, DAS28-ESR remission rate has been corrected for drug discontinuation by using the LUNDEX formula [1].

Results: The overall study population included 591 patients (female 77.3%, mean age ± standard deviation, SD) 54.2±13.2 years, mean disease duration ±SD) 7.4±7.7 years, positive rheumatoid factor 67.5%, positive anti-citrullinated peptide antibodies 77.6%, mean baseline DAS28-ESR 5.1±1.2 treated with TCZ (n=61) or TNFi (n=530) infliximab 43, adalimumab 163, etanercept 195, golimumab 60, certolizumab pegol 69). Baseline characteristics were similar in the two groups, with the exception of mean age (TCZ 58.2 vs TNFi 53.7 years; p=0.021). No significant differences were observed in the 6- to 24-month period (TCZ 88% vs TNFi 84.3%; p=0.752) and 12-month period (TCZ 76.4% vs TNFi 71.5%; p=0.17) between TCZ and TNFi. Clinical remission was achieved in overall 35.7% patients at 6 months (TCZ 59% vs TNFi 35%: p=0.001) and in 36.8% patients at 12 months (TCZ 76% vs TNFi 63.9%: p=0.001). Similar trends were observed after correction by LUNDEX formula at 6 months (TCZ 58.8% vs TNFi 53.7%; p=0.021). No significant differences were observed in the 6- to 24-month period (TCZ 88% vs TNFi 84.3%; p=0.752) and 12-month period (TCZ 76.4% vs TNFi 71.5%; p=0.17) between TCZ and TNFi. Clinical remission was achieved in overall 35.7% patients at 6 months (TCZ 59% vs TNFi 35%: p=0.001) and in 36.8% patients at 12 months (TCZ 76% vs TNFi 63.9%: p=0.001). Similar trends were observed after correction by LUNDEX formula at 6 months (TCZ 58.8% vs TNFi 53.7%; p=0.021). No significant differences were observed in the 6- to 24-month period (TCZ 88% vs TNFi 84.3%; p=0.752) and 12-month period (TCZ 76.4% vs TNFi 71.5%; p=0.17) between TCZ and TNFi.

Conclusions: Despite a similar 1-year remission rate, the proportion of patients achieving DAS28-ESR remission was significantly higher in TCZ+MTX treated group compared with TNFi+MTX, suggesting a deeper clinical response in patients receiving IL6 blockade.

IMPACT OF RITUXIMAB IN COMBINATION WITH LEFLUNOMIDE AND RITUXIMAB RETREATMENT WITH TWO DIFFERENT DOSAGES ON PATIENT-REPORTED OUTCOMES: RESULTS FROM A MULTICENTER RANDOMIZED PLACEBO-CONTROLLED INVESTIGATOR INITIATED CLINICAL TRIAL IN ACTIVE RHEUMATOID ARTHRITIS (AMARA-STUDY)

Methods: A total of 189 patients with active RA (DAS28≥3.2 and at least 3 SJC and 3 TJC) despite stable LEF treatment were screened for a 52-weeks placebo-controlled RCT. Patients were randomized to receive either two-times 1000mg RTX i.v. followed by a retreatment at week 24 with two-times 1000 (RTX-RTXhigh) or 500mg (RTX-RTXlow) or two times PLA at baseline, followed by a retreatment of RTX of either two-times 1000 (PLA-RTXhigh) or 500mg (PLA-RTXlow) at week 24. Adult patients who had inadequate response to more than one antiTNF or failed more than three cDMARDs were excluded. PROs (HAQ, FACIT-F, SF36) were measured at each visit until week 52. Treatment effects on PROs were determined by differences from baseline to week 16, 24 and week52.

Results: Of 189 screened patients 148 were randomized (mean age 56 years; mean proportion of RF- and anti-CCP-positivity 58.4% and 55.7% in the RTX-group; 74% female). DAS28 at baseline was 5.55 for RTX and 5.53 in the PLA-group. All baseline-characteristics were well balanced between treatment groups. An improvement in HAQ from baseline to week 16 was seen with a mean delta of -0.23 in the RTX-group (MCID) vs. -0.11 for PLA. In the RTX-group, retreatment at week 24 resulted in stable HAQ-values compared to week24 independent from its dosage. FACIT-F values increased in the RTX-group from baseline to weeks 16, 24 and 52 by 11.87, 12.3 and 14.25, respectively. All physical and mental domains of the SF36 showed a pronounced increase of levels at week 16 compared to baseline in the RTX-group (Figure 1). A total of 372 adverse events (AE) were observed during the one-year studyperiod, only 14 classified as severe (10 in RTX and 4 in PLA). 43 serious adverse events were reported, 28 of them in the RTX-group during the placebo-controlled period.

Conclusions: Efficacy of LEF plus RTX was demonstrated not only by measurements of disease activity (as presented previously) but also by measurements of PROs (HAQ, FACIT-F, SF36). This treatment regime showed equal effect sizes compared to the combinational therapy of MTX plus RTX. The treatment with LEF plus RTX illustrated an acceptable safety profile.

ASSOCIATION BETWEEN CONVERSION TO ACPA/RF SERONEGATIVE STATUS AND CLINICAL OUTCOMES FOLLOWING TREATMENT WITH ABATACEPT IN COMBINATION WITH METHOTREXATE COMPARED WITH METHOTREXATE ALONE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS AND POOR PROGNOSTIC INDICATORS

D. Jansen, P. Emery, J. Smolen, R. Westhovens, M. Le Bars

Background: RA is characterized by the production of autoantibodies, including anti-citrullinated protein antibodies (ACPA) and RF, which are associated with poor prognosis in RA. More data on the clinical significance of ACPA/RF anti-citrullinated protein antibodies (ACPA) and RF, which are associated with remission achievement in SE positive patients was needed.

Methods: Logistic regression analysis was done in this retrospective cohort. The EULAR good response rate at week 24 were 74.5%/20.0% (SE positive/SE negative, p=0.001, Fisher's exact test), respectively. Simplified Disease Activity Index (SDAI) remission rate at week 24 were 55.3%/20.0% (SE positive/SE negative, p=0.004, Fisher's exact test), respectively. Multivariate logistic regression revealed the odds ratio of EULAR good response and SDAI remission achievement in SE positive patients was 23.2 and 6.73 (95% CI: 5.10–152.0, p<0.0001 and 1.70–32.5, p=0.006), respectively.

Conclusions: Abatacept is strictly effective to SE positive RA patients.

DOES SEROPOSITIVITY INFLUENCE DIFFERENTIALLY DRUG DISCONTINUATION OF BIOLOGIC ANTIHEMATIC AGENTS WITH NON-ANTI-TNF MODE OF ACTION?

A. Finckh1, D. Courvoisier1, J.-E. Gottenberg2, X. Mariette3, J. Morel4, S.A. Bergstra5, V. Hernandez6, C. Codreanu7, T.K. Kvien8, M.J. Santos9, C. Gabay1, R. Van Vollenhoven10, M. Hetland11, K. Pavelka10, M. Hetland11, K. Chatzidionysiou12, J. Askling12, C. Turesson13, 1Albany Medical College and The Center for Rheumatology, Albany, NY; 2Geisel School of Medicine, Dartmouth College, Lebanon, NH; 3Institute of Rheumatology, Prague, Czech Republic; 4Glostrup Hospital, Glostrup, Denmark; 5Karolinska Institute, Stockholm; 6Lund University, Lund, Sweden; 7Univ of Medicine and Pharmacy, Bucharest, Romania; 8Diakonhjemmet Hospital, Oslo, Norway; 9Rheuma.PT, Lisbon, Portugal; 10Institute of Rheumatology, Prague, Czech Republic; 11Glostrup Hospital, Glostrup, Denmark; 12Karolinska Institute, Stockholm; 13Lund University, Lund, Sweden; 14AMC, Amsterdam, Netherlands

Background: Rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) are used as diagnostic tools, but may also be used as prognostic factors or as predictors of response to therapy, as these biomarkers have been associated with better clinical responses to some bDMARDs.

Objectives: To examine whether seropositivity has a similar impact on drug discontinuation of different bDMARDs with a non-anti-TNF mode of action (non-aTNF bDMARDs).

Methods: This is a pooled analysis of 10 observational European RA registries (FR, CZ, DK, NO, PT, RO, ES, SE, CH, NL). Inclusion criteria were a diagnosis of RA, initiation of treatment with abatacept (ABA), rituximab (RTX) or tocilizumab (TCZ) and available information on RF and/or ACPA status. The exposure of interest was seropositivity, which was defined as positive if RF or ACPA was positive and negative if both were negative. The primary endpoint was overall drug discontinuation, defined as the period between treatment initiation and treatment discontinuation. Because national differences may constitute a potential confounder, we only included national registries with information for all 3 bDMARD and pooled data across registries only after excluding significant effect modification by country. Drug discontinuation was analyzed using a Cox proportional hazard model, including drug, seropositivity, and their interaction, adjusting for age, gender, disease duration, baseline DAS28, concomitant DMARD (sDMARDs), number of previous sDMARDs and bDMARDs, and stratifying by country and calendar year.

Conclusions: Data from this pooled European registry analysis suggests that seropositivity is associated with lower drug discontinuation of non-aTNF bDMARDs. This effect differed between drugs and was significant for ABA, but not for TCZ or RTX. The impact of seropositivity on other measures of effectiveness still needs to be investigated.

DOES SEROPOSITIVITY INFLUENCE DIFFERENTIALLY DRUG DISCONTINUATION OF BIOLOGIC ANTIHEMATIC AGENTS WITH NON-ANTI-TNF MODE OF ACTION?

SUSTAINED RESPONSE FOLLOWING DISCONTINUATION OF METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS TOCILIZUMAB: RESULTS FROM A RANDOMIZED CONTROLLED TRIAL (COMP-ACT)

1Albany Medical College and The Center for Rheumatology, Albany, NY; 2Geisel School of Medicine, Dartmouth College, Lebanon, NH; 3School of Medicine, MetroHealth System, Case Western Reserve University, Cleveland, OH; 4Genentech, Inc., South San Francisco, CA, United States

Background: Methotrexate (MTX) is frequently administered in combination with biologics for the treatment of rheumatoid arthritis (RA). MTX may be subsequently discontinued due to intolerance or nonadherence, and/or to reduce medication burden once disease control is achieved. Previous studies have established the efficacy of tocilizumab (TCZ) initiated as monotherapy (MONO), but the impact of discontinuing TCZ in patients with RA who have been treated with MTX for an extended period cannot be ascertained.

Methods: This randomized, controlled, double-blind, placebo-controlled trial included all patients with RA (moderate-severe disease activity) who had been on MTX treatment for at least 3 months and who had not received prior biologic therapies. The primary endpoint was the proportion of patients achieving ACR50 response at week 48. Secondary endpoints included ACR20, ACR70 responses, and other measures of clinical and functional improvement. The trial had a 6-week run-in period, followed by a 48-week randomized treatment phase. Patients were randomly assigned to receive either subcutaneous placebo or TCZ 40 mg weekly.

Conclusions: The results of this study suggest that discontinuing MTX and initiating TCZ monotherapy can lead to sustained clinical improvement in patients with RA who have been on MTX treatment for an extended period. This finding may have important implications for the management of RA patients who have been treated with MTX but are not achieving adequate disease control with current pharmacotherapies.

DOI: 10.1136/annrheumdis-2017-eular.6006
of MTX withdrawal in patients achieving good clinical response to TCZ+MTX (COMBO) has not been evaluated.

Objectives: To evaluate whether TCZ-MONO is non-inferior to TCZ-COMBO in maintaining clinical response in patients who achieve low disease activity with TCZ-COMBO.

Methods: 118 patients with RA who were inadequate responders to MTX were enrolled: initial combination therapy included MTX (15 mg/week orally) plus TCZ 162 mg subcutaneous (SC) either weekly (qw; for patients >100 kg) or every 2 weeks (q2w; for patients <100 kg). Dose escalation from q2w to qw was allowed at week 12 in patients who had not achieved low disease activity (DAS28 ≤3.2) at week 24. Patients achieving DAS28-ESR ≤3.2 were randomized (double-blind) 1:1 to receive either TCZ-MONO or continue TCZ-COMBO until week 52. Patients who did not achieve DAS28 ≤3.2 were assigned to an open-label arm and continued TCZ-COMBO until week 52. The primary outcome was the proportion of patients achieving DAS28-ESR ≤3.2 in the randomized cohort between weeks 24 and 40, between the TCZ-MONO or TCZ-COMBO arms (non-inferiority margin of 0.6). Secondary outcomes included the proportion of patients achieving DAS28 ≤2.6, DAS28 ≤3.2 and American College of Rheumatology 20%/50%/70% (ACR20/50/70) responses at weeks 40 and 52, and safety. Trial registration number: NCT01385789.

Results: Of 718 patients enrolled, 296 were randomized at week 24 (TCZ-COMBO, n=148; TCZ-COMBO, n=148). Early discontinuation in the randomized cohort occurred in 12.2% of patients in the TCZ-MONO group and 10.2% in the TCZ-COMBO group. Baseline characteristics were balanced between treatment groups (mean age 55.5 years: 74.8% female; mean RA duration 6.8 years; mean DAS28-ESR 6.3). At week 24, DAS28 scores were similar in both groups, but ACR responses were ~8–11 lower in the TCZ-MONO group prior to MTX withdrawal (randomization). The mean change in DAS28 was similar between the randomized treatment groups (Table 1). For the primary efficacy analysis, the mean changes in DAS28 from week 24 to week 40 were 0.46 and 0.14 in the TCZ-MONO and TCZ-COMBO groups, respectively (95% CI: 0.04–0.592). This study met the primary endpoint by demonstrating that discontinuing MTX in TCZ responders was non-inferior to continuing MTX. The safety of TCZ-SC in this study was consistent with the known safety profile with no new safety signals observed (Table 2). The most common SAE was infection, occurring in 4.1% of patients. TCZ-COMBO had greater frequency of AEs, SAEs and serious infections than TCZ-MONO.

Conclusions: These results demonstrate that patients receiving TCZ-COMBO who achieve low disease activity can discontinue MTX and maintain disease control.

FR10223 ANTI-CCP IS AN INDEPENDENT PREDICTOR OF 12-MONTH EULAR RESPONSE IN PATIENTS WITH RA TREATED WITH ABATECTAE

A. den Broeder1, T. Kerstens2, J. Fransen2, C. van den Ende1, L. Tweehuysen2, R. Postema3, E. Alemao5, F. van den Hoogen5, S. Maartenstinkelijk and Radboud UMC; 2Radboud UMC; 3Sint Maartenstinkelijk, Nijmegen, Netherlands; 4Bristol-Myers Squibb, Uxbridge, United Kingdom; 5Bristol-Myers Squibb, Princeton, United States

Background: Although anti-cyclic citrullinated peptide (anti-CCP) positivity is regarded as a strong predictive factor for untreated RA outcome, the benefit of anti-CCP tests for personalized medicine is controversial.1 Illustratively, anti-CCP was not predictive for response to anti-TNF in RA, as shown in meta-analyses, although some predictive value was shown for rituximab.2–4 There are, however, indications that better response to abatacept (ABA) is predicted by anti-CCP positivity.5–7

Objectives: To test whether anti-CCP level at baseline (BL) is an independent predictor for treatment response (DAS28 [CRP]-based EULAR response criteria) at 12 months (M) in patients (pts) with RA treated with ABA.

Methods: Conscient pts with RA from Radboud UMC and Sint Maartenstinkelijk were consecutively included if they started treatment with ABA (BL). The anti-CCP values closest before BL were used. DAS28 (CRP) was assessed at BL and at 12M by trained rheumatology nurses or rheumatologists. Demographic and disease-related variables, treatment history and co-morbidity were also assessed. Primary outcome was response to treatment based on DAS28 (CRP) EULAR response criteria at M12. Therapy cessation was regarded as non-response. Multiple imputation with 20 repetitions was used to replace missing predictors. Multivariate logistic regression was used to examine whether anti-CCP positivity was an independent predictor for treatment response, taking confounding BL covariates (Table variables) into account.

Results: Data were available for 200 pts with RA starting ABA. Mean (SD) age was 58 (13) years, 165 (83%) were female and median (p25–p75) disease duration was 12 (7–19) years (Table). Overall, 121 (61%) pts were anti-CCP positive at BL. At 12M, 86 (43%) pts remained on ABA. In the univariate model, anti-CCP was a predictor for treatment response (odds ratio 2.51; 95% CI 1.1, 6.0; p=0.038). No relevant confounding was present.

*Median (p25–p75). RA,+: IgM-Rheumatoid factor positivity. b/cDMARD-biologic/conventional synthetic DMARD.

Conclusions: Anti-CCP positivity was confirmed as an independent predictor for treatment response at 12M in pts with RA treated with abatacept. As indicated by meta-analysis and systematic reviews, anti-CCP is not predictive for the response to anti-TNFs.2–4 Additional studies are needed to evaluate whether abatacept could be a preferable treatment in anti-CCP-positive pts.

**FR10224** RITUXIMAB SELECTIVELY REDUCES IgG4 LEVELS IN RHEUMATOID ARTHRITIS PATIENTS

A. Sarantopoulos, I. Gkougkourelas, M. Mytilinaiou, P. Klonizakis, A. Georgiadou, P. Boura, Clinical Immunology Unit, 2nd Dept of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece

**Background:** Rituximab has been applied as a therapeutic strategy in a variety of diseases, including Rheumatoid Arthritis (RA) and IgG4-Related Disease (IgG4-RD). On IgG4-RD, it has been shown that apart from B-cell depletion, rituximab induces remission by reducing IgG4 levels.2

**Objectives:** On this regard, we investigated weather B-cell depletion in RA is also associated with a selective reduction of any IgG subclass, especially IgG4.

**Methods:** 31 RA patients, 25/6 female/male, median age 59 years (34–73), duration of disease 9.5 years (1–30) on standard care DMARD treatment and rituximab administration every 6 months for 2 years were investigated for alterations on disease activity along with IgG subclasses levels. All parameters were assessed at enrollment (T0), after 6, 12 and 24 months. On this 2-year period all patients had been periodically receiving rituximab every 6 months.

**Results:** After 2 years of rituximab administration, patients achieved a good response to treatment (EULAR criteria). IgG levels were not statistically altered, though all of them declined (data for IgM and IgA not shown). Furthermore, from IgG subclasses, only IgG4 levels statistically declined.

**Conclusions:** This is the first time that IgG4 variations are investigated in a non-ILD RA population after rituximab administration. Our results imply that IgG4 may be actively implicated in RA pathophysiology, since disease remission is accompanied by only IgG4 level reduction among all classes and subclasses of IgGs. Furthermore, in RA patients, rituximab may exert its therapeutic results not only via B-cell depletion, but also via IgG4 levels reduction.

**FR10226** ANEMIA IS A BETTER PREDICTOR FOR RADIOGRAPHIC DAMAGE IN RHEUMATOID ARTHRITIS THAN DAS28 WHEN DETERMINED BEFORE START OF TOCILIZUMAB-TREATMENT – A SECONDARY ANALYSIS FROM THE ACT-RAY TRIAL

B. Möller1, G. Scholz1, M. Dougados2, T. Huizinga3, P. Villiger1, A. Finckh4.

1Rheumatology, Immunology & Allergology, Inselspital - Bern University Hospital, Bern, Switzerland; 2Rheumatology, Hôpital Cochin, Paris, France; 3Rheumatology, Leiden University Medical Center, Leiden, Netherlands; 4Rheumatology, University Hospital Geneva, Geneva, Switzerland.

**Background:** Clinical remission, or at least low disease activity, as measured by DAS28 may not be sufficient to prevent radiographic damage in RA patients. Anemia and low Hb levels are associated with progression of joint damage due to an increase in erythropoiesis, add importantly to the growing body of evidence for the studied association.

**Objectives:** To study the predictive value of anemia in relation to DAS28 when determined before the start of tocilizumab treatment (T12), compared to DAS28 when determined during RA treatment (T12). To analyze the association of anemia to DAS28 and radiographic data over time when obtained in patients already on tocilizumab (TCZ).

**Methods:** We studied 18 patients (13 women /5 men) with ILD associated to RA. The mean age was 65.2 years (58.7 – 71). Of 556 randomised patients, complete datasets for fully adjusted models were available from 285 patients. Overall radiographic progression was regarded to be minimal, with insignificant differences in favor of the add-on strategy. Median DAS28 before inclusion was 2.9 (IQR 1.5–6.4) in patients without and 5.5 (IQR 2.7–11.1) in patients with baseline anemia, but evolved subsequently similar when being on TCZ. Anemia at baseline was a strong predictor of mTSS (per WHO definition: coefficient 14.6, 95% CI 7.6–21.9, p < 0.001; per NHANES definition: coefficient 14.6 95% CI 7.6–21.5 p < 0.001), as well as baseline DAS28 (coefficient 3.9, 95% CI 0.7–7.0, p = 0.016). Mean DAS28 over time (p < 0.001), in contrast to anemia data over time when obtained in patients already on TCZ, was significantly associated with subsequent ΔmTSS. Baseline anemia in contrast to baseline DAS28 remained a significant predictor of mTSS for up to two years on TCZ in fully adjusted multivariate analyses (p < 0.05), including time-variant DAS28.

**Conclusions:** Anemia may be a strong and DAS28-independent long-term predictor of radiographic joint damage progression. Present data from patients on IL-6R blockade, a potent target-specific RA treatment with major impact also on erythropoiesis, add importantly to the growing body of evidence for the studied association.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.6685

SARILUMB SIGNIFICANTLY SUPPRESSES CIRCULATING BIOMARKERS OF BONE RESORPTION AND CARDIOVASCULAR RISK COMPARED WITH ADALIMUMAB: BIOMARKER ANALYSIS FROM THE PHASE 3 MONARCH STUDY

C. Gabay1, J. Mishii2, C. Paccard3, M. Zilberstein3, N.M. Graham4, A. Boypati4, 1University Hospitals of Geneva, Geneva, Switzerland; 2Sanofi R&D, Chilly-Mazarin, France; 3Sanofi R&D, BridgeWater; 4Regeneron Pharmaceuticals, Inc, Tarrytown, United States

Background: MONARCH (NCT02332590) was a randomized, active-controlled, double-blind, double-dummy, phase 3 superiority trial comparing sarilumab monotherapy with adalimumab monotherapy. Exploratory biomarkers associated with inflammation, bone erosion, and cardiovascular (CV) risk were evaluated in this study.

Objective: To compare the effects of sarilumab monotherapy vs adalimumab monotherapy on circulating biomarkers associated with acute-phase response (CRP serum amyloid A [SAA]), bone resorption [RANKL and osteoprotegerin [OPG]], and CV risk (lipoprotein (a) [Lp(a)]) in patients from MONARCH.

Methods: Sera were analyzed at baseline and posttreatment through wk 24 from patients who consented to biomarker analyses and received SC sarilumab 200 mg q2w (N=153) or adalimumab 40 mg q2w (N=154). Biomarkers were assessed using validated ELISAs. Nonparametric methods were used to evaluate differences in the percent change from baseline in biomarker levels between treatments at each time point. Percent change from baseline in biomarkers at wk 24 was also compared, separately by treatment group, between ACR50 responders and nonresponders at wk 24. The Benjamini-Hochberg procedure was used to correct P values for multiplicity and control false discovery rate. Significance level was P=0.05.

Results: A significant difference in RANKL was observed at wks 2 and 24 between sarilumab and adalimumab groups (P<0.0001; Table). Numerically, RANKL decreased after sarilumab and increased after adalimumab treatment. Significantly greater reductions in Lp(a), SAA, and CRP were observed at wks 12 and 24 after treatment with sarilumab vs adalimumab. The difference in OPG between groups was significant at wk 2 only.

OR=34.7; p=1.2×10−4. Elevations remained ≥2 × ULN. Logistic regression with recessive genetic model, adjusting for ancestry covariates.

Conclusions: The association observed between the rs6742078 TT genotype in UGT1A1 and unconjugated bilirubin elevations in sarilumab-treated patients is consistent with previous observations in tocilizumab-treated patients. These findings suggest that sarilumab-related increases in bilirubin levels are likely benign and caused by common genetic variation in UGT1A1 and are not due to underlying liver injury.

FR1022 | SURVEY ON TRANSPORTATION AND STORAGE OF BIOLOGICAL THERAPIES BY PATIENTS

Background: In order to ensure the psychological protection of medicinal drugs, it is mandatory to keep the cold chain unbroken from manufacturing to administration since this tolerance of rules may compromise their efficiency (1,2).

Objectives: To ascertain key aspects of transportation and storage of Biological Therapy (BT) on the part of the patients.

Methods: survey among outpatients who either were treated in the centre or attended the centre for the administration of a BT. Inclusion criteria: patients of over 18 years of age, who were receiving a BT (at least one dose over the last 12 months) whose patient information leaflet indicated, “… must be refrigerated at 2° C to 8° C (36° F to 46° F). Do not freeze.” The survey comprised 31 questions about transportation and storage of the BT. This study was approved by the Bioethics Committee. Every patient signed an informed consent form.

Results: Eighty-three patients were interviewed (76% female and 24% males), 31 years of age at diagnosis was 47.1 (SD=13.4) years with a mean disease duration of 7.2 (7.8) years, and a mean QOL of 43.1 (32.5) at baseline. No significant differences in retention rates were observed in the ABA and anti-TNF groups (Table, Figure). On average, pts treated with anti-TNFs and ABA maintained their treatment for 1.59 (1.91) and 1.90 (2.08) years, respectively. Lack of efficacy (47.6%) and adverse effects (22.0%) were the most commonly cited reasons for treatment discontinuation.

*% (standard error) survival.

Conclusions: Abatacept and TNF inhibitors demonstrate similar sustainability at 8-year, supporting studies that demonstrate that abatacept used after csDMARDs inadequate response is as safe and effective as a TNF targeting agents in the long term.
BMI dynamic was independent of TOFA dose, achieving RA activity, dynamic of DAS 28, SDAI. Use of cardioprotective therapy. Dynamic of lipid levels dependent on statins treatment. An increase in HDL-C level from 1.35 [0.88; 1.91] to 1.90 [1.64; 2.17], p < 0.05, a decrease in LDL-C level from 3.75 [3.11; 4.40] to 2.60 [2.55; 2.93], p < 0.03 was observed in pts treated with statins (n=11). An increase in total cholesterol level from 4.80 [4.14; 5.45] to 5.54 [4.56; 6.64], p < 0.001 was observed in pts who didn’t receive statins (n=17). The change in HDL-C level correlated negatively with dynamic of DAS 28, SDAI (r = 0.4, p < 0.05).

Conclusions: TOFA therapy of RA pts contributes to dramatical increase of BMI. Greater BMI dynamic associated with higher disease activity at baseline. BMI dynamic was independent of achieving RA activity and dynamic of DAS 28, SDAI. Co-administration TOFA and statins resulted in significant favorable changes of LDL and HDL-cholesterol levels.

**FRIO232**

**E. Alemao**, 1 K. Knapp, 2 V. Anupindi, 2 S. Annamalai, 3 G. Craig, 3 Bristol-Myers Squibb, Princeton; 2 Discus Analytics, Spokane; 3 Mu Sigma, Princeton, United States; 4 Mu Sigma, Bangalore, India; 5 Arthritis Northwest, Spokane, United States

**Background:** Poor prognostic factors (PPFs; e.g. elevated anti-citrullinated protein antibody/RF levels and erosions) are associated with higher disability and mortality in RA. 1 2 In addition, high seropositivity or CRP/ESR levels are correlated with erosive disease. 3

**Objectives:** To evaluate if the presence of specific PPFs of seropositivity with erosions (PPF+) in patients (pts) with RA have an effect on treatment with abatacept (ABA) and anti-TNFs.

**Methods:** This retrospective study was based on electronic medical record data. This database includes >6500 pts with RA from 50+ rheumatologists. At each visit, data on diagnosis, medications and test results were collected. A homunculus was used to record joint tenderness, swelling, deformity or decreased range of motion. Disease activity was measured by DAS28 (ESR/CRP), SDAI, CDAI, RAPI D3 and Vectra DA blood tests. For this analysis, pts aged ≥18 yrs with an RA diagnosis from 1 Jan 2009 to 3 Mar 2016 were followed until lost to follow-up, death or end of study period. Date of first ABA/anti-TNF prescription was designated as index date, preceded by the baseline (BL) period. The ABA cohort comprised pts with a record of ABA in the study period, while the anti-TNF cohort comprised pts with a record of anti-TNF and no record of ABA in the study period. Primary outcome was change (Δ) in CDAI at 6 months (M); other outcomes were SDAI, DAS28 (CRP), pain, RAPI D3 and Patient Global Assessment. Descriptive statistics were used for BL characteristics. Univariate and multivariate regression analyses were
used to evaluate \( \Delta \text{CDAI} \). Subgroup analyses were conducted by line of therapy, after excluding switch pts.

**Results:** Overall, 3959 pts met inclusion criteria and 2045 had data on PPF; 344 and 814 pts received ABA and anti-TNF. Mean (SD) age of ABA pts was 60.3 (12.5) yrs and median (interquartile range; IQR) CDAI was 25.5 (18.1). Mean (SD) age of anti-TNF pts was 56.4 (13.3) yrs and median (IQR) CDAI (IQR) was 19.8 (18.1). PPF+ pts treated with ABA (vs all other ABA pts) had a better CDAI outcome at 6M (9.7 [16.1] vs –7.5 [14.4]). In sensitivity analyses, the difference persisted (–10.4 vs –8.4; Fig). PPF+ pts treated with ABA as first-line therapy (vs all other ABA pts) had a better CDAI outcome (–13.4 vs –10.3). Similar trends were not observed in the anti-TNF cohort (Fig). Adjusted mean (SE) \( \Delta \text{CDAI} \) in PPF+ vs PPF– pts treated with ABA was –12.1 (2.01) vs –9.5 (0.79); covariates included in the model were age, sex and BL CDAI (p=0.24). During follow-up, more PPF+ pts treated with ABA changed from high/medium to LDA or remission vs all other pts (34% vs 25%), while this was not seen in anti-TNF pts (45 vs 42%).

**Conclusions:** Pts with RA treated with abatacept had higher disease activity at BL and a greater reduction in disease activity was observed in seropositive pts with RA and erosions compared with all other abatacept pts. Similar trends were not observed in anti-TNF pts. No direct comparisons between treatments were conducted in these cohorts.

**References:**

number of previous anti-TNF use of concomitant DMARDs and prednisone, drug retention rate at 1 year was significantly better for ABA compared to anti-TNF (p=0.02) and for TCZ compared to anti-TNF (p<0.04), but no difference was found between TCZ and ABA (p=0.62) (Figure).

Conclusions: Patients who received ABA following failure of RTX, seem to be better treated with than concomitantly, compared with ABT mono-therapy group. It may reflect rapid rates of ABT at 24 weeks were higher among patients receiving ABT and mPSL. This is the first real world study to investigate whether ABT can be used in a real-world setting. Conclusions: The rates of non-retention were comparable between non-TNFi and TNFi patient groups both at 6 (mean [SD]: -1.16 (2.93) and -1.07 (1.55) respectively, p=0.296) and at 12 months [1.41 (2.93) and -1.39 (1.26) respectively, p=0.670]. In patients who did not receive co-therapy with methotrexate, significantly greater IDAS28 was observed with a non-TNFi (-1.25 (2.93) vs. -0.68 (1.61), p=0.006). When the first TNFi fails, the primary or secondary failure to the 1st TNFi (-0.81 vs -1.48, p=0.18), but this did not reach statistical significance, probably due to the low number of available patients. The 2-year drug survival was higher for non-TNF (64% vs. 39%, log rank p<0.001) due to lower frequency of discontinuations for primary failure (p<0.001) and adverse events (p=0.019). IDAS28 was comparable between non-TNF and TNFi patient groups both at 6 [mean (SD): -1.16 (2.92) and -1.08 mg/dl (± 2.17) in non-mPSL group (p=0.22), and those in ESR were = -8.23 mm/h (± 18.40) in mPSL group and -6.61 mm/h (± 17.93) in non-mPSL group (p=0.75), respectively.

Conclusions: This is the first real world study to investigate whether ABT administrated with intravenous mPSL maintain higher retention rates in rheumatoid arthritis. Although there were no statistically significant differences, the retention rates of ABT at 24 weeks were higher among patients receiving ABT and mPSL concomitantly, compared with ABT mono-therapy group. It may reflect rapid improvement of the disease activity.

**Safety of Biosimilar Infliximab Use in a Medical Day Hospital: A Case-Series**

1 Family Doctor,
2 Internist Medicine; 3 Rheumatology, HU Virgen del Rocio, Sevilla, Spain

**Background:** The first biosimilar anti-TNF (infliximab) approved by the EMA (European Medicines Agency) began to be used throughout Europe in 2015. Since then, it has been widely used throughout the world, even replacing the original treatment approved 1999 Remicade® with Remsima®, a biosimilar drug.

**Objectives:** To report intrainfusion and postinfusion adverse events related to intravenous Remsima® use in a medical day hospital. Besides, we will describe the rehospitalizations and continuation of treatment in the follow up.

**Methods:** We designed a prospective uncontrolled case-series study. Patients referred from March 2015 to October 2016 to our MDH to receive intravenous Remsima® were consecutively enrolled. Demographic data were collected, and a harmonised active monitoring strategy was applied. We recorded the indication for treatment, the doses administered and the number and symptoms of acute transfusion reactions (ATR) occurring both in the infusion period and during the 3 hour postinfusion observation interval.

**Results:** 2828 doses were administered, 0.67% presented ATR, all of them during the infusion and reported to the Regional Pharmacovigilance Center. 53% of those ATR were women and they were on average 35.78 years (SD 14.71). The mean dose used was 4.49 mg/kg (SD 0.47). The indications for treatment in patients suffering ATR were: EC (47%), CU (26%), Spondylitis (21%) and Psoriasis (5%). As a predominant symptom during ATR we found: shortness of breath (36.89%), pruritus (15.75%), flushing sensation (15.75%), urticaria (10.4%), alopecia (5.2%), chest pain (5.2%), paraesthesia (5.2%) and nausea (5.2%). 95% of ATR showed complete recovery of the symptoms, 47% disappeared with the pause of infusion. However, they had prolonged in MDH stay, the infusion was stopped for 30 minutes and restarted at a lower rate according to the protocol. 21% of patients presenting ATR dropped out because of the symptoms, which represents 0.14% of the total infusions.

**Conclusions:** Biosimilar Infliximab seems to be safe in a MDH setting, given the

**Concomitant Use of Intravenous Methylprednisolone to Obtain Higher Retention Rate of Abatacept in Rheumatoid Arthritis**

H Sawada, M. Suda, M. Kishimoto, M. Okada.

**Immuno-Rheumatology Center, St Luke’s International Hospital, Tokyo, Japan**

**Background:** Abatacept (ABA) is a widely used biologic for treating rheumatoid arthritis (RA).

**Objectives:** Concomitant use of intravenous corticosteroids with ABA infusion may contribute to achieve earlier remission and higher retention rates.

**Methods:** We conducted a retrospective cohort study in 2012, St Luke's International Hospital, Tokyo, Japan, from January 2010 to June 2016. Patients who met the 2010 ACR/EULAR classification criteria for RA and treated with ABA were included in the study. We excluded patients who used two or more biologics prior to initiation of ABA. Our primary outcome was treatment retention rates of ABA at week 24. Secondary outcomes were changes in C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) during follow-up (week 0 vs. week 8). We compared these outcomes between the patients receiving concomitant intravenous methylprednisolone (mPSL) with first 3 consecutive doses of ABA and those not receiving it. Log-rank analysis and Fisher’s exact test were applied for statistical analysis.

**Results:** 64 RA patients were included in the study. Mean age was 67.3 ± 14.2 and 55 (85.9%) were female. Among them, 13 (20.3%) received concomitant ABA and mPSL. The dosage of mPSL ranged from 30mg to 250mg (median dosage was 40mg). At week 24, the cumulative retention rates of the patients receiving mPSL (mPSL group) and those not receiving it (non-mPSL group) were 92.3% and 76.5%, respectively. There was no significant difference in the retention rates between the two groups (log-rank test, p=0.21) (Figure). Changes in CRP between week 0 vs. week 8 were -1.56 mg/dl ± 2.92 in mPSL group and -1.08 mg/dl ± 2.22 in non-mPSL group (p=0.75). Changes in ESR between the two groups (log-rank test, p=0.21) (figure). Changes in CRP between week 0 vs. week 8 were -1.56 mg/dl ± 2.92 in mPSL group and -1.08 mg/dl ± 17.93 in non-mPSL group (p=0.75), respectively.

**Conclusions:** This is the first real world study to investigate whether ABT administrated with intravenous mPSL maintain higher retention rates in rheumatoid arthritis. Though there were no statistically significant differences, the retention rates of ABT at 24 weeks were higher among patients receiving ABT and mPSL concomitantly, compared with ABA mono-therapy group. It may reflect rapid improvement of the disease activity.

**Disclose of Interest:** None declared.

**Safety of Biosimilar Infliximab Use in a Medical Day Hospital: A Case-Series**

1 Family Doctor,
2 Internist Medicine; 3 Rheumatology, HU Virgen del Rocio, Sevilla, Spain

**Background:** The first biosimilar anti-TNF (infliximab) approved by the EMA (European Medicines Agency) began to be used throughout Europe in 2015. Since then, it has been widely used throughout the world, even replacing the original treatment approved 1999 Remicade® with Remsima®, a biosimilar drug.

This medicine is currently approved to treat people who have been diagnosed with rheumatoid arthritis, ankylosing spondylitis or psoriatic arthritis in the field of rheumatology, in addition to ulcerative colitis (UC) or Crohn's disease (EC) in gastroenterology. However, safety data of the use of Remsima® infliximab in a medical day hospital (MDH) are lacking.

**Objectives:** To report intrainfusion and postinfusion adverse events related to intravenous Remsima® use in a medical day hospital. Besides, we will describe the rehospitalizations and continuation of treatment in the follow up.

**Methods:** We designed a prospective uncontrolled case-series study. Patients referred from March 2015 to October 2016 to our MDH to receive intravenous Remsima® were consecutively enrolled. Demographic data were collected, and a harmonised active monitoring strategy was applied. We recorded the indication for treatment, the doses administered and the number and symptoms of acute transfusion reactions (ATR) occurring both in the infusion period and during the 3 hour postinfusion observation interval.

**Results:** 2828 doses were administered, 0.67% presented ATR, all of them during the infusion and reported to the Regional Pharmacovigilance Center. 53% of those ATR were women and they were on average 35.78 years (SD 14.71). The mean dose used was 4.49 mg/kg (SD 0.47). The indications for treatment in patients suffering ATR were: EC (47%), CU (26%), Spondylitis (21%) and Psoriasis (5%). As a predominant symptom during ATR we found: shortness of breath (36.89%), pruritus (15.75%), flushing sensation (15.75%), urticaria (10.4%), alopecia (5.2%), chest pain (5.2%), paraesthesia (5.2%) and nausea (5.2%). 95% of ATR showed complete recovery of the symptoms, 47% disappeared with the pause of infusion. However, they had prolonged in MDH stay, the infusion was stopped for 30 minutes and restarted at a lower rate according to the protocol. 21% of patients presenting ATR dropped out because of the symptoms, which represents 0.14% of the total infusions.

**Conclusions:** Biosimilar Infliximab seems to be safe in a MDH setting, given the
low rate of adverse transduction reactions during the 18 months analyzed. The most frequent adverse reaction was shortness of breath.

FR0238  EFFECT OF BASELINE ANTI-CYClical CITRULLINATED PEPTIDE 3 ANTIBODY TITRE ON LONG-TERM DRUG SURVIVAL OF SUBCUTANEOUS ABATACEPT IN RHEUMATOID ARTHRITIS: A PROSPECTIVE CohORT STUDY

J.C. Sarmento-Monroy1,2, N. Molano-González1, M. Rodríguez-Jiménez2, R.D. Mantilla2,1,1* Rheumatology, Center of Dermatology and Rheumatology (FUNINDERMA); 2Center for Autoimmune Diseases Research (CREA), Universidad del Rosario, Bogotá, Colombia

Background: Clinical response to biologics varies widely between individuals with rheumatoid arthritis (RA). To date, there are few, and in some cases, conflicting results in the personalized approach of patients with RA treated with abatacept. Only the seropositive subphenotype (anti-cyclic citrullinated peptide, CCP) was validated in several populations, including a real-life registry (ORA) [1], and non-inferiority trial (AMPLE) [2].

Objectives: To assess whether baseline anti-CCP3 antibody status and concentration correlated with drug survival of subcutaneous (SC) abatacept among patients with RA in a real-world setting.

Methods: This was a prospective study in which well-characterized patients with RA (by 1987 ACR criteria) were included from April 2014 to December 2016. Patients were evaluated at a single rheumatology outpatient center in Bogotá, Colombia. Baseline anti-CCP3 antibody status (positive/negative) and concentration were determined using an anti-CCP3 IgG ELISA (INOVA Diagnostics). Patients with a baseline anti-CCP3 IgG concentration of ≥20 U were considered to be positive and were further divided into equal quartiles according to concentration [Q1–Q4 (highest concentration)]. The Cox proportional hazards regression model was used to test if there were any differences in drug survival curves according to baseline anti-CCP3 antibody status and concentration. The test was performed by the coxph function of the “survival” R package [3].

Results: A total of 129 patients were included. Baseline characteristics: female gender 86%, mean age 52±13 years, median disease duration 10 (IQR 11) years, and erosions 35%. Treatment background was as follows: biological naïve (n=54), switched from IV to SC abatacept administration (n=24), and inadequate response to at least 1 biologic disease-modifying antirheumatic drug (n=51). Forty-three patients (33%) discontinued treatment. The most frequent reasons for drug suspension were loss of efficacy. Rheumatoid Factor and anti-CCP3 was positive in 94%, and 89%, respectively. Median titre of anti-CCP3 was 248 U (IQR 352), and number of patients in each quartile group were Q1 (22–122); Q2 (123–248); Q3 (249–475); Q4 (476–1544). A total of 129 patients were included to obtain parallel descriptive information.

Conclusions: Baseline anti-CCP3 positivity was associated with a better response to SC abatacept in a real-world setting. Patients with lowest baseline anti-CCP3 antibody concentrations had better drug survival than patients with higher concentrations. Our results highlight the importance of identification of factors associated with response to biologics in order to optimize treatment and reduce costs.

FR0229  RESULTS OF A PHASE 2B STUDY OF VOBARILIZUMAB, AN ANTI-INTERLEUKIN-6 RECEPTOR NANOBODY, AS MONOTHERAPY IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS

Background: Vobarilizumab is a Nanobody® consisting of an anti-IL6 receptor domain and an anti-human serum albumin domain in development for treatment of RA.

Objectives: To assess the efficacy and safety of several dose regimens of vobarilizumab monotherapy administered subcutaneously to patients with active RA.

Methods: Patients with active RA who were intolerant to methotrexate (MTX) or for whom continued MTX treatment was inappropriate were randomized in a 1:1:1:1 ratio to 1 of the 3 blinded dose groups of vobarilizumab or to open-label tocilizumab (TCZ), all of which were given subcutaneously. Efficacy was evaluated descriptively at Week 12 using a number of widely accepted clinical endpoints. Adverse events and routine safety parameters including laboratory assessments were recorded. TCZ administered weekly or biweekly according to local labeling directed us to obtain patient descriptive information.

Results: The study enrolled 251 patients in Europe, Latin America and the United States. Baseline demographics and disease characteristics were well balanced across groups with mean DAS28CRP between 5.9 and 6.2.

At Week 12, 73% to 81% of the patients assigned to one of the vobarilizumab groups achieved an ACR20 response, while ACR50 and ACR70 response rates between 37% - 49% and 16% - 24%, respectively, were observed (see table). At the end of the 12-week treatment period, clinically meaningful improvement in HAQ-DI scores and remission based on DAS28CRP and DAS28ESR was observed in a substantial number of patients treated with vobarilizumab, either q4w or biweekly. Between 5% and 10% of the patients achieved remission defined by the more stringent CDAI or SDI criteria. In total, 94% of patients randomized to open-label TCZ received drug weekly. In spite of this disparity in dosing frequency similar efficacy results were obtained in the vobarilizumab and TCZ groups. One vobarilizumab treated patient (225mg q2w treatment group, 1.6%) experienc ed a SAE due to the treatment period as did 2 patients in the TCZ group (3.1%). Frequencies of treatment-emergent adverse events were similar across the groups. Of the vobarilizumab treated patients, 2.1% discontinued study drug due to TEAEs compared with 6% in the TCZ group. One case of severe hypersensitivity, not considered serious, was reported in the 225mg q2w treatment group. Liver function abnormalities were infrequent across all study groups. Grade 3 neutrophil toxicities were less commonly observed with vobarilizumab (1.1%) than with TCZ (4.3%).

Conclusions: In patients with active RA, treatment with vobarilizumab monotherapy had a positive impact on disease activity with no unexpected safety findings.

FR0240  RHEUMATOID ARTHRITIS (RA) IMPACT FOLLOWING TREATMENT WITH SARILUMAB: PATIENT REPORTED OUTCOMES USING THE RAID SCALE FROM TWO RANDOMIZED PHASE III TRIALS

L. Gosses1, V. Strand2, C. Proudfoot3, C. Chen4, S. Guillaumeau5, T. Kimura4, H. van Hoogstraten6, E. Mangan7, M. Reaney1, L. Gossec1, F. Cune1, H. Pilet-Salpétrière, Paris, France; 2Stanford University, Palo Alto, United States; 3Sanofi, Guildford, United Kingdom; 4Regeneron Pharmaceuticals, Inc, Tarrytown, United States; 5Sanofi, Paris, France; 6Sanofi, Bridgewater, United States

Background: Patients with RA experience a variety of signs and symptoms and report significant physical and psychological impairment. The RA Impact of Disease (RAID) scale is a disease-specific measure of the impact of RA on patients’ lives. RAID was assessed in two Phase 3 randomized trials of sarilumab,
A human monoclonal antibody directed against the IL-6 receptor-α (TARGET [NCT01709578]; MONARCH [NCT02332590]).

Objectives: To evaluate patient-perceived impact of sarilumab on RA using the RAID scale vs either placebo + conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) or adalimumab.

Methods: TARGET (NCT01709578): Regired sarilumab 150mg and 200mg added to csDMARDs vs placebo in patients with RA intolerant of or not responding to anti-TNF therapy. MONARCH assessed sarilumab 200mg monotherapy vs adalimumab 40mg monotherapy in patients with RA either intolerant of, inadequate responders to, or considered inappropriate candidates for continued treatment with methotrexate. Treatments were administered subcutaneously every 2 weeks. RAID has 7 single-item domains, each rated by patients on an 11-point numeric rating scale from 0 (absence) to 10 (extreme). A total score from 0 to 10 (with lower scores indicative of less impact of disease) is calculated by weighting responses for each item based on patient assessment of the relative importance of the item. RAID was assessed at baseline (BL), Weeks 12 and 24. Least square mean (LSM) changes from BL in total score (Weeks 12 and 24) and domains (Week 24 only) were analysed with a mixed model for repeated measures, including treatment, region, visit, and treatment-by-visit interaction (and prior csDMARD therapy in TARGET) as fixed effects and BL as a covariate. RAID was tested outside of trial hierarchy and statistical significance is not claimed; nominal p-values are provided. Post-hoc categorical change analyses were conducted to identify “responders” in the total score (improvements ≥ 25% in total score) in patients continuing therapy requiring rescue medication prior to endpoint were classified as non-responders.

Results: Sarilumab was superior (nominal p<0.05) to placebo (TARGET) and adalimumab (MONARCH) at Weeks 12 and 24 for RAID total score (Table). There was a greater proportion of responders in sarilumab groups vs placebo at Week 24 at both time points (TARGET) and in sarilumab 200mg vs adalimumab at Week 24 (MONARCH). The effect of sarilumab was consistent across all 7 individual RAID domains (nominal p<0.05) at Week 24, except for sleep difficulties vs placebo in TARGET. Effects of placebo were least on pain and effects of sarilumab were lowest on emotional well-being (TARGET) and coping (MONARCH).

Conclusions: Assessed using RAID, sarilumab either with csDMARDs or as monotherapy reduced the impact of RA on patients’ lives to a greater extent than placebo+csDMARDs or adalimumab monotherapy, with benefits shown on total RAID and all 7 individual domain scores.

The Effect of Abatacept on Cytokine Profile in Patients with Rheumatoid Arthritis

Background: Pathological activation of T-cells with the overproduction of pro-inflammatory cytokines is playing a major role in the pathogenesis of rheumatoid arthritis (RA). The influence of the selective co-stimulation modulator abatacept (ABA) on the dynamics of cytokine profile in patients with RA is not fully understood.

Objectives: To assess the changes in cytokine profile in patients treated with ABA.

Methods: 44 patients with RA and an inadequate response to synthetic DMARDs or biologics were enrolled in the study. Most of them were middle aged females (46,9±13.9 years) with median RA duration 2 years (1,4–3), high disease activity (DAS28=5,2±0,8), RF-positive (80%) and ACPA-positive (79,5%). 16 healthy individuals were included in the study as control. The serum levels of IL-1, IL-6, IL-17, TNF-α, VEGF, IP-10 (μg/ml) were measured by ELISA immunoassay, YKL-40 by MicroVue immunoassay at baseline and 24 weeks. Disease activity was measured by DAS28, results were assessed every 2 weeks by EULAR criteria. ABA was administered intravenously every 4 weeks.

Results: Levels of IL-6 (2,4 (1,1–6,4) vs 0.7 (0,62–1,0), p=0,0002), YKL-40 (97 (68,4–97,9) vs 64 (52,4–107,5), p=0,030), IP-10 (21 (12,9–49,6) vs 14 (9,2–15,2), p=0,005) were significantly higher in patients treated with ABA. ABA significant reduced disease activity already after 12 weeks of therapy (p<0,05). After 24 weeks of ABA therapy good and moderate response by EULAR criteria was achieved in 86%, low disease activity by DAS28 in 52%. By the 6-th month ABA significantly decreased levels of IL-6 (1,29 (0,9–2,2, p=0,006), IP-10 (7,5–8,2, p=0,007) as well as MMP3: before 30,1 (13,8–82), after 24 weeks 10 (7,4–5,5), p=0,0003 and RF: before 218 (9,6–187), after 24 weeks 159 (9,7–15,5), p=0,02. Lowering of the IL-6 (r=0,5) and IP-10 (r=0,32) levels were significantly (p<0,05) associated with a decrease of DAS28.

Conclusions: ABA therapy leads to a significant reduction in serum levels of IL-6, IP-10, MMP3 and RF. The serum levels of IL-6 and IP-10 correlate with decrease activity of RA.

Association Between Clinical and Radiographic Responses, and Physical Function in a Phase 3 Study of Sarilumab Plus Methotrexate in Patients with Active, Moderate-to-Severe Rheumatoid Arthritis

M.C. Genowese1, H. van Hoogstraten2, W. Kampman3, S. Jayawardena2, T.W. Huizinga1, T. Stanford University Medical Center, Palo Alto; 2Sandoi Genzyme, Bridgewater; 3Regeneron Pharmaceuticals, Inc., Tarrytown, United States; 4Leiden University Medical Centre, Leiden, Netherlands

Background: In MOBILITY (NCT01061736), SC sarilumab (150 or 200 mg qw) + MTX demonstrated efficacy in adults with RA and inadequate response to MTX. The most common TEAEs were infections, neutropenia, injection site reactions, and increased transaminasins.

Objectives: To examine association between clinical response and radiographic progression and functional response (HAQ-DI) in MOBILITY.

Methods: In this post hoc analysis, associations between HAQ-DI and clinical efficacy categories (CDAI, DAS28-CRP, SDAI, and Boolean-based ACR/EULAR remission) were tested at wk 16. Trend for change from baseline (BL) in HAQ-DI across response categories was assessed using the Jonckheere-Terpstra test.

Results: Regardless of definition, percentage achieving remission (CDAI ≤ 2,8, DAS28-28,CRP ≤ 2,6, SDAI ≤ 3,3) or no x-ray progression was higher with sarilumab vs Pbo (P<0,05). Overall, there was a significant trend between magnitude of clinical response at wk 16 and improvement in physical function (Table). This trend was also observed for radiographic progression (mTSS change from BL),
regardless of cut-off (<0.5 and <0). In patients achieving remission, there was a numerically greater improvement in HAQ-DI with sarilumab vs placebo (Pbo). Even if patients did not achieve remission or LDA, the sarilumab group had generally greater numerical improvements in HAQ-DI vs Pbo.

Conclusions: Achieving LDA or remission, or absence of radiographic progression, was associated with overall greater improvement in physical function. Irrespective of whether patients achieved remission or LDA, sarilumab + MTX showed greater improvements in HAQ-DI than Pbo + MTX.

FR0244 | LOW DOSE OF RITUXIMAB IS EFFECTIVE FOR MAINTENANCE OF CLINICAL REMISSION OR LOW DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Avgoustidis, I. Flouri, C. Adamichou, E. Kabouraki, A. Eskinitzis, P. Kyfonidou, I. Papapoulos, A. Fanou, A. Repa, N. Kougkas, G. Bertsias, P. Sidirooulos. Department of Rheumatology, Clinical Immunology and Allergy, University Hospital of Heraklion, Crete, Greece, Heraklion, Greece

Background: Although existing data support the effectiveness of the low dose regimen (LDR, 1gr every 6 months) of rituximab as initial treatment for active rheumatoid arthritis (RA) (1), the extent of improvement that this regimen may be used to maintain the therapeutic effect in patients achieved clinical remission or low disease activity (LDA) upon treatment with conventional rituximab regimen (2gr every 6 months)

Objectives: To evaluate the effectiveness of the rituximab LDR regimen in patients with RA in clinical practice.

Methods: Long-term prospective study of RA patients who received rituximab in the Rheumatology Department of the University Hospital of Heraklion during 03/2005-07/2016. All patients on clinical remission [DAS 28 (ESR) <2.6] or LDA [DAS28 (ESR) <3.2] for at least 12 months were treated with the LDR after obtaining verbal consent.

Results: We analysed 247 patients who received conventional rituximab regimen, of median age (IQR) 62 (54.7–70.4) years, females (84%), disease duration 9.6 (5.6–18.3) years, 22% seropositive (2.4% anti-CCP). Patients have failed in (median) 3 (2–3) non-biologic (ndbDMARDs) and 1 (1–2) biologic DMARD, ndbDMARDs before rituximab initiation. At baseline of rituximab treatment, 58.3% and 91.1% of them were on steroids and (ndb)DMARDs respectively, while the disease activity was high [mean DAS28 (ESR): 5.84 (5.20–6.49)] and they had impaired physical functioning [mean HAQ 1.0 (0.63–3.18)].

Overall, 27/247 patients (11%) received the LDR. Before the initiation of LDR, the duration of rituximab treatment was 24 (18–48) months and cumulative rituximab “exposure” was 8 (6–15) gr. At the time of LDR initiation, disease activity [DAS28 (ESR)] was 2.8 (2.2–3.6) and HAQ 0 (0–0.4), while the time needed for achieving remission was 9.2 (5–26) months. A median duration of follow-up of patients on LDR was 12 (6–20) months. 23 (85%) of patients remained in remission or LDA with median DAS28 (ESR) 2.85 (2.23–3.52) and HAQ 0 (0–0.5) at last follow-up. Only 3 (11%) of the patients experienced an increase of DAS28 (1.2) or LDA in 2 (2%) of patients return to conventional dose.

Conclusions: In clinical practice, RA patients who achieved remission or low disease activity with conventional dose of rituximab may sustain clinical responses if treated with LDR. These preliminary findings support the use of LDR as maintenance treatment regimen and this may allow cost savings. (1)

FR0243 | SIRUKUMAB TREATMENT REDUCES LEVELS OF IRON-SCAVENGING PROTEINS AND AMELIORATES INFLAMMATION-ASSOCIATED ANEMIA IN RHEUMATOID ARTHRITIS PATIENTS

M. Loza1, K. Campbell1, K. Sweet1, B. Hsu2, S. Daga2, B. Dasgupta3

1Janssen Research & Development, LLC, Spring House, PA, United States; 2GlaxoSmithKline, Uxbridge, United Kingdom

Background: Anemia of chronic disease, a common comorbidity of rheumatoid arthritis (RA), is detrimental to patients’ (pts) quality of life, productivity, and long-term health.

Objectives: Sirukumab (SIR), a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, has recently demonstrated efficacy in RA. It was hypothesized that SIR, compared to placebo (pbo) and tumor necrosis factor-inhibitors (TNFi), increases hemoglobin (Hb) concentrations in RA pts by decreasing levels of iron-scavenging proteins and increasing transferrin levels, thus ameliorating anemia. This hypothesis was tested in post hoc analyses of 4 phase 3 studies of SIR in RA: SIRROUND-M, -D, -T, and -H studies, respectively: SIR 100mg q2w, n=61, 205, 61, 128, 100; pbo, n=0, 118, 56, 0; adalimumab (ADA), n=0, 0, 0, 0.

Methods: Standard hematologic measurements, including Hb levels, were made throughout the studies by a central laboratory. Anemia was defined as Hb level <125 g/L (males) and <115 g/L (females). In a subset of pts, iron-regulatory proteins (hepcidin, haptoglobin, hemopexin, transferrin) were measured in serum at baseline (BL) and Wk 4 using the SomaLogic SOMAscanTM platform (for responders [IR]); -D (disease-modifying antirheumatic drug [DMARD] IR); -T phase 3 studies of SIR in RA: SIRROUND-M (methotrexate [MTX] inadequate therapy). This hypothesis was tested through Wk 16; however, greater changes were seen in pts anemic at BL (13±13 to 16±12 g/L increase). Significant Hb elevations were observed (mean±SD) through Wk 16; however, greater changes were seen in pts anemic at BL (13±13 to 16±12 g/L increase). Significant Hb elevations were observed at BL (13±13 to 16±12 g/L increase). Significant Hb elevations were observed at BL (13±13 to 16±12 g/L increase).

Results: SIR consistently reduced the prevalence of anemia to a greater extent than was observed for pbo (p<0.05; eg, in SIRROUND-D, anemia decreased from 25% of pts at BL to 10% at Wk 16 post-treatment with SIR 50mg q4w vs increase from 24% of pts to 28% with pbo) and ADA (SIRROUND-H). Across studies on SIR 50mg q4w, increases in Hb levels ranged from 7±10 to 10±11 g/L (mean±SD) through Wk 16; however, greater changes were seen in pts anemic at BL (13±13 to 16±12 g/L increase). Significant Hb elevations were observed at Wk 2, with comparable results for SIR 100mg q2w. Statistically significant increases in Hb levels were not observed with ADA (Fig.1) or pbo, regardless of BL anemia status. Changes in Hb levels with SIR were independent of changes in RA disease activity. Mean haptoglobin levels were modestly higher at BL in RA pts with anemia compared to pts without anemia. Across studies, both SIR doses similarly strongly decreased levels of hepcidin, haptoglobin, and hemopexin and increased transferrin levels at Wk 4, regardless of BL anemia status. The modulation of these proteins by ADA was considerably less (Fig.1) and by pbo non-significant. After SIR treatment, greater decreases in hepocidin levels were consistently observed in pts with vs without BL anemia across studies by Wk 4.

Conclusions: SIR consistently increased Hb levels in RA pts (DMARD-IR, TNFi-IR, monotherapy), most prominently in pts with BL anemia, resulting in significant reductions in the prevalence of anemia. These effects were independent of the extent of improvement in RA disease activity, suggesting additional benefits of SIR beyond clinical response in RA. By inhibiting IL-6, SIR may decrease key iron-regulatory proteins, such as hepcidin, and shift homeostasis towards an increase in the iron pool available for red blood cell Hb, thus ameliorating anemia of chronic inflammation associated with RA.

DOI: 10.1136/annrheumdis-2017-eular.3570

Figure 1. for the SIRROUND-H study, changes in (A) hemoglobin (week 15 change from baseline in g/L) and (B) haptoglobin (week 15 change from baseline in g/L) are plotted for each available patient stratified by treatment group and baseline (BL) anemia status (Y, blue; N, red). * p<0.05 for baseline anemia Y vs. N within treatment group; † p<0.05 vs. adalimumab, within baseline anemia group. ADA, adalimumab; SIR, sirukumab.
IMPROVEMENTS IN HEALTH-RELATED QUALITY OF LIFE WITH SIRKUMAB ARE STATISTICALLY SIGNIFICANT, CLINICALLY MEANINGFUL, AND MEET OR EXCEED NORMATIVE VALUES IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO DISEASE-MODIFYING ANTIRHEUMATIC DRUGS: POST HOC ANALYSES OF A PHASE 3 TRIAL

V. Strand1, K. McQuarrie1, N. Li2, R. Ganguly2,1, Stanford University, Palo Alto, CA, 2Janssen Research & Development, LLC, Spring House, PA, 3GlaxoSmithKline, Collegeville, PA, United States

Background: Rheumatoid arthritis (RA) is associated with impaired health-related quality of life (HRQoL). Sirkumab (SIR) is an anti–interleukin-6 (IL-6) monoclonal antibody.

Objectives: These post hoc analyses evaluated improvements in HRQoL compared with an age/sex-matched normative population in a phase 3 randomized, controlled trial of SIR in RA pts with inadequate response to conventional disease-modifying antirheumatic drugs (DMARD-IR; SIRROUND-D).

Methods: 1670 pts received SIR 50mg every 4 weeks (q4w), SIR 100mg every 2 weeks (q2w), or placebo (pbo) q2w. Health-related physical/emotional well-being was measured at baseline (BL) and Wk 24 by the 36-item Short Form Questionnaire (SF-36), fatigue by Functional Assessment of Chronic Illness Therapy (FACT)-Fatigue (FACT-F), and physical function by Health Assessment Questionnaire-Disability Index (HAQ-DI).

Results: SF-36 physical and mental component summary (PCS and MCS) mean scores at BL were comparable for pbo, SIR 50mg q4w and 100mg q2w (PCS: 33.8, 34.2, and 33.5; MCS: 40.5, 40.5, and 41.8) and indicative of substantial impairment. At Wk 24, treatment with SIR 50mg q4w and 100mg q2w resulted in significantly greater mean improvements from BL vs pbo in SF-36 PCS (5.4 and 5.9 vs 2.3) and MCS (4.9 and 4.2 vs 2.9) scores (all P<0.001), exceeding the minimum clinically important difference (MCID) of 2.5. Least squares mean changes in all SF-36 domain raw scores were significantly greater with both doses of SIR than pbo at Wk 24 and all ≥MCID of 5.0 (Table; Figure). Substantial proportions of pts treated with SIR 50mg q4w or 100mg q2w reported scores ≥normative values in SF-36 domains at Wk 24 (ranges: 20–33% and 21–36%) vs pbo (range: 10–28%). For pbo, SIR 50mg q4w, and SIR 100mg q2w, BL FACT-F scores were 27.2, 27.1, and 27.5. Significantly greater proportions of pts reported clinically meaningful improvements in FACT-F (MCID=4) with SIR 50mg q4w and 100mg q2w vs pbo (61.4 and 59.4% vs 43.9%; P<0.001). FACT-F scores ≥normative values were reported by 33% of pts on SIR 50mg q4w and 100mg q2w vs 22% on pbo. HAQ-DI scores at BL were 1.56, 1.50, and 1.52 with pbo, SIR 50mg q4w, and 100mg q2w, with clinically meaningful improvements (MCID=0.22) reported by 63.0 and 63.4% with SIR 50mg q4w and 100mg q2w vs 46.9% with pbo (P<0.001). HAQ-DI scores ≥normative values were reported by numerically more pts receiving SIR 50mg q4w (22%) and 100mg q2w (21%) vs pbo (10%).

Prospective, real-world data on abatacept (ABA) retention in patients (pts) with RA.

Objectives: To assess the retention rate and to identify prognostic factors of ABA retention in the overall ACTION population and by treatment line over 2 yrs.

Methods: ACTION is a 2-yr, international, observational study of pts with RA who initiated IV ABA as first- or as second/third-line biologic therapy in routine clinical practice. Biologic-naïve and biologic-failure pts were enrolled during three periods between May 2008 and December 2013. The primary endpoint was crude ABA retention rate over 2 yrs (Kaplan–Meier plot). Prognostic factors (p<0.02) from univariate analyses with no collinearity, clinically relevant variables and known risk factors were entered into a multivariate model; factors with p<0.31 were retained by backward selection. EULAR response was compared by Fisher’s exact test.

Results: In the ACTION cohort, 2350/2364 enrolled pts were evaluable for analysis; 673 (28.6%) were biologic naïve and 1677 (71.4%) had failed biologic treatment. Most biologic-failure pts (56.6%) had previously received ≥2 biologics. Some expected differences in baseline characteristics were observed between groups; mean (SD) RA duration was shorter (7.2 [8.2] vs 121 [9.1] yrs; p<0.001), more pts had RA for ≥2 yrs (35.7 vs 9.0%; p<0.001) and fewer pts had radiographic erosions (58.2 vs 71.5%; p<0.001) for biologic-naïve vs biologic-failure pts. At Yr 2, the overall retention rate was 47.9% (95% CI 45.7, 50.0). The retention rate was higher in biologic-naïve vs biologic-failure pts (54.5 vs 44.3%; p<0.001) and in pts with 1 vs ≥2 previous biologics (Fig). Reasons for discontinuation were comparable between groups; main reasons were lack of efficacy (61.4 vs 67.7%) and safety (21.3 vs 21.2%). RF and anti-citrullinated peptide antibody (ACPA) seropositivity were prognostic factors for higher retention in biologic-naïve (p=0.030) and biologic-failure pts (p=0.028); other positively impacting factors were diabetes mellitus (p=0.044); biologic naïve; geographic location (p=0.001; biologic naïve) and ABA combination therapy (p<0.001; biologic failure). Only PI Global Assessment (p=0.035) biologic failure) predicted lower retention. Among pts continuing ABA, a greater proportion of biologic-naïve vs biologic-failure pts had a good/moderate EULAR response (90.7 vs 81.6%; p=0.005) and RF/ACPA seropositivity was associated with a better response (p=0.002). There were no new safety signals.

Conclusions: In this first prospective, international, non-interventional research evaluating the long-term IV abatacept retention, RF and ACPA seropositivity were predictors of 2-yr higher retention and better outcomes. Higher retention rates may be achievable with earlier vs later initiation of abatacept treatment, consistent with prior findings from a pooled analysis of EU and Canadian registries.

FR0247 | MEDIAN TIME TO LOW DISEASE ACTIVITY IS SHORTER IN TOCILIZUMAB COMBINATION THERAPY WITH CSDMARS AS COMPARED TO MONOTHERAPY IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSES TO CSDMARS AND OR TNF INHIBITORS: SUBANALYSIS OF THE SWISS AND AUSTRALIAN PATIENTS FROM THE ACT-SURE STUDY

1Division of Rheumatology, Kantonsspital St. Gallen, St. Gallen, Switzerland; 2Division of Rheumatology, Medical University of Graz, Graz, Austria; 3F. Hoffmann-La Roche Ltd., South San Francisco, United States; 4Roche Austria GmbH, Vienna, Austria

Background: To analyze efficacy and safety of tocilizumab in patients with rheumatoid arthritis (RA) and an inadequate response to conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) and/or tumour necrosis factor (TNF) inhibitors of the Swiss and Austrian patients from the ACT-SURE study.

Objectives: Methods: Sub-analysis of RA patients from Switzerland and Austria, who participated in the international phase IIIb, open-label, ACT-SURE study. Patients with an inadequate response to csDMARDs or TNF antagonists were included into the study receiving 8 mg/kg of IV tocilizumab every 4 weeks during a 24 week time period. Therapy with one or more csDMARDs could be continued as combination therapy with tocilizumab (Combo) or stopped, resulting in tocilizumab monotherapy (Mono), at the treating physician’s discretion. These two treatment groups were analyzed in separate and compared.

Results: Overall, 107 (22 on Mono vs 85 on Combo) and patients were treated with tocilizumab. The percentage of patients with at least one adverse event was significantly lower in the tocilizumab combination (58.8%) as compared to the monotherapy group (81.8%, p=0.0458). No differences in ACR20/50/70/90 response rates were observed between both treatment groups at week 24 (Mono: 63.6%, 49.0%, 22.7%, and 18.2% vs. Combo: 61.2%, 43.5%, 25.9%, and 10.6%). The median time to low disease activity (LDA) was significantly shorter in patients treated with tocilizumab combination therapy Mono: 9.1, Combo 7.9 weeks, Log Rank p<0.038.

Conclusions: This post hoc regional sub-analysis of the ACT-SURE study no differences for disease activity were found comparing the two patient groups at week 24. However, median time to LDA was statistically shorter in patients treated with tocilizumab combination therapy as compared to tocilizumab monotherapy. Consequently, adding tocilizumab to csDMARD therapy rather than changing to tocilizumab monotherapy may be, in our opinion, the safest strategy to reach remission in RA patients with active disease despite treatment with csDMARDs. csDMARDs may be withdrawn early due to adverse events or after at least low disease activity has been reached.

FR0248 | INCIDENCE OF MELANOMA IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOCILIZUMAB

1Genentech, South San Francisco, CA, United States; 2Roche Products, Welwyn Garden City, United Kingdom; 3F. Hoffmann-La Roche, Basel, Switzerland

Background: There have been conflicting reports whether patients with rheumatoid arthritis (RA) receiving conventional or biologic immunosuppressive therapies are at increased risk of specific malignancies. Melanoma is an aggressive malignancy with risk factors including sex, age, fair skin and elevated cumulative UV exposure. Interleukin-6 (IL-6) has a role in pro- and antiinflammatory pathways. Whether tocilizumab (TCZ), a biologic that alters IL-6 signaling, increases the risk of melanoma in patients with RA is unclear.

Objectives: This age- and sex-adjusted standardized incidence ratio (SIR) analysis compared the observed reports of melanoma in patients with RA treated with TCZ in clinical trial and postmarketing settings with the expected number of cases across geographic regions.

Methods: SIRs for melanoma were calculated from the TCZ clinical trials all exposure population. Postmarketing rates were estimated from the TCZ Global Safety Database population. Both databases were searched cumulatively from 11 April 2005 to 10 October 2015. For clinical trials, observed reports of melanoma in patients with RA treated with TCZ were compared with expected number of cases in the general population based on the 2012 US Surveillance, Epidemiology, and End Results using an age- and sex-adjusted SIR. Postmarketing regional SIRs were calculated based on the estimated commercial exposure in each region and the incidence of melanoma as reported by Globocan by age and sex (2012).

Results: In the clinical trial setting, 4 qualifying cases of melanoma were identified among 7093 patients with RA treated with TCZ (20,828 PY of exposure). The SIR (95% CI) of 1.17 (0.56–2.43) for melanoma incidence with RA treated with TCZ in clinical trials was comparable to that in the general population (Table 1). In the postmarketing setting, the number of observed reports of melanoma was comparable to the expected number of cases in Europe and Japan and fewer than expected in North America (Table 2). The exception is Australia, where SIR estimates indicated more than the expected number of cases in patients with RA receiving TCZ in Australia compared with the general population in that region (SIR 3.71 [95% CI: 2.16, 5.93]).

Conclusions: In clinical trials, no evidence was found to suggest there were more cases of melanoma in patients with RA treated with TCZ compared with the general population. Consistent with this, no evidence was found to suggest that patients with RA treated with TCZ in Europe, North America or Japan had more cases of melanoma than expected compared with the general population in each region. In contrast, the estimated SIR of melanoma in patients with RA treated with TCZ in Australia indicated more than the expected number of cases in the general population. This finding is consistent with reports of elevated risk of melanoma in patients with RA in Australia (compared with the general population), where UV exposure is high and methotrexate is a common first-line therapy.

FR0249 | CIRCULATING FOLLICULAR HELPER-LIKE T CELLS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ABACETEP

S. Piantoni1, M. Scarsi2, F. Regola1, A. Tincani1, P. Airo1, 1Rheumatology and Clinical Immunology Unit, Spedali Civili and University of Brescia, Brescia; 2Internal Medicine Unit, Esine-Vallecamonica Hospital, Esine, Italy

Background: Rheumatoid arthritis (RA) is characterized by synovial inflammation and, in most cases, by autoantibodies, including rheumatoid factor (RF) and anti-cyclic citrullinated peptide antigen (ACPA), whose presence is associated to a more severe disease. The capability of producing autoantibodies is acquired by B cells with the “help” of specialized T lymphocytes, known as Follicular helper T (TFH) cells, in the germinal centers (GC) of secondary lymphoid tissues. TFH express the inducible co-stimulator (ICOS), and are characterized by a high expression of CXC-chemokine receptor 5 (CXCR5), which mediate their migration into the GC, where its ligand CXCL13 is expressed. Here, TFH promote the GC development and B cell maturation. These cells are reported to exist in greater quantities in the peripheral blood (circulating TFH-like cells) of RA patients.

Abacetep (ABA) is a fusion protein, which through its CTLA4 portion can bind to CD80 and CD86 on antigen presenting cells, thereby inhibiting CD28 costimulation. Data from animal models and phenotypic analysis of circulating T cells in RA suggest that ABA may act in the secondary lymphoid organ, and not directly on the synovium (1,2). While experimental models show that ABA can block the generation of TFH (3), little is known on the effect of ABA on circulating TFH-like cells of RA patients (4).

Objectives: To analyze the effect of the blockade of costimulation performed by
ABA on the levels of circulating TFH-like cells of RA patients.

Methods: 55 RA patients (FM=18/7; median age: 52.5th-75th percentile): 57 (44–63 years; ACPA+: 16 (64 %); RF+: 17 (68 %)), treated for at least 6 consecutive months with ABA were evaluated. Circulating TFH-like cells were identified by flow-cytometry as CD4+ICOS+CXCR5+. The response to treatment was evaluated with the EULAR Criteria.

Results: After 6 months of therapy with ABA the percentage of circulating TFH-like cells among total CD4+ T-cells tended to decrease from a median of 1.8 (0.6–3.8) to 0.8 (0.1–2.3) (p 0.07; Wilcoxon signed rank test). The percentage of circulating TFH-like cells at baseline was higher among patients who did not respond to ABA (n:8; 2.6 (2.0–3.6)); than in those who achieved a moderate or good EULAR score (n:17; 1.0 (0.5–5.4) (p:0.01; Mann–Whitney test), but their trend of reduction was similar in the two groups of patients. No difference in the levels of circulating TFH-like cells was found between ACPA+ and ACPA− RA patients.

Conclusions: ABA tends to reduce the number of circulating TFH-like cells in RA patients, suggesting the relevance of costimulation via CD28 in their generation. A higher percentage of these cells is present in patients not responding to ABA. While this observation suggests their possible use as predictors of clinical response to ABA, further studies are destined to evaluate whether it reflects different localizations of TFH, or functional variability within this T-cell subset in patients with RA.

FRI0250
SERIOUS ADVERSE EVENTS IN PATIENTS WITH RA TAKING ABATACEPT COMPARED WITH OTHER DMARDs BY LINE OF TREATMENT
S. A. Pedro1, R. Schumacher1, K. Michaud1, 2, National Data Bank for Rheumatic Diseases, Wichita, KS, 3University of Nebraska Medical Center, Omaha, NE, United States

Background: Observational studies are critical in assessing medication safety and effectiveness in the real world. Nonrandom assignment can provide insight into how and when medications are prescribed. Since the US introduction of TNF inhibitors (TNFi) in 1998, several newer biologics with varying mechanisms of action are available to patients and physicians.

Objectives: To compare baseline characteristics and serious adverse events (serious infections (SI), malignancies) of patients who received abatacept (ABA) compared to those who received other comparison cohorts: conventional DMARDs (cD) and biologic DMARDs (bD) by line of therapy. (LT).

Methods: Participating patients from 2005–2015 with RA in the National Data Bank for Rheumatic Diseases (NDB) provided treatment and other characteristics (physical demands, time management); the 3-level EuroQol-5 Dimension (EQ-5D) questionnaire measured 5 dimensions of health status (mobility, self-care, usual activities, pain/discomfort, anxiety/depression).

Results: A total of 2, 430, 360 patients (54.0% cD; 34.0% bD) were identified. Baseline characteristics were similar across groups. ABA patients were more likely to be female, white, and have a lower BMI, insurance, comorbidity index, RA severity, and co-medications.

Conclusions: Abatacept leads to the highest self-reported quality of life and physical demand. ABA patients had better self-reported health status compared to other DMARDs at baseline. No overall increased risk of malignancy was found for ABA compared to other DMARDs.

FRI0251
SIRKUMAB, AN ANTI-IL-6 CYTOKINE MONOCLONAL ANTIBODY, LEADS TO IMPROVEMENTS IN WORK PRODUCTIVITY AND GENERAL HEALTH STATUS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS REFRACTORY TO ANTI-TNF THERAPY: RESULTS FROM THE PHASE 3 SIRROUND-T STUDY
Y. Tanaka1, D. Aletaha2, S. Peterson3, R. Ganguly4, R. Kurrasch4, S. Popik3, P. Agarwal3, N. Li4, 1University of Occupational & Environmental Health, Kitakyushu, Japan; 2Division of Rheumatology, Medical University of Vienna, Vienna, Austria; 3Janssen Research & Development, LLC, Spring House, PA; 4GlaxoSmithKline, Collegeville, PA, United States

Background: Sirkumab is an anti-interleukin-6 (IL-6) monoclonal antibody that selectively binds to the IL-6 receptor with high affinity and is in development for rheumatoid arthritis (RA) and other diseases.

Objectives: This study evaluated the effects of sirkumab on work productivity/interference and health status in patients with active RA despite treatment with anti-tumor necrosis factor (TNF) therapy.

Methods: In this randomized, double-blind, phase 3 trial, 878 eligible patients with active RA who were intolerant/refractory to anti-TNFs were randomized 1:1:1 to sirkumab subcutaneous (SC) 50mg every 4 weeks (q4w; n=292), sirkumab SC 100mg every 2 weeks (q2w; n=292), or placebo SC q2w (n=294). At Week 16, placebo patients were re-randomized to 1 of the sirkumab doses if insufficient (<20%) improvement; at Week 24, all patients remaining on placebo crossed over to sirkumab. The Work Limitations Questionnaire (WLQ) evaluated health-related job limitations and productivity loss in 4 domains (mental-interpersonal, output, physical demands, time management); the 3-level EuroQol-5 Dimension (EQ-5D) questionnaire measured 5 dimensions of health status (mobility, self-care, usual activities, pain/discomfort, anxiety/depression).

Results: At Week 24, mean total WLQ scores improved significantly from baseline for sirkumab 50mg q4w and 100mg q2w versus placebo (mean change, −2.2 and −2.3 vs 0.2, respectively; both p<0.001), as did all 4 mean QoL domain scores (all p<0.001). Improvements from baseline in mean total WLQ and all 4 domain scores were maintained through Week 52 for both sirkumab doses. Mean EQ-5D index and health state visual analog scale (VAS) scores improved significantly from baseline at Week 24 for sirkumab 50mg q4w and 100mg q2w versus placebo (mean index change, 0.2 and 0.2 vs 0.0, respectively; mean VAS change, 13.9 and 15.4 vs 4.8, respectively; all p<0.001); improvements from baseline were maintained through Week 52 with both sirkumab doses.

Conclusions: Sirkumab treatment led to significant improvements in work-related productivity and general health status in patients with active RA despite anti-TNF therapy, consistent with demonstrated effects of sirkumab on RA disease improvement.

SUMMARY OF NEUTROPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SIRKUMAB IN THE SIRROND PHASE 3 CLINICAL TRIALS

T. Takeuchi1, Y. Tanaka2, M. Schiff3, M. Harigai4, K. Brown5, R. Rao6, K. Fei7, S. Popik7, K. Yoshizawa8, Q. Wang7, B. Hsu7. 1Division of Rheumatology, Keio University School of Medicine, Tokyo; 2University of Occupational and Environmental Health, Kitakyushu, Japan; 3University of Colorado School of Medicine, Denver, CO, United States; 4Tokyo Women’s Medical University, Shinjuku-ku, Japan; 5GlaxoSmithKline, Collegeville, PA, United States; 6GSK Medicines Research Centre, Hertfordshire, United Kingdom; 7Janssen Research & Development, LLC, Spring House, PA, United States; 8Janssen Pharm Ka Kk, Chiyoda-ku, Tokyo, Japan

Background: Neutropenia has been reported with interleukin-6 (IL-6) pathway inhibition. However, it is not clear how much neutrophil count should be associated with increased rates of infection. The reduced neutrophil counts seen with IL-6 inhibitors may be due to effects on margination of circulating neutrophils as opposed to a decrease in bone marrow production or reduced survival. Efficacy of sirukumab (SIR), a human anti-IL-6 cytokine monoclonal antibody, has recently been shown in several phase 3 trials.

Methods: Neutrophil counts were compared for SIR 50 mg q4w and 100 mg q2w doses vs placebo (pbo) in the pbo-controlled period (Wks 0–18) of 2 phase 3 trials (SIRROND PHASE IIIA and PHASE IIIB) for the 5-trial, phase 3 program. The distribution of neutropenia by grade was similar in pts who did or did not use disease-modifying antirheumatic drugs (DMARDs) at baseline.

Grade 3 neutrophil counts were National Cancer Institute Common Terminology Criteria for Adverse Events grade 0/1, within the normal range, and the incidence of grade 3/4 decreases was low across groups (Table). Neutropenia began at Wk 2 and persisted through the study period. In long-term analysis, the proportions of pts with grade 1, 2, or 3 neutropenia were slightly higher than in the 18-wk pbo-controlled period, suggesting the majority of events occurred early. No dose effect of SIR on neutrophil counts was observed in the pbo-controlled period such that no change in dose schedule was required.

Conclusions: Across phase 3 studies, there was no dose effect of SIR on neutropenia, and the use of DMARDs did not have an apparent effect on neutropenia. The majority of grade 4 neutropenia with SIR was not associated with infections.

Conclusions: In BREVACTA, TCZ-SC + csDMARDs resulted in significantly greater improvements across all PROs and significantly more pts reporting scores ≥ minimal clinically important differences.
Efficacy of tocilizumab for suppressing radiographic progression of cervical lesions in patients with rheumatoid arthritis comparison with methotrexate treatment: Two years of follow-up - A multicenter registry study -

Y. Kanayama, T. Kojima, Y. Hirano, Y. Yabe, N. Takahashi, Y. Oishi, N. Ishiguro on behalf of TBCR study group. Orthopedic Surgery and Rheumatology, Toyota Kosei Hospital, Toyota; 2 Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya; 3 Rheumatology, Toyohashi Municipal Hospital, Toyohashi; 4 Rheumatology, Japan Community Healthcare Organization Tokyo Shinjuku Medical Center, Tokyo, Japan

Background: Cervical lesions are known to occur at high frequency as a complication of rheumatoid arthritis (RA). Treatment with biological agents are more clinically effective than the DMARDs that were in use previously. In particular, with their efficacy in suppressing joint destruction having been emphasized. We reported the efficacy of infliximab, anti-tumor necrosis factor antibodies for suppressing the radiographic progression of RA cervical lesions at ACR2009, EULAR2010, 11, 12, 13, 14 and 16. However there is still few studies of efficacy of against RA cervical lesions of Tocilizumab (TCZ), anti-interleukin 6 receptor antibody.

Objectives: To evaluate the efficacy of TCZ for suppressing the radiographic progression of RA cervical lesions comparison with MTX for 2 years.

Methods: We used TCZ or MTX for treating Japanese patients with active RA who fulfilled the ACR criteria in 1987. The final study cohort of each 38 and 71 patients received continuous TCZ and MTX treatment for at least 2 years. For evaluation of cervical lesions, the atlanto-dental interval (ADI), and the Ranawat value were measured by plain lateral radiographs in the flexion position, at initiation and Year 1,2.

Results: In the patients receiving TCZ (n=38) and MTX (n=71), the number of female were each 28 (72%) and 51 (72%) cases (p=0.999). The mean age was 57.3±12.4 and 63.3±10.9 years (p=0.929) and the mean dose of MTX was 9.0±3.4 and 8.3±2.9 mg/w (p=0.335). Clinical findings related to RA were as follows: CRP 3.8±3.1 and 1.5±2.1 mg/dl (p<0.001); ESR 52.7±25.3 and 30.0±20.8 mm/h (p<0.001); MMP3 400±300 and 213±356 ng/ml (p=0.001); the number of RF-positive 30 (79%) and 44 (62%) cases (p=0.087) and 30 (79%) and 41 cases (58%) receiving TCZ and 49 (69%) cases (p=0.367) after 2 years. Also the number who was able to show progression in ADI, SAC and Ranawat value were each 30 (79%) and 41 (58%) cases (p=0.035); 30 (79%) and 44 (82%) cases (p=0.007) and 30 (79%) and 49 (69%) cases (p=0.367) after 2 years. Also the number who was able to suppress progression in all three parameters were each 29 cases (76%) receiving TCZ and 41 cases (58%) receiving MTX (p=0.062) after 2 years (Fig.2).

Conclusions: This study suggested that TCZ treatment can be used to suppress the progression of RA cervical lesions more than MTX treatment.

Patterns of disease activity impact on organ damage in Systemic Lupus Erythematosus

A. Bortoluzzi, M. Padovan, E. Silvagni, C.A. Scirè, M. Govoni. Department of Medical Sciences, Rheumatology Unit, University of Ferrara and Azienda Ospedaliero-Universitaria Sant’Anna, Cosa (Ferrara), Italy

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease characterized by fluctuating disease activity in which adverse long-term outcomes remain a major challenge. In the face of extreme individual unpredictability of the disease course over time, four different patterns can be defined, as elsewhere described [1], using SLEDAI-2K (Systemic Lupus Erythematosus Disease Activity Index-2K) evolution in order to focus on clinical activity. The patterns are clinical quiescent disease (CQD), chronic active disease (CAD), relapsing-remitting disease (RDR) and minimal disease activity (MDA).

Objectives: The aim of our study was to assess the association between different disease activity patterns and damage accrual in SLE patients.

Methods: Patients with SLE registered at our Lupus Clinic at the Rheumatology Unit, between 1 January 2013 and 1 October 2016, were included. Demographic and clinical variables included age, gender, age at SLE onset, major organ involvement. SDI (Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index) was categorized as absent (SDI=0) or present (SDI>0). Disease activity patterns (CQD, MDA, RRD, CAD) were retrospectively assessed. Drugs used in the treatment of SLE, including hydroxychloroquine, cumulative dose of glucocorticoid (prednisone equivalent >10 g) and other immunosuppressive drugs, were also collected. Multivariate logistic regression analyses were performed to identify disease patterns associated with damage accrual. Results are presented as odds ratio (OR) and 95% confidence intervals (CI).

Results: A total of 473 Caucasian patients were observed, mainly female (89.4% F:10.6% M), mean age 52.6 years (±14.9 SD). In our cohort, the disease activity pattern distribution was as follows: 65.4% CQD (290 pts), 21.5% RDR (91 pts), 6.1% MDA (28 pts) and CAD in 19.1% of the cases (84 pts). Damage was significantly more frequent in CAD subset (81.2%, 52/64 pts) versus 54.5% in CQD (158/290 pts), 50% in MDA (14/28 pts) and 58.2% in RDR (53/91 pts). Compared to a CQD course, CAD pattern was independently associated with overall disease after controlling for factors including gender, disease duration, cumulative glucocorticoid dosage, major individual organ involvement (neuropsychiatric and renal), positive antiphospholipoid antibody profile, exposure to cyclophosphamide and hydroxychloroquine (Table 1).

*adjusted for: age, gender, disease duration, NP and renal involvement, cumulative dosage of Cs; aPL positivity, HCoC, CnC (NP), neuropsychiatric aPL, antiphospholipid; CyC, cyclophosphamide; HCoC, hydroxychloroquine; M, male; C, corticosteroid; F, prednisone.
Conclusions: Our results demonstrated that a clinically and persistently CAD triples the risk of damage compared to milder or relapsing courses, while hydroxychloroquine appeared to have a “protective” effect. Identifying the prevailing pattern of disease activity in every patient can be translated into a more effective personalized preventing strategy to reduce damage accrual and improve outcomes.

<th>FRIO256</th>
<th>ULTRASOUND CONSENSUS DEFINITIONS ON NORMAL AND ABNORMAL FINDINGS IN SALIVARY GLANDS IN SJÖGREN’S SYNDROME: RESULTS OF AN OMERACT DELPHI PROCESS</th>
</tr>
</thead>
</table>

Background: Ultrasonography (US) of salivary glands (USSG) may support the diagnostic workup for primary Sjögren’s syndrome (pSS), a chronic inflammatory autoimmune disease characterized by salivary gland (SG) involvement. The OMERACT Delphi process has been utilized in the development of definitions for imaging in various areas of medicine. In limited literature, consensus definitions of salivary gland disease have been established in Sjögren’s syndrome. To our knowledge, formal consensus definitions concerning normal and abnormal USSG findings in the context of Sjögren’s syndrome have not been established.

Aims: To develop, through a Delphi process, a definition of normal and abnormal USSG findings in patients with Sjögren’s syndrome.

Methods: A 2-step Delphi process was performed. Step 1: a questionnaire with open-ended questions was administered to 25 experts from 17 countries. Step 2: An electronic Delphi questionnaire was administered with a 3-grade (1=Agree, 2=Undecided, 3=Disagree) scoring system.

Results: Of the 25 experts who completed the questionnaire, 18 agreed to participate in the Delphi process. Step 1: 120 responses were collected. The majority of experts (72%) were rheumatologists, the rest were radiologists. Step 2: 123 responses were collected. A Consensus Conference was held to discuss the draft definitions. The experts agreed on definitions for normal ultrasound findings of salivary glands. For abnormal ultrasound findings, extensive discussion took place concerning the use of ultrasound in patients with primary Sjögren’s syndrome.

Conclusions: A Delphi process successfully established definitions for normal and abnormal ultrasound findings of salivary glands in primary Sjögren’s syndrome. These definitions will be tested in a prospective cohort study to ascertain their validity.

Background: The value of urinary angiostatin, CXCL4 and VCAM-1 in differentiating between active renal and non-renal SLE was determined by 2x2 contingency tables. In patients with active renal disease, correlation between these urinary biomarkers with clinical renal parameters was also performed.

Results: 227 SLE patients (80 inactive SLE; 67 active non-renal disease; 80 active renal disease; 94% women, age 39±13.8 years) and 53 controls were studied.

Urinary angioatin, CXCL4 and VCAM-1 levels normalized for creatinine were significantly higher in patients with active renal than non-renal disease (angiostatin 18.4±27.1 vs 1.6±2.91 pg/μg; p<0.0001; CXCL4 9.11±15.7 vs 5.12±10.4 pg/μg; p<0.003; VCAM-1 4.1±3.11X10^5 vs 0.72±1.10X10^5 pg/μg; p<0.0001). The levels of these urinary protein markers were also significantly higher in active SLE patients than inactive SLE patients or healthy controls. Urinary angiostatin, CXCL4 and VCAM-1 correlated significantly with the renal SLEDAI (Rho 0.66, 0.45 and 0.51, respectively; p<0.001 in all), total SLEDAI score (Rho 0.60, 0.46 and 0.53, respectively; p<0.001 in all) and urine protein-to-creatinine (upCr) ratio (Rho 0.73, 0.51, 0.59, respectively; p<0.001 in all) in the same patients studied. Urinary angioatin was more specific (specificity 0.82) than elevated anti-dsDNA and low C3 (specificity 0.64 and 0.66) in differentiating active renal SLE from non-renal SLE. In a subset of patients with biopsy proven active lupus nephritis (N=68), these urinary protein markers could not differentiate between proliferative (III/IV) from non-proliferative (I/II) types of lupus nephritis. However, urinary CXCL4 (Rho 0.25; p=0.049) and VCAM-1 (Rho 0.28; p=0.02), but not angiostatin (Rho 0.11; p=0.39), correlated significantly with the histologic activity index. There was no significant association between these protein markers and the histologic chronicity index or renal SLEDAI score. On the other hand, urine angioatin levels (Rho 0.36; p<0.003) were correlated with the renal SLEDAI score in SLE (Rho 0.36; p<0.003), but not CXCL4 (Rho 0.07; p=0.59) or VCAM-1 (Rho -0.11; p=0.36), correlated significantly with the upCr ratio in this subgroup of patients.

Conclusions: Urinary angiostatin, CXCL4 and VCAM-1 are potentially useful biomarkers for SLE, in particular lupus nephritis. Further longitudinal studies are necessary to delineate the sensitivity and specificity of these two urinary protein markers in predicting renal flares and prognosis in SLE patients.

<th>LONG-TERM PROGNOSISOFPATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION: CSTAR-PAH COHORT STUDY</th>
</tr>
</thead>
</table>

Background: SLE-associated pulmonary arterial hypertension (PAH) is common in Asian countries, and the clinical outcome of patients with SLE-associated PAH is dramatically impaired.

Objectives: This study aimed to identify the long-term clinical outcomes and prognostic factors of patients with SLE-associated PAH confirmed by right heart catheterization (RHC).

Methods: A multicenter cohort of SLE-associated PAH was established. Baseline and follow-up records were collected. The primary endpoint was death from any cause.
cause. The secondary experimental end point was treatment goal achievement (TGA), defined as an integrated outcome.

**Results:** Among the 310 patients enrolled from 14 PAH centers, the median follow-up was 24.0 months. The 1-, 3-, and 5-year survival rates were 92.1%, 84.8% and 72.9%, respectively. The 1-, 3-, and 5-year TGA rates were 31.5%, 53.6% and 62.7%, respectively. Serositis, 6MWD >380 m and Cl × 2.5 [L/min × m²] were identified as independent prognostic factors of TGA. TGA within 5 years was identified as a factor associated with survival in patients with SLE-associated PAH (Figure 1).

**Conclusions:** TGA was associated with the long-term survival, which supports and provides evidence to the treat-to-target strategy in SLE-associated PAH. Early diagnosis, intervention and heart function preservation are priorities for better long-term outcomes.

**Disclosure of Interest:** None declared

**FRI0259 LUPUS LOW DISEASE ACTIVITY STATE (LLDAS) IN PATIENTS WITH LUPUS NEPHRITIS (LN)**

D.V. Monova, S. Monov, M. Ivanov, E. Peneva. Department of Internal Medicine, Medical Institute, Sofia, Bulgaria

**Background:** Lupus Low Disease Activity State (LLDAS) is a consensus-based definition of minimally acceptable disease activity in patients with Systemic lupus erythematosus (SLE).

**Objectives:** The aim of this study was to evaluate what proportion of patients with LN fulfills the definition of LLDAS and to evaluate the effect of LLDAS attainment on damage accrual over a period of 5 years.

**Methods:** This is a retrospective analysis of data prospectively collected in a longitudinal observational cohort of LN patients. The conceptual definition of LLDAS is fulfilled when all of the following criteria are met: (1) SLE Disease Activity Index (SLEDAI-2K) ≤ 4, with no activity in major organ systems (renal, central nervous system, cardiopulmonary, vasculitis, fever) and no haemolytic anaemia or gastrointestinal activity; (2) no new features or changes in major organ systems (renal, central nervous system, cardiopulmonary, vasculitis, fever), and no increase in SLEDAI-2K of ≥3 points; (3) no new features of lupus disease activity compared to the previous assessment; (4) a Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA)-SLEDAI physician global assessment (PGA) (scale 0–3) ≤ 1; (4) a current prednisolone (or equivalent) dose ≤ 7.5 mg daily; and (5) well-tolerated standard maintenance dose of immunosuppressive drugs and approved biologic agents, excluding investigational drugs. The definition of LLDAS was applied to each patient for each visit; organ damage was calculated with the SLICC/SDI score (SDI) at study entry and at last observation.

**Results:** 294 patients were eligible for the study (89.79% females, mean age at first visit 31.4±11.9 years, mean disease duration at last visit 19.8±8.7 years). At last observation 219 patients (85.37%) were on treatment with glucocorticoids (GC) and/or immunomodulators. According with all the items of the definition, at last observation LLDAS was present in 146 patients (49.65%); among these, 37 patients (20.8%) maintained a stable LLDAS during the last 5 years of follow-up (LLDAS fulfilled for all visits). LLDAS accrued less organ damage during the follow-up; in the cohort as a whole the mean increase in SDI was 0.40±0.67 resulting in a mean final SDI of 1.2±1.8. Patients who maintained LLDAS were younger (p<0.005), had a lower disease activity score at study entry (p<0.001) and were more likely GC-free at last observation (p<0.001). Patients who maintained LLDAS accrued less organ damage but this difference did not reach statistical significance.

**Conclusions:** High percentage of patients fulfills the proposed definitions for LLDAS at last visit but only a minority maintained this state for all the follow-up period. A minimally acceptable disease activity state is associated with a successful GC tapering and, probably, better long-term outcomes. LLDAS was shown to be associated with protection from damage accrual.

**FRI0260 ULTRASOUND STUDY OF PLEURAL PROFILE AND CHEST HIGH-RESOLUTION COMPUTED TOMOGRAPHY (HRCT): DIAGNOSTIC ROLE IN PRIMARY SJÖGREN'S SYNDROME-INDUCED LUNG INVOLVEMENT**

F. Ferro1, A. Bulleri2, A. Delle Sedie1, E. Elefante1, N. Luciano1, M. Mosca1, C. Baldini1, 1 Clinical and Experimental Medicine, Rheumatology Unit, University of Pisa; 2 Radiology Unit, University of Pisa, Pisa, Italy

**Background:** Ultrasound pleural irregularity (PI-US) is a novel promising tool for non-invasive diagnosis of intestinal lung involvement (ILD) in connective tissue diseases (CTDs). Few data are available on its diagnostic usefulness in primary Sjögren's syndrome (pSS)-induced ILD.

**Objectives:** (a) To assess the accuracy of PI-US to diagnose ILD in pSS when compared to chest tomography (HRCT) (i.e. gold standard imaging technique); b) to explore PI-US diagnostic value in early preclinical phases of lung involvement.

**Methods:** PI-US was performed by a single operator using a MyLab-25 (Esaote), 10 MHz, 5 cm linear probe. PI was defined as the loss of the normal hyperechoic linear pleural contour (score 0–2: normal, minimal and major changes at each intercostal space). Abnormal findings at HRCT were quantified by an expert radiologist according to a semiquantitative score (0–2: absent, moderate, severe). Semi-quantitative scores assigned by PI-US and HRCT to 6 lung fields (2 for the anterior, 2 for postero-superior and 2 for postero-inferior chest surface) were compared. Total and partial scores (for each lung fields) were evaluated. For statistical analysis chi-square, Mann-Whitney test, R-Spearman, and ROC-curve analysis were used.

**Results:** Validation study phase (PI-US vs HRCT): We enrolled 32 pSS patients [M/F: 5/27; median age (IQR): 67 yrs (51.5–71); median disease duration (IQR): 7 (4–11) yrs; anti-Ro/SSA (+) 78.1%]. To be included patients should have performed a HRCT evaluation within 6 months. Thirteen patients (41%) presented HRCT lesions suggestive for ILD. HRCT total score and PI-US total scores were strongly correlated (r=0.744, p<0.000). Similarly, PI-US and HRCT partial scores related to the postero-inferior fields showed a strong correlation one to each other (r=0.780, p=0.000). ROC-curve analysis identified a total PI-US score of 28.5 (Youden index) as able to predict HRCT-diagnosis of ILD with a sensitivity (SE) of 84.6% and a specificity (SP) of 89.5%. Analogously, a postero-inferior PI-US score of 12.5 demonstrated a SE of 100% and a SP of 89.5% for the ILD diagnosis. Prospective study phase exploring the usefulness of PI-US for ILD early pre-clinical diagnosis: We included 24 consecutive pSS patients without overt respiratory symptoms [M/F: 12/12; median age (IQR): 65 yrs (47–67); median disease duration (IQR): 4 yrs (1–12); anti-Ro/SSA (+) 60.9%]. Out of them, at the end of the diagnostic work-up, four new cases of HRCT-proven pSS-ILD were diagnosed. Their PI-US mean total score was significantly higher than that observed in non-ILD patients (48±18 vs 16±12, p=0.001) as well as their mean postero-inferior PI-US score (19±9 vs 15±5, p=0.003). The total PI-US and postero-inferior PI-US cut-off retrieved in the first part of the study (i.e. 28.5 and 12.5) allowed us to identify those patients with an HRCT-proven pSS-ILD with a SE of 75% and 100%, a SP of 95% and 89.5%, a PPV of 75% and 57% and a NPV of 95% and 100%, respectively.

**Conclusions:** Even if preliminary, this study demonstrated a strong correlation between PI-US and HRCT in the detection of ILD-pSS also in asymptomatic patients, opening new perspectives for the early non-invasive screening of lung involvement in pSS.

SKIN CANCER IN A COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS

1. Internal Medicine Unit, Mellini Mellini Hospital, Chieri (Brescia); 2. Dermatology Unit and Chair, University and Spedali Civili of Brescia; 3. Rheumatology Unit, Spedali Civili of Brescia; 4. Rheumatology Unit and Chair, University and Spedali Civili of Brescia, Brescia, Italy

Background: Conflicting results about the prevalence of skin cancer in Systemic Lupus Erythematosus (SLE) have been reported in the literature [1,2].

Objectives: The aim of this study was to retrospectively evaluate the prevalence of malignancies, with a particular focus on skin cancers, in a cohort of SLE patients followed in a single Center.

Methods: All the SLE patients classified according to the ACR and SLICC criteria, attending the Rheumatology and Clinical Immunology Unit of Spedali Civili, Brescia, were retrospectively evaluated. Clinical and laboratory data were obtained from clinical charts. Diagnoses of skin cancers (melanoma and non-melanoma: basalioma, squamous cell carcinoma) and other malignancies were recorded together with the time elapsed from diagnosis of SLE. Univariate analysis was performed to compare characteristics of patients with (K+) and without (K-) cancer. We also compared the prevalence of cancer in our population to that reported in the Italian general population (from the Italian National Institute of Statistics, ISTAT, report 2014).

Results: In a cohort of 511 SLE patients (92% females, 95% caucasian) regularly followed from 1972 to 2016 (mean age at diagnosis 31 years, range 1–13 and median follow-up 12 years, range 1–40) we detected 51 cases (9.9%) with a history of malignancy: melanoma was reported in 3 (0.5%), non melanoma skin cancer (NMSC) in 11 (2%) and other malignancies in 38 cases (7.4%). Table 1 reports the comparison between patients with and without cancer. Patients with cancer, as well as cases with NMSC and non cutaneous malignancies, showed a higher age at disease onset (p < 0.0001; p = 0.002 and p < 0.0001 respectively) and higher SLE damage (p < 0.0001; p = 0.019 and p < 0.0001 respectively) compared with patients without malignancies. Patients with melanoma showed the same age at SLE onset, but a higher prevalence of discoid lupus (p < 0.0001) and oral ulcer history (p = 0.02). No difference in serological SLE features or in disease activity were detected between groups. The prevalence of melanoma in our cohort (0.5%) was only slightly higher than the one reported in the northern Italian general population (from the Italian National Institute of Statistics, ISTAT, report 2014). Its prevalence appeared to be higher than that reported in the same population (prevalence of spinocellular and basal cell cancer 0.1% and 0.5% respectively).

Conclusions: Non-melanoma was the most common skin cancer observed in our SLE cohort. Its prevalence appeared to be higher than that reported in the general population. SLE patients with melanoma showed a higher frequency of cutaneous lupus history compared with other SLE patients. Melanoma was reported in 3 (0.5%), non melanoma skin cancer (NMSC) in 11 (2%) and other malignancies in 38 cases (7.4%). The frequency of major organ involvement was as follows: biopsy-proven lupus nephritis (40.7%), nephropathic involvement (19.4%), secondary antiphospholipid antibody syndrome (6.1%) and lupus pneumonitis (1.7%). Class IV (41.1%) was the most common type of lupus nephritis followed by class V (15.5%).

EPIDEMIOLOGIC PROFILE OF ERECTILE DYSFUNCTION IN SLE: A MULTI-CENTER STUDY IN LATIN AMERICAN PATIENTS

1Rheumatology unit, Karolinska University hospital; 2Department of Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán; Mexico City; 3Rheumatology, Hospital Central “Dr. Ignacio Monroyes Prieto”; San Luis Potosí; 4Rheumatology, Hospital Universitario “Dr. Vivian Pellas”; Managua, Nicaragua; 5Rheumatology, Instituto Salvadoreño del Seguro Social, Guadalajara; 6Rheumatology, Hospital Universitario “Dra. Teresa Monero del Seguro Social, San Salvador, El Salvador; 7Rheumatology, Instituto Mexicano del Seguro Social, Guadalajara; 8Department of Reumatología, Hospital Universitario Doctor Arístides Martínez; 9Rheumatology, Instituto Mexicano del Seguro Social, Guadalajara; 10Internal Medicine, Hospital Universitario de la Santaniana; 11Internal Medicine, Hospital Militar Central, Bogotá, Colombia

Background: Although systemic lupus erythematosus (SLE) has a higher prevalence in women, the disease usually has a more aggressive course in men. Information regarding erectile function in men with SLE is quite scant.

Objectives: The aim of this study was to describe the prevalence of erectile dysfunction (ED), as well as associated demographic and clinical features, in men with SLE from a multi-center, standardized epidemiologic study.

Methods: We performed a transversal study in eight tertiary care centers in Latin America. We included male patients ≥16 years who fulfilled ≥4 ACR criteria for SLE, and who had regular sexual activity in the previous 6 months. Patients with other rheumatic diseases (except for APS), chronic viral infections and late-onset SLE were excluded. All patients answered the IIEF-5 Questionnaire, which has been validated in Spanish. Other relevant demographic, clinical and serological characteristics were documented. We included two control groups: the first one was made up by healthy men and the second by men with autoimmune diseases different from SLE (control group).

Results: We included 279 subjects (174 SLE, 55 non-SLE and 50 healthy controls). The prevalence of ED in SLE group 68% (vs 22% in healthy group, p<0.001). The mean age of patients with ED in the SLE group was 36.1±10.3, while in patients without ED it was 32.5±12.7 (p<0.022). Whereas there was no difference regarding ED prevalence between SLE patients and the non-autoimmune group (68 vs 60%, p=0.25), patients with other autoimmune diseases were 10 years older (46.3±10.6 years, p<0.001).

Among SLE patients with and without ED, the presence of persistent lymphopenia (>1000cells/mcl at three consecutive times, p=0.006), the prednisone dose (9.3±2.1 vs 5.3±1.2mg, p=0.026), as well as the SLICC damage score (1.2±0.1 vs 0.8±0.1 points, p=0.026), were significantly different. Comorbidities and other demographic, serological and treatment variables were not different between those groups. Multivariate analysis showed the following independent risk factors for ED in SLE patients: persistent lymphopenia (OR 2.79 CI95% [2.79–7.90], p<0.001) and corticosteroid use (any dose) in the previous year (OR 2.15 CI95% [1.37–3.37], p<0.001). Only 7% of patients had been questioned about their sexual function in the previous three visits to the rheumatologist; also, 81% of subjects considered it would be appropriate to be asked about their sexual function.

Conclusions: Regardless of comorbidities, treatment (excluding steroids) and type of disease activity, SLE patients have a high prevalence of ED, especially considering most patients are young and sexually active. Rheumatologists should be aware of the relevance of this problem in male SLE patients and should ask about this issue in regular visits.

FR0265 CYTOKINES AND CORRELATIONS WITH PATIENT REPORTED OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS AND POPULATION CONTROLS

S. Myasoedov1,2, H. Idborg3, S. Ekstedt4, I. Gunnarsson1, E. Svennungsson1,2.

1Rheumatology unit, Karolinska University hospital; 2Department of Neurobiology, Care Sciences and Society, Karolinska Institutet; 3Rheumatology unit, Department of Medicine, Karolinska Institutet; 4Cardiac Hospital, Stockholm; 5Cardiovascular and Metabolic Diseases, Innovative Medicines and Early Development Biotech Unit, AstraZeneca, Integrated Cardio Metabolic Centre (ICMC), Karolinska Institutet, Huddinge, Sweden

Background: In open questions patients with systemic lupus erythematosus (SLE) report fatigue as the most distressing symptom. Pro-inflammatory cytokines are generally suggested to contribute to fatigue in chronic diseases, however results are contradictory (1, 2). Patient reported outcome measures (PROMs) quantify patients’ experiences of qualities like fatigue and depression, which have great impact on both physical and psychological wellbeing. If PROMs are associated with pro-inflammatory cytokine activity in SLE has not yet been well investigated.

Objectives: In this study we explored the relationship between a large set of cytokines and self-assessments of fatigue, anxiety, depression and quality of life in a large group of patients with SLE and in matched controls.

Methods: In a cross-sectional setting, persons with SLE and age- and gender-matched population controls responded to PROMs, assessing fatigue (Multidimensional Assessment of fatigue Scale), depression/anxiety (Hospital Anxiety and Depression Scale) and health related quality of life (Medical Short Form 36 (SF-36)). 30 cytokines were analyzed (MSD 30-plex cytokine assay). Spearman’s rank correlation coefficient (rs) between cytokines and PROMs were calculated.

Results: 423 patients aged 46.6±15.3 and 315 controls aged 47.5±14.6 (p=0.43) were included. Of 30 analyzed cytokines 20 gave reliable results and were correlated to PROMs. Five of the cytokines (IL-6, TNF-αf, IL-15, MCP-1 and MIP-1-beta) correlated best (rs ≥0.37) with investigated PROMs (table 1). Fatigue correlated to TNF-αf (rs=0.26**), IL-6 (rs=0.27**) and MCP-1 (rs=0.35**), as well as MIP-1-beta (rs=0.29**), p<0.01 for all. When summarizing SF-36 results we noted a pattern of stronger correlations between investigated cytokines and the physical component than the mental component. Anxiety and depression correlated, but weakly (rs<0.25).

**Spearman correlation is significant at the 0.01 level (2-tailed). From SF-36.

Conclusions: Most PROMs were positively associated with pro-inflammatory cytokines (Fatigue and PROMs reflecting physical aspect of disease correlated most convincingly, while correlations with mental aspects were weaker.

References:
BACKGROUND: Jaccoud arthropathy (JA) is a non erosive reversible joint disorder commonly associated with systemic lupus erythematosus (SLE), and occurs in roughly 5% of all cases. Some studies suggest different profiles of clinical and immunological features between SLE patients with or without JA.

OBJECTIVES: To compare the clinical and serological manifestations of patients with SLE with and without JA in a tertiary care hospital of Madrid.

METHODS: We performed a retrospective observational study of a cohort of patients diagnosed with SLE (4 or more ACR criteria) from 45 Rheumatology Units across Spain who fulfilled the Pego-Reigosa criteria and received treatment in a large Spanish cohort of SLE patients.

RESULTS: Of the 2,765 patients with SLE included in the study, 13.1% (range: 7.5–21.2) had JA. JA was more frequent in women (88.7%) and the mean age at diagnosis was 34.2±12.2 years. JA occurred in 100% of the patients with SLE with secondary Sjögren’s syndrome (SS). The main triggers of JA were infections, followed by SLE activity flares. At the time of diagnosis, in the other 2 cases the diagnosis of both entities was simultaneous.

CONCLUSIONS: JA is a rare life-threatening SLE manifestation. It must be considered in patients with persistent fever who do not respond to antibiotics, cytopenias and evidence of multiorgan involvement. Relapses and death are common in SLE associated with SLE. The diagnosis requires in order to better identify these differences, so a multicenter initiative could be of great help.

HEMOPHAGOCYTIC SYNDROME IN PATIENTS FROM SLE REGISTRY FROM THE SPANISH SOCIETY OF RHEUMATOLOGY (RELESSLER)

A. Lois-Iglesias 1, R. Rua-Figueroa 2, F. de Turo-Santos 1, A. Zea-Mendoza 3, J. López-Longo 1, J. Calvo 4, M. Galindo 3, E. Uriarte-Isaceliaya 2, J. Pego-Reigosa 5,6 on behalf of EASSER-RELESSLER.

University Hospital A Coruña, A Coruña; Hospital Universitario Dr Negrín, Gran Canaria; University Hospital Ramón y Cajal; HGU Gregorio Marañón, Madrid; Hospital, Araba; University Hospital 12 de Octubre, Madrid; University Hospital Donostia, Donostia; Hospital Vigo; IISGS, Vigo, Spain

BACKGROUND: Systemic Lupus Erythematosus (SLE) is an autoimmune systemic rheumatic disease that, in our area, presents hematologic manifestations in approximately 70% of cases. Some of them are very rare so there are no large series whose analysis could provide relevant information.

OBJECTIVES: To study the characteristics of patients with Hemophagocytic Syndrome (HS) in a large sample of SLE patients.

METHODS: SLE patients from RELESSLER database were studied. We analysed SLE manifestations present at 12 different domains (mucocutaneous, renal, musculoskeletal, constitutional, hematologic, vascular, cardiac, respiratory, neuropsychiatric, gastrointestinal, ophthalmic and serological) before, during and after SLE diagnosis.

RESULTS: 3,656 SLE patients (≥4 ACR criteria) from 45 Rheumatology Units across Spain were studied. Seven patients (0.5%) with HS were identified. 71.4% were women, with a mean age (± S.D.) of 35.1 (± 7.1) years. In 5 of the cases the HS occurred 115.5 (± 162.9) months after SLE diagnosis. In the other 2 cases the diagnosis of both entities was simultaneous.

The main triggers of HS were infections, followed by SLE activity flares. At the time of HS diagnosis, they had high SLE activity with a high SLEDAI score of 13.1 (± 11.3) and 1.4 (± 2.3) SDI score.

CONCLUSIONS: HS is a rare life-threatening SLE manifestation. It must be suspected in SLE patients with persistent fever who do not respond to antibiotics, cytopenias and evidence of multiorgan involvement. Relapses and death are common in SLE associated with SLE. The diagnosis requires in order to better identify these differences, so a multicenter initiative could be of great help.

DOI: 10.1136/annrheumdis-2017-eular.2542
Objectives: To assess the accuracy of US and MRI and to define possible cutoff values for the diagnosis of pSS.

Methods: Thirty-three patients with pSS according to AECG criteria and typical histology of the SG biopsy and 12 patients with sicca syndrome and normal SG histology were included in the study. Two experienced ultrasound experts (C.D. 6y, T.D.) were blinded to the identity of the SG using a B-mode score (0–48 points [1]) and real-time sonoelastography (RTS: 0–16 pts [2]). Morphology of the parotid glands was also assessed by MRI (0–12 pts). We obtained clinical data (C-reactive protein (CRP), antinuclear antibodies (ANA), Ro/La-antibodies, Gamma globulins, patient questionnaires ESSDAI and SSDI). The statistically analysis was carried out using the immunohistochemistry, student’s t-test, or Mann-Whitney-U test. Correlations were performed using Spearman-rank-correlations.

Results: Patients with pSS had significantly higher B-mode- (average =25 [2–44] vs. 9 [1–20], p<0.001) and RTS-scores (6.5 [2–13] vs. 4 [1–9], p<0.001) than sicca-patients. The same was also found for MRI-assessment (6.96 vs. 2.33, p<0.001). In a Spearman rank correlation, clinical parameters were linked to the imaging techniques. The B-mode showed significant inverse correlations with the Saxon-test (r=0.505, p<0.002) and a positive correlation with MRI (r=0.792, p<0.001). No correlation was found for the activity scores ESSDAI (p=0.221) or SSDI (p=0.219). The MRI score had an inverse correlation with the Saxon-test (r=-0.523, p<0.001). Both imaging techniques showed no relationship with ESR or CRP. We also generated ROC curves of both imaging methods to define possible cutoff values for the diagnosis. For B-Mode we would recommend a value of 12 points (sensitivity 82.6% and specificity 91.7%) and for MRI 3.5 points (78.3% and 87%).

Conclusions: Sonography and MRI detected typical morphological changes in the SG of pSS with high sensitivity and specificity. Both methods could become valuable tools for the diagnosis of pSS.

Background: Demyelinating syndrome with atypical features for MS may exhibit an underlying connective tissue disease.

Objectives: To examine whether patients with demyelinating syndrome and atypical features for MS could be distinguished from non-specific lesions of microvascular etiology. In cases of demyelinating syndromes not fulfilling criteria for MS, features of an underlying CTD, suggestive of SLE, are frequently found. A small percentage of patients may go on to develop frank MS during follow up, thus longitudinal monitoring is necessary.

URINARY AND SERUM NEUTROPHIL GELATINASE-ASSOCIATED LIPOCALIN AS A BIOMARKER IN INDIAN CHILDREN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RELATION TO RENAL INVOLVEMENT AND OVERALL DISEASE ACTIVITY

B. Abujam 1, S. Singh 1

1. Pediatric Allergy Immunology unit, Post Graduate Institute Medical Education Research; 2. PGIMER, Chandigarh, India

Background: Renal involvement often results in long-term morbidity in childhood Systemic Lupus Erythematosus (cSLE). Neutrophil gelatinase associated lipocalin (NGAL) has been shown to be a reliable structural biomarker for the early diagnosis of kidney injury in many clinical scenarios.

Objectives: This study aimed to detect levels of urinary and serum NGAL and changes in flare and improvement on longitudinal follow up in cSLE in a real world clinical scenario.

Methods: Children <14 years of age attending the Pediatric Rheumatology clinic, fulfilling the 1997 SLE criteria were recruited. Urine and serum samples were collected during routine clinical review and urine analysis was assessed. Children were divided into 3 categories, active renal, active non-renal and inactive lupus. Active lupus was defined as SLEDAI >4. Urinary and serum levels of NGAL (uNGAL; sNGAL) were assessed by ELISA. Urinary values were normalized for urinary spot creatinine. In addition, some patients were longitudinally followed up and resampled when their disease activity changed.

Results: The study included 122 (F:M =91:31) children, 54 had active renal,14 had active non-renal and 54 had inactive disease. Median (IQR) age was 8.8 (6.5–10.7) years and disease duration was 10 (3–24) months. 26 children with nephrotic syndrome and 49 age and gender matched healthy controls were also recruited. Children with active renal lupus had significantly higher uNGAL as compared to other categories. Although sNGAL was significantly higher in active renal as compared to inactive lupus, there was no difference between renal and non-renal active lupus (Table 1). On longitudinal follow up, uNGAL levels increased markedly prior to a flare, significantly higher in renal compared to a non-renal flare (p<0.05). On the other hand, active lupus children had a significant fall in their uNGAL on follow up. Their was good correlation between change in SLEDAI and change in absolute uNGAL levels (r=0.84, p<0.01). Overall, on ROC analysis, uNGAL classified active renal versus active non-renal and inactive combined with an AUC of 0.986 (95% CI 0.972–1.0). The sensitivity and specificity of a uNGAL cutoff off value of 25750 ng/ml was 96.3 and 91.2% respectively.

Conclusions: Urinary NGAL is a sensitive marker of renal involvement in SLE disease activity and can also be a reliable tool for monitoring renal disease activity changes.

PREVALENCE AND ASSOCIATED FACTORS OF DEPRESSIVE DISORDERS IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)
C.C. Mok 1, L.Y.T. Lo 2, K.S. Poon 2, C.W. Cheng 2, Medicine, Tuen Mun Hospital 2, Psychiatry, Castle Peak Hospital, HK, Hong Kong

Background: Psychiatric symptoms are common in patients with SLE. Most studies utilized self-rated scales of psychiatric symptoms for evaluation. Formal diagnosis of depression was not established by psychiatric interviews. 

Objectives: To determine the prevalence of depressive disorders, severity of depressive symptoms, and the associated clinical and socioeconomic factors in Chinese patients with SLE.

Methods: Patients who fulfilled ≥4 ACR criteria for SLE were randomly recruited from rheumatology out-patient clinics and hospital admission in a 9-month period. Psychiatric disorders were diagnosed by a direct interview with the psychiatrist using the Chinese-bilingual Structural Clinical Interview for DSM-IV Axis I disorders, patient research version (CB-SCID-IP). The severity of depressive symptoms was assessed by the validated Chinese Hamilton Depression Rating Scale (HAM-D). Patients were also asked to complete the Beck Depression Inventory (BDI), Medical Outcomes Study Social Support Survey (MOS-SSS-C), and the WHO Quality of Life Measure-Abbreviated Version (WHOQOL-BREF, BREF (HK)). SLE disease activity (SLEDAI), organ damage (SLICC/SDI) and socio-demographic were collected and correlated with the presence of psychiatric disorders. Logistic regression models were used to study the independent factors associated with depressive disorders and the severity of depressive symptoms.

Results: 175 SLE patients were studied (95% women, age 39.2±12.4 years, SLE duration 10.3±6.7 years). 27 (15%) and 37 (21%) patients were diagnosed with a current depressive (52%major depressive disorder, 22% dysthymia) or anxiety (29%generalized anxiety, 14%social phobia, 8%post-traumatic disorder) disorder, respectively. Patients with depressive disorders, as compared to those without psychiatric disorders, had more active SLE (p=0.03) and were more likely to have a history of psychiatric diagnosis (p<0.001) and financial assistance from Government (p=0.04). Independent factors associated with a depressive disorder were SLEDAI score (1.13 [1.02–1.24]; p=0.02), perceived poor social support (p=0.03) and a past history of psychiatric disorders (p=0.003). Age, disease duration and other socio-economic variables such as educational level and marriage status were not correlated with the presence of a depressive disorder. Being separated/divorced (β=-0.18; p=0.02), having a higher SLEDAI score (β=0.16; p=0.02), SLE duration (β=-0.18; p=0.02) and a past history of psychiatric disorders (β=0.18; p=0.01) were independently associated with higher HAM-D scores, which reflect more severe depressive symptoms. Depressive disorders and severity of depressive symptoms were significantly associated with poorer quality of life. ROC analysis showed that a cut-off of 14 points of the self-rated BDI had a sensitivity of 89% and a specificity of 83% for differentiating a current depressive disorder from those without.

Conclusion: A diagnosis of depressive disorders is prevalent in Chinese patients with SLE. Independent risk factors are more active disease, perceived poor social support and a past history of psychiatric disorders. Patients with more active SLE, shorter disease duration, a past history of psychiatric disorders and being separated were associated with more serious depressive symptoms. The self-rated BDI provides a good screening tool for identifying depressive disorders in SLE patients.

ROLE OF PROCALCITONIN AND C-REACTIVE PROTEIN IN SCREENING OF INFECTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS
C.H. Ho, A.M.H. Leung, Department of Medicine, Queen Elizabeth Hospital, Tuen Mun, Hong Kong

Background: Previous studies revealed conflicting results regarding the role of procalcitonin in predicting infections in patients with systemic lupus erythematosus (SLE).

Objectives: This retrospective study aimed to analyse the role of procalcitonin (PCT) and C-reactive protein (CRP) in predicting infections in SLE patients, and to determine an optimal cut-off value for PCT and CRP for defining sepsis.

Methods: This study was carried out in one single tertiary centre. Adult patients (18-year-old) with underlying SLE who were admitted to hospital between 1st Jan 2007 and 31st Dec 2015 were included. Demographic data, PCT and CRP upon admission, and other clinical parameters were obtained. Infection was defined by positive culture, or based on clinical and radiological evidence with substantial response to antibiotics. The presence of SLE activity was defined by SLEDAI, and also by SLE-related manifestations not included in SLEDAI. Mann-Whitney test was used to test the difference between numerical parameters between patients with and without infection. Spearman’s correlation was used to analyse the correlation between PCT and CRP. Receiver operating characteristic (ROC) curves were plotted to define an optimal cut-off values for PCT and CRP in infection.

Results: 33 (27 female & 6 male) SLE patients were included. Both mean and median age were 42-year-old. Among the 21 septic patients, 9 had active lupus and 12 had inactive disease. All but one of the 12 non-septic patients had active lupus. All 4 patients with underlying renal failure belonged to the infection group. There were 13 and 3 patients on immunosuppressive treatments in infection and non-infection groups respectively. In patients with infection, mean PCT was 5.74ng/ml and mean CRP was 77.22mg/L. In those without, those were 0.29ng/ml and 20.04mg/L respectively. Both PCT (p<0.014) and CRP (p=0.016) levels were significantly higher in patients with infection than those without. There was no significant difference between the PCT and CRP levels in both septic patients (PCT p=0.862, CRP p=0.247) and non-septic patients (PCT p=1.000, CRP p=0.500) regardless of their SLE disease activity.

PCT level correlated positively with CRP level (r=0.456, p=0.008), but it had no correlation with age (p=0.978), gender (p=0.424), underlying renal failure (p=0.307), and organ damage at baseline (p=0.503) or other immunosuppressants (p=0.132) use. ROC curves of PCT and CRP showed a similar area under curve (AUC) of 0.756 and 0.752 respectively. The cut-off for PCT was 0.78mg/L (sensitivity 61.9%, specificity 91.7%), giving a positive predictive value (PPV) of 92.9%. The cut-off for CRP was 9.35mg/l (sensitivity 85.7%, specificity 66.7%), giving a PPV of 81.2%. Combining both PCT and CRP above their cut-offs, the specificity of predicting infection improved to 100% but the sensitivity worsened to 52%.

Conclusions: Both PCT and CRP were useful in predicting infection SLE patients regardless of their disease activity. The cut-off of PCT at 0.78mg/L and CRP at 9.35mg/l gave satisfactory positive predictive value for infection.

**FRI0274 MORPHOLOGICAL INDEXES IN LUPUS NEPHRITIS – DO THEY HAVE PROGNOSTIC VALUE?**

D. Navarro, A.C. Ferreira, H. Viana, F. Carvalho, F. Nolasco. Nephrology Department, Hospital Curry Cabral, Lisboa, Portugal

Background: Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE). With current therapies, a high remission rate is observed, thus determining the most important prognostic factor. Currently, therapy is guided by findings in the renal biopsy, following the ISN/RPS classification. Although recommended by EULAR, Austin and Hill’s morphological indexes are not routinely obtained.

Objectives: To analyze the importance and applicability of the different morphological indexes in predicting response to treatment and prognosis.

Methods: Retrospective single center study of consecutive SLE and biopsy proven LN patients, diagnosed from 2010 to 2016. We evaluated the following outcomes: clinical remission, renal function and proteinuria at end of follow-up (FUP) (g/24h). Complete remission was defined as a reduction of proteinuria to <0,5g/24h, inadmissible urinary sediment, creatinine <115% of baseline, partial remission same parameters, except proteinuria <1g/24h if initial value >3,5g/24h, or reduction to <3g/24h if initial value >3g/24h. The studied predictors were the INS/RPS LN classification and the morphological indexes described by Austin (Activity and Chronicity) and Hill, obtained after histomorphological review of renal biopsies. Statistical analysis was performed with STATA software.

Results: During 6 years, there were 46 biopsy-proven LN cases, 84,8% (n=39) woman, median 35 years old (27 – 42,5) and 57,6% (n=19) caucasian, 39 patients were already known to have SLE, 7,4% (1,5 – 12,3) years previous to the biopsy. The median FUP was 31,9 (13,2 – 45,6) months. Based on biopsy findings, 35 patients were started on immunosuppression – induction in 50% of cases with clinical activity. We observed that Class IV patients had, at presentation, lower eGFR (67,3 vs 99,8 ml/min (71,2 – 116,8) and proteinuria of 0,6 g/24h (0,2 – 3g/24h).

Conclusions: The correlations between clinical findings and morphological indexes (Hill and Austin) are summarised in table 1.

**FRI0276 PREVALENCE OF DEPRESSION BY BECK II AND IMPORTANCE OF FATIGUE BY FACIT IV QUESTIONNAIRES IN SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS VS CONTROLS IN A SINGLE CENTER OF ARGENTINA**

E. Avid, A. Braillard-Pocard, M. Garcia Carrasco, N. Perez, G. Nasswetter, D. Dubinsky, Rheumatology Division, Hospital de Clinicas Jose de San Martin, Capital Federal, Argentina

Background: Estimated prevalence of neuropsychiatric symptoms in SLE is among 17 to 71%2. Depressive symptoms are around 54%1,2. Fatigue is frequently referred, predicts high morbidity and may be influenced by lifestyle and individual psychological characteristics1.

Objectives: To evaluate the prevalence of depressive symptoms and its association with demographics and clinical variables in patients with SLE. To determine the predictive value of FACIT for fatigue in SLE vs controls.

Methods: Observational, retrospective case-control design. Patients ≥18 years old with SLE (ACR 97) were consecutively evaluated in our centre from January to July 2015. We analyzed age, disease duration, clinical manifestations, antibodies profile, SLEDAI (>4 scored as active) and SLICC. We recorded familiar psychiatric diseases, educational and socioeconomic level (Graffar Scale), employment and marital status. Beck II and FACIT (IV version) questionnaires were used for evaluate depression and fatigue respectively. We tested two cut points for fatigue: <22 and <40 to determine sensitivity/specificity for this tool in SLE patients vs controls.2. Continues data were compared using t Student and Mann Whitney. Categorical data: chi-square or Fisher’s exact test by SPSS version 20.0. To predict fatigue we calculated the area under the curve by Receiver Operating Characteristic (ROC). Statistical significant p<0.05.

Results: 77 SLE and 100 controls, all female. SLE vs control group: Mean of age: 34 (19–49) vs 38 (18–90). Prevalence of depression: 52% (44/77) vs 27% (27/100) (p<0.005). FACIT –40: prevalance of fatigue (FACIT–40 <22): 24% (19/77) and 36% (36/100) (p<0.05). Mean disease duration (months) 48 (24–114). Socio-demographic characteristics, SLICC/SLEDAI, clinical and serological manifestations were not correlated with major depression p>0.05. FACIT: Median values: FUP (range 22–40) SLE group: FACIT–22 total SLE: 12/77 (15%) and FACIT–40: 33/77 (42%). Cut points FACIT SLE vs controls: <22: 15% (12/77) vs 1% (1/100) (p>0.05). 30% sensitivity/100% specificity, 100% PPV and 57% NPV. AUC FACIT–22: 0.65 (0.65–0.77). FACIT–40 in SLE vs controls: 42% (33/77) vs 26% (26/100) (p<0.05). 99% sensitivity and 84% specificity, 82% PPV and 70% NPV. FACIT: AUC FACIT–40: 0.75 (0.64–0.87).

Conclusions: Prevalence of depression was high in our cohort and similar to...
ANTI-SSA ANTIBODY STATUS IN COMBINATION WITH ULTRASOUND OF MAJOR SALIVARY GLANDS: A SHORTCUT IN THE CLASSIFICATION OF PRIMARY SJÖGREN’S SYNDROME?

E. Mossel1, K. Deli2, J.F. Van Nimwegen1, A.J. Stel1, F.G.M. Kroese1, M.A. Saavedra1, D. Miranda-Hernández1, A. Sánchez 1, F. K.L. Spijkervet2, A. Vissink 2, S. Arends 1, H. Bootsma 1 on behalf of EULAR

Background: Ultrasound of major salivary glands (SUS) is an upcoming diagnostic method to assess the involvement of major salivary glands in primary Sjögren’s syndrome (pSS). In the AECG, ACR and recently published ACR-EULAR criteria, a positive salivary gland biopsy or presence of anti-SSA antibodies are necessary to classify the patient according to the AECG criteria and not included as a diagnostic item.

Objectives: To assess whether combining anti-SSA antibody status with SUS outcome can predict classification of patients as pSS in our inception cohort study.

Methods: Consecutive outpatients clinically suspected with pSS underwent SUS of the parotid and submandibular glands. Parenchymal echogenicity, homogeneity, hypoechogenic areas, hyperechogenic reflections and clearness of salivary gland border were scored according to the Hocevar scoring system (total score 0–48).1 Positive SUS was defined as total score ≥15. Patients underwent a diagnostic work-up according to the AECG, ACR and ACR-EULAR criteria. We determined the positive predictive value of the combination of anti-SSA antibody status and SUS outcome for classification as pSS or non-pSS. Separate analyses were done considering either i) parotid gland biopsy or ii) labial gland biopsy as an item, when applying these classification criteria.

Results: Anti-SSA antibody status was positive in 53 (51%) patients and SUS was positive in 40 (39%) patients. When parotid gland biopsy outcome was considered as an item of the criteria, 45 of 97 patients were classified as pSS according to the AECG, 44 of 93 according to the ACR and 52 of 99 according to the ACR-EULAR criteria. The combination of presence of anti-SSA antibodies with positive SUS showed a very high positive predictive value for classification as pSS (94–97%) and the combination of absence of anti-SSA antibodies with negative SUS highly excludes classification (negative predictive value 96–100%). When labial gland biopsy outcome was considered as an item of the criteria, 49 of 96 patients were classified as pSS according to the AECG, 43 of 93 according to the ACR and 55 of 97 according to the ACR-EULAR criteria. The combination of presence of anti-SSA antibodies with positive SUS showed a high positive predictive value for classification as pSS (94–97%). However, the combination of absence of anti-SSA antibodies with negative SUS did not per se exclude classification (negative predictive value 89–93%).

Conclusions: In our prospective inception cohort study derived from daily clinical practice, the combination of anti-SSA antibodies and positive SUS outcome highly predicts classification as pSS according to the AECG, ACR and ACR-EULAR classification criteria.

PREVALENCE AND FACTORS ASSOCIATED WITH AUTOIMMUNE RHEUMATIC DISEASES IN WOMEN WITH AUTOCOLPENCHONCLE COUNSELING IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

G. García-Garza1, M.A. Saavedra1, D. Miranda-Hernández1, A. Sánchez1, G. García- Collinot2, R. Bustamante-Gonzáles1, L. Jara3, F. Rheumatology, 2Research Division; 3Education and Research Direction, Hospital de Especialidades, Cnn la Raza, IMSS, Mexico, Mexico

Background: Adequate prenatal counseling in women with autoimmune rheumatic diseases (ARDs) may help minimize maternal-fetal complications. However, the available information about the frequency and quality of prenatal counseling given to these women is limited.

Objectives: To estimate the prevalence of preconceptional counseling and associated factors in women with ARDs.

Methods: A survey was conducted on socio-demographic data, gynecological-obstetric history, and domains related to preconception counseling in women with ARDs at the reproductive stage. It was defined as adequate preconception counseling if the patient knew that the pregnancy should be medically planned, that the complications are associated with severity/activity of the disease, that they should use an effective contraceptive method and that their medications may or may not be used during pregnancy. Descriptive statistics, Student’s T test for quantitative variables with normal distribution, Mann-Whitney U test for non-normal and chi-square distribution were used for categorical or ordinal variables.

Results: Of a total of 146 surveys, 131 were analyzed. Only 49 (37.4%) patients received adequate preconception counseling. Two thirds of the patients had systemic lupus erythematosus (Table). The time of evolution of the disease was a factor associated with receiving adequate counseling (5.6 vs 3.6 years, p=0.023), illness, marital status, and level of education were not factors associated with adequate counseling.

Disclosure of Interest: None declared

PREVALENCE OF PRIMARY SJÖGREN’S SYNDROME IN A POPULATION-BASED COHORT IN THE UNITED STATES

G. Maciel1, C. Crowson2, E. Matteson2, D. Conroe4,5,6, Maciel Hospital, Montevideo, Uruguay; 2Rheumatology; 3Division of Biomedical Statistics and Informatics, Department of Health Sciences Research, Mayo Clinic, Rochester Minnesota, United States; 4Rheumatology, CHRU Brest, Brest, France; 5Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester Minnesota, United States

Background: Different studies worldwide reported highly discrepant estimates for the prevalence of primary Sjögren’s syndrome (pSS), ranging from 0.01% of the general population to more than 3%. No previous study reported the prevalence of pSS in the United States.

Objectives: To report the 2015 point prevalence of pSS in the first population-based study performed in the U.S.

Methods: Cases of all potential pSS patients living in Olmsted County, Minnesota on January 1, 2015 were retrieved using the Rochester Epidemiology Project resources, and ascertained by manual medical record review. Definite pSS cases were defined according to physician diagnosis. All patients with doubtful cases and all patients with an associated systemic autoimmune disease were excluded. The remaining cases were classified as pSS or non-pSS.

Results: A total of 106 patients with pSS were included in the study: 86% were female, with a mean (SD) age of 64.6 (15.2) years and disease duration of 10.5 (8.4) years. A majority were anti-SSA positive (75%) and/or anti-SSB positive (58%), but only 22% met American-European Consensus Group or American College of Rheumatology criteria because the other tests required for disease classification were rarely performed in clinical practice (ocular dryness objective assessment, salivary gland functional or morphologic tests, or salivary gland biopsy). According to the physician diagnosis, age and sex adjusted prevalence of pSS was 10.3/10,000 inhabitants, but according to classification criteria this prevalence would be only 2.2/10,000. The analysis based on previous incidence data projected a similar 2015 prevalence rate of 11.0/10,000. Using figures from the 2015 general U.S. population census, a total of 248,000 patients with pSS (35,000 males and 213,000 females) would currently live in the country. If only cases fulfilling classification criteria are considered, there would be only about 53,000 prevalent cases of pSS in the U.S.

Conclusions: This study reports the first prevalence rate of physician-diagnosed pSS in a well-defined population in the U.S. The estimated prevalence of 10.3/10,000 inhabitants in 2015 is higher than previous results obtained in other geographical areas, probably due to different methodological designs of the studies. Because physicians rarely used tests included in the classification criteria to diagnose the disease in this community setting, current classification criteria do not reflect accurately the diagnosis of pSS in routine clinical practice.

DOI: 10.1136/annrheumdis-2017-eular.6198
adequate counseling. The adoption of a contraceptive method and the number of pregnancies were not different between the two groups. The history of use of embolotoxic/teratogenic drugs was associated with a higher frequency of adequate counseling (79.6% vs 41.5%, p<0.001). According to the patients, adequate counseling was given by the rheumatologist in 75.3% of the cases (p<0.001).

Conclusions: Preconception counseling in the reproductive stage is deficient. A multidisciplinary strategy is required to improve the frequency and quality of preconception counseling in patients with ARDs.

ASSOCIATION BETWEEN INSULIN RESISTANCE, SUBCLINICAL ATHEROSCLEROSIS AND ACTIVITY/DAMAGE STATUS IN SLE PATIENTS

H. Sánchez-Pérez 1, B. Tejera Segura 1, M.A. Gonzalez-Gay 2, I. Ferraz-Amaro 1.

1Rheumatology, Hospital Universitario de Canarias, la Laguna; 2Rheumatology, Hospital Marques de Valdecilla, Santander, Spain

Background: Insulin resistance (IR) may contribute to an increase in cardiovascular risk in general population as well as in Systemic Lupus Erythematosus (SLE) patients.

Objective: The aim of this study was to examine the association between IR and disease activity, disease characteristics, drug exposure and subclinical atherosclerosis in patients with SLE.

Methods: Cross-sectional study that encompassed 87 SLE patients and 82 sex-matched controls. IR by homeostatic model assessment (HOMA2), insulin, C-peptide serum levels and lipid profile were assessed in both groups. Activity (SLEDAI), severity (Katz) and damage (SLICC) scores, carotid intima-media thickness (cIMT) and carotid plaques (ultrasound) were assessed in SLE patients. A multivariable regression analysis, adjusted for IR related factors, was performed to evaluate the differences between groups in IR indexes and, in SLE patients, the interaction between IR and disease activity/characteristics as well as subclinical atherosclerosis.

Results: Median disease duration was 16 years (IQR 9–21). Body mass index, abdominal circumference, hypertension or dyslipidemia did not differ between groups. According to the SLEDAI score, 40% of patients were in non-active, while 32%, 21%, 18% and 1% were in mild, moderate, high and very high activity respectively. HOMA-IR-C-peptide (beta coefficient 0.53, [95% CI 0.25–0.82], p=0.00) was increased in SLE patients when compared to controls, as well as HOMA %B C peptide levels (beta coeff. 35, [95% CI 16–52], p=0.00). Similarly, insulin sensitivity estimated through HOMA-IR-C-peptide was inferior in SLE patients (-beta coeff. -37, [95% CI -63–11], p=0.01). This differences remained significant even after adjustment for IR related factors. SLICC damage index was clearly associated with IR indexes; higher index values were related to higher HOMA-IR-C-peptide (beta coeff. 37, [95% CI 16–57], p=0.00) and lower HOMA-5% levels (beta coeff. 30%, [95% CI -47–14], p=0.00). Katz severity index showed correlation with HOMA-IR-C-peptide (beta coeff. 5, [95% CI -11–0], p=0.04). These associations remained significant after adjustment for age, gender, smoking, hypertension and dyslipidemia, and, in relation with the SLICC index, also after adjustment for prednisone intake. SLEDAI activity index was not related to IR indexes. The use of prednisone was positively associated with HOMA-IR both when considered binary (beta coeff. 47, [95% CI 31–63], p=0.00) and continuous (beta coeff 2 [95% CI 0–5] per mg, p=0.03). Hydroxychloroquine (or other drugs) use was not associated with IR indexes, neither were disease duration, antiDNA titers and complement serum levels. Carotid plaques were found in 20% of the SLE patients. The presence of carotid plaques was correlated with a higher HOMA-IR-C-peptide (OR 3.15 [95% IC 1.17–8.51], p=0.02), and a higher cIMT value was associated with a lower HOMA-IR-S%-%-C-peptide (beta coeff. 0.98 [95% CI 0.96–0.99], p=0.03). Nevertheless, after adjustment for cardiovascular risk factors this relation was lost.

Conclusions: Activity and damage indexes in SLE patients are independently related to the development of IR. IR is associated with subclinical carotid atherosclerosis in SLE patients on the univariate analysis.

CARdiovascular damage in decreasing patients with SYSTEMIC LUPUS ERYTHEMATOSUS

I. Padenj 1, 2, M. Erceg 3, M. Cerovec1, 2, M. Maye1, 2, R. Stevanovic 3, B. Anic 1, 2.

1Department of Internal Medicine, Division of Clinical Immunology and Rheumatology, University Hospital Centre Zagreb; 2University of Zagreb, School of Medicine; 3Croatian Institute of Public Health, Zagreb, Croatia

Background: Cardiovascular comorbidities are a major contributor of damage in patients with SLE. They are driven by classical, as well as SLE-related risk factors, i.e. disease activity and immunosuppressive treatment.

Objectives: We aimed to analyze cardiovascular damage (CVD) in a group of 90 deceased SLE patients regularly followed-up in a routine academic setting at our Department, and to identify features associated with accrual of CVD.

Methods: We retrospectively observed 90 SLE patients (68 females) deceased within the 2002–2011 period. All patients were ≥18 years of age and Croatian residents at the time of death, fulfilling ≥4 classification criteria of the American College of Rheumatology (ACR). We identified patients with CVD, including the following components of the Systemic Lupus International Collaborating Clinics (SLICC)/ACR damage index: cardiovascular damage as defined by the index (cardiac damage), peripheral vascular damage, cerebrovascular accident, pulmonary infarction, bowel infarction and avascular necrosis. An extensive set of variables was compared between patients with and without CVD: demographics, ACR criteria at diagnosis and death, damage (according to the SLICC/ACR index) and its components one year following diagnosis and at the time of death, disease activity at diagnosis (according to the European Consensus Lupus Activity Measurement indexes, ECLAM), as well as features of the metabolic syndrome, smoking and immunosuppressive treatment. Frequencies were compared using χ2, and Fisher’s exact test, and continuous variables using the t-test and Mann-Whitney U test. Variables associated with CVD in the univariate analysis were included in a multivariate logistic regression model.

Results: We identified 63/90 patients with CVD, including 46/63 (73%) with cardiac damage, 19/63 (30%) with peripheral vascular damage, 21/63 (33%)
with cerebrovascular accident, 4/63 (6%) with bowel infarction, 14/63 (22%) with avascular necrosis and a single patient with pulmonary infarction (Figure 1). Patients with CVD had a higher disease duration at time of death compared to patients without CVD (12±8 vs. 7±6 years), as well as higher cumulative proportions of hematologic disorder (60/63 vs. 15/27), lymphopenia (48/63 vs. 10/27), peripheral vascular disease (19/63 vs. 1/27), fractures (25/63 vs. 2/27), higher overall damage (6.0±3.0 vs. 2.4±2.0) and a higher proportion of secondary antiphospholipid syndrome (14/63 vs. 1/27) (p<0.05). Conversely, patients with CVD had a lower proportion of discoid lupus at diagnosis (7/49 vs. 9/24) and a lower proportion of skin damage one year following diagnosis (2/63 vs. 5/27) (p<0.05). Parameters associated with cardiovascular damage in the multivariate model were cumulative fulfillment of lymphopenia as a classification criterion (odds ratio, OR 4.7 (95% confidence interval, CI 1.3–17.0)) and accrual of pulmonary damage (OR 13.1 (95% CI 2.2–76.3)).

Figure 1. Distribution of cardiovascular damage in the analyzed group (numbers represent frequencies of each subtype of cardiovascular damage)

Conclusions: More than two thirds of deceased patients accrued CVD over the disease course. Lymphopenia and pulmonary damage may be associated with CVD in deceased SLE patients.

FR0283 | AN IMMUNOLOGICAL PROFILE COMBINING INNATE AND ADAPTATIVE IMMUNITY BIOMARKERS IDENTIFY RISK FOR EVOLUTION INTO SLE IN WOMEN WITH RECURRENT PREGNANCY LOSS

J. Carbone, E. Sarmiento, J.P. Navarro, E. Fernandez-Cruz. Clinical Immunology, Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: Autoantibodies, low complement levels and higher NK cell counts are present in a subset of women with recurrent pregnancy loss (RPL). The combination of these abnormalities might be a surrogate profile for the presence of a subclinical inflammatory or autoimmune condition.

Objectives: In a cohort of women with unexplained RPL we evaluated if an immunological profile combining innate and adaptive immunity mediators was associated with the presence of distinct clinical characteristics that are commonly observed in autoimmune diseases and if it was a risk factor for developing these diseases. In a small subset of women with the immunological profile we evaluated the activation status of CD4+ and CD8+ cells.

Methods: We evaluated 366 women with RPL defined as 2 or more pregnancy losses and 93 control women. We defined the immune profile as the presence of 2 or more of the following abnormalities: Peripheral blood NK cell percentages >15%, positive antiphospholipid antibodies, positive anuclear antibodies, positive anti-thyroid antibodies, low complement C3 levels and low C4 complement levels. Evolution to autoimmune diseases was detected during follow-up. Lymphocyte subsets were evaluated by flow-cytometry. Statistics: Chi-square test. Logistic regression.

Results: The prevalence of women with 2 or more immunological abnormalities was 57 out of 366 women (15.6%) and was significantly higher than in control women. Demographic clinical characteristics were similar in women with 2 or more immunological abnormalities as compared with women with only one immunological alteration or no abnormalities. The presence of the immunological profile was significantly associated with the presence of the following clinical characteristics: Leucopenia (p=0.048), lymphopenia (p=0.007), livedo reticularis (p=0.01), cutaneous rash (p=0.009), and arthritus (p=0.001). During follow-up 17 patients (4.6%) developed an inflammatory or autoimmune disease that was not present at the time of diagnosis of RPL including SLE and lupus like disease. Women with the immunological profile were at higher risk for evolution into these diseases: OR 4.19, 95% confidence interval 1.52–11.51, p=0.0055. In 10 women with the immunological profile we observed significantly higher levels of CD4+DR+ and CD8+DR+ T-cells as compared with women without the immune profile.

Conclusions: A subpopulation of women with unexplained RPL are at risk of developing clinical characteristics of an inflammatory or autoimmune disease. In this regard, the immunological evaluation of women with RPL might be necessary not only to identify a potential cause of abortion but also to identify women that could require a more careful clinical follow-up. Higher CD4+DR+ and CD8+DR+ T-cells might be a pathogenic pathway leading to development of autoimmune diseases in RPL women.

FR0284 | PREDICTORS OF ARTERIAL VASCULAR EVENTS IN A COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS

Background: Arterial vascular events (AVE) are among the major causes of morbidity and mortality in patients with Systemic Lupus Erythematosus (SLE). Several studies have been carried out to identify the main factors related to AVE in this population. The ankle brachial index (ABI) is one of the tools currently used to identify patients at greater risk of arterial events in the general population; however it has been scarcely studied in patients with SLE.

Objectives: The objectives of this prospective cohort study were to determine the predictive value of the ABI for occurrence of AVE in patients with SLE and to identify other possible factors associated with an increased risk of AVE.

Methods: 216 patients with SLE were evaluated using an ABI and followed up for 5 years. Pathological ABI is considered an ABI <0.9. Different potential vascular risk factors (traditional, non-traditional and related to SLE and/or the treatments used) were jointly evaluated. AVE: coronary events (angina pectoris, acute myocardial infarction, coronary revascularization by angioplasty or surgery), cerebrovascular events (transient ischemic attack, cerebrovascular accident), peripheral arterial disease (symptomatic intermittent claudication, distal ischemia, revascularization by angioplasty or surgery), and death related to vascular disease. Survival analysis was performed using a competitive risk regression approach, considering non-vascular death as a competitive event, to identify the predictive value of ABI and other factors studied. The Ethical Committee for Clinical Research at Cruces University Hospital approved the study protocol in accordance with the Declaration of Helsinki (CEIC 3216). All patients signed an informed consent at the time of entry into the study.

Results: During follow-up, 4/216 (1.8%) patients were lost to follow-up. 18 AVE were identified in 17 patients, with one patient having 2 episodes of angina requiring angioplasty (4 coronary events, 11 cerebrovascular events, 2 peripheral arterial disease events and 1 sudden death) and 14 deaths (6 per AVE or their sequelae, 4 due to neoplasias and 4 due to cardio-respiratory pathology).

In the competitive risk regression analysis, independent predictors of higher risk of AVE were identified: pathological ABI (subhazard ratio (SHR) 3.51, 95% confidence interval 0.96–12.79, p=0.057), family history of AVE (SHR 6.3, 95% CI 1.97–20.21, p=0.002), cumulative total prednisone (grams) (SHR 1.02, 95% CI 1.01–1.04, p=0.004) and a history of arterial thrombosis (SHR 4.60, 95% CI 1.97–20.21, p=0.002).

Conclusions: Being male, having a higher cumulative dose of prednisone, having a family history of early vascular disease and having suffered previous arterial thrombosis are independent risk predictors of an AVE in patients with SLE. Having abnormal ABI, even without statistical significance, showed a marked tendency to increase this risk despite the low number of events recorded in the studied cohort.

FR0285 | LUPUS NEPHRITIS IS ASSOCIATED WITH INCREASED RATES OF HOSPITALIZATION AND IN-HOSPITAL MORTALITY COMPARED WITH NON-RENAL LUPUS AND MATCHED CONTROLS: AN ANALYSIS OF INSURANCE CLAIMS DATA

K.A. Belendiuk, H. Trinh, M.D. Cascino, L. Dragone, D. Keebler, J. Garg. Genentech, Inc., South San Francisco, CA, United States

Background: Systemic lupus erythematosus (SLE) is heterogeneous in its clinical presentation, course, and prognosis and lupus nephritis (LN) continues

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.6004
to be a major cause of morbidity and mortality among children and adults with SLE. Up to 60% of adult and 80% of pediatric SLE patients (pts) will eventually develop overt renal disease [1]. To date the excess burden of comorbidities, risk of inpatient hospitalization, and in-hospital death associated with SLE and LN remains incompletely understood.

Objectives: To identify differences in comorbidities, hospitalizations, and in-hospital mortality of SLE and LN cohorts compared to: 1) each other; 2) reference populations of pts without an autoimmune condition (non-AI) matched on gender and age. Reference populations were allowed to have claims for non-autoimmune conditions.

Methods: We conducted a retrospective cohort study using the Truven Healthcare MarketScan® Commercial Claims and Encounters and Medicare Supplemental and Coordination of Benefits database, which together comprise 65 million insured US lives between 1999 and 2014. Cohort identification is based on validated algorithms [2, 3] for identification of pts with SLE or LN without renal involvement using claims data. Pts were matched on age and gender at index date. All eligible participants had 365 days of enrollment prior to and after the index date. End of study for post-index follow-up was captured as whichever of the following occurred first: 1) end of enrollment; 2) end of database; 3) date of death. Results are presented separately for pediatric and adult pts.

Results: 54,813 SLE pts without renal involvement and 8,839 LN pts were identified and matched to reference non AI populations. Compared to the non-renal SLE cohort, pts in the LN cohort were older (49.9±16.6 vs. 48.6±14.3 years) with a higher proportion of males (15.4% vs. 11.2%), Pts with LN had the highest scores on the Charlson Comorbidity Index modified to exclude renal involvement (Table 1). Additionally, adults with LN had higher rates of hospitalizations and longer hospitalizations compared with adults with non-renal SLE, who already had higher rates of hospitalizations and longer hospitalizations than matched controls (Table 2). This pattern of findings was consistent for children. Rates of in-hospital mortality were highest among those with LN but also increased among those with SLE compared with matched controls (Figure 1).

Conclusions: An SLE diagnosis was associated with a higher burden of comorbidities and higher rates of hospitalizations and in-hospital mortality than non-AI matched controls. Pts with LN had the highest burden of comorbidities and rates of hospitalizations and in-hospital mortality. SLE and LN disproportionately high burden of morbidity and mortality and the medical need for safe and effective treatments of LN and SLE remains unmet. Clinicians should consider these factors in their assessment and treatment of pts with SLE and LN. The retrospective, claims-based results do not permit pt-level assessment of the relative contributions of disease, treatment, and potential confounders to these findings.

FRIO287 SEROLOGICAL EVOLUTION IN PATIENTS WITH THROMBOTIC ANTIPHOSPHOLIPID SYNDROME

L. Riancho-Zarrabeitia 1, S. García-Canale 1, M. Cubería 1, G. Daroca 1, M. Agudo 1, M. López-Hoyos 2, P. Muñoz 1, V. Martínez-Taboada 1, 1Hospital Universitario Marqués de Valdecilla, Santander, Spain; 2Immunology, Rheumatology, Hospital Universitario Marqués de Valdecilla, Santander, Spain

Background: Antiphospholipid syndrome (APS) is an autoimmune disease characterized by the presence of antiphospholipid antibodies (aPL) and at least one clinical event (thrombosis and/or pregnancy morbidities). The titers of aPL can fluctuate and eventually become negative. This negativization, particularly if persistent, may be associated with a lower frequency of clinical events.

Objectives: To describe the clinical and serological course of patients with thrombotic APS as well as the factors related with the aPL negativization.

Methods: We performed a retrospective study including patients attended at the Rheumatology clinic from a tertiary hospital in Northern Spain. We included 94 patients with thrombotic APS according to Sidney criteria of 2006. They were classified according to the serological evolution as persistently negative aPL, transiently positive, and persistently positive aPL according to previously established criteria.

Results: After a mean follow-up of 145±56 months, 48.9% of patients presented a persistently negative serology, whereas in 12.8% it was transiently positive, and persistently positive in 38.3%. When analyzing potential factors related to the negativization (table 1), we found that patients with positive lupus anticoagulant tended to have a persistently negative serology during follow-up, but it did not reach statistical significance (OR 2.7; 95% CI 0.8–9.4; p=0.145). We found no association between traditional cardiovascular risk factors or previous treatments and the serological evolution.

Conclusions: After a mean follow-up of 12 years, 49% of thrombotic APS patients presented a persistently negative serology. We found no significant association between immunological, traditional cardiovascular risk factors or previous treatments and the persistently negative serology.

American SLE population have shown a higher prevalence of LN, higher severity, and less favorable outcomes (1).

**Objectives:** To determine the incidence of lupus nephritis and end-stage renal failure, as well as evaluate progression of renal function and proteinuria during an 18-month follow up in colombian patients with SLE.

**Methods:** A retrospective cohort study was conducted in 1448 patients with SLE, 41 of which were diagnosed with LN between August/2014 and July/2015. Follow up was made for 18 months, analyzing glomerular filtration rate (GFR) and proteinuria, induction and maintenance therapy, renal relapses, hospitalizations and mortality. Univariate analysis was done to describe sociodemographic and clinical variables. Longitudinal data analysis was performed using linear mixed models with random intercepts. In all cases, a p value <0.05 was considered statistically significant.

**Results:** Clinical characteristics of patients with LN are shown in table 1. Eighty-five percent of LNs where biopsy-proven. Incidence of LN was 2.83 cases/100 SLE patients/year. The incidence of end-stage renal failure was 7.31 cases/100 SLE patients/year. A high proportion of patients with refractory response to multiple immunomodulatory treatments for LN were identified.

**FR01291** | **CEREBROVASCULAR DISEASE IN THE ANTIPHOSPHOLIPID SYNDROME**

M. Estévez, A. Argibay, L. Rodriguez, M. Freire, B. Gimena, J. Fernandez-Martín, A. Rivera. Systemic Autoimmune diseases and Thrombosis Unit, University Hospital Complex of Vigo, Vigo, Spain

**Background:** Antiphospholipid syndrome (APS) is a thrombophilic disorder characterized by recurrent arterial and venous thrombosis, and also pregnancy losses associated to antiphospholipid antibodies (APA). Cerebrovascular disease (CVD) is the most common and severe arterial thrombotic manifestation in patients with APS.

**Objectives:** 1. To determine the prevalence and the type of CVD in patients with APS. 2. To compare the recurrent strokes, affected brain areas, hospitalization, treatment and mortality between patients with CVD, with and without APS.
Methods: Retrospective and descriptive study of patients with APS (Sidney criteria) and CVD followed for a long period of time in a specific Systemic Autoimmune Diseases and Thrombosis Unit. Subsequently, retrospective case-control study was performed. Case definition: patients with CD4 and CD8 counts in patients with APS. Control definition: patients with APS without CD4 and CD8 counts. The controls were matched by sex and age (within the same decade). Chi-square and t-student were used, according to the statistical package SPSS22.0.

Results: 25 patients (25/88 28.4%) had CVD. 19 (76%) of primary APS, 6 (21%) of secondary APS. 17 patients (71.6%) were female. The mean age was 57.48±21.52 (range 13–89), with a mean follow-up of 8.64±6.72 years. 24% of patients had atrial fibrillation, 80% had one cardiovascular risk factor and 48% had two or more factors (hypertension 68%, hypercholesterolemia 36%, diabetes 20%, tabaquism 4%). Echocardiographic study was performed in 72% of patients with APS. Mitral valve was mainly involved. Most CVD were ischemic events (92%). The brain areas most involved were the basal ganglia (36%), together with the parietal and temporal lobe (16% respectively). 40% had two or more affected regions. 44% of the patients had two or more episodes of stroke. Lupus anticoagulant was positive in 40%, and anti-cardiolipin antibodies in 70%. 20% had anti-glycoprotein antibodies in 20%. No differences were found with isotypes of APA and recurrent thrombosis or mortality. The treatment applied was oral anticoagulants (OAC) (48%), antiplatelet therapy (APT) (20%) and low molecular weight heparin (20%). In 10 patients (40%) CVD was diagnosed before APS (mean 8.64±6.7 years). The mortality was 44% and 40% of the patients were hospitalized more than once. When we compared the groups: treatment, performed echocardiogram, valvular disease, affected brain areas, recurrent strokes and follow-up time, revealed significant differences (see table 1). OAC were more used in the patients with APS and APT was the most common in control group. Valvular disease was more frequent in case group. The brainstem and the frontal lobe were the areas more affected in patients without APS. The number of strokes was higher in APS group. The patients with CVD and APS had a long-term follow-up.

Conclusions: The prevalence of CVD in our series of APS was 28.4% and most often were ischemic events. Most of the patients were women with high recurrent strokes and mortality. No differences were found with isotypes of APA and recurrent thrombosis or prognosis. CVD with APS patients had more recurrent strokes and longer follow-up.

**FRIO290**

**INTERLEUKIN 10 GENE POLYMORPHISMS IN PRIMARY SJÖGREN SYNDROME IN A TUNISIAN POPULATION**

**Background:** Primary Sjögren syndrome (PSS) is one of the most common autoimmune rheumatic diseases although its prevalence ranging between 0.6 and 1.7%. PSS affects exocrine glands and lead to sicca syndrome. Interleukin-10 (IL-10) is a pleiotropic cytokine that is involved in the inflammation process of PSS.

**Objectives:** The aim of our study was to determine in a Tunisian population, clinical and biological characteristics of patients with primary PSS, allelic and genotypic frequencies of -1082G/A, -819C/T and -592 C/A polymorphisms in IL-10 gene and to evaluate the association of these polymorphism with PSS.

**Methods:** The population studied consisted of 242 subjects with female predominance (average age at diagnosis 49 years), divided into 84 PSS patients fulfilling the revised AECG criteria 2002 and ACR proposed criteria 2012, recruited from the internal medicine of the Rabta hospital. 158 controls recruited in the Greater Tunis. IL-10 level was assessed by ELISA. Polymorphisms genotyping of the IL-10 gene was done using PCR-RFLP technique.

**Results:** IL-10 plasma level was lower in PSS patients (23.71±9.2 ml, n=73) compared to healthy volunteers (42.2±9.2 ml, n=60) and the difference was statistically significant (p<0.01). The genotype frequencies of our population respected Hardy-Weinberg equilibrium distribution both in patients by primary SS than in controls. In PSS patients, the genotype frequencies of -592C/A are 53% for the CC genotype, 41% for the CA and 6% for the AA genotype. In controls these frequencies are respectively 60.3%, 32.9% and 6.8%. The genotype frequencies of -1082 G/A are 29.6% for the AA genotype, 63% for the AG and 7.4% for the GG genotype. In controls these frequencies are respectively 41.5%, 52.1% and 6.3%.

No significant differences in genotypic frequencies were observed between cases and controls in the three polymorphisms.

Statistical analysis preformed revealed that there was neither protective nor aggravating haplotype. However ACP haplotype seems to have a protective impact in controls (p=0.06 and OR=0.2)

**Conclusions:** IL10 level was significantly higher in PSS patients in precedent studies (1) (2). In our case IL10 level was associated with PSS in Tunisian patients but it was statistically lower than controls. Our results show that the three polymorphisms of gene of IL-10 are not a marker of SGS in the Tunisian population. This result might be explained by allelic variation or ethnic group.

ANTI-PHOSPHATIDYLSERINE/PROTHROMBIN (APS/PT) ANTIBODIES IN PRIMARY ANTIPHOSPHOLIPID SYNDROME

1. Immunology and Rheumatology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; 2. Department of Medicine, The Ottawa Hospital, University of Ottawa, Ottawa, Canada.

Background: Several studies have shown conflicting results regarding the presence and meaning of anti-phosphatidylserine/prothrombin (aPS/PT) antibodies. However, aPS/PT antibodies seem to be a risk factor for thrombosis. Nevertheless, most of the studies have focused on patients with SLE and secondary antiphospholipid syndrome (APS).

Objectives: To assess the prevalence of aPS/PT antibodies, as well as their association with other antiphospholipid (aPL) antibodies (specially lupus anticoagulant [LA]) and thrombosis, in a well-established cohort of primary APS from a single center.

Methods: We included 96 consecutive patients with primary APS according the Sydney classification criteria and/or patients with hematological features (thrombopenia and hemolytic anemia) attending a referral center in Mexico City. Patients from both groups fulfilled the Sydney laboratory criteria for APS. We registered demographics, disease duration and type of manifestation. aCL (IgG and IgM), antibodies to purified human anti-2GP1-IgG and aPS/PT (IgG and IgM) and aPS/PT antibodies (IgG and IgM) were assessed by ELISA (INOVA Diagnostics). LA was determined by LA/1 screening reactant and a confirmatory test LA/2 according to published guidelines. We used chi-square (χ²) test, Spearman correlation analysis and logistic regression.

Results: Most patients were females (69.7%), mean age 44.5±14.6 and median disease duration 7.3 years. The main clinical features were thrombosis (n=74.77%), hematology involvement (n=49 patients, 51%) and obstetric events (n=24, 25%) (non-exclusive groups). The prevalence of LA was 69.8%, aCL-IgG 56.8%, anti-2GP1-IgG 43.1%, aCL-IgM 31.5% and anti-2GP1-IgM 21.1%. The frequency of aPS/PT antibodies was 61.2% and 61.6% for IgG and IgM isotype, respectively. When we compared patients with LA+ (n=58) vs. LA− (n=25), the first group had a higher prevalence of aPS/PT-IgG (79.3% vs. 16%, p<0.0001) and aPS/PT-IgM antibody (81.5% vs. 8.1%, p=0.0001), as well as higher titers (aPS/PT-IgG 103.5 U vs. 2.2 U and aPS/PT-IgM 21.5 U vs. 1.1 U, p=0.0001). aPS/PT-IgG antibodies correlated with aCL-IgG (ρ=0.59, p=0.0001) and anti-2GP1-IgG (ρ=0.63, p=0.0001) and anti-2GP1-IgM (p=0.35, p=0.001). On the other hand, aPS/PT IgM antibodies correlated with aCL-IgM (ρ=0.57, p=0.0001), anti-2GP1-IgM (ρ=0.42, p=0.001) and anti-2GP1-IgG (ρ=0.48, p=0.001) and anti-2GP1-IgG (ρ=0.59, p=0.0001). We found moderate agreement between the presence of LA and both aPS/PT isotypes (κ=0.58, p<0.001 for IgG, and κ=0.47, p=0.001 for IgM). Thrombosis was associated with aPS/PT-IgG antibodies (87.7% vs. 61.1%, p<0.0001) but not with aPS/PT-IgM (73.6% vs. 81.8%, p=0.37). At the logistic regression analysis, the aPS/PT IgG antibodies remained associated with thrombosis after adjusting by all other aPL antibodies, OR 8.6 95% CI 2.1–33.8, p=0.002.

Conclusions: In this cohort of patients with primary APS, aPS/PT antibodies were highly prevalent, correlated with other aPL antibodies and were associated independently with thrombosis.

CHARACTERIZATION AND RISK ESTIMATE OF CANCER IN PRIMARY SJÖGREN SYNDROME: ANALYSIS IN 1300 PATIENTS

Objectives: To characterize the risk of solid and hematological cancer in a large, well-characterized cohort of patients with primary Sjögren syndrome (SjS).

Methods: The GEAS-SEMI registry is a network of Spanish reference centers with specific clinical experience in the management of SjS patients. By January 2016, we had analyzed the development of cancer in 1300 consecutive patients fulfilling the 2002 SjS classification criteria. Multivariate Cox proportional-hazards regression analysis allowed adjustment for age at diagnosis, gender and the statistically-significant baseline variables associated with cancer for the univariate analysis. The sex- and age-specific incidence rates (SIR) of cancer were estimated from 2012 Spanish mortality data modeling, using a set of age-, sex- and site-specific incidence/mortality ratios.

Results: After a mean follow-up of 91 months (9922.3 person-years), 127 (9.8%) patients developed 133 cancers. The most frequent type of cancer was B-cell lymphoma (34% of cancers, including 27 MALT and 19 non-MALT B-cell lymphomas). Systemic activity at diagnosis of primary SjS correlated with the risk of hematological neoplasia (HR 1.06, p<0.001). Positive cryoglobulins at SjS diagnosis were independently with thrombosis.

DOI: 10.1136/annrheumdis-2017-eular.5391

ULTRASOUND OF THE SALIVARY GLANDS HELPS TO DISTINGUISH BETWEEN PRIMARY AND SECONDARY SJÖGEN SYNDROME

Background: Previous studies have demonstrated typical findings in the ultrasound of salivary glands (USG) in patients with primary Sjögren syndrome (pSjS) compared with healthy controls. However, it is unknown, if these findings are only seen in patients with pSjS but also in patients with secondary Sjögren syndrome (sSjS) or other connective tissue diseases with positive Ro-SSa/La-SSb antibodies.

Methods: We used an ultrasound score developed by Zhang [1] to investigate salivary glands with a score ranging from 0–48. We compared the score from patients with pSjS according the criteria of the American-European Consensus Group (group 1) with patients who fulfilled the criteria (1–4), but were Ro-SSa/La-SSb negative (group 2), with patients who had another rheumatic disease, but had sicca symptoms and were Ro-SSa and/or La-SSb positive (sSjS) (group 3), with patients with other rheumatic disease without Ro-SSa or La-SSb antibodies (group 4), with patients with other rheumatic disease with Ro-SSa antibodies but no sicca symptoms (group 5) and with patients with no rheumatic disease (group 6), respectively. We investigated the parotid and the submandibular salivary glands bilaterally. The USG was assessed with a score from 0–48 points with a maximum of 12 points for 4 items each (hyoechoic areas, hyperrechoc reflexes, inhomogeneity and distinct organ border). If available the score was correlated with the scoritgraphically measured function of the salivary glands.

Results: We included USG of 92 patients in our study. Group 1 (n=33) had a score of 16.6±11.6; group 2 (n=7) 2.4±3.5; group 3 (n=16) 6.9±5.5; group 4 (n=16) 5.3±7.8; group 5 (n=11) 4.5±5.7 and group 6 (n=9) 1.9±2.3, respectively. The score in patients with sSjS was significantly higher than the score of patients with pSS (p<0.01), with no significant differences between all other groups. In 25 patients a scintigraphy of the salivary glands was available. The excretory function in the scintigraphy highly significantly correlated with the ultrasound score (r=0.53, p<0.001).

Conclusions: USG showed significantly higher scores in patients with pSjS, than in patients with sSjS or other rheumatic disease. USG as a non invasive investigation might be similarly helpful for the diagnosis of pSjS like salivary gland functional tests. USG findings can reliably distinguish between pSjS and sSjS associated with other rheumatic disease, also if they are positive for Ro-SSa/La-SSb.

FR0295 HIGH RISK OF IDIOPATHIC OSTEONECROSIS IN SLE PATIENTS WITH HIGH ANTI PHOSPHOLIPID SCORE AND HYPERTRIGLYCERIDEMIA

P. Hisada, M. Kato, N. Ohsishi, M. Kono, S. Tanrimu, E. Sugawara, H. Nakamura, K. Ohmura, S. Shimamura, Y. Fujieda, K. Oku, T. Bohgaki, O. Amengual, S. Yasuda, T. Atsumi. Division of Rheumatology, Endocrinology and Nephrology, Hokkaido University Graduate School of Medicine, Sapporo City, Japan

Background: Systemic lupus erythematosus (SLE) patients are prone to develop idiopathic osteonecrosis (ION) compared to other connective tissue disease patients or healthy subjects. ION has shown to occur as a result of ischemia, however, the involvement of antiphospholipid antibodies (aPL) in its pathophysiology remains to be elucidated. In the last years, our group introduced a quantitative marker of aPL “antiphospholipid score (aPL-S)”, which well reflected the risk of developing thrombosis [1].

Objectives: We newly identified high aPL-S as a risk factor for ION. Further-

Methods: A single center retrospective study comprising 82 consecutive patients who were diagnosed SLE at the Rheumatology department of Hokkaido University Hospital and underwent magnetic resonance imaging (MRI) of hip joints from January 2000 to December 2016. Among all the enrolled patients, aPL-S, which is calculated from 0 to 86, as well as classical risk factors for ION were evaluated.

Results: All 82 patients (13 males and 69 females) were given glucocorticoids. ION of the femoral head was diagnosed by MRI scan in 37 patients. Male ION(+): ION(-) 10/37 (27%) vs 16/45 (36%), p=0.058, malar rash ION(+): ION(-) 22/37 (59%) vs 16/45 (36%), p=0.045, aPL positivity ION(+): ION(-) 22/37 (59%) vs 15/35 (44%), p=0.026, high aPL-S ION(-30) ION(+): ION(-) 9/37 (24%) vs 3/45 (7%), p=0.001, hypertriglyceridemia (fasting triglyceride levels >100 mg/dL) ION(+): ION(-) 23/37 (62%) vs 12/45 (27%), p=0.002, and high dose infections requiring treatment or bacterial infections requiring admission due to immunosuppression, 12 (4%) had malignancy. SLE is an autoimmune disease requiring multi-faceted approach.

FR0297 ROLE OF SERUM INTERLEUKIN-6 IN BLOOD BRAIN BARRIER DAMAGES IN NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

S. Hirohata 1, Y. Matsueda1, T. Yanagida2, T. Yoshio3, Divisions of Rheumatology, Endocrinology and Nephrology, Department of Internal Medicine, Kitasato University, Japan.

Background: Neuropsychiatric systemic lupus erythematosus (NPSE) is one of the most serious complications of the disease. We have recently demonstrated that the breakdown of blood brain barrier (BBB) plays a crucial role in the development of diffuse psychiatric/neuropsychological manifestations (diffuse NPSE), allowing influx of neuron-reactive autoantibodies from systemic circulation into the brain. However, the mechanism of BBB damages remains unclear. On the other hand, although CSF interleukin-6 (IL-6) has been shown to be elevated in NPSE, there has been no report on serum IL-6 in NPSE.

Objectives: The present study was designed in order to elucidate the roles of serum IL-6 in the pathogenesis, especially in development of BBB damages, in NPSE.

Methods: Paired serum and cerebrospinal fluid (CSF) samples were obtained from 101 SLE patients when they presented active neuropsychiatric manifestations (69 patients with diffuse psychiatric/neuropsychological syndromes [diffuse NPSE]) and 32 patients with neurologic syndromes or peripheral nervous system involvement [local NPSE] and from 22 non-SLE control patients with non-
inflammatory neurological diseases. The levels of albumin and IL-6 in CSF and serum were measured by ELISA.

**Results:** Serum IL-6 as well as CSF IL-6 was significantly elevated in acute confusional state (ACS) compared with non-ACS diffuse NPSLE (anxiety disorder, cognitive dysfunction, mood disorder and psychosis) or focal NPSLE (figure). ANA and cryo-antibodies (including anti-neutrophil cytoplasm AT, Y. Asaklu, A. Ed-Din, R. Thanawala, D. Andrew, I. Albert, C. May, M. Sokhova, T. Popkova, D. Novikova, E. Alexandrova, E. Nasonov, V.A. Nasonov Research Institute of Rheumatology, Moscow, Russian Federation

**Objectives:** This study was aimed to determine NT-proBNP serum levels in patients with untreated SLE, thus ruling out any potential effect of SLE therapy to analyze any possible correlation between NT-proBNP values and traditional risk factors (TRF), inflammatory markers and myocardial function parameters. PS matching will allow comparison of long-term organ damage in patients with untreated lupus erythematosus (SLE) have established the efficacy and safety of belimumab plus standard SLE therapy (SoC) vs SoC alone. 10.1136/annrheumdis-2017-eular.3735

**FRIO299 | APPLICATION OF PROPENSITY SCORE-MATCHING METHODS TO COMPARE DATA FROM LONG-TERM EXTENSION TRIALS WITH DATA FROM AN EXISTING LUPUS REGISTRY**

M.B. Urowitz 1, R. Wielage 2, K.A. Kelton 3, R.L. Oslefield 2, Y. Asaklu 4, S. Ramachandran 4 1 Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, Toronto, Canada; 2 Medical Decision Modeling Inc, Indianapolis, United States; 3 Value Evidence & Outcomes, GSK, Stockley Park, United Kingdom; 4 Value Evidence & Outcomes, GSK, Philadelphia, United States

**Methods:** Potential PS model criteria were a) Medical Decision Modeling Inc, Indianapolis, United States; b) Value Evidence & Outcomes, GSK, Stockley Park, United Kingdom; c) Value Evidence & Outcomes, GSK, Philadelphia, United States. The study included 28 pts (82% females, aged 28.5 [25.0–32.0] years (median [interquartile range 25%–75%]) with untreated SLE (ACR criteria, 1997) and 27 healthy controls (89% females, age 30.0 [23.0–49.0] years). Mean NT-proBNP levels in patients with untreated SLE were higher than in healthy controls (30.5 [12.2–94.0] vs 12.5 [5.0–26.1] pg/ml, p<0.05). NT-proBNP was significantly negatively correlated with CRP, IL-6, INF-α, immunoglobulins G, A and M, C3 and C4 complement fragments and others, autoantibodies (ANA, antiDNA, ENA-SSA, -SSB, -Sm, -RNPs-70, aPL), echocardiography was performed using standard techniques. Serum levels of NT-proBNP (pg/ml) were measured using electrochemiluminescence method Elecsys proBNP II (Roche Diagnostics, Switzerland). Normal NT-proBNP levels should vary within 125.0 pg/ml.

**Results:** Mean SLE duration was 21.0 [5.0–60.0] months, SLEDAI 2K score - 11 [8–9], SLICC/DI score - 0 [0–0]. SLE pts had higher levels of NT-proBNP vs control (160.7 [98.6–335.4] vs 55.2 [36.6–70.3] pg/ml, p=0.001). Elevated levels of NT-proBNP (75.0–125.0 pg/ml) was detected in 18 (64%) SLE pts. In SLE pts NT-proBNP serum levels showed positive correlation with creatinine (r=0.480, p<0.01), uric acid (r=0.427, p<0.05), ACL IgG (r=0.710, p<0.001), antiDNA (r=0.395, p<0.05), ANA levels (r=0.256, p<0.05), left ventricle (LV) end-systolic dimension (r=0.442, p<0.05), mean pulmonary artery pressure (r=0.488, p<0.05); and negative correlation with hemoglobin level (r=-0.493, p<0.01), C4 complement component (r=-0.475, p<0.05), glomerular filtration rate (r=-0.558, p<0.01) and LV ejection fraction (r=0.505, p<0.01); left ventricular diastolic dysfunction (DDLV) was only in pts with NT-proBNP levels >125.0 pg/ml. Mean NT-proBNP concentration in verified DDLV cases (n=5) (18%) considerably exceeded normal values, reaching up to 799.2 [27.6±177.0] pg/ml.

**Conclusions:** Untreated SLE patients without a history of myocardial infarction, coronary procedure or any evidence of heart failure demonstrated higher NT-proBNP concentration as compared to healthy controls (p<0.001). NT-proBNP levels showed correlation with numerous SLE markers (ACL IgG, ANA, antiDNA, C4 fragment of complement), kidney function (creatinine, uric acid, glomerular filtration rate) and myocardial function (end-systolic dimension of the LV, mean pulmonary artery pressure, LV ejection fraction). No correlation was documented between NT-proBNP concentration and TRF or inflammatory markers (CRP, IL-6, INF-α). All abovementioned data suggest presumable SLE-associated autoimmune damage of cardiomyocytes and/or mediated decrease of myocardial function caused by kidney disease.

**Disclosure of Interest:** None declared

**FRIO300 | NEUROLOGICAL INVOLVEMENT IN PRIMARY SJÖGREN SYNDROME**

T. Ben Salem 1, 2, I. Naceur, M. Tougour, M. Lamlovlu, I. Ben Ghorbel, M.H. Houman, Internal Medicine, Rabta university hospital, Tunis, Tunisia

**Background:** Prevalence of neurological involvements (NI) in primary Sjögren Syndrome (pSS) varies from 10 to 60% and depends on whether they are screened systematically or only when they are symptomatic. The aim of the study was to describe the prevalence, clinical patterns and treatment of NI in pSS.

**Methods:** We performed a retrospective study of patients with pSS (American-European Consensus Group criteria) and followed in an internal medical department over a period of 15 years. Patients with NI were enrolled after excluding other potential causes. We did investigate neurologic systems only when patients were present with NI. The two groups were compared:

**Results:** Primary Sjögren Syndrome was diagnosed in 155 patients, 41 had neurological manifestations (26.4%). They were 5 male and 36 female. The mean age at disease onset was 49 ±13 years. The average delay from NI onset to pSS diagnosis was four months for peripheral nervous system (PNS) and 12
months for central nervous system (CNS). NI revealed the disease in 14 cases (34%). CNS and PNS involvements were respectively found in 27 and 19 cases (six patients had both CNS and PNS). In patients with CNS disorders, headache was the most frequent symptom (n=11). Pyramidal syndrome was found in 9 cases and cerebellar syndrome in one patient. Aseptic meningitis was noted in two cases. Brain MRI was performed in 22 cases and showed abnormalities in 82% of cases. T2 and flair weighted hyperintensities were periventricular (n=11), subcortical (n=5), frontal (n=3) and parietal (n=2). Myelitis was found in one patient.

Patients with PNS showed paresthesia (92%), motor deficit (22%) and decreased tendon reflex (12%). Sensory-motor neuropathy was described in 4 cases, pure sensory neuropathy in 6 cases (including one case of small fiber neuropathy) and motor neuropathy in one patient. Mononeuropathy multiplex was found in 4 cases and polyradiculoneuritis in one patient. Neuromuscular biopsy was performed in five patients and showed vasculitis in two cases. Trigeminal nerve and cochlear nerve were respectively involved in four and one patients. Antinuclear antibodies, anti-SSA and anti-SSB antibodies were respectively positive in 71%, 50% and 28% of cases. NI were treated with corticosteroids and immunosuppressive therapy in respectively 56% and 41% of cases. Outcome was good in 46% of the patients. Comparison of clinical and biological features in patients with and without NI showed no significant differences, only fatigue was significantly associated to NI (45.5% vs 12.9%; p<0.005).

Conclusions: In our series, NI prevalence was similar to other groups. CNS involvements were more frequent than PNS manifestations whereas in other ethnic groups they are less frequent.

FR10301 | CHARACTERIZATION OF FEVER IN HOSPITALIZED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: LESSONS FROM THE JIANGSU COHORT

X. Feng 1, W. Pan 2, L. Liu 3, M. Wu 4, L. Sun 1 on behalf of Jiangsu Lupus Collaborative Group, 1Department of Rheumatology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing; 2Department of Rheumatology, Huaian First People’s Hospital, Huaian; 3Department of Rheumatology, Xuzhou No. 4 People’s Hospital, Xuzhou; 4Department of Rheumatology, The 3rd Affiliated Hospital of Suzhou University, Changzhou, China

Background: Fever is one of the main symptoms leading to the admission of patients with systemic lupus erythematosus (SLE) and its causes are usually complicated.

Objectives: To explore the prevalence and clinical characteristics of fever in Chinese SLE patients at the time of their first admission and to find out whether fever is related to a poor prognosis.

Methods: A follow-up study aimed to delineate SLE prognosis had been conducted by our Lupus Collaborative Group under the supervision of Jiangsu Rheumatology Association to collect the data of patients who had ever recorded first admissions during the 1999–2009 decade (1). Among which, those with admission temperature documented were extracted for the assessment of potential factors associated with fever. The independency of various clinical features linked to fever was established by binary logistic regression analysis, and the relation between fever and patient’s survival was determined by Cox regression analysis.

Results: Totally 1,348 patients were enrolled, in which 1,048 (77.8%) had normal temperature, 221 (16.4%) had low and moderate fever and 78 (5.8%) had high fever at the time of their first hospitalization. Compared with those having normal temperature, fever patients were more likely to have short disease duration (RR 0.74), concurrent infection (RR 3.29) and gastrointestinal (RR 1.57) as well as hematological involvements (RR 1.56), High C reactive protein level (RR 2.08) and positive anti-Sm antibody (RR 1.55) were the two laboratory factors related to fever at admission. However, age, gender, SLEDAI score or erythrocyte sedimentation rate was not independently associated with fever in this cohort. Cox regression analysis showed that there was no correlation between fever and overall deaths (Figure 1) as well as infection induced deaths.

Conclusions: Both infection and lupus itself (especially gastrointestinal and hematological involvements) contribute to fever in SLE patients. Although the presence of fever increases the complexity of disease treatment, it does not constitute a risk factor for patient’s long-term outcome.

FR10302 | ELEVATED CYSTEINE-RICH PROTEIN 61 IN SYSTEMIC LUPUS ERYTHEMATOSUS-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION

Y. Fan 1, J. Qian 2, Y. Hao 3, M. Li 2, L. Gao 2, X. Zeng 2, Z. Zhang 1, 1Department of Rheumatology and Clinical Immunology, Peking University First Hospital; 2Department of Rheumatology, Peking Union Medical College Hospital, Peking Union Medical College & Chinese Academy of Medical Sciences, Key Laboratory of Rheumatology and Clinical Immunology, Ministry of Education; 2Department of Rheumatology, Beijing Shijitan Hospital, Capital Medical University, Beijing, China

Background: Pulmonary arterial hypertension (PAH) is a complex and devastating complication of connective tissue diseases that leads to severe morbidity and mortality. Unlike in Caucasians, it is systemic lupus erythematosus that recognized as the the major underlying cause of CTD associated PAH in Asian countries, especially in China [1]. Early diagnosis and intervention is vital for better long-term outcome in SLE-PAH patients. Previous study has demonstrated Cysteine-rich protein 61 (Cyr61) was highly expressed in SLE patients [2]. However, the role of Cyr61 in pulmonary arterial hypertension (PAH) remains unknown.

Objectives: To explore the value of Cyr61 for PAH in SLE patients by comparing the plasma Cyr61 levels in SLE patients with/without PAH.

Methods: Plasma samples from two tertiary medical centers were obtained from 54 patients with definite SLE-PAH, 52 age, gender and SLEDAI matched SLE patients without PAH, and 54 age and gender matched healthy controls. Plasma Cyr61 concentration was measured by enzyme-linked immunosorbent assay.

Results: Plasma Cyr61 concentration in SLE-PAH patients was significantly higher than the matched SLE patients and healthy controls (median (IQR): 172.5 (143.8, 218.2), 124.9 (104.1, 154.7), 58.17 (28.9, 80.4) respectively, P<0.001 (Figure 1). The sensitivity and specificity of Cyr61 in predicting the presence of PAH in entire SLE patients were 79.6% and 67.3%. Receiver operating characteristic curve analysis showed the area under the curve was 0.757 (95% CI: 0.682–0.852), with 140.6 pm as the cut off concentration (Figure 2). Further multivariate logistic regression analyses revealed high Cyr61 level (>140.6) is an independent risk factor for SLE patients to develop PAH (OR:7.822 (95% CI: 2.224–41.138) (Table 1)). Additionally, weak to moderate positive correlations were observed between Cyr61 concentration and serositis, hematological involvement, red blood cell distribution width, right ventricular systolic pressure and right ventricular diameter measured by echocardiography in entire SLE population.

Conclusions: Plasma Cyr61 level was significantly higher in SLE-PAH patients than SLE patients without PAH. Cyr61 may be used as a biomarker for PAH complication in SLE patients.

The IgG4:IgG RNA ratio is a new and promising disease activity marker in granulomatosis with polyangiitis

A. Al-Soudi 1, M. Doorenspleet 1, R. Esveldt 1, S. Tas 1, R. van Vollenhoven 1, P. Klarenbeek 1, N. de Vries 1,2, 1Amsterdam Rheumatology and Immunology Center, 2Department of Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands

Background: Granulomatosis with Polyangiitis (GPA) is a form of vasculitis characterized by inflammation of blood vessels in lungs, kidneys, and the ear, nose and throat region. Regular monitoring and treatment adjustments are common, as the disease activity tends to fluctuate over time. Unfortunately, good markers for disease activity are lacking. This leads to both over- and undertreatment.

Immunoglobulin G4 positive (IgG4+) B-cells and plasma cells are implicated in the pathogenesis of GPA, but the level of serum IgG4 does not seem to be a good disease activity marker. Recently we developed a test that indirectly measures the presence of IgG4+ B-cells/plasma cells by measuring the IgG4/IgG RNA ratio. We hypothesized that this test could be used as disease activity marker.

Objectives: To test the IgG4:IgG RNA ratio in peripheral blood as a disease activity marker in GPA.

Methods: 27 PR3-ANCA positive GPA patients were included in this cross-sectional study. Mean age was 52 years, 56% were female, and 39% had active disease. For each patient the ESR, CRP, BVAS, and ANCA titre were measured and peripheral blood samples were obtained. Patients were defined as having active disease if the BVAS was $\geq 3$. In addition we included 10 healthy controls, and 63 patients with other immune mediated inflammatory diseases (systemic lupus erythematosus (SLE) (n=24), rheumatoid arthritis (RA) (n=19), primary sclerosing cholangitis (PSC) (n=20)). A validated qPCR test was performed in all groups to measure the IgG4:IgG RNA ratio in peripheral blood samples

Results: The median IgG4:IgG RNA ratio was significantly higher in the GPA cohort (5.7, IQR 2.6 - 19.7) compared to all control groups: 1.2 in SLE (0.7 - 4.1; p $< 0.001$), 2.5 in RA (1.0 - 2.8; p $< 0.001$), 1.3 in HC (0.6 - 1.8; p $< 0.001$). In addition, the median IgG4:IgG RNA ratio was significantly higher in patients with active disease (23.8; IQR 12.1 – 29.1) compared to patients in remission (3.5; IQR 2.0 – 5.5; p $< 0.0001$). The height of the IgG4:IgG RNA ratio significantly correlated with height of the BVAS (r² = 0.76, p $< 0.0001$), while the ESR, CRP and ANCA titre did not. Interestingly, IgG4/IgG RNA ratios among patients with active disease were consistently above 9.3, and among patients in remission they were below this threshold.

Conclusions: The IgG4/IgG RNA ratio distinguishes active GPA from GPA in remission with excellent specificity and sensitivity. Moreover the ratio shows a significant correlation with disease severity, in contrast to ESR, CRP and ANCA titre. Retesting in another, prospective study is indicated to validate the IgG4/IgG RNA ratio as a novel, highly sensitive and specific marker of disease activity in GPA.

limits and aorta were less in benign RPF; however, significant differences were only observed when comparing with lymphoma (p values: all <0.001) but not with metastatic carcinoma (p value: 0.396, 0.181, 0.112 and 0.64). A greater frequency of retroperitoneal lesions with high FDG-uptake (100% vs 77.5%, p value: 0.017) and a higher mean SUVmax (12.2 vs 4.8, p value: <0.001) were observed in malignant RPF. The frequencies of LNs in malignant FDG-uptake were greater with significance in malignant RPF except for hilar/mediastinal and cervical LNs, hence the rest LNs were regarded as specific LNs. At ROC analyses, the AUCs of SUVmax and specific LNs were 0.893 and 0.947. The sensitivity and specificity were 85.7% and 81.4% when the SUVmax was 6.23. The AUC of logistic regression model combining SUVmax and specific LNs was 0.974 with sensitivity of 90.5% and specificity of 90.1%.

Conclusions: PET/CT could help distinguish benign from malignant RPF, especially when taking into account the FDG-uptake of retroperitoneal process and LNs.

Disclosure of Interest: None declared

**RELATIVE FDG ACCUMULATION OF THE AORTIC WALL LESIONS TO AORTIC BLOOD POOL IN 18F-FDG-PET AND PET/CT COULD BE A USEFUL PARAMETER FOR THE PREDICTION OF DISEASE RELAPSE AFTER SUCCESSFUL TREATMENT IN TAKAYASU ARTERITIS**

A. Ihata 1, Y. Kunishita 1, K. Minegishi 2, R. Yoshimi 2, Y. Kinno 2, H. Nakajima 2.

1Department of Rheumatology, Yokohama Medical Center; National Hospital Organization; 2Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan

**Background:** The assessment of disease activity of Takayasu arteritis (TA) is difficult if symptoms and serum inflammatory marker were not detected. Even in those conditions, relapses were frequently observed during the dose reduction of corticosteroid and immunosuppressant. There is accumulating evidence that 18F-fluorodeoxyglucose-positron emission tomography (FDG-PET) and PET/ computed tomography (PET/CT) is useful for monitoring patients with TA when TA was clinically active. However, it is not clear the significance of FDG accumulations when TA was inactive.

**Objectives:** To investigate a quantitative predictor in FDG-PET or PET/CT scans for the relapse of TA.

**Methods:** We retrospectively investigated 76 FDG-PET or PET/CT scans and extracted 37 scans which were performed in inactive status. These scans were divided in two groups according to relapse of TA for 5years. The relapse was defined the increase of CRP and steroid dose or addition of immunosuppressant. FDG accumulations in aortic wall lesions of TA was evaluated by semi-quantitative index; the standardized uptake value (SUV), in addition to SUVmax in the aortic wall, we also calculated SUV ratio of maximum aortic wall uptake to mean lung uptake (ratio Lu), SUV ratio of maximum aortic wall uptake to mean liver uptake (ratio Li), and SUV ratio of maximum aortic wall uptake to mean aortic blood pool uptake (ratio BP). We compared groups using these parameters. We also determined the cutoff levels, sensitivity, and specificity of 4 sets of parameters was calculated as follows: SUVmax 1.4, ratio Lu 5.31, ratio Li 1.01, and ratio BP 1.41, respectively. Using these cut-off level, relapse rates of these parameters was calculated (Table 1). Using Receiver Operating Characteristic (ROC) analysis, the AUCs of SUVmax and specific LNs were 0.893 and 0.947. The sensitivity and specificity were 85.7% and 81.4% when the SUVmax was 6.23. The AUC of logistic regression model combining SUVmax and specific LNs was 0.974 with sensitivity of 90.5% and specificity of 90.1%.

**Conclusions:** PET/CT could help distinguish benign from malignant RPF, especially when taking into account the FDG-uptake of retroperitoneal process and LNs.

**FR10306**  
**LONG TERM DRUG-FREE REMISSION IS FEASIBLE IN SEVERE BEHCET’S DISEASE AFTER CESSATION OF SUCCESSFUL ANTI-TNF TREATMENT: A SINGLE CENTER, RETROSPECTIVE LONGITUDINAL OUTCOME STUDY**

P.P. Stilakis, A. Aride, S. Panopoulos, K. Fragiadaki, G. Pentazos, A. Laskari, M. Teotonidou, N. Markomichelakis. First Department of Propaedeutic and Internal Medicine and Jointed Rheumatology Program. National and Kapodistrian University of Athens Medical School, Athens, Greece

**Background:** The efficacy of anti-TNF treatment for patients with severe forms of Behcet’s disease (BD) is well established (ref), but long term data on the outcome after cessation of such treatment are lacking.

**Objectives:** To examine whether sustained long term remission of severe BD is feasible after cessation of successful anti-TNF treatment.

**Methods:** This retrospective longitudinal outcome study was conducted in December 2016 and included all patients with severe BD refractory to conventional immunosuppressive therapy who were considered complete responders to continuous anti-TNF treatment in our center, the first being treated in 2000.
Study's endpoint was the proportion of patients achieving sustained complete remission of BD for at least 3 years after cessation of the anti-TNF agent.

**Results:** A total of 28 patients in whom infliximab and/or adalimumab treatment was given, always combined with azathioprine unless not tolerated (n=2), and discontinued anytime before December 2013 were eligible for analysis. Following cessation of successful anti-TNF treatment, median duration of 2 years, 13/28 patients achieved the study's end-point. The main reason for anti-TNF administration was sight-threatening ocular disease (n=12) or intestinal disease (n=1). The remaining 15 patients relapsed within 1.5 year (main reason for anti-TNF: ocular disease, n=9; neuro-BD, n=2; severe mucocutaneous disease, n=3; intestinal disease, n=1; median treatment duration of 24 months); 12/15 were successfully re-treated with anti-TNF. So far, 3 of them (ocular disease, n=2; neuro-BD, n=1) have achieved the study's end-point (median re-treatment duration of 2 years). Overall, our 16 patients who achieved the study's end-point (57%) are in complete disease remission ranging from 3 to 12 years (5.7 years, median). Nine patients with severe ocular disease are currently any drug-free (32%), whereas the 7 remaining patients are on low doses of conventional immunosuppressive therapy (25%). Notably, those patients on drug-free remission had shorter median disease duration at initiation of anti-TNF treatment, compared to the remaining patients (1 versus 3 years, respectively).

**Conclusions:** Sustained drug-free remission for many years after cessation of successful anti-TNF treatment is feasible in some patients with severe BD. Since anti-TNF-induced "cure" can never be differentiated from a spontaneous remission by natural history, further studies should examine whether early anti-TNF treatment must be intended for every patient with severe BD.

**PREDICTORS OF HYPOGAMMAGLBULINAEMIA IN RITUXIMAB TREATED PATIENTS. A RETROSPECTIVE ANALYSIS ON A MONOCENTRIC COHORT**

**R. Padovan, M. Felicetti, M. Gatto, P. Polito, F. Ometto, D. Astori, L. Friso, F. Cozzi, A. Doria, L. Punzi, F. Schiavon. Operative Unit of Rheumatology, Department of Medicine DIMED, University of Padova, Padova, Italy**

**Background:** Rituximab (RTX), a chimeric monoclonal antibody against CD20, is increasingly used in the treatment of B-cell lymphomas and autoimmune conditions. It has been shown that some patients develop hypogammaglobulinaemia after treatment.

**Objectives:** To assess frequency and predictors of hypogammaglobulinaemia after RTX treatment in a monocentric cohort of patients affected with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and connective tissue diseases (CTD).

**Methods:** We retrospectively reviewed all patients receiving RTX and concomitant immunosuppressants between 2007 and 2016 in a single rheumatologic center. Serum levels of total Ig and lymphocyte subsets were recorded at the time of RTX administration and 3–6 months later. We assessed the frequency of hypogammaglobulinaemia (IgG <6 g/L) and its related events.

**Results:** 72 patients, 30 (41.6%) GPA/MPA, 25 (34.7%) systemic lupus erythematosus, 13 (18.1%) systemic sclerosis and 4 (5.6%) polyarthritis mutilans were treated with RTX. We analyzed 113 RTX infusions, with 41 (36.2%) treatments (median 2 [2–6]). We excluded 12 patients/18 infusions due to incomplete data. RTX was administered at the dosage of 1000 mg twice in 68.1% of patients and 275 mg/m² weekly in 31.9%. IgG levels after RTX infusions were available in 68 (71.6%) patients. We observed a significant decrease of IgG levels between baseline and 3–6 months after RTX infusion in all patients (0.001). The frequency of patients with IgG <6 g/L was 22.1%, and 8.8% had IgG <4 g/L, significantly higher in GPA/MPA patients (0.008), with short disease duration (0.011), lower IgG levels at baseline (0.008), higher prednisone equivalent (PDE) cumulative dosage per year (0.006) and higher daily PDE dosage after RTX (0.001) (Table 1). After RTX, all patients had complete B-cells depletion.

At univariate analysis, IgG <6 g/L was associated with GPA/MPA diagnosis (0.006, OR 6[1.5–24.2]), disease duration <1 year (0.001, OR 0.2[0.1–0.9]), RTX 375 mg²/m² protocol (p=0.017, OR 4.1[1.2–13.9]), PDE cumulative dosage per year <0.001, OR 6.6 [1.3–33.6], daily PDE intake >15 mg/day after RTX (<0.001, OR 12.7[3.5–25.2]) and IgG levels before RTX (<0.001, OR 18[1.8–178]). At multivariate analysis, daily PDE intake after RTX (>15 mg/day) and GPA/MPA diagnosis resulted independent predictive factors for hypogammaglobulinaemia (p=0.03, OR 9.5, [2.2–41.7] and p=0.43, OR 4.7, [1.1–21.5]).

Patients affected with GPA/MPA were compared to CTD, as reported in Table 2. GPA/MPA patients at infusion were older (0.002), presented shorter disease duration (0.001), lower IgG levels at baseline (<0.001) despite lower rate of nephritic syndrome (0.003). Moreover they were treated more frequently with Azathioprine (0.007), RTX 375 mg²/m² weekly protocol (<0.001) and higher PDE cumulative and daily dosage (<0.001, 0.01 respectively).

Only 5 patients (5.2%) experienced severe infections within 12 months, more frequently in IgG <6 g/L patients (0.007).

**Conclusions:** In autoimmune rheumatic diseases, diagnosis of GPA/MPA and glucocorticoid therapy resulted independent predictors of hypogammaglobulinaemia after RTX treatment. Despite low IgG levels were associated with higher infections risk, rare severe infectious events were observed.
Background: Several chronic inflammatory diseases are associated with cardiovascular disease, but the cardiovascular risk in ANCA-associated vasculitis is poorly quantified.

Objectives: The aim of the present study is to review the evidence for the increased cardiovascular risk in patients with ANCA-associated vasculitis.

Methods: A comprehensive systematic review was conducted in accordance with guidelines of preferred reporting items for systematic reviews and meta-analyses (PRISMA). The databases PubMed, Embase.com and the Cochrane Library (Wiley) were searched for original observational studies reporting an estimate of the association between ANCA-associated vasculitis and cardiovascular events, including ischemic heart disease, cerebrovascular accidents and/or peripheral arterial disease. The quality of the included studies was assessed with the Newcastle–Ottawa Scale. Summary estimates were derived with a random-effects model and reported as relative risks.

Results: 1375 studies were identified and 7 studies were included comprising 14098 ANCA-associated vasculitis patients versus general population controls in 6 studies and chronic kidney disease patients in 1 study. ANCA-associated vasculitis carried a relative risk of 1.65 (95% confidence interval, 1.23–2.22) for all cardiovascular events, 1.60 (1.39–1.84) for ischemic heart disease and 1.20 (0.98–1.48) for cerebrovascular accidents. We did not find studies that addressed all cardiovascular events, 1.60 (1.39–1.84) for ischemic heart disease and 1.20 (0.98–1.48) for cerebrovascular accidents. We did not find studies that addressed the risk for peripheral arterial disease separately. No heterogeneity was seen in the estimates.

Conclusions: This meta-analysis of observational studies supports an increase in cardiovascular risk of about 65% in patients with ANCA-associated vasculitis, similar to that found in other chronic inflammatory diseases. Hence, there is a clear need for active cardiovascular risk management in patients with ANCA-associated vasculitis.

The frequency and severity of patient-reported symptoms in giant cell arteritis

S. Monti 1,2, A. Leong 3, J. Robson 4, A. C. Raven 2, P. A. Merkel 5, R. Watts 6, R. Luqmani 1,2, A. Ueno, Y. Yamamura, K. Fujita, N. Shibutou, M. Yamamura. Center for Rheumatology, Okayama Saiseikai General Hospital, Okayama, Japan

Background: A better understanding of the patients’ perspectives is pivotal in the development of patient-reported outcomes (PROs) in vasculitis.

Objectives: To assess patients’ perspective of disease amongst cases with Giant Cell Arteritis (GCA) compared to comparator illnesses mimicking large vessel vasculitis (LVV) included in the Diagnostic and Classification Criteria in Vasculitis Study (DCVAS) database.

Methods: Patient Description (PDI) forms from 89 patients with GCA and 28 comparators (COM) were analysed. There was no difference in age and sex distribution between groups (mean age 70±8 for GCA and 69±12 for COM). The symptoms description and frequency of the first most severe aspect of disease, including the patient’s own words, is presented in Table 1. The symptom regarded as the most severe by both groups was headache. While there were no differences in the frequency of sudden visual loss, visual symptoms were reported more commonly as the most severe feature by COM vs GCA (21% vs 8%, p=0.05). Headache was the most frequently reported symptom in both groups. Patients with GCA reported jaw claudication (37%) as the second most frequently reported symptom, while COM reported arthralgia/arthritus (32%). Shoulder/neck pain was the third most important symptom in GCA (33%), while fatigue was the third most common complaint among COM (21%). Fatigue was reported as the fourth most common feature by 30% of GCA patients.

Conclusions: Headache was the most frequent and most severe symptom reported by patients with GCA and comparators. However, the reported frequencies and severities of other symptoms were significantly different between the two groups.

FR0313 THE EFFICACY AND SAFETY OF TOCILIZUMAB THERAPY IN PATIENTS WITH POLYMYALGIA RHEUMATICA WHO WERE RESISTANT OR INTOLERANT TO GLUCOCORTICOIDS AND ADDITIONAL METHOTREXATE

A. Ueno, Y. Yamamura, K. Fujita, N. Shibutou, M. Yamamura. Center for Rheumatology, Okayama Saiseikai General Hospital, Okayama, Japan

Background: A recent trial of tocilizumab (TCZ) in patients with newly diagnosed polymyalgia rheumatica (PMR), conducted in Europe and the United States, has shown its efficacy and safety.

Objectives: We examined the efficacy and safety of TCZ for patients with PMR who had been primarily resistant or intolerant to glucocorticoids (GC) and additional methotrexate (MTX).

Methods: Sixty patients had been diagnosed with having PMR since 2011. The patients are all compatible with the 2012 EULAR/ACR provisional classification criteria for PMR, and had been treated first with GC, if they were resistant or intolerant to GC, were added MTX, similarly to the 2015 EULAR/ACR recommendations for the management of PMR. The disease activity were measured by PMR-AS.

Results: There were 17 patients with GC/MTX resistant or intolerant PMR (28%). Of them, 9 patients with PMR agreed to the proposal of TCZ addition, and their therapeutic responses to TCZ and its safety were determined. They were at the age of 68±10.6, including three males and six females. Before TCZ addition, the patients were treated with prednisolone (PSL) at 7.6±3.0 mg/day plus MTX at 7.1±5.1 mg/week, and serum CRP were at 1.8±1.0 mg/dL. After 8.4±5.7 months of TCZ treatment, PSL and MTX had been reduced to 1.1±1.3 mg/day and 3.3±4.5 mg/week, respectively, with CRP at 0.02±0.05 mg/dL. GC were able to be withdrawn in 5 patients, and MTX were further withdrawn in 4 patients. Two patients reached drug-free remission (PMR-AS=0.02). During TCZ therapy, each one patient showed the worsening of depression and occlusion of the central retinal vein.

Conclusions: These results indicate that TCZ may provide a therapeutic option for patients with severe PMR who were resistant or intolerant to GC and additional MTX.

Background: Evidence supporting the classification of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) based on ANCA type is accumulating.1

Objectives: To evaluate serum cytokine profiles in patients with AAV classified by ANCA specificity (proteinase 3 (PR3)-ANCA versus myeloperoxidase (MPO)-ANCA) or by clinical diagnosis (granulomatosis with polyangitis (GPA) versus microscopic polyangiitis (MPA)) and clinical phenotypes.

Methods: An antibody array testing 30 soluble mediators, already shown to be implicated in the pathogenesis of AAV, was performed in each patient with active AAV at inclusion in the Rituximab in ANCA-Associated Vasculitis (RAVE) trial, as previously described.2,3 By means of Wilcoxon signed rank test for univariate analyses, we analyzed the association of levels of these cytokines with ANCA specificities, clinical diagnosis, and distinct clinicopathologic phenotype characteristics derived from the BVAS/WG items recorded at the time of enrollment (capillaritis, granulomatous manifestations, renal involvement, and alveolar hemorrhage; new diagnosis and relapsing disease), as described.4

Results: All cytokines tested (see Figure 1 and legend for the complete list), except for RANTES, ACE, bFGF and VCAM-1, were significantly increased in the RAVE cohort when compared to healthy controls (p < 0.05). Median Birmingham vasculitis activity score and steroid use at screening did not significantly differ between PR3-AAV and MPO-AAV, and between GPA and MPA. Within both ANCA specificities, levels of 9 mediators were significantly higher in PR3-AAV (IL-6, NGFβ, GM-CSF, IL-15, IL-18, IL-18Bβ, sIL-2Ra, IL-8, TARC) than with MPO-ANCA specificity (Table 1). Similarly, the differences associated with PR3-AAV (Figure 1).

Conclusions: Cytokine profiles separate patients more clearly by ANCA specificity than by clinical diagnosis, suggesting important differences in underlying pathophysiology and validating stratification of patients by ANCA specificity for clinical trials.

FRI0316 FACTORS ASSOCIATED WITH SURGICAL OUTCOMES OF SEVERE AORTIC REGURGITATION IN PATIENTS WITH BEHÇET’S DISEASE
B. Ghang1, D.-H. Lim2, W.J. Seo3, Y.-G. Kim1, B. Yoo1. 1Rheumatology, Asan medical center, Seoul; 2Rheumatology, Ulsan University Hospital, Ulsan; 3Rheumatology, Seoul Veterans Hospital, Seoul, Korea, Republic Of

Background: In rare cases, Behcet’s disease (BD) can cause severe aortic regurgitation (AR) or aortic root destruction that might have lethal outcomes. Conventionally, simple aortic valve replacement (AVR) is performed for the management of severe AR in BD patients; however, the reoperation rate is as high as 78 to 100%, while mortality rate range from 20 to 47%. Recently, several series of case reports showed that compared to AVR, aortic root replacement (ARR) improved the surgical outcomes of AR in BD patients.

Objectives: To identify the factors associated with the long-term surgical outcomes of AR in BD patients.

Methods: We identified 23 patients who had been surgically treated for AR caused by aortic root involvement of BD from January 1996 through December 2013. We evaluated the occurrence of post-surgical adverse events, which were defined as follows: death, aortic valve/graft problem, infective endocarditis, cerebral infarction, and/or re-operation of aortic valve or root. Types of surgery were classified as simple aortic valve replacement (AVR), bioprosthesis aortic root replacement (ARR), and mechanical valve composite graft aortic root replacement (cARR). Clinical parameters including baseline characteristics, C-reactive protein (CRP), erythrocyte sedimentation rate, and medications were extracted from electronic medical records.

Results: Appropriate aortic valve or root surgery cases were 35 in total, with a mean follow up duration of 11±5 years in 23 patients. Out of the 11 cases

Elevated levels of 10 mediators were significantly higher in patients with vascular involvement (Table 1). AR involvement was detected in 52 (28.9%) of 176 patients with vascular involvement. Deep venous thrombosis alone was present in 125 (71%) patients, arterial involvement alone in 12 (6.8%) patients, arterial and venous involvement together detected in 40 (22.7%) patients. Arterial involvement was most commonly seen as pulmonary artery involvement in 45 (25.6%) patients (pulmonary artery thrombosis 35 (20%), aneurysm 10 (7.7%) and thrombosis + aneurysm 6 (3.4%) patients). Twenty (11.3%) patients had other arterial involvement except pulmonary, 8 of them had thrombosis and 12 had aneurysm.

Conclusions: Vascular involvement in Behcet’s disease is commonly seen in males. Deep vein thrombosis is the most common form of vascular involvement. Arterial involvement is important because of its higher risk of mortality (especially pulmonary artery aneurysm). The incidence of EN and uveitis is higher in patients with vascular involvement.

FRI0315 CLINICAL CHARACTERISTICS OF VASCULAR INVOLVEMENT IN BEHÇET’S DISEASE
A. Ates1, M. Torgutalp1, E. Okatan2, E. Uslu2, B. Dinçer2, E. Y ayla2, M. Turgay1. 1Rheumatology, Antakya Training and Research Hospital, Turkey; 2Rheumatology, Ankara University School of Medicine, Ankara, Turkey

Background: Behcet’s disease (BD) is a multisystem inflammatory disorder classified as vasculitis, which can affect all types of vessels. The prevalence of vascular involvement has been reported at rates ranging from 15 to 50%.

Objectives: In this study, we aimed to determine the characteristics of vascular involvement in patients with BD.

Methods: Six hundred and ninety-two patients with BD, who applied to the multidisciplinary BD polyclinics from 2006–2016, were retrospectively analyzed. The diagnosis of vascular involvement was made on clinical signs, by Doppler ultrasonography and/or angiography using computed tomographic or magnetic resonance techniques where appropriate.

Results: One hundred and seventy-six patients (64.4%) had vascular involvement. The mean age of patients with vascular involvement (n=176) and non-vascular involvement (n=516) was similar to 42±13.2 and 42±12.2 years, respectively, while male sex frequency was significantly higher in patients with vascular involvement (72% vs 42%, p<0.001). Uveitis (45%) and erythema nodosum (EN) (47.7%) were significantly higher in patients with vascular involvement than those without vascular involvement (for Uveitis OR: 1.7, p=0.003/for EN: OR: 2.5, p<0.001) (Table 1).

DOI: 10.1136/annrheumdis-2017-eular.5672
that underwent AVR, post-surgical events were observed in 8 (73%) cases. Out of the 12 BARR cases ( xenograft in 5 cases and homograft in 7 cases), 9 (75%) cases had post-surgical adverse events. Out of the 12 cARR cases, post-surgical adverse events occurred in 4 (33%) cases. Multivariable Cox proportional hazards model indicated that levels of CRP at 1 month after discharge and age at admission were independent prognostic factors associated with event-free probability. Notably, performing cARR was the most significant factor that affected the surgical outcome (HR [95% CI] 0.147 [0.028 – 0.766], p=0.023).

Conclusions: In BD patients with severe AR, the occurrence rate of post-surgical adverse events was associated with the levels of CRP at 1 month after discharge, age at operation, and type of surgery. cARR may be a better surgical option in BD patients with aortic root involvement

FR10317 | HUMORAL AND CELLULAR IMMUNITY TO VARICELLA-ZOSTER VIRUS IN GIANT CELL ARTERITIS PATIENTS: NO EVIDENCE OF VIRAL REACTIVATION AT ONSET OF DISEASE
C. Rondaan, K. van der Geest, E. Eelsing, N. Bos, J. Westra, E. Brouwer. Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen, Netherlands

Background: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are strongly overlapping diseases that are thought to have a shared etiology [1]. The observation of varicella-zoster virus (VZV) antigen in temporal artery biopsies of GCA patients led to the hypothesis that VZV might be a trigger for the onset of the disease [2]. Herpes zoster occurs when the latently present VZV reactivates. It has been reported that patients with GCA do not appear to be at increased risk of herpes zoster compared with age and sex matched controls, even during treatment with high dose glucocorticoids [3]. Levels of VZV specific immunoglobulin G (VZV-IgG) are known to only slowly decline again after a reactivation [4]. We therefore hypothesized, in line with the proposed etiologic role, to find higher VZV-IgG levels in GCA and PMR patients at disease onset, compared to healthy controls. Furthermore, we expected to find no differences in cell-mediated immunity to the virus between patients and controls assuming that the incidence of herpes zoster is not increased in GCA.

Objectives: To investigate humoral and cellular immunity to VZV in GCA and PMR patients and compare these to results in age-and sex matched healthy controls.

Methods: Antibody responses to VZV glycoprotein were measured in serum samples of 35 GCA patients and 26 PMR patients at baseline (before glucocorticoid treatment) and during follow up, and in 58 healthy controls by an enzyme-linked immunosorbent assay (ELISA). Cell-mediated immunity to VZV was determined by performing interferon-γ (IFNγ) enzyme-linked immunosorbent spot (ELISPOT) and intracellular cytokine flow cytometry measurements in 11 GCA patients and 15 PMR patients, and in 26 age and sex matched healthy controls.

Results: Similar levels of VZV-IgG were found in GCA and PMR patients at baseline, and healthy controls. The number of VZV specific IFNγ spot-forming cells was significantly lower in GCA patients than in healthy controls (p<0.02), but not different in PMR patients compared to healthy controls.

Conclusions: Since antibody levels at baseline were not different in GCA and PMR patients compared to healthy controls it seems unlikely that VZV has an important role in the aetiology of GCA or PMR. The finding of a decreased cell-mediated immunity in GCA patients, especially after treatment with high dose corticosteroids may indicate an increased risk of developing herpes zoster.

**FR0319** PREDICTORS OF COMPLETE REMISSION IN POLYMYALGIA RHEUMATICA

D. Birra, A. Zoli, G. Peluso, S.L. Bosello, E. Gremese, G. Ferraccioli. Dipartimento di Reumatologia e Scienze Affini, Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy

**Background:** Polymyalgia rheumatica (PMR) is an inflammatory rheumatologic condition characterized by aching and morning stiffness in the shoulders, hip girdle, and neck that typically occurs in adults over the age of 50. A rapid resolution of symptoms with low-dose glucocorticoids is a feature of PMR although some patients may experience a disease flare-up during steroid tapering.

**Objectives:** The aim of the study was to investigate possible clinical or laboratory prognostic factors of remission during a 12 month follow up in PMR patients treated with a starting low prednisone dose following the 2015 ACR-EULAR guidelines.[1]

**Methods:** From 86 consecutive outpatients, diagnosed with PMR following ACR/EULAR 2012 provisional clinical criteria for PMR,[2] 79 patients (56 women and 23 men), that achieved a complete follow up of at least 12 months, were selected. Clinical evaluation and laboratory tests were performed every 3 months. Clinical remission was defined as lack of shoulder and hip girdle pain and as levels of ESR ≤ 40 mm/h and CRP ≤ 0.5 mg/dl.

**Results:** 37 PMR patients reached a complete remission after twelve months follow-up. We didn’t find any significant difference in the mean age and in ESR and CRP values at the beginning of the disease in patients in remission after 12 month of follow up when compared with patients not in remission. Presence of obesity, dyslipidemia, hypertension, diabetes and smoking habits were not significantly different in the two groups of patients. No significant difference in steroid therapy at the beginning and after 6 month of follow up was noted between the two groups of patients. No significant difference in the mean age and in ESR and CRP levels of ESR [33.9% versus 78.2%, p=0.000] Moreover it was shown that the patients achieving clinical remission at the 12 month follow up had statistically significantly higher CRP values, instead of ESR ones, when compared with male complete clinical remission patients. A statistically significant female low clinical remission was seen at the end of 12 month follow up when compared with patients not in remission.

**Conclusions:** The sixth month of therapy is a crucial target for the management of PMR, because it can help to identify patients at greater risk of exacerbations, which may benefit from a tighter follow up and a more aggressive therapeutic strategy. Among prognostic factors female sex and high CRP values at sixth months appear to be associated with higher relapse risk and a longer duration of treatment.

**FR0320** PREDICTIVE VALUE OF PLATELET TO LYMPHOCYTE RATIO IN RENAL INVOLVEMENT IN PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS

H. Kucuk 1, D. Tecer 1, O. Varan 2, H. Babaoglu 1, S.C. Guven 2, A. Tufan 1, S. Haznedaroglu 1, M.A. Ozturk 1, B. Goker 1. 1Department of Internal Medicine, Division of Rheumatology; 2Department of Physical and Rehabilitation Medicine, Division of Rheumatology, Gazı University Faculty of Medicine, Ankara, Turkey

**Background:** Granulomatosis with polyangiitis (GPA) is a granulomatous necrotizing vasculitis with high morbidity and mortality. Anti-neutrophil cytoplasmic antibody (ANCA) is a valuable diagnostic marker, however its titer lacks predictive value for the severity of organ involvement. Platelet to lymphocyte ratio (PLR) and mean platelet volume has been regarded as a potential marker in assessing systemic inflammation.

**Objectives:** We aimed to investigate PLR and MPV as inflammatory marker in patients with GPA.

**Methods:** GPA patients and age-sex matched healthy controls were included. Demographic, clinical and laboratory information were extracted from medical records. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), white blood cell (WBC), platelets (PLT), lymphocyte and neutrophils counts and mean platelet volume were analyzed. Disease activity was assessed with Birmingham Vasculitis Activity Score for WG vasculitis (BVAS/WG).

**Results:** 56 patients with GPA and 53 healty controls were included. Clinical characteristics and laboratory findings of the study population are shown in Table 1. ESR, CRP, MPV and PLR were significantly higher in patients with GPA than controls. PLR positively correlated with ESR and CRP (r=0.389, p<0.005 and r=0.512 p<0.001 respectively). In contrast, MPV negatively correlated with ESR and CRP (r=-0.308, p=0.028 and r=-0.337 p=0.014 respectively). There were no significant correlation between PLR, MPV and BVAS/WG. Patients with renal involvement had statistically significantly higher PLR than patients without renal involvement (303.01±287.33 vs 177.98 + 75.43, p: 0.020 respectively). Moreover PLR negatively correlated with glomerular filtration rate (r=-0.266 and p:0.009, n=0.389). Receiver operating characteristic curve of PLR, ESR and CRP for differentiating renal involvement is presented in Figure 1. Area Under Curves (AUCs) for PLR, ESR and CRP were 0.703 (95% confidence interval [CI], 0.558–0.849, p=0.016), 0.577 (95% CI: 0.416–0.738, p=0.382), 0.508 (95% CI: 0.337–0.678, p=0.929), respectively. The cutoff level of PLR was 204 (sensitive 65.6%, specifity 62.5%, positive predictive value 70%, negative predictive value 57.7%). Patients with alveolar hemorrhage tended to have higher PLR but this difference did not reach statistically significance (266.60 + 182.90 vs 240.61 + 252.43 p=0.382, respectively).

**Conclusions:** Results suggest that PLR exhibit favorable diagnostic performance in predicting renal involvement in patients with GPA.

Circulating IL-6 and Other Metabolic Biomarkers as Assessment of Damage and Prognosis in Patients Comparing Biopsy Proven Giant Cell Arteritis in

E. Miller, S. Maplebeck, C. Mackerness, L. Wilson, T. Aung, D. Gayford, J.P. Schofield, D. Dasgupta, S. Southend University Hospital NHS Foundation Trust, Westcliff-on-Sea; Napp Pharmaceuticals Limited, Cambridge Science Park, Milton Road, United Kingdom

Background: GCA may be an interleukin-6 (IL-6) driven disease and IL-6 blockade is emerging as an exciting therapy of IL-6. We measured serial IL-6 levels in new patients with GCA treated in an RCT of modified-release prednisone (MR) versus immediate-release prednisolone (IR) used in a tapering regimen conforming to BSR guidelines.

Methods: Patients (n=12) were randomised into two treatment arms (7 MR, 5 IR) and followed up over 26 weeks. IL-6 samples were collected at 09h at weeks 4, 10, 18 and 26 and were measured using Beckman Coulter IL-6 immunoassay, validated in a controlled study according to ACB criteria. We also measured bone markers (CTX, P1NP, vitamin D), HaB1c, cortisol, ACTH and PTH.

Results: Significantly higher overall mean IL-6 levels were seen in the IR arm (n=5) compared to MR (n=7) [unpaired two-tailed Student’s t test]. IL-6 levels in both arms were lowest between weeks 4–10 and continued to decrease in the IR arm to week 26, whereas lower but constant levels were seen in the MR arm (Figure).

Mean CTX concentration was significantly higher at week 4 (M =0.29, SE =0.04) compared to Week 26 (M =0.13, SE =0.02) p=0.002. No significant difference was seen between treatment arms.

Patients on MR had complete suppression of ACTH compared to IR (p<0.05) without a significant difference between groups in 9am cortisol levels (p=0.3412).

Conclusions: Our study suggests that elevated levels of IL-6 are better suppressed by MR prednisone therapy compared to IR prednisolone in new GCA. Bone resorption marker CTX was significantly reduced in both treatment arms. ACTH suppression with MR prednisone may reflect a greater impact on the HPA axis although cortisol levels were not affected.

Our findings suggest that MR prednisone may warrant further clinical trial investigation in GCA.

Assessment of Damage and Prognosis in Patients with Adult IGA Vasculitis: Retrospective Multicentered Cohort Study

F. Alibaz-Onler, A. Omma, A. Sari, O. Karadag, D. Uskudar Cansu, C. Bes, F. Yildiz, M.F. Öksüz, S. Yilmaz, A. Balkiri, S. Ureyen, H. Direskeneli, I. Rheumatology, Marmara University, School of Medicine, Istanbul; I. Rheumatology, Ankara Numune Education and Research Hospital; I. Rheumatology, Hacettepe University, School of Medicine, Ankara; I. Rheumatology, Osmangazi University, School of Medicine, Eskisehir; I. Rheumatology, Bakirkoy Sadi Konuk Education and Research Hospital, Istanbul; I. Rheumatology, Van Education and Research Hospital, Van; I. Rheumatology, Uludag University, School of Medicine, Bursa; I. Rheumatology, Selcuk University, School of Medicine, Konya; I. Rheumatology, Antalya Education and Research Hospital, Antalya; I. Rheumatology, Sakarya Education and Research Hospital, Sakarya, Turkey

Background: IGA Vasculitis is a leukocytoclastic vasculitis involving small vessels with depositions of immune complexes containing IgA. There is limited data for the prognosis of adult IGA Vasculitis, with also no damage assessment.

Objectives: We aimed to evaluate the clinical characteristics, treatment, outcome and damage of patients with adult IGA Vasculitis.

Methods: We assembled a retrospective cohort of patients with adult IGA Vasculitis, from tertiary Rheumatology Centers in Turkey. All data were abstracted from medical records. Birmingham Vasculitis Activity Score (BVAS),prognostic Five Factor Score (FFS) and vasculitis damage index (VDI) were calculated.

Results: The study included 52 (male/female:40/12) patients with adult IGA Vasculitis. The mean age was 42.2±17 years. Infection history within 6 weeks before presentation was present in 22 (42.3%) patients (18 upper respiratory tract, 3 gastrointestinal and 1 urinary tract). Cutaneous manifestations were the most common clinical manifestations (Table 1). All patients were treated with oral glucocorticoids (GC). As additional immunosuppressive agents, azathioprine was given to 21 (40.4%) and pulse cyclophosphamide to 11 (21.2%) patients. Twenty-eight patients (53.9%) had follow-up of 28.6 months. Five (17.8%) patients relapsed during follow-up. While 3 relapses were major, 2 of them were minor relapses. At the last visit, disease status was evaluated as active or treatment failure by the treating physician in 6 (21.4%) patients. Mortality was 3.6% (n=1) during follow-up, due to pneumonia. The mean VDI score was 0.6 in the last visit. Nine (32.1%) patients had at least one damage item at the end of follow-up period.

Conclusions: Our results showed that approximately one fifth of patients with adult IGA Vasculitis had relapses during follow-up. At the end of follow-up, one third of patients had at least one damage item. Although, 45% of patients had FFS=1, the mortality rate was observed to be low in the present study.

Comparison of Biopsy Proven Giant Cell Arteritis in North America and Southern Europe: A Population-Based Study

F. Muratore, C.S. Crowson, L. Boiard, J.M. Koster, G. Restuccia, T.A. Kermani, E.L. Matteson, C. Salvarani, K.J. Warrington, R. Rheumatology Unit, Arcispedale Santa Maria Nuova IRCCS, Reggio Emilia, Italy; Division of Rheumatology, Mayo Clinic, Rochester, MN; Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles, United States

Objectives: To compare clinical characteristics, treatment, long-term follow-up and prognosis of two population-based cohorts of patients with biopsy-proven giant cell arteritis (GCA) from Olmsted County, Minnesota, USA (Olmsted cohort) and the Reggio Emilia area, Northern Italy (Reggio cohort).

Methods: All patients residing in Olmsted County and the Reggio Emilia area

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.8458
with a new diagnosis of biopsy-proven GCA in 1986–2007 were retrospectively identified. Patients were followed from GCA diagnosis to death, migration or September 2011. Comparisons were performed using Chi-square and rank sum tests, Kaplan-Meier methods and Cox models.

**Results:** The study included 110 patients in the Olmsted and 144 in the Reggio cohort. Compared with the Olmsted cohort, patients from the Reggio cohort were younger (mean±SD age 74.6±7.4 years vs 77.8±7.6, p=0.002), more likely to have cranial symptoms (93% vs 86%, p=0.048), temporal artery abnormalities at physical examination (68% vs 42%, p<0.001), partial or complete unilateral or bilateral permanent vision loss (21% vs 6%, p=0.001), systemic symptoms (87% vs 46%, p=0.001) and polymyalgia rheumatica at or before GCA diagnosis (47% vs 26%, p<0.001). Scalp tenderness was less common in the Reggio cohort (36% vs 49%, p=0.033). ESR and CRP were higher (mean 88±22 mm/h vs 73±77, p=0.001 and mean 89±60.2 mg/L vs 35±24.3, p=0.001 respectively) and gait was more likely lower (mean 11.2±1.4 g vs 11.8±1.4, p=0.004) in Reggio than in the Olmsted cohort. Patients from the Olmsted cohort received a higher initial prednisone dose (mean 53.6±15.3 mg/day vs 49.5±12.8, p=0.001). There were no differences in relapse rates, cumulative glucocorticoid (GC) dosages at 1, 2 and 5 years, and time to first GC discontinuation. However, the Reggio cohort reached a prednisone dose <10 mg/day sooner (median 4.9 months vs 7.9, p=0.012) and had a first relapse later (median 13.6 months vs 7.9, p=0.003) than the Olmsted cohort. Patients from the Reggio cohort had a significantly higher mortality compared to those from the Olmsted cohort (HR 1.72, 95% CI 1.12–2.65 for age and sex).

**Conclusions:** Genetic and/or environmental factors may contribute to the differences in clinical characteristics and disease outcomes observed in this study comparing patients with GCA from North America and Southern Europe.

**SMALL VESSEL VASCULITIS SURROUNDING A PRESERVED TEMPORAL ARTERY: A DIAGNOSTIC ALGORITHM TO ASSESS CLINICAL SIGNIFICANCE**

**Hospital Clinic of Barcelona, Barcelona, Spain; 2Medicine Department, Hospital de Santa Maria, Lisboa, Portugal; 3Institut d’Investigacions Biomèdiques Pi i Sunyer (IDIBAPS), CELLEX, Barcelona, Spain; 4Hospital Clinic of Barcelona, Barcelona, Spain; 5Department of Internal Medicine, Hospital Clinic of Barcelona, Barcelona, Spain**

**Background:** Systemic vasculitides are complex and heterogeneous diseases, with overlapping features that frequently pose a diagnostic challenge to clinicians. The temporal artery biopsy (TAB) is the gold standard for the diagnosis of giant cell arteritis (GCA) but, occasionally, TAB show inflammation of small vessels surrounding a spared temporal artery (SVV) as the only pathologic finding. Ultimate diagnosis and, consequently, optimal treatment remain uncertain in these patients.

**Objectives:** To analyze the final diagnosis of patients with SVV surrounding a spared temporal artery after a pre-established diagnostic algorithm and to identify clinical and laboratory findings with potential usefulness in predicting the ultimate diagnosis.

**Methods:** Patients with TAB showing SVV were subjected to the diagnostic algorithm displayed in figure 1, completed by at least 1 year follow-up. Clinical and laboratory features at the time of diagnosis were recorded. The algorithm led to the following final diagnosis: GCA, other systemic vasculitides and undetermined condition. Chi-square and/or X2-squared and/or ANOVA tests were used for statistical comparison using IBM SPSS Statistics 20.

**Results:** From 1998 to 2007, 380 TAB were performed in our institution. Biopsy disclosing small vessel inflammation surrounding a normal temporal artery (SVV) was described in 47 (12%) patients. In all patients TAB was selected as the first invasive procedure because GCA was initially considered the most likely diagnosis. Accordingly, 24 (51%) fulfilled at least 3 ACR classification criteria for GCA. 7 patients declined to undergo subsequent work-up to complete the diagnostic algorithm, 10 died or were lost to follow-up before completing 1 year follow-up. The study cohort consisted of 30 patients (19 women and 11 men) aged 77±10.4 years followed for 55.16±55.20 months. In 13 patients the final diagnosis was consistent with GCA based on the absence of SVV in other territories, large-vessel inflammation by imaging or subsequent development of aortic aneurysm; in 12 SVV was subsequently demonstrated in other territories and were diagnosed with other systemic vasculitis (7 AAV, 0 cryo, 3 PAN, 0 vasculitis associated to autoimmune diseases, 2 unclassified small vessel vasculitis), and in 5, diagnosis remained undetermined. No significant differences in clinical or routine laboratory abnormalities were found among patient subgroups stratifying according to the final diagnosis.

**Conclusions:** Inflammation of small vessels surrounding a spared temporal artery in a TAB conveys a substantial diagnostic uncertainty. After a detailed diagnostic work-up most of patients can be diagnosed with GCA. However other systemic vasculitides requiring more aggressive treatment may disclose similar histopathologic findings and are therefore frequent diagnosis remaining undetermined in a substantial proportion of cases. Search for more accurate molecular biomarkers is necessary for a better interpretation of these findings.

**PREVALENCE OF TAKAYASU ARTERITIS IN YOUNG WOMEN WITH ACUTE ISCHEMIC HEART DISEASE**

G. Cavalli, A. Tomelleri, E. Baldissera, L. Dagna. Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UniRAR), Vita-Salute San Raffaele University, Milan, Italy

**Background:** Takayasu arteritis (TA), a systemic vasculitis typically occurring in female patients aged <40, can affect the coronary arteries and cause ischemic heart disease. The prevalence of TA among young females with acute ischemic heart disease is undetermined.

**Objectives:** In this study, we investigated the prevalence of TA in young women presenting with ischemic heart disease in the Emergency Department.

**Methods:** We conducted a retrospective evaluation of the hospital records of 172,790 consecutive female patients aged <45, who accessed the Emergency Department of our institution over 8 consecutive years (2007–2015). The prevalence of TA and of other etiologies of ischemic heart disease was determined. Diagnosis of TA was established based on the 1990 American College of Rheumatology criteria.

**Results:** Overall, 2,090 women aged <45 presented to the Emergency Department with chest pain, dyspnea, palpitations, angina, heart failure, or cardiac arrest; 40 had confirmed acute ischemic heart disease. The etiology was "classic" atherosclerosis in 24 cases (60%), TA in 4 cases (10%), vasospasm and sympathomimetic drug abuse in 3 cases each (7.5%), coronary artery dissection and microvascular angina in 2 cases each (5%), Takotsubo and radiation-induced cardiomyopathy in 1 case each (2.5%).

**Conclusions:** Although a diagnosis of TA is likely to be overlooked, TA is not infrequent in younger females presenting with acute ischemic heart disease. Specifically, TA accounted for 10% of cases of acute ischemic heart disease in female patients aged <45, a finding relevant to the diagnosis and management of these young patients.

**RECOMMENDATIONS FOR THE MANAGEMENT OF NEURO-BEHÇET DISEASE BY JAPANESE RESEARCH COMMITTEE FOR BEHÇET DISEASE**

1Department of Internal Medicine, Teikyo University School of Medicine; 2Department of Internal Medicine 3, Tokyo Medical University School of Medicine; 3Immunology-Rheumatology Center, St. Luke’s International Hospital; 4Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo; 5Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, Yokohama, Japan; 6Department of Neurology, Niigata University Medical and Dental Hospital, Niigata; 7Department of Neurology, Osaka University Graduate School of Medicine; 8Department of Neurology, Keio University School of Medicine, Osaka; 9Department of Rheumatology and Infectious Diseases, Kishida University School of Medicine, Kanagawa, Japan

**Background:** Central nervous system involvement is one of the most serious complications in Behçet’s disease (BD). This condition is referred to as neuro-
Behçet’s disease (NB) and can be classified into acute type (ANB) and chronic progressive type (CPNB) based upon differences in the clinical course and responses to corticosteroid treatment. Diagnostic criteria were generated in 2013 based on a multicenter clinical survey performed by the Behçet’s Disease Research Committee of the Ministry of Health, Labor and Welfare of the Japanese Government. Although “Guidelines for Treatment of NB” was also proposed based on the survey, it is still preliminary.

Objectives: The aim of the current study is to develop evidence-based recommendations for the management of NB supplemented by expert opinions where necessary.

Methods: First, clinical questions (CQs) on NB were extracted from a literature search for problem areas and related keywords, and draft CQs and a flow chart were prepared. The expert committee, a task force of the research subcommittee for NB, consisted of 7 board-certified rheumatologists (one was also a board-certified neurologist) and 3 board-certified neurologists. A systematic literature search was performed using Medline and the Japanese Medical Abstract Society databases from 1997 to 2016. A total of 15 initial CQs were generated. These yielded the final recommendations developed from 3 blind Delphi rounds, in which the rate of agreement scores on CQs (range 1 [disagree]–5 [strongly agree]) was determined through voting by the whole committee.

Results: Thirteen recommendations were developed for the management of NB (general 1, ANB 7, CPNB 5). The strength of each recommendation was established based on the evidence level as well as rate of agreement. There was excellent concordance between the level of agreement of rheumatologists and that of neurologists. Based on these recommendations, a flow chart was established for the management of ANB and CPNB (Figure).

Conclusions: The recommendations generated in this study are mainly based not only on expert opinions but on the results of uncontrolled evidence from open trials and retrospective cohort studies. Guidelines that can be used for international studies are needed, for which verification by further properly designed controlled clinical trials is required.

GASTROSCOPIC FEATURES AND CLINICAL CHARACTERISTICS IN 172 CASES OF CHILDREN WITH HENOCH-SCHONLEINPURPURA

H. Zeng. Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children’s Medical Center, Guangzhou, China

Objectives: To investigate gastroscopic features and explore the relationship between clinical characteristics in children with Henoch-Schönlein purpura (HSP).

Methods: To take gastroscope in 172 cases of children with HSP in our hospital and summarize the gastroscopic performance. All the case were divided into two groups by gastroduodenal mucosal bleeding or not. It was compared among the total time of abdominal pain, pain relief, hospitalization, fasting and kidney injury case in the groups.

Results: Gastroscope with varying degrees of injury of 172 cases has accounted for 169 cases (98.3%). Gastroscopic manifestations include gastroduodenal mucosal congestion, edema, rough, erosion, bleeding and ulcer, which involved 148 cases of gastric (86.0%), 158 cases of duodenal involvement (91.9%). Mucosal erosion and bleeding occurs mainly in duodenum, mostly in the descending duodenum. Duodenal bleeding accounted for 36 cases (21.8%) in the bulb and 92 cases (55.8%) in the descendant. Only five cases (2.9%) of duodenum occurred in the duodenum, where four cases of bulb ulcer, one case of descending ulcer. Esophageal and gastric cardia mucosal just occurred in one case. There were not significant difference (P>0.05) among the time of abdominal pain, pain relief, hospitalization and fasting in the group. There was no significant difference (P>0.05) in the incidence of kidney injury between two groups of children during hospitalization.

Conclusions: Gastroscopic features of HSP in children is characterized by bleeding, erosion of duodenal mucosa and occasional duodenal ulcer formation, which mostly involve the antral mucosa, rarely involving the esophagus, cardia. There was no significant difference (P>0.05) among the severity of gastroscopic performance and the time of abdominal pain, fasting, hospitalization and kidney injury of the cases during hospitalization.

THE DIAGNOSTIC VALUE OF ALPHA-1-ANTITRYPSIN PHENOTYPE IN SYSTEMIC VASCULITIS

I. Belyaeva1, A. Chudinov2, M. Pervakova3, V. Mazurov1, S. Lapin2, O. Inamova2. 1North-West State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russia; 2Clinical Rheumatological Hospital no. 25, Saint-Petersburg, Russia; 3First Pavlov State Medical University of St. Petersburg, Saint-Petersburg, Russian Federation

Background: Deficiency of alpha-1 protease inhibitor, or alpha-1-antitrypsin (A1AT) is a frequent genetic disorder, which is characterized by low serum level of A1AT and usually manifests as pulmonary emphysema and liver disease. Also the deficiency of A1AT is known to be associated with granulomatosis with polyangiitis (GPA). The influence of A1AT deficiency on GPA clinical course is not clarified.

Objectives: The aim of this study was to estimate the prevalence of pathological A1AT phenotypes in GPA and other systemic vasculitides and to define the influence of A1AT phenotype on clinical course of GPA.

Methods: We enrolled 86 patients with systemic vasculitides, including GPA (N=47), microscopic polyangiitis (MPA, N=16), eosinophilic granulomatosis with polyangiitis (EGPA, N=12), polyarteritisnodosa (PN, N=11). 46 healthy donors were included in the control group. All blood samples underwent A1AT phenotyping by isoelectrofocusing (IEF) and turbidimetric A1AT measurement. The results of phenotyping were compared to clinical data, such as BVAS activity rate (Birmingham Vasculitis Activity Score), VDI index (vasculitis damage index), organs involvement, inflammatory markers, including antineutrophil cytoplasmic antibodies (ANCA), total IgG concentration and serum levels of C3, C4 complement factors.

Results: Pathological A1AT phenotypes were found in 17% (8/47) of GPA patients, 6.25% (1/16) of MPA patients, 2% (1/46) of healthy donors and were never found in EGPA, PN. The abnormal phenotypes in GPA were ZP2Z, 4P4M, 2P2M, 1P2MS, and 1P1MS phenotype was identified in MPA patient. Levels of lung and upper respiratory tract was observed in all patients with pathological phenotypes A1AT (N=4), while in normal phenotype A1AT it was present in 72% and 82% respectively. The mean concentration of A1AT was significantly lower in GPA patients with abnormal A1AT phenotypes, than in patients with normal phenotype A1AT (respectively 100±148.8 and 196±127.9 mg/L, p<0.01). The average activity index by BVAS index in GPA was significantly higher in patients with pathological phenotype A1AT than in patients with normal phenotype A1AT (24.6±2.897 and 18.5±1.44 points, p<0.05). Also we revealed excess levels of VDI in cohort of patients with abnormal phenotypes A1AT, rather than in cohort of patients with normal phenotype A1AT (6.3±3.1 versus 5.4±2.6, p<0.05). The average values concentration of antibodies to proteinase-3 in GPA patients with pathological phenotype A1AT were significantly higher compared to GPA patients with normal phenotype A1AT (11.1±3.4 and 2.3±1.1 (p<0.05)) respectively. In GPA patients with mutated A1AT phenotypes levels of serum creatinine (<0.05), levels of total IgG concentration and serum levels of C3 and C4 complement factors (<0.05) also were significantly higher than in group of GPA patients with normal A1AT phenotype.

Conclusions: Pathological A1AT phenotypes are more often observed in GPA patients who have more severe GPA clinical course and higher immunological disease activity.

EFFICACY AND SAFETY OF INFlixIMAB ORIGINATOR IN PATIENTS WITH TAKAYASU ARTERITIS WITHIN THE RTU (TEMPORARY RECOMMENDATION OF USE) IN FRANCE

J.-F. Kleinmann 1, L. Arnaud 1, E. Sauleau 2, N. Gouyette 3, R. Tajima 4, L. Silibia 1 on behalf of CRI (Club Rhumatismes et Inflammation), 1Rheumatology, 2Public Health, Strasbourg’s University Hospital, Strasbourg; 3MSD France, Courbevoie, France

Background: The benefit/risk ratio of infliximab in refractory patient with Takayasu arteritis (TA) is assumed to be favorable, based on retrospective studies with limited sample size [1, 2] in which infliximab has been prescribed off-label. Since 2013, the French Temporary Recommendation of Use (RTU) provides a temporary framework allowing the use of infliximab originator in “TA patients refractory to conventional treatment” during a 3-year period.

Objectives: The aim of the study was to evaluate the real-life efficacy and safety of infliximab originator in TA patients initiating or with ongoing infliximab treatment.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.4412
**Methods:** Prospective, multicenter, observational, open-label, study of TA patients treated with infliximab originator.

**Results:** As of 2016 (2 years of follow-up), the study included 14 patients (13/14 were female; median age 32 [range 12–56] years) with TA (diagnosis according to Ishikawa criteria). At study entry, the median TA duration was 4.7 (0.4–16) years, 11 patients had pathergy and 1 patient had pseudofolliculitis. 9 had uveitis, 9 had erythema nodosum, 12 had arthritic involvement, 5 patients had gastrointestinal involvement, 4 had pathergia, 1 had orchitis and 1 had gastrointestinal involvement. Thirtwoy seven had BVAS ≥ 1. As shown in Table 1, both the HADS-depression (HADS-D) (4.7 vs 2.5) and HADS-anxiety (HADS-A) (8.3 vs 5.7) scores were elevated in BD patients compared to healthy controls. FACIT-F was higher in healthy controls in comparison with BD group (44.1 vs 36.6), revealing lower levels of fatigue. There were no differences between gender on these scores.

**Conclusions:** In our study, fatigue and increased levels of anxiety and depression were more common in BD patients. Contrary to the study of Ilhan et al., we found that fatigue was not higher in patients with active disease. Similarly, there were no correlation between the assessed scores and gender. In spite of these results, the authors believe that controlling the symptoms may improve the quality of life in BD patients.

**FR0331 | IDENTIFICATION AND VALIDATION OF POTENTIAL METABOLOMIC BIOMARKERS FOR RELIABLE DIAGNOSIS OF BEHÇET’S DISEASE USING GAS CHROMATOGRAPHY WITH TIME-OF-FLIGHT MASS SPECTROMETRY**

J. K. Ahn 1, J. Hwang 2, H.-S. Cha 3, E.-M. Koh 2. 1: Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine; 2: Department of Internal Medicine, National Police Hospital; 3: Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of

**Background:** Although many diagnostic criteria have been developed and revised by experts in the field, diagnosing Behcet’s disease (BD) is still complicated and challenging. Metabolomic studies can lead to a better understanding of pathophysiological processes and may uncover new diagnostic markers for classification of disease subgroups and assessment of disease activity in rheumatic diseases. No metabolomic studies on serum have been attempted to improve the diagnosis and to identify potential biomarkers of BD.

**Objectives:** The purpose of this study was to investigate distinctive metabolic changes in serum samples of BD patients and to identify metabolite candidate biomarkers for reliable diagnosis of BD using the metabolomics platform.

**Methods:** Metabolomic profiling of 90 serum samples from 45 BD patients and 45 healthy controls (HC) was performed via gas chromatography with time-of-flight mass spectrometry (GC/TOF-MS) with multivariate statistical analyses. Thirty-five patients with BD and age- and sex-matched 35 HCs were randomly selected to form the discovery set, and the validation set is composed of 10 patients with BD and 10 HCs.

**Results:** We identified a total of 104 metabolites in the serum samples of the discovery set. To maximise the discrimination between groups BD and HCs, we applied supervised partial least squared-discrimination analysis (PLS-DA). A PLS-DA score plot of the discovery set indicated that the cluster of BD patients is well separated from HC clusters in component 1. The variation values of the PLS-DA model were R² = 0.246, Q² = 0.852, indicating strong explanation and prediction capabilities of the PLS-DA model. The PLS-DA models did not show clear and consistent discrimination between groups according to drug administration, indicating that drugs used in patients with BD had a negligible effect on the distinct metabolic profiles discriminating BD patients from HCs. A panel of five metabolic biomarkers, namely, decanoic acid, fructose, tagatose, linoleic acid, and oleic acid were selected based on their variable importance on projection values and adequately validated as putative biomarkers of BD (sensitivity 100%, specificity 97.1%, area under the curve 0.993) in the discovery set and validation set. Principal component analysis showed clear discrimination of BD and HC groups by the five metabolite biomarkers in the validation set.

**Conclusions:** This is the first report on detection of a characteristic metabolic profile of BD and identifying and validating potential metabolite biomarkers in BD.
The topical corticosteroid therapy was prescribed in 27, 14% of cases, oral in 47, 51% and bolus in 28, 41%. 47, 51% of patients received Cyclophosphamide and 19% received Azathioprine. Cyclosporine was administered in 3 cases, interferon and Infliximab in 2 cases each. The evolution was good in 111 cases (50.22%), treatment failure was noted in 24% of cases and recidivism in 16.74% of cases. 63 patients have evolved into blindness which was bilateral in 51.1% of cases.

**Conclusions:** Only early diagnosis and appropriate management can improve the prognosis of ocular involvement in BD.

**Disclosure of Interest:** None declared

**DIFFERENCES BETWEEN TEMPORAL ARtery**

**BIOPSY-POSITIVE AND BIOPSY-NEGATIVE GIANT CELL ARTERITIS: A COMPARATIVE COHORT STUDY**

K. Yeruva, K.J. Warrington, C.S. Crowson, M.J. Koster. Rheumatology, Mayo Clinic, Rochester, United States

**Background:** Giant cell arteritis (GCA) is the most common systemic vasculitis in patients aged 50 years or older. The presence of atypical features in temporal artery biopsy have historically been the primary focus for diagnosis of this condition. A notable percentage of patients with symptoms of GCA have negative temporal artery biopsies, however, few cohort studies exist comparing the presentation and outcome of patients based on temporal artery positivity.

**Objectives:** To establish a large, single institution cohort of patients with temporal artery biopsy-negative GCA. To identify differences in presentation and outcome among patients with temporal artery biopsy-negative and temporal artery biopsy-positive GCA.

**Methods:** Patients presenting with temporal artery biopsy-negative GCA diagnosed between 1/1/1998 and 12/31/2013 were identified retrospectively. Final diagnosis was confirmed by consensus among two rheumatologists and a physician abstractor. Baseline characteristics and outcomes were compared to a previously established temporal artery biopsy-positive GCA cohort (n=286) from the same institution.

**Results:** 110 patients with temporal artery biopsy-negative GCA were identified. Unilateral biopsies were performed in 73, bilateral-sequentual in 10, and bilateral same day in 27 cases. Median duration between steroid initiation and biopsy was 3 days. Median length of first biopsy was 14mm and second biopsy (if performed) was 22mm. Among biopsy-negative patients with advanced imaging with features of temporal artery vasculitis, 37% (13/35) had evidence of large vessel vasculitis.

Patients with biopsy-negative GCA were younger (72.0±9.0 vs 75.0±7.6; p<0.001), met fewer ACR criteria (≥ 3 criteria 64% vs 95%; p<0.001) and had a shorter time from symptom onset to diagnosis (median 1.1 vs 2.1 months; p<0.001). Vascular risk factors evaluated at diagnosis showed a higher rate of pre-existing hypertension and obesity among patients with biopsy-negative GCA but similar rates of smoking and diabetes mellitus. Frequency of headache and vision loss at time of presentation were similar between groups. However, biopsy-negative GCA patients had more temporal artery tenderness (35% vs 16%; p<0.001) and arm claudication (13% vs 2%; p<0.001) but less frequent jaw claudication (19% vs 52%; p<0.001). Anorexia, fatigue, and arthralgia were also more commonly noted in biopsy-negative patients. Baseline CRP was lower among patients with negative biopsies (44±53±6 vs 70±6±3 mg/L; p<0.001).

Initial prednisone dose was similar among both cohorts. Although cumulative glucocorticoid (GC) was lower in biopsy-negative patients at 1 year (6±3±2.6 vs 7±2±2.7 g; p=0.004), cumulative GC doses at 2-years and 5-years were equivalent. Biopsy-positive patients (5-years, 56±3%) were able to discontinue GC sooner than biopsy-negative patients (5-years, 30±5%; p<0.001). The number of relapses, time-to-first relapse, annual relapse rate and mortality did not differ based on biopsy positivity.

**Conclusions:** While similarities are present, notable differences are observed at diagnosis in patients with biopsy-negative GCA. Further research is needed to confirm and understand the variability in GC duration.

**WHAT IS THE ABSOLUTE RISK OF DEVELOPING DIABETES MELLITUS IN PATIENTS WITH GLUCOCORTICOID-TREATED POLYMYALGIA RHEUMATICA AND GIANT CELL ARTERITIS? A SYSTEMATIC REVIEW AND META-ANALYSIS**

L. Lea1, E. Harris 1,2, R.M. West3, S.L. Mackie1,4. 1 Leeds Institute for Rheumatic and Musculoskeletal Medicine, University of Leeds; 2 School of Human and Health Sciences, University of Huddersfield; 3 Leeds Institute of Health Sciences, University of Leeds; 4 NIHR-Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom

**Background:** Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are treated with glucocorticoids (GCs) but long-term GC use is associated with diabetes mellitus (DM). The absolute incidence of this serious complication in this patient group remains unclear.

**Objectives:** To quantify the absolute risk of GC-induced DM in PMR and GCA in published literature.

**Methods:** We identified literature from inception to February 2016 reporting diabetes following exposure to oral GC in patients with PMR and/or GCA without pre-existing diabetes. A random-effects meta-analysis was performed to summarise the literature. Risk of bias was assessed using the Cochrane Collaboration tool.

**Results:** 21 eligible publications were identified. In studies of patients with GCA, mean cumulative GC dose was almost two times higher than in studies of PMR (8.9g vs 5.0g), with slightly longer treatment duration but much longer duration of follow-up (8.8years vs 4.4years). The incidence proportion (cumulative incidence) of patients who developed new-onset DM was 6% (95% CI: 3–9%) for PMR and 12% (95% CI: 8–17%) for GCA. Heterogeneity between studies was high (I²=78.2%), as there were differences in study designs, patient population, geographical locations and treatment strategies. Based on UK data on incidence rate of DM in the general population, the expected background incidence rate of DM over 4.4 years in PMR patients and 8.8 years in GCA patients (the duration of follow-up) would be 4.8% and 9.7%, respectively. Very little information on predictors of DM in PMR or GCA patients was found. The overall risk of bias was high for many of the observational studies, especially relating to definition and recording of outcome and prognostic variables.

**Conclusions:** Physicians should screen patients treated for PMR/GCA for DM but it remains unclear what is the time-period of greatest risk and the influence of risk factors. Our meta-analysis produced plausible estimates of DM incidence in patients with PMR and GCA but there is insufficient published data to allow precise quantification of the DM risk or, crucially, which patients are at greatest risk.

**DOI:** 10.1136/annrheumdis-2017-eular.4942
Background: Behcet’s disease (BD) is a multisystem disease in which central nervous system involvement – neuro-Behcet’s disease (NBD) – may strike young patients with devastating consequences. In this regard, early diagnosis and treatment are essential to prevent injury.

Objectives: This study aimed to analyze NBD clinical features compared to non-neurological BD in order to distinguish disease patterns.

Methods: A retrospective study was performed in 101 BD outpatients from a single tertiary center followed between 2011 and 2016. BD diagnosis was based on the 2014 International Criteria for Behcet’s Disease. Demographic, clinical and imaging features of 28 NBD patients were compared to 73 BD patients without neurological involvement.

Results: Earlier disease onset was found in NBD compared to BD (26±10.2 vs. 30±22.8 years, p=0.08). There were no differences between goiter presentations, with a female predominance in both groups (64.3 vs. 72.6%, p=0.05). Over half of patients (53.6%) presented NBD as the first symptom and the mean time between diagnosis and NBD onset was 3.8±5.9 years. Uveitis was less frequent in NBD patients (25% vs. 47.9%, p=0.04), together with cutaneous disease (95.5% vs. 73%, p=0.01), upper airways involvement (7.9% vs. 17.9%, p=0.01), and articular involvement (67.9% vs. 32.1%, p=0.001). Most patients (82.1%) had a single neurological attack whereas relapsing disease was similar in both groups. Regarding NBD presentation, brainstem involvement was the most prevalent (67.9%), followed by central venous thrombosis (32.1%), aseptic meningitis (17.9%), stroke (3.6%) and peripheral neuropathy (3.6%). Most patients (53.6%) presented NBD as the first symptom and the mean time between diagnosis and NBD onset was 3.8±5.9 years. Uveitis was less frequent in NBD patients (25% vs. 47.9%, p=0.04), together with cutaneous disease (95.5% vs. 73%, p=0.01), upper airways involvement (7.9% vs. 17.9%, p=0.01), and articular involvement (67.9% vs. 32.1%, p=0.001). Most patients (82.1%) had a single neurological attack whereas relapsing disease was found in 18.5%.

Conclusions: Our study found an earlier disease onset in NBD patients and a lower frequency of ocular, cutaneous and articular involvement. Moreover, several patients may unfold the disease as NBD, with lack of other manifestations. In addition, brainstem lesions occurred in most patients. Recognizing these disease patterns might support to expedite NBD diagnosis.

FR0336 Efficacy of tocolizumab in 31 patients with giant cell arteritis

Background: Giant cell arteritis (GCA) is often a disease refractory to corticosteroids and, besides, the efficacy of immunosuppressive agents is not well established. In this work, we describe the clinical characteristics and the long-term outcome of all the patients with GCA treated with Tocilizumab (TCZ).

Objectives: Our aim was to assess in a clinical practise setting the short and long-term outcomes in patients with refractory GCA.

Methods: A retrospective analysis of all GCA patients treated with TCZ between January 2014 and December 2016 at the University Hospital of Alicante - San Juan de Alicante, Spain was performed. We collected demographic data, clinical parameters, laboratory tests, and long-term outcomes in all patients. TCZ was administered intravenously at standard dose of 8 mg/kg/monthly (n=29), and subcutaneously at a dose of 162 mg/week (n=2). The dose was reduced due to side effects (n=2). The median follow-up of 18 [interquartile range, 6–30] months we observe a reduction of the median of: a) CRP from 1.9 [1.1–3.7] to 0.1 [0.1–0.7] mg/dL; b) ESR from 44 [17–74] to 12 [4–16] mm/1st hour; and c) the dose of prednisone from 20 [10–45] to 2.5 [0–7.5] mg/day. In this follow-up period, the outcome of patients was as follows: a) discontinuation of TCZ (n=8) due to sustained remission; b) dose reduction due to improvement (n=5) or side effects (n=2); c) withdrawal of TCZ because of side effects (n=7); and d) the same dose that at onset (n=8). The reasons why TCZ had to be discontinued were: severe neutropenia; colon adenocarcinoma; cytomegalovirus infection; hypertensive crisis during infusion; myelodysplastic syndrome; and overall health deterioration. The latter patient died because of stroke. Another patient also died after the second TCZ infusion due to stroke in the context of an infective endocarditis.

Conclusions: TCZ therapy leads to a rapid and maintained improvement in patients with refractory GCA and/or with unacceptable side effects related to corticosteroids. However, the risk of neutropenia and infection should be kept in mind when using this biologic agent in patients with GCA.

FR0337 ANCA pattern in granulomatosis with polyangiitis and micropolyangiitis. a retrospective analysis of outcomes on a multicentric inception cohort

M. Felicetti 1, R. Padoan 1, S. Morin 2, A. Berti 3, G. Paolazzi 3, G. Brunori 4, R. Caporal 1, F. Schiavon 1

Background: ANCA-associated vasculitides (AAV) are characterized by their specific antibody profile (ANCA pattern). ANCA-positive granulomatosis with polyangiitis (GPA) is subdivided into ANCA-antineutrophilic cytoplasmatic antibody (c-ANCA) or anti-neutrophil cytoplasmatic antibody (p-ANCA) types. The ANCA pattern has been shown to influence disease presentation, clinical manifestations, and long-term outcomes.

Objectives: To analyze how ANCA could influence clinical manifestations and long-term outcomes in AAV-affected patients, previously classified as GPA or MPA, from three different referral centers of Northern Italy.

Methods: Clinical manifestations and long-term outcomes of GPA and MPA patients were retrospectively collected. We considered clinical (including BVASv3), laboratory (including ANCA and c-ANCA/p-ANCA ratio) and long-term outcomes1.

Recently ANCA pattern has been reported to define different clinical manifestations and long-term outcomes1.

Results: We identified 171 patients, 90 (52.6%) anti-PR3 positive, 52 (30.4%) anti-MPO positive and 25 (14.6%) ANCA negative. Patients were mainly middle aged (52.5±15.9 years), Caucasian (98.2%) and both sexes were equally represented (Female 53.2%). Anti-PR3 positive patients were older (65 [52.5–69.7] years) at disease onset (p=0.001), affected by more comorbidities (p=0.045). They presented more frequently renal involvement (p=0.001) with higher creatinine levels at diagnosis (0.98 [0.75–1.92] mg/dL, p=0.001) (Fig. 1), systemic symptoms (p=0.039) but lower frequency of upper airways involvement (p=0.005).

Anti-MPO positive patients were older (65 [52.5–69.7] years) at disease onset (p=0.001), affected by more comorbidities (p=0.045). They presented more frequently renal involvement (p=0.001) with higher creatinine levels at diagnosis (0.98 [0.75–1.92] mg/dL, p=0.001) (Fig. 1), systemic symptoms (p=0.039) but lower frequency of upper airways involvement (p=0.005).

ANCA negative showed a longer diagnostic latency (8.5 [3.5–49] months, p=0.0001) than the other two groups. They presented a higher HLA-DRB1*0401 allele frequency (p=0.001).

Conclusion: ANCA pattern is associated with clinical and long-term outcomes in AAV-affected patients.
and the highest frequencies of sinuses (p=0.031), laryngeal (p=0.026) and CNS (p=0.020) involvement.

Long-term outcomes were available only in 113 patients. A low long-term mortality rate (8.7, 1.1% deaths) was noted (mean follow-up of 66.6±30.6 months), significantly higher in anti-MPO positive patients (7.21%) when compared to anti-PR3 positive (0.8, 1% ANCA negative 0 (0%) (p=0.011). Nevertheless, the highest number of relapses/years were associated with anti-PR3 positivity (0.7±1.3 vs 0.1±0.3 in anti-MPO and 0.4±0.7 in ANCA negative, p=0.012). At multivariate analysis, anti-PR3 pattern resulted an independent predictive factor of relapses (p=0.036, OR 5.8, IC95%: 1.1–29).

Conclusions: Our study confirms the hypothesis that each ANCA pattern could define a specific disease subset with different clinical manifestations and outcomes in AAV. Furthermore, in our cohort we observed a lower rate of recurrence and a better long term survival (92.9%) than in literature.

FR02338 THERAPEUTIC CONFORMITY TO GUIDELINES AND DRUG-APPROVAL IN ADAMANTIADES-BECHTSEL’S DISEASE: A RETROSPECTIVE ANALYSIS OF A MIDDLE-EUROPEAN COHORT
T.M. Moosmann1, C. Veraar1, A. Frech2, G. Ratzinger 3, B. Teuchner4, K. L. Petelytska1, O. Iaremenko
1Internal Medicine VI; 2Vascular Surgery; 3Dermatology; 4Ophthalmology, Lkh - Medizinische Universität Innsbruck, Innsbruck, Austria

Background: Adanantades-Bechtels disease is a chronic systemic vasculitic disease. Because of multiorgan involvement with diagnostic and therapeutic challenges for physicians, treatment decisions can be very difficult.

Objectives: To retrospectively assess the use of medication for ABD-therapy in view of 1) current guidelines and 2) approval by authorities in a Middle-European tertiary care center.

Methods: Data between 1997 and 2016 from a Middle-European ABD-cohort were retrospectively analysed. First, medical treatment was evaluated for conformity with the EUROLAR-recommendations for ABD-management and the anti-TNF therapy recommendations by Silfakis et al. (1,2). Second, medical treatment was evaluated for use according to indications approved by authorities. Therefore official prescribing informations of the Bundesamt für Sicherheit im Gesundheitswesen (BASG)/European Medicines Agency (EMA), exemplary for Europe, and the Food and Drug Administration (FDA), exemplary for the USA, were screened (3–5). The study was approved by the local ethics committee.

Results: A total of 174 medical interventions were identified in 76 patients. Until 2008, treatment of ABD was based only on few clinical trials. According to EUROLAR-recommendations 93.7% were considered as being treated appropriately, including 55.2% of therapeutic approaches exactly matching the recommendations. 88.9% of TNF-depletion were indicated according to the anti-TNF therapy recommendations (n=8/9). Out of 27 used drugs only prednisolone was approved by BASG/EMA- and FDA-authorities for ABD. Cyclosporin A had the specific BASG/EMA-indication for ABD-uveitis. Another 12 medications had the indications for different symptoms of ABD, and thirteen medications were not authority-approved for any ABD-treatment.

Conclusions: Approvals by BASG/EMA- and FDA-authorities are often missing the indication of ABD. Therefore physicians not only face the complexity of ABD as a rare multiorgan disease, but also have to treat their ABD-patients with unapproved drugs. We propose that medications recommended by international guidelines for the management of rare diseases should be recognized by BASG/EMA- and FDA-authorities, even in case of low evidence.

FR0340 B-CELL REPOLUPATION KINETICS AFTER RITUXIMAB TREATMENT IN ANCA-ASSOCIATED VASCULITIDES COMPARED TO RHEUMATOID ARTHRITIS, AND CONNECTIVE TISSUE DISEASES: A LONGITUDINAL OBSERVATIONAL STUDY ON 120 PATIENTS
J. Thiel, M. Rizzi, A. Troilo, U. Salzer, A. Venhoff, R. Lorenzetti, R. Voll, N. Venhoff Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany

Background: B cell depletion with rituximab (RTX) is approved for treatment of anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitides. Recently, RTX has been shown to be effective in AAV maintenance therapy, but an optimal RTX treatment schedule is unknown and the time to B cell repopulation after RTX has not been studied.

Objectives: To compare kinetics of B cell repopulation after RTX treatment in AAV, RA and connective tissue diseases (CTD) to improve the design of RTX-therapy in AAV and CTD.

Methods: Retrospective single-center analysis of patients with AAV, RA or CTD treated with RTX and a follow-up of >9 months were included. B-cell-repulation was defined as a peripheral B-cell count >0.5x and ≤5x. Prolonged B cell depletion was defined by a B cell repopulation starting later than 12 months after RTX treatment.

Results: 120 patients were included in the study. Sixty-six patients had AAV with 65 classified as granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) and 11 as eosinophilic granulomatosis with polyangiitis (EGPA). Fifty one patients had RA and 19 were treated with RTX because of CTD. There were no significant differences between the groups regarding age and sex. Most patients were treated with RTX 1000mg twice, two weeks apart. Cumulative CYC doses were higher in patients with AAV or CTD than in RA patients. In RA and CTD we observed a B-cell repopulation in all patients (100%) while only 33 AAV patients (50%) had started B-cell repopulation (<0.0001). 93% of the RA and 88% of the CTD patients showed a normal repopulation within the first 12 months after RTX compared to only 10% in GPA and 0% in EGPA (<0.0001). Mean time to repopulation was significantly longer in GPA/MPA (21 months) and in EGPA (20 months) compared to RA (8.5 months) and CTD (8.7 months). Median time of persistent depletion was 26 months in GPA/MPA, 21 months in EGPA compared to 9 months in RA and 6 months in CTD (p<0.0001). In 25 AAV patients B cell depletion persisted longer than 24 months (mean time 4.4±1.81 years). In ten of 55 GPA/MPA patients B-cells were still depleted 4 years, in six patients even after more than 5 years after only one RTX treatment cycle. One patient had a complete B cell depletion even 8 years after the second RTX treatment. Immunoglobulin production was affected by RTX-treatment with a significant decreased decrease in IgG, IgM and IgM compared to baseline values in GPA/MPA but not in RA or CTD. In EGPA only IgM declined significantly. Significantly more patients with GPA/MPA and EGPA developed a hypogammaglobulinemia (IgG<7g/L, IgM<0.4g/L). In some AAV patients hypogammaglobulinemia became clinically relevant and required IVIG treatment.

Conclusions: In contrast to RA and CTD, in AAV RTX induces long-lasting depletion of B cells that is associated with decreased antibody production. This observation points towards potential defects in the B cell compartment in AAV and has important implications for the design of maintenance treatment schedules using RTX. The TNF-inhibitors were indicated for GPA/MPA, but not in RA or CTD. In EGPA only IGM declined significantly. Significantly more patients with GPA/MPA and EGPA developed a hypogammaglobulinemia (IgG<7g/L, IgM<0.4g/L). In some AAV patients hypogammaglobulinemia became clinically relevant and required IVIG treatment.

DOI: 10.1136/annrheumdis-2017-eular.4783
RESULTS: The levels of BAFF were significantly higher in group 3 (0.88±0.19 ng/ml) compared with group 1 (0.68±0.13 ng/ml, p<0.05), but did not distinguish from the group 2 (0.90±0.35). There were not significant differences in ESR between groups. ROC analysis indicated that the AUC for ESR is 0.63±0.10 (p=0.17) and for BAFF – 0.72±0.12 (p=0.05), which indicates fair capacity for BAFF differentiation of patients with low activity or remission of SNV and pts with severe SNV (sensitivity - 61.5%, specificity - 88.9%), while it was poor for ESR (sensitivity - 85.7%, specificity - 46.4%).

CONCLUSIONS: There are significant differences in levels of BAFF between pts with BVAS≤24 and pts with BVAS<11. According to ROC analysis evaluation of serum ESR level and pts with active SNV from pts with low activity of remission better than determination of ESR.

FR10341  CLINICO-PATHOLOGICAL DISCREPANCIES AND CAUSES OF DEATH IN TAKAYASU ARTERITIS: A RETROSPECTIVE ANALYSIS OF 60 FATAL CASES

O. Zimba1, M. Bagry2. 1, the Department of Internal Medicine, Danylo Haltsky Lviv National Medical University, Lviv; 2Department of Pathological Anatomy, Ivan-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine.

BACKGROUND: Takayasu arteritis (TA) may present with a wide spectrum of symptoms common to other diseases leading to delayed or missed diagnosis.

OBJECTIVES: To investigate the rate of undiagnosed clinically cases of TA, and provide a detailed analysis of the wrong diagnoses and the underlying causes of death.

METHODS: A retrospective clinicopathological analysis of sixty autopsy cases (52 males and 8 females aged 18 to 45 years) of TA over period of 11 years have been performed. The median age at disease onset was 25, 7 years.

RESULTS: In 33 cases (55%), TA was not diagnosed during the clinical stages but only in autopsy. The most common incorrect clinical diagnosis was atherosclerosis of the aorta and its branches (celiac trunk, renal, mesenteric and iliac arteries) that has misdiagnosed in 14 cases (42.4%) of TA. TA was misdiagnosed as myocardial infarction/ischaeic heart disease in 5 (15.1%), perforated peptic ulcer in 3 (9.1%), polyarteritis nodosa in 3 (9.1%), and infective endocarditis in 2 cases (6.1%). There were other diagnostic errors in 6 cases in 18.2%); in these cases, cerebral haemorrhage, rheumatic heart disease, pulmonary embolism, pheochromocytoma, chronic glomerulonephritis and lung cancer were the wrong clinical diagnoses. The leading position in the mortality structure due to TA belongs to septic shock that observed in 19 cases (31.7%) due to peritonitis/acute abdomen caused by mesenteric artery occlusion with subsequent intestinal necrosis in 12 (63.1%), lower limb gangrene in 6 (31.6%), and prosthetic aortic graft infection in 1 (5.3%). The second-leading cause of death was acute heart failure due to myocardial infarction, and renovascular arterial hypertension (25%).

The third most frequent cause of death was hemorrhagic shock in 14 cases (23.3%).

The acute bleeding was caused by ruptured aortic aneurysm in abdominal in part 6 cases (42.8%) and ascending aorta with cardiac tamponade in 4 (26.6%). In 2 cases (14.3%), the source of hemorrhage was ulcers of gastrointestinal tract. The surgery has complicated by lethal bleeding in 2 cases (14.3%). In other patients, causes of death were chronic renal failure in 6 (10%), facial failure in 3 (5%), respiratory failure in 1 (1.7%), and revascularization syndrome in 1 (1.7%). In one case, TA coexisted with scleroma of larynx, and asphyxia was direct cause of death.

CONCLUSIONS: Our data show a high number of cases of TA (55%) that were identified at autopsy but were not diagnosed clinically. It can be assumed that aortic atherosclerosis, myocardial infarction/ischaeic heart disease were the most common wrong diagnoses in TA. The leading causes of death in TA are septic shock, acute heart failure, and haemorrhagic shock. In addition, it should be noted that in our series of autopsy cases of TA, males (86, 7%) were most frequently affected compared with results other investigations. Interestingly, that the correct diagnosis of TA was established before death in all females’ cases. It seems to be a trend to miss the clinical diagnosis of TA in male patients.

FR10342  DISTRIBUTION OF VASCULITIDES IN EASTERN MEDITERRANEAN: RESULTS OF A PROSPECTIVE COHORT

BACKGROUND: The ethnic and geographical differences have been commented on, mainly from European data. We lack large data sets from the eastern part of Europe.

OBJECTIVES: This study is aimed to present the distribution of vasculitides in the Pediatric and Adult Vasculitis patient groups.

Methods: Hacettepe University is one of the main referral centers in the capital of Turkey, serving approximately 470,000 adult and pediatric patients/a year. Hacettepe University Vascularitis Centre (HUVAC) was established to organize a prospective cohort in 2014. All patients starting from October 2014 have been recorded to the database. Additionally electronic patient recording database between October 2014-December 2016 was searched for the patients having any of the 10th revision of the International Statistical Classification of Diseases (ICD)-10 code for the particular vasculitis. The study group of Hacettepe University Vascularitis Centre (HUVAC) re-evaluated the ascertainment patients’ hospital records to review their diagnosis according to the 2012 revised Chapel Hill nomenclature criteria.

RESULTS: A total of 1196 patients had been newly followed in this period. 271 (22.7%) of them were pediatric patients and 31.8% of them were newly diagnosed. The leading vasculitis among adult patients was Behcet’s Disease whereas in pediatric patients it was HSP/IgA Vasculitises (Table). Granulomatous polyangiitis was the most common small vessel vasculitis in adults. Takayasu arteritis was more frequent than giant cell arteritis among the adult patients. There was a female predominance in patients with large vessel vasculitises. During prospective follow up, 22 (1.9%) patients deceased; 7 due to the primary disease, 6 due to infections, 7 due to cardio and cerebrovascular diseases.

Table. Distribution and gender of Adult and Pediatric Vasculitides Patients:

FR10343  COGNITIVE DISORDERS IN BEHÇET’S DISEASE: SOME CLINICAL AND PATHOGENESIS RELATIONS

P. Ovcharov1, T. Lisitsyna1, D. Veltishchev2, D. Burenchev2, D. Ishchenko2, 1Nasonova Research Institute of Rheumatology, Moscow, Russia; 2Moscow Research Institute of Psychiatry; 3City policlinic No. 12 Moscow Department of Health, Moscow, Russian Federation

BACKGROUND: the cognitive disorders (CD) is a special psychopathological problem for Behcet’s Disease (BD) patients. The causes of CD aren’t enough investigated. Anxiety/depressive disorders and primary neural parenchymal lesions due to BD are the main causes of CD in these patients.

OBJECTIVES: to determine the prevalence of CD in BD patients and its associations with some clinical and magnetic resonance imaging (MRI) scan features.

METHODS: the investigation has been realized in accordance with the interdisciplinary program "Stress factors and mental disorders in immune-mediated inflammatory rheumatic diseases".

RESULTS: 106 BD patients were enrolled in the study. The majority of patients were men (72.6%), natives of the North Caucasus (51.9%), with mean age (Mt±m) 33.3±10.8 years. All the patients met the criteria of the International Study Group for BD (1990) classification. The disease activity was assessed by scoring system BDCF.

CD were diagnosed with psychology and neuropsychology methods. Mental disorders (MD) were diagnosed by psychiatrist in accordance with the ICD-10 in semi-structured interview. The severity of depression and anxiety was evaluated
**FR0344** NOVEL BIOMARKERS OF SUBCLINICAL ENDOTHELIAL DYSFUNCTION IN BEHÇET’S SYNDROME: EVALUATION OF CLINICAL, DENTAL, VASCULAR AND INTIMA-MEDIA-THICKNESS IN A HOSPITAL-BASED POPULATION

P. Talarico 1, C. Stagnaro 1, S. Barsotti 1, R. Neri 1, C. Tani 1, C. Baldini 1, N. Di Lascio 2, E. Bianchini 2, A. Morales 2, M. Mosca 1, 1Department of Clinical and Experimental Medicine, University of Pisa, Rheumatology Unit; 2CNR, Institute of Clinical Physiology, Pisa, Italy

**Background:** Growing interest exists on the role of markers of subclinical cardiovascular disease as independent predictors of cardiovascular events. Poor data are available on the role of these markers as prognostic factors for Behçet’s syndrome (BS).

**Objectives:** The primary aim was to explore Intima-Media-Thickness (IMT), mean arterial diameter and distensibility (DC) in a group of patients with BS, comparing these data with a healthy control group and a disease control group; the secondary aim was to correlate the vascular parameters with demographic clinical/critical profiles.

**Methods:** Thirty BS patients (females:12;mean age±SD:43±10.5; mean disease duration±SD:13±8.8) fulfilling the ISG criteria were prospectively enrolled. Demographic data, level of disease activity, frequency of smokers, hypertension, family history of cardiovascular risk factors, body mass index (BMI) and current therapies were analysed. For each subject, ultrasound B-mode image sequences of right common carotid arteries were acquired and analysed by an automatic system (Cardiotro Studio,Quup) for the measurement of IMT and mean arterial diameter. In addition, carotid pulse pressure was estimated between IMT and DC coefficient was obtained. The systolic and diastolic carotid diameters were automatically measured on the distal wall of the common carotid artery, 1–2 cm beneath the bifurcation. Carotid diameter was calculated as the distance between media-adventitia interfaces. Cross-sectional DC was estimated through the variations in arterial cross-sectional area and blood pressure during systole. DC was computed as DC=ΔA/(PP*A) where A is the distal lumen area, ΔA is the stroke change in lumen area, and PP is the local pulse pressure.

**Results:** At time of evaluation, 4/17 patients presented active disease (50% of them in moderate-severe and 25% joint involvement, 25% gastro-enteric involvement; mean BS activity score 5). Mean IMT±SD value resulted of 0.57±0.81, mean arterial diameter±SD value was 6.87±0.91 and mean DCs SD 27.3±14.34. All the vascular parameters considered were significant correlated with BMI, while only IMT and DC were also significantly correlated with arterial hypertension. Using a correction analysis for age and sex, we found significant correlations between mean arterial diameter and disease activity and between DC and disease duration. These data resulted significantly different compared to healthy control and a disease control groups, in terms of smaller arterial diameter and higher DC. Duration. These data resulted significantly different compared to healthy control with and without CD (28% vs 32%, p=0.44). The patients with CD were older (34.3±10.7 vs 29.9±2.14, p=0.006), more often had chronic/recurrent depressive disorders (41% vs 50%, p=0.001) of moderate severity (MADRS 16,1±5.7 vs 12.2±1.06, p=0.005), stressful life events (91.5% vs 62.5%, p=0.001) and multifocal subcortical parenchymal MRI changes (57.6% vs 9%, p=0.005).

**Conclusions:** The results have shown high rates of different CD in both BS patients. CD were not associated with BS activity and presence of neurological symptoms. CD were related to the diagnoses of stress-related mild to moderate chronic depressive disorders and minor brain multifocal subcortical parenchymal MRI lesions.

**FR0345** CLINICAL IMPACT OF ALPHA-1-ANTITRYPSIN DEFICIENCY IN GRANULOMATOSIS WITH POLYANGIITIS

S. Deshayes 1, A. Aoubal 1, F. Grandhomme 2, K. Kathy 3, D. Mariotte 3, J. Bouteyn 4, G. Maingay 1, C. Briere-Bellier 4, C. Delmas 1, B. Bienvenue 1, N. Martin Silva 1, 1Department of Internal Medicine; 2Department of Biochemistry; 3Department of Immunology, CHU Côte de Nacre, Caen; 4Department of Infectious Diseases, CH Mémorial, Saint-Lô, France

**Background:** Deficiency in α-1-antitrypsin (AAT), which is the main proteinase 3 (PR3) inhibitor, is now recognized as a pathogenic factor in some cases of anti-PR3 anti-neutrophil cytoplasmic antibodies (ANCA)-associated granulomatosis with polyangiitis (GPA). However, the clinical impact of AAT deficiency remains poorly established in this setting.

**Objectives:** The purpose of our study was to describe the clinical phenotypes and outcomes of anti-PR3 GPA patients according to their AAT status.

**Methods:** A retrospective monocentric study carried out in Caen University Hospital led to identify anti-PR3 GPA patients, from 09/21/2011 to 06/10/2016. AAT dosage and phenotype (isoelectric focusing in agarose gel) were performed for all patients. Categorical variables were reported as percentages and compared using Chi² or Fisher’s tests according to expected frequencies. Continuous variables were expressed as means and analysed using Student’s t-tests. Associations between survival, renal survival or relapse-free survival, and AAT phenotype were evaluated by the log-rank test. A p-value <0.05 was considered to be statistically significant.

**Results:** Among the 72 identified anti-PR3 GPA patients, 40 (56%) were male. Median age at diagnosis was 60.5 years old. Patients mainly had constitutional symptoms (51,71%), pulmonary (52,72%), ear, nose or throat (ENT) (49,68%), rheumatologic (45,63%), and renal (44,61%) involvements. Median initial BVAS score was 2 (IQR: 1-5). The maximum score was 17 (IQR: 12-22). Thirty (41.7%) patients were noted (median follow-up: 55 months). Forty-eight (67%) patients had MM phenotype, 10 (14%) MZ phenotype, 8 (11%) MS phenotype, 3 (4%) M variant phenotype, 2 (3%) ZZ phenotype and 1 (1%) ZS phenotype. Allele frequencies of M, Z and S allele were 81, 10 and 6%, respectively. The whole cohort had the same immunosuppressant drug regimen.

**Conclusions:** Our observations confirm the epidemiological association of anti-PR3 GPA with AAT deficiency. The frequency of neurological manifestations (headache, seizures, myelopathy, ataxia) did not differ significantly in patients with and without CD (28% vs 32%, p=0.44). The patients with CD were older (34.3±10.7 vs 29.9±2.14, p=0.006), more often had chronic/recurrent depressive disorders (41% vs 50%, p=0.001) of moderate severity (MADRS 16,1±5.7 vs 12.2±1.06, p=0.005), stressful life events (91.5% vs 62.5%, p=0.001) and multifocal subcortical parenchymal MRI changes (57.6% vs 9%, p=0.005).

**FR0346** RENAL INVOLVEMENT IN GRANULOMATOSIS WITH POLYANGIITIS

N. Bulanova 1, E. Makarov 2, E. Kuznetsova 1, M. Bulanova 2, P. Novikov 1, S. Moiseev 1, 1Sechenov First Moscow State Medical University; 2Lomonosov Moscow State University, Moscow; 3Vladimir Regional Clinical Hospital, Vladimir, Russian Federation

**Objectives:** We assessed the frequency, clinical features and prognosis of renal involvement in granulomatosis with polyangiitis (GPA) and current treatment approaches.

**Methods:** We performed a retrospective analysis of 234 patients with GPA, diagnosed according to Chapel-Hill Consensus Conference 2012 classification, 81 male and 153 female, aged 53 (41; 62) years. 54 patients (23.1%) had renal involvement developed at disease. We performed a retrospective analysis of chronological follow-up of 234 patients with GPA, 81 male and 153 female, aged 53 (41; 62) years. 54 patients (23.1%) had renal involvement developed at disease.

**Results:** 25 patients (24.3% of 103) renal involvement developed at disease.
onset, the other 78 patients (75.7%) developed glomerulonephritis after a median onset of 3 (11.12) months. Hematuria was present in 84 (91.3%), proteinuria in 85 patients (82.5%), nephrotic syndrome in 11 patients (10.7%), hypertension in 31 patients (30.1%). Rapidly progressive glomerulonephritis (RPGN) defined by the doubling of serum creatinine within ≤ 3 months developed in 29 patients (28.2% of 103). Myeloperoxidase-ANCA-positive patients (n=12) developed RPGN significantly more often than proteinase-3-ANCA-positive patients (n=78): 7 (58.3%) vs 22 (28.2%) (p=0.0049). 11 (10.7%) patients developed AKI, stage 3 being the most common (in 8 patients). 40 (38.8%) patients exhibited indolent renal disease course, i.e. without worsening of renal function. By the end of the follow-up, 33 (32.0%) patients were diagnosed with CKD grade 3-5, among them 11 patients (10.7%) developed end-stage renal disease (ESRD). 6 patients (5.8%) died. As a result, 73 patients (71.8%) developed one or more severe relapses with a relapse rate of 0.27 per patient-year. 50 (48.5%) patients had renal relapses (0.096 per patient-year).

Conclusions: Prevalence of renal involvement in the studied group was lower than expected, most likely because of a large proportion of patients with localized GPA. Our study showed that RPGN was not the most common feature of renal involvement. Almost 40% of patients developed indolent course of kidney disease. Nevertheless one third of patients developed CKD G3B or worse by the end of the follow-up. During the induction therapy with high-dose corticosteroids, cyto toxic agents and/or RTX relapses, both renal and extrarenal, are frequent.

</tr>
</tbody>
</table>

Conclusions: TA does co-occur with IBD, AS or BS in about 1/5 of the patients, at least in a hospital setting and without a clear temporal pattern. This could be due to the close association of TA with MHC class-1 diseases. In addition, the high prevalence of inflammatory back pain in the dorsal spine in TA needs further scrutiny.

DOI: 10.1136/annrheumdis-2017-eular.4555
them into three groups according to the allele at the SNP, AA (n=26), AC (n=43) and CC (n=16) (A is a risk allele), and investigated the association of the SNP and organ involvements.

**Results:** There were no differences in the complication rates of carotid arterial lesions among the groups (AA 78.9%, AC 63.9% and CC 80.0%). The proportion of patients with lesions in descending aorta (Numano classification22) Ilb–Vc was 75.0% in AA, 44.2% in AC 44.2% and 25.0% in CC and the proportion in AA was significantly higher than in CC (p=0.0096). Moreover, estimated glomerular filtration rate (eGFR) was significantly lower in AA than in CC (61.3±26.9 ml/min/1.73m² vs. 81.5±28.8 ml/min/1.73m², p=0.042).

**Conclusions:** The SNP rs6871626 located in 12q12 may influence on the occurrence of descending aortic lesions in TAK patients and this may lead to renal dysfunction.

**PAPULOPUSTULAR LESIONS ACCORDING TO AGE, SEX AND LOCALIZATION IN BEHCET'S SYNDROME PATIENTS COMPARED HEALTHY AND DISEASED CONTROLS**

Z. Kutlubay1, Y. Ozgücer1, C. Hameti1, K. Tascilar3, C. Mat1, H. Yazıcı2.
1Department of Dermatology; 2Department of Internal Medicine Division of Rheumatology; 3Department of Internal Medicine. Okmeydani Research and Training Hospital, Istanbul, Turkey

**Background:** Papulopustular lesions (PPL) are the most common skin lesions in Behcet’s syndrome (BS).

**Objectives:** To assess whether PPL are different in BS according to localization, age, sex and medications used when compared to rheumatoid arthritis patients (RA) and apparently healthy subjects (HS).

**Methods:** 209 consecutive BS patients who were routinely followed in our dedicated BS center were studied. Patients with RA (n=146) who were followed up in the rheumatology outpatient clinic of the same unit and HS (n=149) were used as controls. All subjects were clinically evaluated by the same dermatologist and all skin lesions (papules, pustules, comedones, folliculitis, cysts, nodules) on the face, trunk and legs were separately counted. Information regarding the demographic and clinical features of primary disease and medications used were obtained from patients’ charts.

**Results:** Subjects without PPL were excluded before analyses. Demographic features and mean number of PPL according to site of body were summarized in Table-1. Mean number of total PPL were similar between BS and HS and significantly higher than in RA (p<0.001). Mean number of total PPL according to sex were similar in RA and HS but higher in male BS patients compared to female BS patients (p<0.04). When we analyzed the number of PPL according to different body sites, we observed that BS patients had significantly more lesions on the legs when compared to the RA patients and HS (p<0.0001). Number of PPL lesions tend to decrease as the patient ages in BS similar to RA and HS. When leg lesions were analyzed according to age, this difference remained in the age groups 31–50 and >50 but not in the age group <30. Corticosteroid use did not impact the results.

**Conclusions:** BS patients have significantly more PPL on the legs when compared to HS and RA. Number of PPL tend to decrease as the patient ages in BS similar to RA and HS however BS patients still have more PPL on the legs after the age of 50 suggesting that these lesions somehow differ from acne vulgaris, in pathogenesis.

**EFFICACY OF BIOLOGICS IN PATIENTS WITH REFRACTORY TAKAYASU ARTERITIS AND ANALYSIS OF THEIR GENETIC BACKGROUNDS**

Y. Gon 1, H. Yoshifuji 1, T. Nakajima 1, K. Murakami 1, R. Nakashima 1, K. Ohmura 1, C. Terao 2, T. Mimori 1, 1Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University; 2Center for Genomic Medicine, Kyoto University, Kyoto, Japan

**Background:** Takayasu arteritis (TAK) is a rare disease that mostly affects young females and causes inflammation, stenosis, and dilation of the aorta and its main branches. Although glucocorticoids are effective, relapses occur frequently [1]. Recently, the efficacy of biologics has been reported in refractory TAK. HLA-B*52 is a major genetic risk factor and associated with the severity [2].

**Methods:** We analyzed serum samples of 3 patients with SSc and ILD (2 limited SSc: one ANA positive and one anti-Scl70 positive, and one diffuse SSc anti-Scl70 positive), 3 patients with SSc and no ILD (ACA positive limited SSc), and 4 healthy controls. All subjects were women and age matched.

**Results:** Serum proteomic profiling was performed using the SOMAScan platform (SomaLogic, Inc., Boulder, CO, USA). Statistical analysis included Student’s t-test and were performed using the IBM SPSS software (IBM, Armonk, NY, USA).

**Conclusions:** Circulating microparticle subsets are associated with serum proteomics profile in systemic sclerosis.

---

**CIRCULATING MICROPARTICLE SUBSETS ARE ASSOCIATED WITH PATIENTS WITH EXTENDED FIBROTIC PHENOTYPE IN SYSTEMIC SCLEROSIS**

K. Sakata 1, H. Yasouka 1, M. Koseki 1, K. Yoshimoto 1, M. Kuwana 2, K. Takeuchi 1, 1Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; 2Department of Allergy and Rheumatology, Keio University School of Medicine, Tokyo, Japan

**Background:** In systemic sclerosis (SSc), systemic remodeling, microvascular injuries and production of autoantibodies are well known as disease hallmarks. However, the master regulator of these characteristics is still unclear. Microparticle (MP) is a small membranous vesicle, released from various kinds of cells, and distributes systemically through circulation [1]. Recent reports revealed that MP contains various growth factors, proteases and cytokines including TGF-β1, suggesting that MP can contribute to immune and mesenchymal responses as a conveyor [2] and involve with disease process of SSc. Although, the possible involvement of MPs in the pathogenesis of SSc is indicated, the detailed association of MPs including MP subsets with SSc is not well clarified.

**Objectives:** To elucidate the association between circulating MP subsets and patients’ characteristic of SSc.

**Methods:** Thirty-six patients with SSc and 13 healthy controls were involved in this study. Platelet-rich plasma containing microparticles was isolated from whole blood using gradient centrifugation and analyzed using flow cytometer. MP was defined as particles smaller than 1 μm diameter using Megamix® and identified each MP subsets based on expression of cell type-specific surface markers: platelet (CD31, CD41), endothelial cell (CD31, CD41) and monocyte (CD14, CD45) using fluorescence-tagged antibodies. Clinical information was retrospectively collected from medical records, and the correlation with the number of each MP subset was analyzed.

**Results:** Mean age of 36 patients with SSc was 60±1.8 years, 94% was female, and mean disease duration was 11.2±9.5 years. Patients with diffuse cutaneous SSc: one ANA positive and one anti-Scl70 positive, and one diffuse SSc anti-Scl70 positive.

**Conclusions:** The association between circulating MP subsets and patients’ characteristic of SSc.
IL-17A UP-REGULATION IN PERIPHERAL BLOOD MONONUCLEAR CELLS CO-CULTURED WITH AUTOLOGOUS SKIN FIBROBLASTS IS ASSOCIATED WITH DOWN-REGULATION OF PRO-FIBROTIC MEDIATORS AND INCREASED FIBROBLAST APOPTOSIS

Background: IL-17A has been implicated in the pathogenesis of systemic sclerosis (SSc) (1). We previously showed that skewed peripheral blood mononuclear cell (PBMC) activation by IL-17A from SSc patients can induce Fas-mediated apoptosis in co-cultured autologous skin fibroblasts (2).

Objectives: We therefore aimed to investigate IL-17A expression and effects in these co-cultures.

Methods: PBMCs and skin fibroblasts from 5 SSC and 5 healthy control patients with disease duration less than 3 years were co-cultured up to 10 days in presence of IL-17A [20 U/ml] in a 1:1 ratio, as previously described. IL17A, IL17RA, CXCL1, CCL2, CCL3, TGFB2R2, SMAD3, CTGF, COL1A1, COL3A1 mRNA expression was assessed by Sybr Green real-time PCR. Chemokine production was further investigated at the protein level by multiplex immunosassay. In subset experiments, co-cultures were treated with either IL-17A receptor A neutralizing antibody or recombinant IL-17A in order to re-activate mononuclear cells (anti-IL-17 receptor A; neutralizing monoclonal antibodies (anti-IL-17A mAb), then cells were stained with Annexin V, anti-IL17RA, and anti-FAS antibodies and were investigated by flow-citometry.

Results: IL17A mRNA in co-cultured PBMCs was increased by 11.5 fold (p < 0.01) and IL17RA by 4.3 fold (p < 0.05) in co-cultured fibroblasts. CXCL-1, CCL2, and CCL3 were also up-regulated at both mRNA (11.9 fold, 773.3 fold, and 29 fold, respectively; p < 0.05) and protein level (8.9 fold, 11.2 fold, and 252.4 fold, respectively; p < 0.05). Profibrotic mediators, such as COL1A1, COL3A1, and CTGF mRNA expression in co-cultured fibroblasts was reduced to 0.33 fold, 0.24 fold, and 0.31 fold, respectively (p < 0.05). This effects were associated with mRNA down-regulation of two key effectors of TGF-β signaling, TGFB2R2 and SMAD3 to 0.59 and 0.79 fold, respectively. Flow cytometry analysis, we observed a robust increase in co-cultured fibroblasts apoptosis by adding IL-17A neutralizing mAb to IL-17A treated cells (39% to 16.8%; p < 0.05). Compared to controls treated with IL-17A and isotype controls, moreover, IL17RA mAb addition also reduced Fas expression in co-cultured fibroblasts as compared to IL-17A treated cells (47.7% to 10.69%; p < 0.05).

Conclusions: Our results support the role of IL-17A in the pathogenesis of SSc. Furthermore, we here first show that IL-17A up-regulation in co-cultured PBMCs might play antibiotic effects in autologous skin fibroblasts and might be implicated in fibroblast apoptosis, interphering with the FAS/FASL pathway.

Disclosure of Interest: None declared

MIRCNPCASES AS A BIOMARKER AND A REDOX-DEPENDENT REGULATOR OF NEUTROPHIL ACTIVATION AND PROTEOLYTIC ACTIVITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

N. Maugeri, P. Rovere Querini, S. Franchini, E. Tombetti, G. Ramirez, V. D’Albèrti, M.G. Sabbadini, M. Bianchi, C. Lunardi, A. Gabrielli, A. Manfredi. AILS Patient Association on Scleroderma, Milan, Italy

Background: Persistent oxidative stress and unrelenting vascular inflammation are hallmarks of Systemic Sclerosis (SSc). Platelet-derived microparticles (PD-uP) that express a bioactive redox-dependent moiety, HMGB1 accumulate in the peripheral blood of SSc patients, but their biological actions is not fully characterized.

Objectives: To verify whether PD-uP might represent a biomarker of SSc clinical involvement and whether their biological actions is regulated by environmental redox.

Methods: Fifty-four patients with SSc and 20 healthy controls were enrolled so far. Twenty healthy controls (HC) matched for sex and age were studied in parallel. PD-uP were characterized and quantified by flow cytometry. Leukocyte features, including expression and distribution of myeloperoxidase (MPO), were assessed by flow cytometry and confocal microscopy. PD-uP ability to regulate neutrophil activation and pro-inflammatory action was assessed in vitro in defined redox conditions and in vivo upon intravenous (i.v.) injection in immunocompromised NSG mice, and traced at various times based on recognition of the human platelet antigen CD61.

Results: PD-uP are present in the blood of SSc patients. Their concentration is significantly higher than in the blood of HC (p<0.001). A substantially higher fraction of SSc PD-uP express the prototypic DAMP, HMGB1 (70% SSc vs 5% HC). Among SSc patients, those with pulmonary hypertension had a significantly higher concentration of HMGB1 + PDuP (p<0.002). In contrast other disease-associated variables, including the extent of fibrosis and the presence of active SSc pattern at the NVC, were not apparently influential. Neutrophils of SSc patients were activated, as demonstrated by the MPO redistribution from the primary granules to the plasma membrane. Circulating neutrophils appeared to be viable and the fraction of cells undergoing apoptosis was similar in SSc patients and HC. The extent of neutrophil activation was associated with the concentration of HMGB1 + PD-uP (p<0.001). SSc PDuP but not HC PD-uP induced MPO redistribution in vitro. The effect was dependent on HMGB1 and increased by oxidizing moieties. Injection in immunocompromised mice resulted in time-dependent association of SSc PD-uP to mouse neutrophils, which contextually redistributed MPO at the plasma membrane.

Conclusions: HMGB1 expression on PD-uP of SSc patients could help identify functionally relevant population of microparticles, involved in neutrophil activation/function and possibly valuable as a novel biomarker of vascular remodeling.

MARKER FOR INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS

L. Guo 1, 2, J. Schnirring 1, R. Schibill 1, A. Blanck 1, D. Chioco 4, S. Yeh 2, O. Distler 1, M. Béhé 3, B. Maurer 1.
1 Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; 2 Department of Rheumatology, Renji Hospital, Shanghai Jiao Tong University, Shanghai, China; 3 Center for Radiopharmaceutical Sciences, Paul Scherrer Institute, Villigen-FS, Switzerland; 4 Advanced Accelerator Applications, Colletteo Giacosa, Italy

Background: Interstitial lung disease (ILD), the primary cause of death in systemic sclerosis (SSc) in early to late course, is premature and difficult to diagnose. Apoptosis is considered the first pathophysiologic event in SSc-ILD. Monitoring of apoptotic processes with nuclear imaging, a sensitive, specific and noninvasive
methodology might be a promising new approach for the diagnosis of early SSC-ILD.

**Objectives:** To evaluate the radiotracer $^{99m}$Tc-rhAnnexin V-128, which specifically targets a pathophysiological key molecule of early apoptosis, for the detection of earliest stages of lung involvement in animal models of SSC-ILD with single photon emission computed tomography (SPECT/CT).

**Methods:** C57BL/6J mice were treated with a single intratracheal injection of bleomycin or saline. Animals were euthanized at days 3, 7, 14 and 21 post-injection (n=6). Lung injury was evaluated by analysis of HE and Sirius red staining. The Ashcroft score was applied for the semi-quantitative evaluation of fibrotic changes. Immunofluorescence using the TUNEL assay and double staining with specific cell markers were performed to determine apoptotic cells. Positive nuclei were quantified by manual and automatic counting with ImageJ analysis software. Three days after injection with bleomycin or saline, mice were injected with $^{99m}$Tc-rhAnnexin V-128 (Advanced Accelerator Applications, Italy). After 1h, images were acquired using small animal SPECT/CT, followed by ex vivo autoradiography.

**Results:** In the model of bleomycin-induced lung fibrosis, inflammatory infiltrates developed from day 7 as assessed by Sirius red staining and was $^{(CD45^+)}$ occurred as early as day 3 with peak at day 7, whereas pulmonary fibrosis from day 7 as assessed by Sirius red staining was most pronounced at day 21 (mean Ashcroft score=4.6, p=0.0286). Notably, the number of apoptotic cells evaluated by TUNEL staining, was highest at day 3 (mean ± SE=6.5±1.5 positive cells/HPF, p=0.0438) compared with saline controls (mean ± SE=0.7±0.1, p=0.0095) and then decreased over time. To determine the type of cells undergoing apoptosis, we performed co- stainings with different cell markers. Data displayed that endothelial cells (vWF+) and epithelial cells (cytokeratin+), but not inflammatory cells (CD45+) were the primary cells undergoing apoptosis in earliest inflammatory stages of ILD.

In accordance with the findings on tissue level, at day 3 post-injection, we detected ex vivo with autoradiography, yet not with in vivo SPECT/CT, an increased pulmonary uptake of $^{99m}$Tc-rhAnnexin V-128 in the lungs of bleomycin-induced mice compared with saline treated controls.

**Conclusions:** Apoptosis of epithelial and endothelial cells preceded the development of pulmonary inflammation and fibrosis in the model of bleomycin-induced lung fibrosis. Thus, the use of $^{99m}$Tc-rhAnnexin V-128 might be a promising approach for the diagnosis of earliest stages of ILD. However, sensitivity of **in vivo** imaging has to be further improved.

**Conclusions:** The cumulative doses of 1200 J/cm² and 600 J/cm² of narrowband UVA1 effectively reduced the dermal thickness, and the impact was dose-dependent. Phototherapy course did not up-regulate p53 nor Ki-67 proteins in the healthy mice and mice with scleroderma skin. UVA1 radiation caused the increase of the active caspase-3 expression in the skin of mice with scleroderma reflecting the apoptotic feature of narrowband UVA1. The results of this study indicate that 365±5 nm UVA1 phototherapy is safe and effective for the treatment of dermal fibrosis.

mononuclear cells (PBMCs), and a relationship among specific inflammatory mediators, ECS, and organ involvement has not been established.

**Objectives:** To analyze ECS elements and related inflammatory molecules in PBMCs of SSC patients, and evaluate their relationship with the clinical profile of the disease.

**Methods:** 24 SSCs patients [including 5 Pre-SSc, 13 limited cutaneous SSc (lc-SSc) and 6 diffuse cutaneous SSc (dc-SSc)] and 24 healthy donors (HD) were included. Purified PBMCs were used for analysis of gene expression of molecules belonging to the ECS: CB1, CB2, GPR55, P2Y1, FAAH, MAGL and TRPV1. Inflammatory mediators were evaluated in PBMCs by RT-PCR. Clinical evaluation of patients was performed and correlation/association studies were developed.

**Results:** Cannabinoid type-2 receptor, GPR55 and TRPV1 gene expression were reduced in PBMCs of SSC patients, while FAAH showed a high level of expression in the same populations. In addition, in the patient group’s of Pre-SSc, specific elevated in various cytokines was demonstrated (i.e. IL-1β, IL-17, VEGF-A), suggesting that these cytokines might act as early biomarkers of disease development. Patients’ positive for anti-centromere antibodies showed increased expression of IL-4, IL-17 and MCP-1 in relation to those positive for anti-Sc70. PBMCs expression levels of GPR55, IL-12 and MCP-1 were higher in lc-SSC compared to dc-SSc. Interestingly, we observed a direct correlation between levels of these cytokines and the occurrence of pulmonary hypertension, a pathology more frequent in lc-SSc, thus suggesting a role for these inflammatory molecules in pulmonary involvement in this form of the disease. Correlation studies demonstrated an interrelation among deregulated expression of various molecules belonging to the ECS (i.e. FAAH, GPR55 and TRPV1) and inflammatory mediators over-expressed in serum and immune cells (i.e. CRP, ESR, MCP-1, TNFα and VEGF-A).

**Conclusions:** SSCs patients show altered gene profile of ECS and inflammatory mediators in PBMCs, which might allow the discrimination between limited and diffuse forms of the disease, and are associated with the presence of specific auto-antibodies and the internal organ involvement. Our overall data suggest an appealing potential target of ECS for treatment of SSCs, as it seems to be related to the inflammatory profile.

**INTERLEUKIN-4 INDUCES CLASS-SWITCHING TO IGG4 AND SYNERGISTICALLY CONTRIBUTES TO PLASMABLASTS DIFFERENTIATION WITH INTERLEUKIN-21 THROUGH CD40 DEPENDENT MANNER IN IGG4-RELATED DISEASE**

M. Akiyama, H. Yasuoka, K. Yoshimoto, T. Takeuchi. Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

**Background:** IgG4-related disease (IgG4-RD) is a lymphoproliferative disorder characterized by elevated serum levels of IgG4 and increased numbers of circulating plasmablasts. We have previously reported that class-switching to IgG4 and plasmablast differentiation are mediated by follicular helper type 2 T cells which are known to secrete interleukin (IL)-4, IL-13, IL-10 and IL-21 (1, 2). However, the cytokines which play a role in the IgG4 class-switching and plasmablast differentiation through correlation to cell contact remain unclear in IgG4-RD.

**Objectives:** The aim of this study was to elucidate the role of follicular helper type 2 T cell cytokines (IL-4, IL-13, IL-10, and IL-21) and cell to cell interaction in the IgG4 class-switching IgG4-RD.

**Methods:** Peripheral blood mononuclear cells (PBMCs) were prepared from seven consecutive patients with active, untreated, newly diagnosed IgG4-RD and five healthy controls. To identify the cytokines which induce IgG4 class-switching, the cells were stimulated with IL-4, IL-13 or the combination with other cytokines, such as IL-10 or IL-21. The amounts of IgG4 and IgG in the culture supernatants were measured by cytometric bead arrays. The expression level of activation-induced cytokine deamidase (AID; an enzyme essential for class-switch recombination) was analyzed by quantitative PCR to confirm the induction of class-switching by stimulation with cytokines. The numbers of plasmablasts and plasma cells induced by cytokines stimulation were examined by flow cytometry. Moreover, an anti-CD40 antibody was added to the culture to elucidate the effects of cell to cell interaction on the differentiation of plasmablasts or plasma cells.

**Results:** IL-4 significantly induced CD40-stimulated PBMCs to undergo IgG4 class-switching to IgG4-RD, while IL-13 did not show any positive effects. Moreover, the IgG4/IgG ratio in culture supernatants was also significantly higher in the stimulation with IL-4 compared to other cytokines in IgG4-RD. In addition, the expression levels of AID mRNA were increased by stimulation with IL-4 compared to that by no stimulation or CD40 stimulation in IgG4-RD. On the other hand, PBMCs from healthy controls showed no significant difference in IgG4 production after stimulation with either IL-4 or IL-13. Furthermore, IgG4 production stimulated with IL-4 was significantly higher in IgG4-RD than that in healthy controls. Assessing additional effects of IL-10 or IL-21 on IL-4, IL-10 and IL-21 did not increase IgG4 production and IgG4/IgG ratio compared to IL-4 alone. However, importantly, IL-21 synergistically induced plasmablasts or plasma cells differentiation in combination with IL-4, whereas no obvious change was observed in PBMCs stimulated with IL-4 alone in IgG4-RD. Of note, the differentiation of plasmablasts and plasma cells by IL-4 and IL-21 was markedly abolished in the absence of CD40 stimulation.

**Conclusions:** Our results strongly suggest that IL-4 plays a pivotal role in IgG4 class-switching, and the effective collaboration between IL-4 and IL-21 contributes to plasmablasts and plasma cells differentiation via CD40 dependent manner in patients with IgG4-RD.

**ANGIOGENIC T CELL EXPANSION CORRELATES WITH SEVERITY OF PERIPHERAL VASCULAR DAMAGE IN SYSTEMIC SCLEROSIS**

M. Manetti, S. Pratesi, E. Romano, I. Rosa, A. Martiradonna, S. Bellando-Randone, S. Guiducci, L. Ibbà-Mannessi, E. Maggi, M. Matucci-Cerinic. Experimental and Clinical Medicine, University of Florence, Florence, Italy

**Background:** The mechanisms underlying endothelial cell injury and defective vascular repair in systemic sclerosis (SSc) remain unclear. Recent studies suggest that a novel T cell subset, the so-called angiogenic T (Tang) cells, may have an important impact on the repair of damaged endothelium. Tang cells are characterised by the co-expression of CD3, CD31 (platelet-endothelial cell adhesion molecule-1) and CXCR4 (or CD184, receptor for the CXC chemokine stromal cell-derived factor-1 (SDF-1)/CXCL12). Tang cells may promote the formation of new blood vessels and endothelial repair by stimulating the function and differentiation of endothelial progenitor cells possibly through the secretion of proangiogenic cytokines, thus fostering postnatal vasculogenesis.

**Objectives:** This study aimed to analyse the Tang cell population in relation to disease-related peripheral vascular features in SSC patients.

**Methods:** Tang cells (CD3+CD31+CXCR4+) were quantified by flow cytometry in peripheral blood samples from 39 patients with SSc and 18 matched healthy controls (HC). CD3+CD31+CXCR4- Tang cells were expressed as a percentage of total CD3+ T cells. Circulating levels of SDF-1α were assessed in paired serum samples by immunoassay. Skin sections from patients with early diffuse cutaneous SSc (n=7) and HC (n=6) were subjected to CD3/CD31 and CD3/CXCR4 double immunofluorescence staining.

**Results:** The percentage of circulating Tang cells was not different between the whole SSc patient cohort (median 29.9, interquartile range (IQR) 22.3–36.2) and HC (median 25.2, IQR 23.3–33.5). Subgroup analysis revealed that Tang cells were significantly increased in SSc patients with digital ulcers (DU) (median 35.5, IQR 32.2–42.5) compared either with SSc patients without DU (median 23.3, IQR 18.5–29.6) or with HC (p<0.001 for both). Furthermore, Tang cell percentage was significantly higher in SSc patients with “late” nailfold videocapillaroscopy (NVC) pattern (median 34.9, IQR 25.0–42.0) than in those with “early”/“active” NVC patterns (median 26.8, IQR 20.4–32.9) and in HC (p=0.01 and p=0.04, respectively). No difference in circulating Tang cell counts was found when comparing either SSc patients without DU or patients with “early”/“active” NVC patterns and HC. In SSc peripheral blood, the percentage of Tang cells was inversely correlated to the levels of SDF-1α (Spearman’s rho = -0.59, p<0.0001).

**Conclusions:** Our findings demonstrate for the first time that Tang cells are expanded in patients with SSc displaying most severe peripheral vascular complications. Such an expansion may be an ineffective attempt to compensate for the need increased angiogenesis and endothelial progenitor cell function. In SSc, Tang cells might represent a potentially useful biomarker reflecting peripheral vascular damage severity. Further studies are required to clarify the function of Tang cells and investigate the mechanisms responsible for their change in SSc.

Scleroderma, myositis and related syndromes

**FRI0363** KL-6 AND NOT CCL-18 IS A PREDICTOR OF EARLY PROGRESSION IN SYSTEMIC SCLEROSIS RELATED INTERSTITIAL LUNG DISEASE

Background: Pneumoproteins are attractive biomarker candidates in systemic sclerosis (SSc) related interstitial lung disease (ILD) because they are easily obtainable and lung-specific. KL-6 and CCL-18 (PARC) have been previously reported as promising predictive biomarkers of lung parenchymal damage in multiple disorders including SSc-ILD.

Objectives: Our goal was to determine the predictive significance of these two pneumoproteins for forced vital capacity % (FVC) decline within the first year of follow-up in patients with early SSc-ILD, in order to inform individualized care in routine clinical practice and facilitate enrichment strategies in clinical trials.

Methods: GENISOS (Genetics versus ENvironment In Scleroderma Outcome Study) cohort patients who had ILD verified by imaging and available pulmonary function tests at enrollment plus 12–18 months thereafter, were included in this study. All patients had disease duration ≤5 years at enrollment. FVC, expressed as percentage of predicted value was used as surrogate for severity of ILD. Annualized percent change in FVC at one year follow up was calculated. Baseline demographic, clinical variables and two pneumo-proteins, KL-6 and CCL-18 were investigated. KL-6 and CCL-18 were measured in the plasma by commercially available, validated ELSA. Multiple linear regression with baseline clinical and demographic variables as independent variables was performed in univariable and multivariable models. Only variables that reached p<0.1 were included in the multivariable analyses.

Results: A total of 82 patients with early SSc-ILD were included. 18 were male and 45 had diffuse cutaneous involvement. Mean disease duration was 2.3 years. Rate of FVC% predicted change over time ranged from -0.23 to 0.38, indicating a highly variable course. Baseline KL-6 levels were higher in patients than healthy controls (p=0.0001). Baseline higher KL-6 levels were predictive of faster FVC% decline at the one year follow-up (b=-0.03, p=0.04). Upon categorizing KL-6 using a previously determined optimal cut-off of 1273 u/mL (1), its predictive significance remained in the univariate (p=0.01) and multivariable analyses adjusted for Sci-70, disease type and gender (b=-0.03, p=0.04). Twenty-nine (34.5%) patients had KL-6 levels equal or above 1273 u/mL. Although CCL-18 was higher in patients than controls (<0.0001), its levels did not predict rate of FVC decline (provide p-value).

Conclusions: KL-6 but not CCI-18 is predictive of early SSc-ILD progression. In this study, we also validated the previously proposed cut-off of 1273 for KL-6 in an independent cohort. KL-6 is a promising pneumoprotein that can inform individualized clinical care and contribute to enrichment strategies in clinical trials of SSc-ILD.

**FRI0364** USEFULNESS OF SERUM HAPTOGLOBIN LEVELS AS A NOVEL MARKER FOR PULMONARY ARTERIAL HYPERTENSION COMPLICATED WITH CONNECTIVE TISSUE DISEASE

Background: Pulmonary arterial hypertension (PAH) is of great clinical significance as a life-threatening complication of connective tissue diseases (CTD). Pulmonary artery thrombotic microangiopathy (PATM) is an important pathophysiology of PAH. The concept of PATM refers to localized thrombotic microangiopathy to be defined histologically and should be discriminated from systemic thrombotic microangiopathy characterized by microangiopathic haemolysis and thrombocytopenia. The degree of PATM has been suggested to be associated with vascular remodeling, severity and prognosis of PAH, and anticoagulation therapy might be effective in PAH patients with features of PATM [1]. Haptoglobin (Hp) is a plasma protein mainly produced by hepatocytes, which binds free haemoglobin released from erythrocytes and protects the kidneys from damage induced by haemoglobin. The Hp is measured in clinical setting as a sensitive marker to detect intravascular haemolysis including thrombotic microangiopathy [2].

Objectives: We hypothesized that serum Hp levels decreased in patients with PAH due to pulmonary microangiopathic haemolysis. The aim of this study was to investigate the association between serum Hp levels and pulmonary artery systolic pressure estimated by echocardiography (ePASP) in patients with CTD.

Methods: This study included CTD patients with suspicion of PAH who were attending Rheumatology Department in Hokkaido University Hospital between August 2015 and August 2016 and underwent echocardiography. PAH was diagnosed based on right heart catheter findings. Serum Hp levels were measured by standardised turbidimetric immunoassay in all patients. Demographic data, laboratory results, and echocardiographic findings were extracted from the medical records. Decreased serum Hp levels were defined as below 15 mg/dL based on the 95th percentile of healthy controls.

Results: Twenty-four CTD patients with confirmed PAH (CTD-PAH) and 32 CTD patients without PAH (non-PAH) were enrolled. Decreased serum Hp levels were significantly frequent in patients with CTD-PAH compared with non-PAH patients (29% vs 6%, p=0.03). In patients with CTD-PAH, serum Hp levels had a significant negative correlation (r = -0.692, p<0.0001, Figure 1) with ePASP, and serum lactate dehydrogenase (LDH) levels were significantly elevated in patients with decreased Hp levels (233±47 U/L vs 187±42 U/L, p=0.01). Follow up study showed lowering ePASP led to normalizing serum Hp levels.

Conclusions: Serum Hp levels correlated negatively with ePASP in patients with CTD-PAH, and serum LDH levels were higher in CTD-PAH patients with decreased Hp levels. These findings suggest that decreased Hp levels in CTD-PAH patients may reflect PATM and subsequent subclinical haemolysis. Serum Hp levels are a candidate of additional non-invasive marker of CTD-PAH to assess the degree of PATM.

FR10365 NEW COLLAGEN BIOMARKERS PREDICT PROGRESSION OF FIBROSIS IN SYSTEMIC SCLEROSIS

P. Dobrota1, S. Jordan1, P. Juhl1, B. Maurer1, L. Wildi1, A.-C. Bay-Jensen2, M.A. Karsdal2, A.S. Siebuhr2, O. Distler1. 1Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; 2Nordic Bioscience, Herlev, Denmark

Background: Systemic sclerosis (SSc) is a complex autoimmune disease with extensive fibrosis of the skin and internal organs in which extracellular matrix (ECM) remodelling is a key pathogenic process. Imbalance in the formation and degradation of collagens results in fibrosis. Quantifying the tissue turnover in a highly fibrotic disease such as SSc is very important for the prediction of disease progression and therapeutic efficacy. Given the clinical heterogeneity of SSc patients, biomarkers facilitating personalized medicine approaches are highly needed.

Objectives: To evaluate the potential of selected ECM neo-epitopes as serological biomarkers for diagnosis, prediction of clinical outcomes and disease progression in SSc.

Methods: Healthy controls (HC; n=29), stable SSc (n=149), and progressive SSc patients (n=23), progression defined either as 10% decrease in FVC% predicted or increase in mRSS >25% and 5 points on one year clinical follow up), meeting the 2013 ACR/EULAR classification criteria were analyzed. Longitudinal clinical assessment, data recording and sera collection were done according to EUSTAR standards. ECM-degradation (C3M, VICM, C4M2, BGM) and ECM-formation biomarkers (P1NP, P4NP7S, Pro-C3, Pro-C5, Pro-C6) were measured in serum using newly developed ELISA-based assays (Nordic Bioscience). Differences in biomarker levels were analyzed with respect to several fibrosis-related clinical outcomes. Statistical analysis was performed by Man-Whitney U, Kruskal-Wallis and Spearman tests. Biomarkers’ sensitivity and specificity was examined by ROC analysis.

Results: Both ECM-degradation and ECM-formation biomarkers differed between SSc patients and HC: The expression of C4M2, Pro-C3, BGM and C3M was significantly increased in SSc patients compared to HC (p<0.0001, AUC=0.93; p<0.0001, AUC=0.74; p=0.003, AUC=0.67; p<0.0001, AUC=0.94, respectively), whereas P1NP was significantly lower (p<0.0001, AUC=0.78), Figure 1. Furthermore, Pro-C3, VICM and Pro-C6 levels were significantly higher in SSc progressors vs. HC (p<0.0001, AUC=0.86; p=0.003, AUC=0.75; p<0.0005, AUC=0.81, respectively).

Conclusions: There is no fully validated biomarker predicting worsening of fibrosis. In this regard, most interestingly, the ECM-degradation markers C4M2, BGM, C3M were significantly lower in SSc patients showing progression of fibrosis on follow up versus SSc patients being stable on follow up (p<0.0001; p<0.008; p<0.0001, respectively). Consistently, the formation marker Pro-C6 was significantly increased (p<0.001, AUC=0.71) indicating a profound imbalance of ECM turnover in progressors. The strongest difference between progressive and stable SSc patients was seen for the ratio between the formation and degradation biomarkers Pro-C3/C3M which showed an AUC of 0.86 in progressive vs. stable SSc patients (p<0.0001).

FR10366 A PILOT STUDY ON ISCHEMIA AND REPERFUSION INJURY DURING A RAYNAUD’S ATTACK: SEQUENTIAL ASSESSMENT OF REDOX STRESS PARAMETERS IN A UNIQUE COOLING AND REWARMING EXPERIMENT

A.M. Van Roon1, A. Eman Abdulle1, A.M. van Roon1, J.D. Lefrandt1, A.J. Smit1, H. Bootsma2, B.O. Fernandez3, M. Minnion3, M. Feelisch3, H. van Goor4, D.J. Mulder5. 1Internal Medicine - Vascular Medicine, 2Rheumatology and Clinical Immunology, University of Groningen - University Medical Center Groningen, Groningen, Netherlands; 3Clinical and Experimental Sciences, University of Southampton, Southampton, United Kingdom; 4Pathology, University of Groningen - University Medical Center Groningen, Groningen, Netherlands

Background: Oxidative stress plays a role in systemic sclerosis (SSc), but the molecular mechanisms involved are incompletely understood. During an attack of Raynaud’s phenomenon (RP) a period of ischemia (I), followed by a period of reperfusion (R) occurs frequently, associated with the severity of vasculopathy. [1] Only in secondary RP digital ulcers develop. We hypothesized that I/R injury may play a role in the pathogenesis and could offer new therapeutic targets.

Objectives: To explore the course of oxidative stress in patients with SSc compared with primary RP and healthy controls.

Methods: A total of 30 patients were included: 10 with limited cutaneous SSc (age: 57 (53–61) yr, male/female 5/5), 10 with primary RP (age: 54 (41–58), 2/8), and 10 healthy controls (age: 29 (22–25), 3/7). A standardized cooling experiment was performed and digital perfusion was assessed in all 5 fingers using photo-electric plethysmography: at baseline (T=0) the dominant hand was submerged in water at 33°C, followed by cooling in steps of 3°C every 4 minutes, until 6°C or when pain became intolerable (T=1). Recording was continued 10 (T=2) and 30 (T=3) minutes of rewarming to ambient temperature (23°C). Blood was drawn from ipsilateral cubital vein at T0, 1, 2 and 3, markers for tissue injury (lactate, LDH, creatinine phosphokinase (CPK) [routine methods]), redox status ([N-2NO- [NO-R] were measured in plasma. [1–3] Numbers are in median (IQR).

Results: Baseline free thiols were significantly decreased in RP vs. controls (5.18 (4.79–5.63) vs 5.87 (5.41–5.99) umol/g, p=0.013), with no differences in lactate, LDH, CPK, and NO activity. Raynaud’s attack was induced in all RP patients but not in controls. Median duration of hypoperfusion was greater in SSc vs. PRP (30 (27-35) vs. 12 (9–14) min, p=0.010), with a considerably longer recovery time (8 (4–10) vs 9 (0–1) min, p=0.006). No changes were observed in lactate, LDH, and CPK levels. A rise in free thiols occurred at recovery (T4) in all 3 groups (figure 1). The concentrations of NO-related products did not change during cooling or recovery. No association was detected between the extent of I/R and plasma parameters.

Conclusions: In patients with RP free thiols were significantly reduced, indicating increased redox stress. During the cooling and rewarming experiment, a clear rise in free thiols was observed during rewarming, irrespective of the underlying disease or finger perfusion. Meanwhile, NO-related products remained stable.
Although these findings need further study, they may suggest activation of ubiquitous antioxidant defense mechanisms during cooling and/or rewarming and should be explored for future use as a potential therapeutic target in RP.

FR0367 NEW AUTOIMMUNE TARGETS IN IDIOPATHIC INFLAMMATORY MYOPATHIES - AN AGENT BEAD ARRAY APPROACH

A. Notarnicola 1, C. Hellstrom 2, C. Mattsson 2, E. Andersson 2, H. Lidberg 2, E. Jermsby 2, M. Neman 1, P. J. Jakobsson 2, P. Nilsson 2, I.E. Lundberg 1
1 Department of Medicine, Rheumatology Unit, Karolinska University Hospital and Karolinska Institutet; 2SciLifeLab, KTH - Royal Institute of Technology, Solna, Stockholm, Sweden

Background: The Idiopathic Inflammatory Myopathies (IIM) is a group of rare systemic inflammatory diseases characterized by severe organ involvement and premature mortality. Several myositis specific auto-antibodies (MSAs) have been recognized and associated with specific clinical manifestations and prognosis, still many patients are autoantibody negative. Identification of new autoimmune targets will be helpful in improving diagnosis, better stratifying into subgroups, prediction of prognosis, tailoring treatment and to understand underlying biological pathways.

Objectives: To identify new autoimmune targets in IIM by antigen bead array (1).

Methods: A bead array with 354 antigens was used to explore the autoimmune reactivity in 881 plasma samples from patients with IIM (N=225), Systemic Lupus Erythematosus (SLE) (N=350) and population controls (N=350). The antigens were selected from initial screenings of 160 SLE-samples on a total of 5760 antigens on planar arrays, and a first verification bead array with 355 antigens. The IIM samples represented three groups of patients with distinct diagnoses: Dermatomyositis (DM, N=83), Polymyositis (PM, N=111) and Inclusion Body Myositis (IBM, N=21), who were regularly followed at the Rheumatology Unit of the Karolinska University Hospital from January 2003 until March 2014. Based on 2 possible levels of cutoff, each sample was classified as reactive to each single antigen (Ag) at low or high cut off or non-reactive.

Results: In general, depending on the cutoff stringency, 86–88% of the 354 selected antigens showed reactivity in at least one sample with no difference between IIM, SLE and controls. Comparing PM, DM according to the cut off was observed towards E3 ubiquitin protein ligase 2 (SIAH2), leiomodin 2 (LMO2) and RAD23 homolog A (RAD23A). In the group of IIM patients with extensive clinical and nailfold capillaroscopy (NFC) pattern assessment, as well as quantification of serum E-sel, ICAM-1, ET-1, vWF, IL-6 and C-reactive protein (CRP) were performed on all patients. Associations between vascular biomarkers and disease characteristics were evaluated by Mann-Whitney U-test and Spearman correlations.

Conclusions: Serum biomarkers reflecting endothelial cell activation and/or dysfunction are elevated in patients with more severe SSC-associated vasculopathy and correlate with serum CRP. Together with NFC data they might be used for assessing vasculopathy severity in SSC and identifying patients who would benefit from more aggressive vasoactive treatment.

Acknowledgements: This work was performed as part of the project “Development of a computer-based nailfold videocapillaroscopy (NVC) system for longitudinal evaluation of patients with systemic sclerosis” (QUANTICAP), financed by the UEFISCDI PN-IP JPT-PCCA-2013–4-1589 grant.

FR0358 NAILFOLD CAPILLAROSCOPY CHANGES REACT-ENDOTHELIAL ACTIVATION AND INJURY IN PATIENTS WITH SYSTEMIC SCLEROSIS

A.M. Gheorghui 1, R. Strest-Cornateanu 2, D. Marta 3, M. Bojinca 1, S. Magda 4, T. Constantinescu 5, A. Soare 6, R. Robota 6, L. Macovei 6, V. Stoica 1, C. Bara 2, C. Mihal 1, 1Internal Medicine and Rheumatology, Cantacuzino Hospital; 2Immunology and Physiopathology Department, Carol Davila University of Medicine and Pharmacy; 3Victor Babes National Institute of Research and Development; 4Cardiology Department, University Emergency Hospital; 5Maris Nasta National Pneumology Institute, Carol Davila University of Medicine and Pharmacy; 6Internal Medicine and Rheumatology, Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background: Systemic sclerosis (SSc) is a severe connective tissue disease characterized by vascular and fibrotic changes in the skin and various internal organs. Pathogenesis of SSc includes early-onset vasculopathy with endothelial cell activation, microvascular injury and impaired angiogenesis.

Objectives: We aimed to determine the association of several biological molecules reflecting endothelial cell activation or dysfunction: E- selectin (E-se1), inter-cellular adhesion molecule 1 (ICAM-1), endothelin 1 (ET-1), von Willebrand factor (vWF) and interleukin 6 (IL-6), with distinct capillaroscopic SSc patterns and with more severe disease.

Methods: Forty consecutive SSc patients attending our EUSTAR SSc clinic, aged [median (IQR)] 52 (18) years, male gender 4/40 (10%), diffuse cutaneous subset (dcSSc) 14/27 (35%) were enrolled in this study. Extensive clinical and nailfold capillaroscopy (NFC) pattern assessment, as well as quantification of serum E-sel, ICAM-1, ET-1, vWF, IL-6 and C-reactive protein (CRP) were performed on all patients. Associations between vascular biomarkers and disease characteristics were evaluated by Mann-Whitney U-test and Spearman correlations.

Conclusions: Serum biomarkers reflecting endothelial cell activation and/or dysfunction are elevated in patients with more severe SSc-associated vasculopathy and correlate with serum CRP. Together with NFC data they might be used for assessing vasculopathy severity in SSC and identifying patients who would benefit from more aggressive vasoactive treatment.

FR0359 PROSPECTIVE EVALUATION OF THE CAPILLAROSCOPIC SKIN ULCER INDEX (CSURI) IN CLINICAL PRACTICE

U.A. Walker 1, V.K. Jaeger 2, L. Arletta 3, M. Banyai 4, J. Beron 4, C. Chizzolini 4, E. Gröchenig 5, R.B. Mueller 5, F. Spertiini 6, P. Villerisse 7, O. Distler 8, 1University Hospital Basel, Basel; 2Hôpital du Valais, Sion; 3Kantonsspital Luzern, Luzern; 4Aetherion Pharma Schweiz AG, Baden; 5Hôpitaux Universitaires de Genève, Genève; 6Kantonsspital Aarau, Aarau; 7Kantonsspital St. Gallen, St. Gallen; 8Centre Hospitalier Universitaire Vaudois, Lausanne; 9University Hospital Bern, Bern; 10University Hospital Zurich, Zurich, Switzerland

Background: Nailfold videocapillaroscopy (NVC) is an imaging technique representing a reliable tool for the classification, diagnosis and monitoring of systemic sclerosis (SSc) patients. The capillaroscopic skin ulcer index (CSURI) was suggested to identify patients at risk of developing digital ulcers (DU) [1].

Objectives: This study aims (1) to describe the practicality of the CSURI in clinical practice, (2) to describe the change of CSURI during follow-up, and (3) to assess associations between the change in CSURI and demographic and disease characteristics.

Scleroderma: A Validation Study Using Nailfold Video-Capillaroscopy

G. Abignano 1,2, L. Green 1,2, S. Eng 1,2, P. Emery 1,2, F. Del Galdo 1,2.

Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; 2 NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

Background: Optical Coherence Tomography (OCT) of the skin has been proposed as imaging biomarker of fibrosis in Systemic Sclerosis (SSc) [1]. However, over the past few years, growing efforts have been made to enable OCT to the study of human skin microcirculation including human nailfold [2].

Dynamic OCT (D-OCT) is a newly developed OCT technology that allows detection of blood flow in vivo in addition to the images of traditional OCT scans [3].

Objectives: Aims of this study were: 1) to evaluate face/criterion validity and feasibility of nailfold capillary D-OCT imaging as compared with nailfold video-capillaroscopy (NVC) capillary patterns in SSc patients; 2) to investigate whether D-OCT could offer a complementary value to NVC through the 3-dimensional reconstruction and quantification of nailfold capillary abnormalities in SSc patients.

Methods: Fifty subjects including forty SSc patients all fulfilling 2013 EULAR/ACR classification criteria (10 with normal/non-specific, 10 with early, 10 with active, 10 with late capillary pattern respectively) and ten age/gender-matched healthy volunteers (HV) were enrolled in this study. All subjects had NVC done on 8 fingers and classified according to the capillary pattern. Nailfold of the finguer with the worst capillary score in SSc patients and the 4th finger (the most affected in the SSc groups) of the dominant hand in subjects with normal capillary pattern was subsequently scanned using Viviosight D-OCT (Michelson Diagnostics Ltd., Kent, UK). D-OCT images were analyzed using the proprietary software tool to extract a quantitative measure of the speckle variance (SV)-signal. Results were expressed as mean±standard error. Statistical analysis was performed using GraphPad Prism software V.7.0.

Results: The finger with the worst capillary score was the 4th (33%) in the SSc patients. The typical nailfold capillary features seen at NVC were visualized at D-OCT images. Representative images are shown in figure 1. Each nailfold D-OCT scan lasted 60 seconds, was well tolerated and did not require use of gel or immersion oil. OCT mean SV-signal measurements were significantly different between HV and SSc patients with any specific capillary pattern (0.14±0.01 vs 0.10±0.01, p=0.0028) and between SSc patients without and with specific capillary pattern (0.14±0.01 vs 0.10±0.01, p=0.02). The mean SV-signal was higher in HV than in SSc patients without specific capillary pattern however the difference was not statistically significant. When analyzing the three specific capillary patterns, SV-signal measurements were not significantly different. Interestingly, within the late capillary pattern, mean SV-signal was significantly lower in patients displaying capillary loss as main feature compared with those with remarkable neoangiogenesis (p=0.03).

Conclusions: D-OCT is a feasible technique able to reproduce the capillary changes seen at NVC in SSc patients. More importantly D-OCT could offer a complementary value to quantify peripheral blood flow at capillary level. Future longitudinal studies are needed to evaluate the sensitivity to change over time and the potential of D-OCT as quantitative outcome measure of microvasculopathy in SSc.

DOI: 10.1136/annrheumdis-2017-eular.5598
Background: Interstitial lung disease (ILD) is currently the primary cause of death in systemic sclerosis (SSc). Thoracic high-resolution computed tomography (HRCT) is considered the gold standard for diagnosis. Recent studies have proposed several clinical algorithms to predict the diagnosis and prognosis of SSc-ILD.

Objectives: To test the clinical algorithms to predict the presence and prognosis of SSc-ILD, and to evaluate the association of extent of ILD with mortality in a cohort of SSc patients.

Methods: Prospective cohort study, including 177 SSc patients assessed by clinical evaluation, laboratory tests, pulmonary function tests, and HRCT. Three clinical algorithms, combining lung auscultation, chest radiography and % predicted forced vital capacity (FVC) [1], were applied for the diagnosis of different extents of ILD on HRCT. Univariate and multivariate Cox proportional models were used to analyze the association of algorithms [1,2] and the extent of ILD on HRCT with the risk of death using hazard ratios (HR).

Results: The prevalence of ILD on HRCT was 57.1% and 79 patients died (44.6%) in a median follow-up of 11.1 years. For identification of ILD with extent ≥ 10 and ≥ 20% on HRCT, all algorithms presented a high sensitivity (> 89%) and a very low negative likelihood ratio (< 0.16). For prognosis, survival was decreased for all algorithms, especially the algorithm C (HR 3.47, 95% CI 1.62–7.42), which identified the presence of ILD based on crackles on lung auscultation, findings on chest X-ray or FVC < 80%. Extensive disease as proposed by Goh and Wells (extent of ILD > 20% on HRCT or, in indeterminate cases, FVC < 70%) had a significantly higher risk of death (HR 3.42, 95% CI 2.12 to 5.52). Survival was not different between patients with extent of 10 or 20% of ILD on HRCT, and analysis of 10-year mortality suggested that a threshold of 10% may also have a good predictive value for mortality. However, there is no clear cutoff above which mortality is sharply increased.

Conclusions: Clinical algorithms had a good diagnostic performance for extents of SSc-ILD on HRCT with clinical and prognostic relevance (> 10 and > 20%), and were also strongly related to mortality. Therefore, they probably could be used to obviate the requirement of HRCT in some cases.

The DUCAS: A PROPOSAL FOR A DIGITAL ULCER ASSESSMENT SCORE IN SCLERODERMA

C. Bruni1, T. Ngcozana2, F. Brashchi1, S. Guiducci1, S. Bellando-Randone1, Y.A. Süliman3, J. Grotts4, C.P. Denton5, D.E. Furst6, M. Matucci-Cerinic1.
1Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Firenze, Italy; 2Centre for Rheumatology and Connective Tissue Diseases, UCL Division of Medicine, London, United Kingdom; 3Rheumatology and Rehabilitation Department, Assiut University Hospital, Assiut, Egypt; 4Department of Biostatistics; 5Division of Rheumatology, Department of Medicine, University of California at Los Angeles, Los Angeles, United States

Background: No objective measure is presently available to assess digital ulcer (DU) in SSc patients apart from “healed/non healed” and experience-based clinical judgment.

Objectives: The aim of the current study is to propose a composite DU clinical assessment score (DUCAS) and, to lend it, test its face validity by correlating it with commonly used disease related patient-reported outcomes (PROs) and physician evaluation.

Methods: SSc patients presenting at least one DU and attending the Rheumatology Wound Care Clinic of the Florence University Hospital or the London Royal Free Hospital were enrolled. Patients were assessed with HAQ-DI, Cochin scale, Visual analogic scale (VAS) for DU-related pain (DU_pain, 0–100 mm), patient global assessment (P GA, 0–100 mm) as PROs and physician VAS for DU status (phyGDU, 0–100mm). The DUCAS included 7 DU related variables selected by a committee of 8 SSc DU experts - they are outlined in figure 1. Each variable was weighted on a clinical basis and the DUCAS score was the sum of the values for the 7 variables (max=19.5). Spearman’s correlation tests were calculated for to examine face validity. A linear regression model with forward and backward stepwise analysis was used to determine the relationship of individual variables with the primary clinical parameter, phyGDU.

Results: 44 SSc patients (9 males, mean age 54.3±15.8 years, mean disease duration 9.9±5.8 years) were enrolled in the study. Mean phyGDU was 44.3±23.9mm, mean pGDU was 54±30mm (Wilcoxon p=0.022, phyGDU VAS vs pGDU) and mean DUCAS score was 4.2±2. Overall DUCAS showed significant positive correlations with all PROs, but when all the individual clinician and patient’s variables were modelled, only the overall DUCAS significantly predicted PhyGDU; after backwards stepwise analysis overall DUCAS and phyGDU best predicted PhyGDU, with an adjusted R²=0.437 and AIC=380.3 (Table 2).

Conclusions: DUCAS is a newly proposed clinical score for SSc related DU which has face validity and which may reflect DU status as judged by SSc experts. Further validation of this score will be undertaken.

SUBSTANCE P AND VASCULAR ENDOTHELIAL GROWTH FACTOR PRODUCTION BY PERIPHERAL BLOOD MONONUCLEAR CELLS DERIVING FROM PATIENTS WITH SYSTEMIC SCLEROSIS

A. Corrado, E. Sanpaolo, R. Cola, A. Mele, F.P. Cantatore. Department of Medical and Surgical Sciences - Rheumatology Clinic, University of Foggia, Foggia, Italy

Background: Many cytokines may potentially play a relevant role in the pathogenesis of different aspects of SSC, particularly fibrosis and endothelial injury. Some data suggest that substance P (SP) may act in an autocrine/paracrine manner to regulate vasconstriction and/or immunologic and inflammatory responses. VEGF and MCP1, which are produced by inflammatory cells, may be involved in the pathogenesis of vascular changes and accumulation of extracellular matrix in SSc.

Objectives: The aim of this study was to determine the expression of Substance P (SP), Vascular Endothelial Growth Factor (VEGF), Monocyte Chemoattractant Protein-1 (MCP-1) in SSc patients and their relationship with the main clinical manifestations of disease.

Methods: 34 SSc patients fulfilling the 2013 ACR/EULAR criteria for SSc and classified according to Leroy as having limited cutaneous (ISSc) or diffuse cutaneous disease (dSSc) were recruited. 28 sex and age matched healthy subjects was used as control. For each recruited patient we analyzed the disease characteristic, including the extent of skin fibrosis, the pattern of internal organ involvement, degree of skin involvement (Rodnan Skin Score), bone mass index (BMI). For each recruited patient we analyzed the disease characteristic, including the extent of skin fibrosis, the pattern of internal organ involvement, degree of skin involvement (Rodnan Skin Score), bone mass index (BMI), and autoantibody profile was found.

Results: The results showed that the mRNA and the protein levels of SP and VEGF were significantly higher in SSc patients compared to controls (190.56±5.1pg/mL vs. 85.56±9.1pg/mL, p<0.05); further, SP and VEGF levels were higher in dSSc compared to ISSc and correlated to disease duration. No difference was detected in MCP1 synthesis and expression between SSc subjects and healthy controls (507.17±153.9pg/mL vs 481.21±19.2pg/mL, p>0.05). In SSc patients a slight increase was observed. VEGF production negatively correlated with the prevalence of DU. No correlation between cytokine production and clinical manifestations was evaluated.

Conclusions: The preliminary data of this study show that SP and VEGF are overproduced in PBMCs of SSc subjects and are related to the extent of skin involvement, whereas only VEGF production negatively correlates with the prevalence of DU. The exact role played by SP and VEGF in the pathogenesis of vascular injury and fibrosis in SSc and their relationship with the immune abnormalities observed in this disease is not completely clear and the available data are contrasting. Additional in vitro and in vivo studies are needed to better understand the role of SP and VEGF in the pathogenesis of SSc.

BONE MINERAL DENSITY AND TRABECULAR BONE SCORE IN TWO SUBSETS OF SYSTEMIC SCLEROSIS PATIENTS

A. Corrado, A. Mele, A. Trotta, R. Cola, S. Di Bello, F.P. Cantatore. Department of Medical and Surgical Sciences - Rheumatology Clinic, University of Foggia, Foggia, Italy

Background: Data concerning the relationship between Systemic Sclerosis (SSc) and alterations of Bone Mineral Density (BMD) are very conflicting. The established standard for measuring BMD is Dual X-ray Absorptiometry (DXA), but other methods such as Peripheral Blood Mononuclear Cells (PBMCs) were isolated and cultured from both SSc patients and healthy controls. The expression of SP, VEGF, MCP1 was analyzed by real-time polymerase chain reaction (PCR) and their concentrations in supernatants of cultured PBMCs using enzyme-linked immunosorbent assay (ELISA). The correlation between cytokine expression and clinical manifestations was evaluated.

Results: The results showed that the mRNA and the protein levels of SP and VEGF were significantly higher in ISSc patients compared to controls (190.56±5.1pg/mL vs. 85.56±9.1pg/mL, p<0.05); further, SP and VEGF levels were higher in dSSc compared to ISSc and correlated to disease duration. No difference was detected in MCP1 synthesis and expression between SSc subjects and healthy controls (507.17±153.9pg/mL vs 481.21±19.2pg/mL, p>0.05). In dSSc patients a slight increase was observed. VEGF production negatively correlated with the prevalence of DU. The exact role played by SP and VEGF in the pathogenesis of vascular injury and fibrosis in SSc and their relationship with the immune abnormalities observed in this disease is not completely clear and the available data are contrasting. Additional in vitro and in vivo studies are needed to better understand the role of SP and VEGF in the pathogenesis of SSc.

REAL-LIFE TREATMENT STRATEGIES FOR SYSTEMIC SCLEROSIS ACCORDING TO EXPERTS

A. Fernández-Codina 1, K.M. Walker 2, J.E. Pope 3 on behalf of the participating members of the Scleroderma Clinical Trials Consortium (SCTC) and Canadian Scleroderma Research Group (CSRG).

Background: Second line treatment options for Systemic Sclerosis (SSc) are limited, and scarce data are available for choosing the order of treatment.

Objectives: The aim of this study is to update the SSc treatment algorithms obtained in 2012, based on SSc experts’ daily practice.

Methods: An initial survey was designed based on the 2012 algorithms. The survey asked experts whether they agreed with the 2012 algorithms or not, and which changes should be considered. The questionnaire was completed by 62 of 168 surveyed (67% response) between August and October 2016.

Results: For scleroderma renal crisis (SRC), there was 65% to 69% agreement with the previous algorithms (1st line angiotensin converting enzyme inhibitors [ACE1], 2nd and 3rd adding: calcium channel blockers [CCB] or angiotensin receptor blockers [ARB], and 4th alpha-blocker). In mild pulmonary arterial hypertension (PAH), only 45% of the experts agreed with the old algorithm. The majority suggested first phosphodiesterase 5 inhibitors (PDE5i) or endotelin receptor antagonists (ERA) plus PDE5i, then prostanoids. In severe PAH, 65% agreed with the previous scheme (1st prostanoids, 2nd ERA plus PDE5i, 3rd ERA plus prostanoids). For mild Nailaoud's phenomenon (RP) 66% agreed with the previous algorithm (1st CCB, 2nd adding PDE5i, 3rd ARB or switching to another CCB, 4th prostanoids). Regarding severe RP, 52% agreed with previous (1st CCB, 2nd adding PDE5i, 3rd ERA, 4th prostanoids). Conversely, 60% of the experts did not agree with the prior active digital ulcer (DU) treatment, suggesting 1st CCB, 2nd PDE5i, 3rd prostanoids. For intestinal lung disease (ILD), for induction only 24% agreed with the older proposal. Experts suggested 1st periostitent myophenolate (MMF), 2nd intravenous (IV) cyclophosphamide (CYP), 3rd rituximab. There was a 65% agreement on ILD maintenance (1st MMF, 2nd azathioprine [AZA], 3rd IV CYP, 4th oral CYP). For skin involvement, agreement for patients with a modified Rodnan skin score (mRSS) of 10 was 57% (1st methotrexate [MTX]), 2nd MMF; if the mRSS was 24, 32% suggested 1st MTX, 2nd MMF, 3rd prostanoids. For severe Raynaud’s phenomenon (RP) 65% agreed with the previous algorithm, whereas others suggested 1st MTX, 2nd low dose steroids, 3rd hydroxychloroquine, 4th rituximab or tocilizumab.

Conclusions: There remains some disagreement for 2nd line treatment of SSc. Combination of PDE5i and ERA are prescribed now in mild PAH treatment.

Differences in Right Ventricular Function and Morphology in SSC-PAH and IPAH Assessed by Right Heart Catheterization and Cardiac MRI

A.-M. Hoffmann-Vold1, E. Hopp2, Ø. Midvett3, T. Garen1, P. Szodoray1, Ø. Molberg5, A.K. Andreassen4, 1Rheumatology; 2Radiology; 3Immunology; 4Cardiology, Oslo University Hospital, Oslo, Norway

Background: Systemic sclerosis (SSc) is a serious disorder with high mortality, mainly driven by cardiopulmonary pathologies including pulmonary arterial hypertension (PAH). Patients with SSC-PAH appear to have worse prognosis than idiopathic PAH (IPAH).

Objectives: (A) Compare cardiac magnetic resonance (CMR) of the right ventricle, hemodynamic parameters and immunological markers between patient cohorts with SSC-PAH, IPAH and without PAH, respectively. (B) Evaluate the impact of these variables on PAH-related heart morbidity and mortality.

Methods: The study cohort included SSC-PAH (n=16), IPAH (n=15) and SSc without PAH (n=20). At baseline, all patients were examined by ventricular volumes by short axis summation of cine CMR, echocardiography and right heart catheterization (RHC). Blood samples were analysed for immune-related factors. At a median follow up of 3 years, clinical data, and new onset of PAH and vital status were registered. A composite outcome for PAH related events was created including: PAH progression, end-stage PAH, hospitalization for PAH worsening and all-cause mortality. Association between parameters was assessed using ANOVA, Pearson Chi-square, Fishers exact, or independent sample t-test.

Results: Patients with SSC-PAH were significantly older at PAH onset, had lower 6MWD, DL60% and Hb than the IPAH patients. RHC results are shown in Table 1. CMR showed that SSC-PAH patients had lower right ventricular mass index (RVM), RV to left ventricular ratio and RV mass to volume ratio (Table 1). Multiple immune assays demonstrated higher serum levels of IP-10, VEGF and, IL12 in SSC-PAH than in IPAH. At the end of study, 12/15 SSC-PAH had developed a PAH-related event. Compared to event-free patients, they were marked by significant CMR changes including higher RVM (p=0.006) and RVMI (p=0.005).

In the IPAH subgroup, 7/16 patients developed an event. These patients were characterized by younger age at onset (p=0.001), higher NT-proBNP (p=0.017), lower 6MWD (p=0.034), higher RVM (p=0.010), RV-to-LV ratio (p=0.001) on CMR.

Conclusions: The CMR measures indicate that the RV adapts differently in IPAH and SSC-PAH; with more pronounced RV hypertrophy in IPAH patients. The mechanisms behind the differences in RV hypertrophy in SSC-PAH and IPAH are not known, but may involve microvascular changes and deregulated inflammatory cascades. This study indicates that CMR can predict PAH progression in SSc.

FRI0378 CARDIAC INVOLVEMENT IN UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE AT RISK FOR SYSTEMIC SCLEROSIS. A TISSUE DOPPLER IMAGING STUDY

A. Riccardi1, M. D’Alto2, P. Argentino2, E. Romeo2, I. Di Stefano1, S. Fasano1, A. Materia Iacono2, A. D’Andrea2, A. Sanduzzi2, M. Bocchino3, L. Docimo4, S. Toleone4, M. G. Russo5, G. Valenti1, 1Rheumatology Unit; 2Department of Cardiology, University of Campania “Luigi Vanvitelli”; 3Department of Clinical Medicine and Surgery, University “Federico II”; 4Division of General and Bariatric Surgery, University of Campania “Luigi Vanvitelli”, Naples, Italy

Background: Undifferentiated connective tissue disease at risk for Systemic Sclerosis (UCTD-risk SSCs), previously referred to as very early SSCs, is a condition characterized by Raynaud’s phenomenon (RP) with SSC marker autoantibodies and/or typical capillaroscopic findings and unsatisfying classification criteria for the disease (1). UCTD-risk SSCs patients have been reported to present, in about 40% of the cases, a preclinical vascular internal organ disease as detected by a diffusing lung capacity for CO <80% of the predicted value (lung involvement) and/or a low esophageal sphincter pressure <15 mmHg (oesophageal involvement) and/or a mitral E/A ratio <1 (heart involvement) (2, 3).

Methods: NCM was assessed in consecutive patients with RP (n=759) by widefield videocapillaroscopy, according to standardized procedures at a dedicated vascular laboratory by trained and experienced technicians. The pattern was classified as normal (n=325), non-specific (n=188) or SSc pattern (early (n=106), active (n=140) or late (n=0) based on the Cutolo patterns). Potential pulmonary involvement was defined as forced vital capacity or diffusion capacity <70%.

Gastro-intestinal involvement as scintigraphically (Tc-99M colloid) oesophageal dysmotility. Skin involvement as puffy fingers or sclerodactyly. Patients were classified as primary RP (normal NCM and negative serology, n=226) or secondary RP (abnormal NCM and/or serology) groups: early SSc (n=165), SSc (n=40), incomplete Sjogren’s syndrome (SSS, n=5), primary SS (pSS, n=30), incomplete systemic lupus erythematoses (ISLE, n=42), SLE (n=30), mixed CTD (MCTD, n=7), rheumatoid arthritis (RA, n=15) or when meeting criteria as other (n=169). None were diagnosed with polymyositis or dermatomyositis.

Results: SSc pattern was observed in 33% of patients with pSS, 17% SLE, 71% MCTD and 13% RA. Pulmonary, oesophageal and skin involvement was more frequent in secondary RP patients with an SSc pattern, even when analysing only those fulfilling definite criteria for CTD or after exclusion of early SSc and SSc patients. For secondary RP patients, absence of an SSc NCM pattern had a high negative predictive value for pulmonary (92%), oesophageal (91%) and skin (96%) involvement, while positive predictive values were low.

Conclusions: SSc pattern on NCM is common in CTD patients and is associated with frequent prevalence of organ involvement, even in the absence of (early) SSc. Although this was a retrospective cohort, these data underline the importance of assessing NCM in RP patients to evaluate the risk for organ involvement in CTD other than SSc, already in early disease stages.

FRI0376 ABNORMAL NAILFOLD CAPILLAROSCOPY PATTERN IS COMMON IN PATIENTS WITH CONNECTIVE TISSUE DISEASE AND ASSOCIATED WITH ORGAN INVOLVEMENT

A.M. Van Rooij1, C.C. Huisman1, A.M. van Roon1, D. Zhang2, A.J. Stel3, A.J. Smit4, H. Bootsmam, D.J. Mulder1, Internal Medicine - Vascular Medicine, University Medical Center Groningen - University of Groningen, Groningen, Netherlands

Background: Nailfold capillary microscopy (NCM) has been shown to be associated with disease severity and internal organ involvement in non-consecutive systemic sclerosis (SSc) cohorts. NCM may help in early recognition of connective tissue disease (CTD) but it is unclear to which extent NCM abnormalities occur in several CTD and whether these are associated with organ involvement.

Objectives: To assess NCM in consecutive patients with Raynaud’s phenomenon (RP) and whether these are associated with signs of organ involvement.

Methods: NCM was assessed in consecutive patients with RP (n=759) by wide-field videocapillaroscopy, according to standardized procedures at a dedicated vascular laboratory by trained and experienced technicians. The pattern was classified as normal (n=325), non-specific (n=188) or SSc pattern (early (n=106), active (n=140) or late (n=0) based on the Cutolo patterns). Potential pulmonary involvement was defined as forced vital capacity or diffusion capacity <70%.

Gastro-intestinal involvement as scintigraphically (Tc-99M colloid) oesophageal dysmotility. Skin involvement as puffy fingers or sclerodactyly. Patients were classified as primary RP (normal NCM and negative serology, n=226) or secondary RP (abnormal NCM and/or serology) groups: early SSc (n=165), SSc (n=40), incomplete Sjogren’s syndrome (SSS, n=5), primary SS (pSS, n=30), incomplete systemic lupus erythematoses (ISLE, n=42), SLE (n=30), mixed CTD (MCTD, n=7), rheumatoid arthritis (RA, n=15) or when meeting criteria as other (n=169). None were diagnosed with polymyositis or dermatomyositis.

Results: SSc pattern was observed in 33% of patients with pSS, 17% SLE, 71% MCTD and 13% RA. Pulmonary, oesophageal and skin involvement was more frequent in secondary RP patients with an SSc pattern, even when analysing only those fulfilling definite criteria for CTD or after exclusion of early SSc and SSc patients. For secondary RP patients, absence of an SSc NCM pattern had a high negative predictive value for pulmonary (92%), oesophageal (91%) and skin (96%) involvement, while positive predictive values were low.

Conclusions: SSc pattern on NCM is common in CTD patients and is associated with frequent prevalence of organ involvement, even in the absence of (early) SSc. Although this was a retrospective cohort, these data underline the importance of assessing NCM in RP patients to evaluate the risk for organ involvement in CTD other than SSc, already in early disease stages.

DOI: 10.1136/annrheumdis-2017-eular.1390
Objectives: Aim of the present study was to assess the prevalence of right (RV) or left ventricle (LV) systolic and/or diastolic dysfunction by standard echocardiography and tissue Doppler imaging (TDI).

Methods: Thirty patients with UCTD-risk-SSc (28 female, aged 47±13 years, range 21–70) and 30 age- and sex-matched controls underwent cardiac assessment by standard echocardiography and TDI.

Results: UCTD-risk-SSc patients and controls did not show any difference at standard echocardiographic evaluation. In particular, an inverted E/A ratio was pointed out in 10/30 patients and 7/30 controls (p=ns). TDI showed a mild impairment of LV and RV diastolic (Ea=15±4 vs 19±2, p<0.001; E/e= 6.1±7 vs 4.8±1.2, p=0.001; E: 14.5±3 vs 16.2±2, p=0.02; E/A:0.9±0.4 vs 1.30±3, p=0.002; increased pulmonary artery wedge pressure 9±2 vs 8±1, p=0.001) and systolic function (Smax 3.2±2 vs 5.2±2 cm/sec, p<0.0003; Ss 14±2 vs 16±3 cm/sec, p<0.0001) in UCTD-risk-SSc patients in comparison to controls.

Conclusions: Our study shows that UCTD-risk-SSc patients present a previously unrecognized, mild biventricular systolic and diastolic dysfunction as compared to controls. The pathophysiologic meaning (i.e.intramyocardial artery disease and/or patchy fibrosis) as well the predictive value of developing overt SSc should be elucidated.

FR10379 PREVALENCE OF FAM111 B GENE MUTATIONS IN SYSTEMIC SCLEROSIS

A. Gcely1, G. Deshpande2, A.A. Kalla3, M. Tikly3, B. Mayosi2, B. Hodkinson1. 1Medicine, Division of Rheumatology; 2Cardiovascular Genetics Laboratory, University of Cape town, Cape Town; 3Medicine, Division of Rheumatology, University of Witwatersrand, Johannesburg, South Africa

Background: Systemic sclerosis (SSc) is a prototypic systemic fibrotic disease with unclearly characterized genetic basis. Implicated genes have been associated with autoimmune dysregulation with relatively few variants associated with fibrosis [1]. We have discovered that mutations in FAM111 B gene cause hereditary fibrosing poikiloderma with tendon contractures, myopathy, and pulmonary fibrosis (POIKTMP)[2], a multisystem fibrotic condition with clinical aspects of SSc [3]. This observation has established FAM111B as a candidate gene for SSc.

Objectives: The objective is to investigate whether FAM111B gene mutations are present in SSc patients and further explore relationships between FAM111B mutations and clinical expression of SSc.

Methods: Patients with a definite diagnosis of SSc attending the Rheumatology outpatient departments at Groote Schuur Hospital, Cape Town, and Chris Hani Baragwanath Hospital, Johannesburg, were enrolled into the study. Physical examination assessing the extent of disease was done in all patients and the modified Rodnan skin score (mRSS) was used to determine the extent of the skin involvement. Blood samples were collected for DNA extraction and mutation screening using the high-resolution melt technology. Samples with abnormal electropherograms were selected for Sanger sequencing to identify mutations. Public databases were used to verify the frequency of variants in FAM111B.

Results: 131 patients were genotyped, 13 men and 118 women, with a mean age 57±6 years. The majority of patients were black (59.5%). 72% of patients had diffuse systemic sclerosis (DSSc) with a median mRSS of 11. Genetic analysis revealed seven rare genetic polymorphisms with no functional impact.

Conclusions: Rare genetic variants of unknown significance (GVUS) in FAM111 B gene were found in patients with SSc. It is possible that the GVUS may modify the function of FAM111B, and influence the pathogenesis of SSc or are rare polymorphisms with no functional impact.

FR10380 PATIENT PREFERENCES AND DIFFICULTIES CONCERNING THE HOME TREATMENT OPTIONS IN SYSTEMIC SCLEROSIS (SSC)

B. Pagnotta1, C. Bruni1, S. Bellando Randoni1, S. Guiducci1, G. Lepri1, J. Blagovic1, L. Rasero2, M. Matuscu Cerin1, D.E. Furst1,2,3. 1Division of Rheumatology; 2Division of Research & Development Clinical Practice, AQUIC, Florence, Italy; 3Division of Rheumatology, UCLA, Los Angeles, United States

Background: SSC patients suffer from Raynaud’s phenomenon, hand skin hardening and scarring, digital ulcers, esophagus/gastric dysmotility, dysphagia and mucosal dryness. These symptoms significantly reduce patient’s life autonomy and impair the capacity to handle their therapy usually made by different modalities of administration: oral, topical, inhalation, intramuscular, subcutaneous, intravenous, and rectal.

Objectives: to investigate the methods of administration used by SSC patients, their preferred methods, their compliance to pharmacological therapy, and the difficulties that are encountered by the patients during pharmacotherapy.

Methods: 2 questionnaires were prepared on an ad hoc basis. The first given to patients, the second to be filled out by the patient’s physician. The first questionnaire comprised 25 questions to investigate the problems the patients when taking their medications by correlating these with two validated activities indices: SHAQ-DI (activities of daily living) and the COCHIN scale (hand activities). The second questionnaire was composed of the standard SSC-related clinical information (eg.age, sex, disease duration, symptoms). 80 Ssc patients completed the questionnaires, maintaining anonymity. A “difficulty index” was also filled out, where: 0 = no difficulty to 4 = impossible to use or too difficult to use.

Results: In particular, the dimension of the pills is problematic, and has identified a paradoxical situation because large pills are difficult to swallow (41.25% patients who use pills) but at the same time small pills are difficult to pinch with the fingers (62.25% patients who use pills).

Conclusions: SSC patients experience significant problems in maintaining adherence to treatments due to difficulties in the use of blisters and bottles with children proof stoppers. Pills still remain the most preferred method of treatment. In conclusion, patients unanimously wished to avoid the use of blisters, definitively preferring bottles without the children proof stopper to make the treatment easier and provide a more independent life.

FR10381 INCREASED RISK OF OSTEOPOROTIC FRACTURES IN ADULT PATIENTS WITH POLYMYSITIS AND DERMATOMYOSITIS: A NATIONWIDE POPULATION-BASED COHORT STUDY

C.-C. Lai1, W.-S. Chen1, Y.-P. Tsao1, Y.-S. Chang2. 1Division of Allergy, Immunology, and Rheumatology, Taipei Veterans General Hospital, Taipei City; 2Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Shuang Ho Hospital, Taipei Medical University, New Taipei City, Taiwan, Province of China

Background: Patients with polymyositis and dermatomyositis (PM/DM) are characterized by chronic muscle weakness due to autoimmune-mediated myositis and are usually treated with corticosteroids initially. PM/DM patients prone to develop osteoporosis and subsequent fractures but are rarely investigated.

Objectives: To explore the incidence rate (IR) and risk factors of osteoporotic fractures (OFs) among adult PM/DM patients.

Methods: We conducted a cohort study by utilizing the Taiwan National Health Insurance database. PM/DM patients and respective age- and gender-matched cohort without PM/DM were enrolled. The primary endpoint was the initial event of OFs. We used the Cox proportional hazard model to study the risk factors of OFs in the PM/DM cohort.

Results: Among 2391 PM/DM patients (67.8% female, mean age: 49.5 years) followed for a mean (SD) of 6.1 (5.0) years, 116 developed vertebral fractures, 32 had hip fractures, and 14 experienced radius fractures (IR: 8.18, 2.20, and 0.96 per 1000 person-years, respectively, Table 1). Compared with the matched cohort, the PM/DM patients had higher IR (RRs) (95% CIs) of OFs at all age groups at enrollment: 3.27 (2.19 to 4.81; p<0.0001) for people <50 years and 2.29 (1.85 to 2.82; p<0.0001) for those ≥50 years. The RRs were 2.39 (1.92

to 2.94, p<0.0001) for vertebral fractures and 1.62 (1.07 to 2.38, p=0.0093) for hip fractures. PM/DM patients experienced vertebral fractures and hip fractures at younger ages (62.2 vs 68.4 and 66.0 vs 75.4 years, respectively; both p<0.001). Multivariable Cox regression analyses showed that being female gender, age ≥50 years, having hypertension, coronary artery disease, asthma, and using daily prednisolone equivalent to >5 mg are associated with rQS.

Conclusions: Implementation of DA in a largely asymptomatic non-selected SSc patient population is more sensitive for RHC referral than annual TTE screening. Recommendations for RHC per DETECT score are difficult to predict on symptom and other traditional clinical parameters. The use of DA will lead to increased RHC referrals. Cardiologists may need education on this new method for screening and although the ESC/ERS 2015 guidelines discuss DA, they conclude that its cost-effectiveness has not been clarified as compared with symptom-based detection.

FR10382

USE OF THE DETECT ALGORITHM FOR EARLY PULMONARY ARTERY HYPERTENSION DIAGNOSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS IN EVERYDAY CLINICAL PRACTICE

C. Koutsianas, S. Subasinghe, K. Douglas. Department of Rheumatology, The Dudley Group NHS Foundation Trust, Dudley, United Kingdom

Background: The DETECT algorithm (DA)¹ provides a sensitive tool for early identification of patients with Systemic Sclerosis (SSc) at risk of Pulmonary Arterial Hypertension (PAH) and advocates evaluation with Right Heart Catheterisation (RHC). Few published data look into its implementation in everyday clinical practice and compare it to annual echocardiographic (TTE) screening.

Objectives: To compare DA and TTE screening of SSc patients for RHC referral rates and related patient characteristics.

Methods: Data on 57 consecutive patients with a diagnosis of SSc that had at least one visit to Russells Hall Hospital Scleroderma clinic from February to November 2016 was prospectively collected on Excel (clinical history, physical examination, immunological status, treatment, PFTs, NT-proBNP, urate, ECG, TTE, CXR and HRCT results). DETECT scores were calculated (www.detect-pah.com) and compared with the TTE probability for PAH as per the 2015 ESC/ERS Guidelines.²

Results: 31 patients with a full set of data were included in the final analysis. 93.5% were female with a mean age of 64.4±12.9 years, 87% had limited cutaneous (lc) SSc, 58.1% positive anticentromere antibody and mean time since diagnosis was 6.2±3.2 years. The majority of patients (80%) were asymptomatic for PAH. Mean DLCO was 60.9±18.3% predicted (the DETECT study included on patients with DLCO<60%). We did not exclude patients with renal insufficiency; mean eGFR was 74±17.7ml/min.

The implementation of DA recommended RHC in 18/31 patients (DETECT step 2 score >3.5, 58%, see table 1) compared to just 4/31 (13%) based on TTE by 2015 ESC/ERS guidelines. The additional 14 patients identified by DA were found to have no statistically significant differences in SSc type, dyspnea symptomatology, immunosuppressive treatment, presence of interstitial lung disease (ILD), age, time from diagnosis or symptom onset, eGFR and CRP compared to patients where RHC was not recommended. From the 18 patients identified by DA, only 4 reported shortness of breath. 2/18 had existing cardiac conditions (aortic stenosis, left ventricular hypertrophy), while 9/18 had ILD (5 mild, 2 moderate, 2 severe as per HRCT).

FR10383

DETECT SCREENING FOR PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS: DATA FROM AN EUSTAR COHORT

C. Anuta 1,2, C. Pomileanea 1,2, F. Maxim2, F. Mita1,3. 1University of Medicine and Pharmacy Grigore T Popa Iasi; 2Rheumatology 2; 3Cardiology, Clinical Rehabilitation Hospital, IASI, Romania

Background: Early documentation of pulmonary arterial hypertension (PAH) related to systemic sclerosis (SSc) remains a challenge in daily clinical practice, with major prognostic and therapeutic implications. Although several screening algorithms specifically designed to optimize the detection of secondary PAH have already been proposed (e.g., DETECT, REVEAL), no precise approach received complete validation, especially the use of invasive diagnostic right heart catheterization (RHC).

Objectives: Main objective was to assess the risk of PAH in patients with SSc and to compare with PAH screening promoted by European Society of Cardiology/European Respiratory Society (ESC/ERS) 2009 guidelines, while secondary one to identify predicting factors for developing PAH among clinical and immunological SSc variables.

Methods: Cross-sectional prospective single-center study, applying the DETECT calculator in patients with SSc recruited in EUSTAR 162 center cohort between January 2013- December 2016; all SSc completing at least two monitoring visits at 6 months were considered. Standard assessments included MEDS (minimal data set EUSTAR), annual echocardiography with systolic pulmonary artery pressure (sPAP), pulmonary function tests with forced vital capacity (FVC), percentage predicted/diffusing capacity for carbon monoxide (DLCO) % predicted, ECG, serum biomarkers (serum urate, NT-proBNP).

PAH risk calculator (http://detect-pah.com/pah-risk-calculator), a tool developed and validated in the DETECT study, is able to identify patients requiring echocardiography (STEP 1) respectively RHC (STEP 2), and was systematically applied in our cohort. All sPAP ≥45 mmHg or between 35–45 mmHg in the presence of dyspnea were proposed for invasive testing.

Statistical analysis was performed in IBM SPSS-19 version, p<0.05.

Results: 41 out 56 SSc in our database were recruited: mainly women (85.36%) with diffuse cutaneous SSc (63.41%), anti-topoisomerase (up to half) and anti-centromere (about one third) positive disease; one out of four SSc presented with digital ulcers and one of three with active capillaroscopic pattern.
Using the DETECT PAH calculator, 14/41 (34.14%) were recommended for RH as follows: an initial value above 300 points in STEP 1 (with further indication of echocardiographic assessment) and subsequent STEP 2 over 35 were recorded. On the other hand, only 9/41 (21.95%) cases met the ultrasound criteria to be addressed to an invasive assessment when applying the ESC/ERS 2009 guidelines, the difference being statistically significant as compared to DETECT (p<0.05).

PAH was finally confirmed in 8/41 (19.51%) cases, supporting our preliminary results in a pilot study on a limited number of patients.

**Conclusions:** DETECT is a reliable algorithm for early detection of PAH in patients with SSC, optimizing PAH screening and prompting the rheumatologist-cardiologist collaboration.

**A MINI-INVASIVE TECHNIQUE FOR HAEMODYNAMIC EVALUATION: NEW PERSPECTIVES FOR PULMONARY ARTERIAL HYPERTENSION (PAH) DIAGNOSIS IN SYSTEMIC SCLEROSIS (SSC)**

E. Bellucci 1, M.S. Romano 2, M. Chiostri 2, C. Bruni DLCO 0.94 0.87–1.01 0.072

Right stroke work index 1.12 1.03–1.21 0.007

DLCO 0.94 0.90–0.99 0.021

Right Cardiac Power index 1.11 1.04–1.18 0.002

Arterial Elastance 3.16 0.70–14.24 0.134

Dicrote Pressure 1.04 1.00–1.09 0.064

**Methods:** 40 ssc patients (35 women, mean age 60±9,3 years; mean disease duration 7.5 years) were evaluated with both RHC and PRAM on the same day. Mean pulmonary arterial pressure (mPAP), cardiac index (CI), systemic vascular resistances (SVR), right cardiac power index (RCPI, calculated with mPAP×CO/HR×451) were measured and concordance of the two methods was assessed through Bland-Altman analysis. Systolic pulmonary arterial pressure and TAPSE from echocardiography, forced vital capacity, total lung capacity, both absolute and alveolar volume adjusted Carbone oxide lung diffusion (DLCO and DLCO/VA) from pulmonary function tests, blood tests parameters, nailfold videocapillaroscopy scleroderma patterns were recorded. Univariate and multivariate logistic regression analysis identified variables correlating with RHC-diagnosed PAH: a scoring system was then created, giving 1 point for value satisfying cut-off level.

**Results:** PRAM showed concordance with RHC estimate of CI and SVR within 95% interval confidence; 14 patients were diagnosed with PAH (mean age 64.4±9.3, mean disease duration 10.5 years, IScE 61.5%). Multivariate logistic regression analysis showed DLCO (cut off value 47% obtained through ROC curve analysis, p=0.004) and RCPI (cut off value 0.12 Watt obtained through ROC curve analysis, p=0.001) as the most highly PAH-associated variables. When combining these two variables in the scoring system, patient with score=0 (DLCO<47% and RCPI<0.12 Watt), score=1 (DLCO≥47% or RCPI<0.12 Watt) and score=2 (DLCO<47% and RCPI≥0.12% were 0%, 21.4% and 78.6% of the PAH population respectively.

**Conclusions:** PRAM is comparable to RHC in detecting haemodynamic parameters such as SVR and CI. The scoring system combining DLCO and RCPI, obtained with non-invasive tools, could offer the possibility of detecting PAH patients with a high specificity.

**JOINT MANIFESTATIONS IN PATIENTS DIAGNOSED WITH IDIOPATHIC INFLAMMATORY MYOPATHY: MULTICENTER REGISTRY**

**Background:** Idiopathic inflammatory myopathies (IIM) comprise a heterogeneous group of autoimmune conditions. Joint involvement can be considered to be part of the IIM systemic manifestations, together with a possible gastrointestinal, cardiovascular or pulmonary involvement. Although articular involvement in the IIM has been described as variable and non-specific with a chronic course it might be an early symptom of dermatomyositis in up to 30% of cases and in those patients with overlap syndromes.

**Objectives:** To evaluate and to identify joint manifestations in IIM patients.

**Methods:** We evaluated a cohort of 479 patients that included 12 hospitals in the Community of Madrid belonging to the IIM registry of the Society of Rheumatology of Madrid (SORCOM-REMICA) with diagnosis from January 1980 to December 2014. All patients were diagnosed of IIM according to Bohan and Peter criteria (1). The presence of arthralgia and arthritis was considered. IIM were classified as dermatomyositis (primary and secondary dermatomatoses) (DM) and polymyositis (PM) including the rest of the patients (classification I). Also, IIM were classified (II) as primary polymiositis (PPM), primary dermatomatoses (PDM), overlap syndrome (OSd), juvenile myopathies (JM), cancer-associated myopathies (CAM), autoimmune necrotizing myopathy and inclusion body myositis (these were grouped as other myositis; OM).

**Results:** We found 70 (18%) patients with acute arthritis (<6 weeks), 74 (19%) patients with chronic arthritis (<6 weeks) and 245 (65%) patients without any joint manifestations. Using the Tanimoto et al. criteria (1), the presence of erosive arthritis was observed in 149/479 (38.3%) of the patients. When comparing the joint manifestations in the PM and DM groups (n=225; 52.2% vs. n=229; 47.8%) no statistically significant differences were observed. However, assessing joint manifestations according to classification II, we observed that the highest prevalence was found in the OSd group, followed by the PDM group (p<0.0001). The group with less joint manifestations was JM compared to OSd and PDM (Table 1).

**Conclusions:** The presence of joint manifestations associated with IIM in our cohort is higher compared to other studies described in the literature so far and

Note: The table above shows the frequency of joint manifestations in IIM according to classification II.
emphasize the importance of an accurate joint examination in these patients. The OSd group showed more joint manifestations which might be explained by the coexistence of SLE and MCTD patients in this group. Currently, no association between the clinical subtypes of IIM, overall, these results are encouraging and suggest that joint assessment in follow up may be helpful in differentiating subtypes of IIM.

**FR01088** | LONG-TERM TREATMENT WITH RITUXIMAB IN SYSTEMIC SCLEROSIS PATIENTS: UPDATE OF OUR CLINICAL EXPERIENCE
---

F. Lumenti, M. Colaci, C. Esposito, E. Cocchiara, C. Vacchi, A. Spinella, D. Troppa, D. Giuggioli, C. Ferri, E. Coccia, University of Modena and Reggio Emilia, Policlinico di Modena, Modena, Italy

**Background:** Systemic sclerosis (SSc) is an immune-mediated disorder characterized by abnormal fibrosis and diffuse microangiopathy with skin and internal organ involvement. The treatment of SSc represents a great clinical challenge because of the complex disease pathogenesis including vascular, fibrotic, and immune T- and B-lymphocyte-mediated alterations. Therefore, SSc should be treated by combined or sequential therapies according to prevalent clinicopathogenic phenotypes. Some preliminary data suggest that rituximab (RTX) may be usefully employed in SSc patients.

**Objectives:** The present study aimed to evaluate the efficacy of RTX in our SSc population, concerning the time to rituximab response (TFRR) in various subsets of SSc.

**Methods:** A series of 15 SSc patients (MF 6/9, mean age 52.7±17.95 years, mean disease duration 10.3±7.15 years, L/D cutaneous subsets 5/10) were treated with one or more cycles of RTX (4 weekly infusions of 375 mg/m²). In all patients RTX was repeated every 6 months for a total of 2–6 cycles. Patients' clinical-serological evaluation, including the self-evaluation of quality of life by means of HAQ and visual analogical scale (VAS) assessment, was performed every 6 months for a mean follow-up period of 42±24SD months.

**Results:** After the first 6 months following RTX treatment the extent of skin sclerosis measured with Modified Rodnan Skin Score (mRSS) significantly improved (from 17.3±10.4 to 13.4±7.6; p<0.01), and remained stable at the end of the follow-up (13.3±8.1; p=0.009). The usefulness of RTX on skin sclerosis was more evident in patients with diffuse cutaneous SSc (n=10) showing a significant decrease of mRSS after the first 6 months (from 24.2±5.1 to 18.1±4.7; p=0.006) and at the end of the follow-up period (18.0±2.0; p=0.005). Similarly, a valuable improvement of other cutaneous manifestations, namely hyperelasticity (12/12 pts), pruritus (11/13 pts), and calcinosis (3/6 pts) was observed. Moreover, arthritis revealed particularly responsive to RTX treatment leading to a clear-cut reduction of swollen and tender joints in 12/13 patients; while lung fibrosis detected in...
FOOT INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS: A SINGLE-CENTRE REPORT

Dipartimento Assistenziale Integrato di Medicina Interna, IUC Medica Interna - Università degli Studi della Campania - Luigi Vanvitelli, Napoli, Italy

Background: Foot involvement can be a source of morbidity and disability in patients with systemic sclerosis (SSc). Some studies have previously reported severity, echographic and radiographic manifestations of foot involvement in SSc.

Objectives: The aim of our study was to assess the nature and prevalence of foot problems in patients with SSc reporting a single centre experience.

Methods: A podiatrist and a rheumatologist assessed 81 (76 female) consecutive patients attending our SSc outpatient clinic. The mean age was 50 years (range 21–70). Thirteen (16%) had diffuse cutaneous SSc with a median disease duration from Raynaud’s Phenomenon of 5 years (range 3–19); 68 (84%) had limited cutaneous SSc with a median disease duration of 11.5 years (range 1–41). The overall median disease duration was 11 years (range 11–41). Thirty (37%) were anticientromere antibodies positive, thirty five (43%) anti-scl70 antibodies positive.

The two investigators evaluated the presence of the following features: colour changes, pain, previous ulceration, current ulceration, pre-ulceration (discoloration and thinning of the skin), toenail changes, hyperkeratosis, calcinosis, onychomycosis, dry skin, skin sclerosis, warts, scleredema, flatfoot. The presence of paresthesias, cramps, metatarsalgia were also investigated.

Results: The diagram reports the prevalence of foot manifestations in the 81 SSc patients. Most SSc patients suffer from symptoms related to their feet, particularly dry skin (70%), hyperkeratosis (plantar 58%, finger V 63%), Raynaud’s phenomenon (59%), cramps (55%). No statistically significant differences were found between diffuse and limited SSc groups.

Conclusions: Our study suggests that, in patients with SSc, foot problems are common and potentially disabling. A careful assessment of the feet should always be performed in these patients, in order to identify problems at an early stage.

EUROPEAN MULTICENTRE STUDY VALIDATES ELF TEST AS BIOMARKER OF FIBROSIS IN SYSTEMIC SCLEROSIS

G. Abignano 1,2, P. Emery 1,2, F. Del Galdo 1,2, M.H. Buch 1,2, P. Emery 1,2, F. Del Galdo 1,2, L.-A. Bissell 1,2, R.B. Dumitru 1,2, S. Eng 1,2, M. Matucci-Cerinic 3, V. Ong 3, M. Messenger 8, M. Hutchinson 1, Y. Allanore 4, J. Avouac 4, S. Bosello 5, C. Denton 6, O. Distler 7, G. Ferraccioli 5, D. Ruta, E. Frongillo, L. Pirro, A. Del Mastro, C. Romano. 1Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; 2NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 3Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Florence, Italy; 4Department of Rheumatology, University of Paris Descartes, Paris, France; 5Division of Rheumatology. Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy; 6Department of Rheumatology, University College London, Royal Free Hospital, London, United Kingdom; 7Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; 8NIHR Diagnostic Evidence Co-operative, Leeds Teaching Hospital NHS Trust, Leeds, United Kingdom.

Background: The Enhanced Liver Fibrosis (ELF) test is a serum test including the serum concentrations of amino-terminal pro-peptide of procollagen type III (PIIINP), tissue inhibitor of matrix metalloproteinase-1 (TIMP-1) and hyaluronic acid (HA). A recent single centre study showed that ELF score and its components are markers of overall fibrosis in systemic sclerosis (SSc) mainly reflecting skin and lung involvement (1).

Objectives: To determine the value of ELF score and its single analytes in an independent multicentre cohort of SSc patients.

Methods: 254 SSc patients from 6 European Rheumatology Centres were included in this study. Clinical data were collected at time of sampling. Serum samples were collected and stored according to EUSTAR biobanking recommendations (2). Sera were analysed employing a high-throughput in vitro diagnostic (Siemens Alpha-Centauro). Statistical analysis was performed with SPSS software V24.

Results: The 254 SSc patients had a mean age 55±13.8 years, and included 209 females and 80 patients with diffuse cutaneous SSc (dcSSc). ELF score was overall higher in males than in females (p=0.0236) as well as in dCSSc compared to limited cutaneous SSc patients (p=0.0015). ELF score and the single markers significantly correlated with the degree of skin involvement (mRSS) and inversely correlated with FVC%, TLC% and DLCO%. Concordancy all markers significantly correlated with skin and lung severity as assessed by the Medsger’s scale (Table 1). TIMP-1 and PIIINP levels were higher in patients with lung fibrosis assessed by chest HRCT scan (p=0.0126 and p=0.0338 respectively). Significant correlation (p<0.0001) was found between ELF score, TIMP-1, PIIINP, HA and total disease severity and activity. Multivariate analysis indicated that age (p<0.0001), mRSS (p<0.0001) and PIIINP (p=0.005) were independently associated with ELF score.

Conclusions: The value of ELF score as independent marker of skin and lung involvement is confirmed in a second independent multicentre cohort of SSc patients. A longitudinal study paired with analysis of large cohort of healthy controls is currently on going to identify a SSc specific test with the highest predictive value for skin and lung progression independently of age and gender.

A PERFUSION-METABOLIC MISMATCH IN 99MTL AND 123I-BMIPP SCINTIGRAPHY PREDICTS WORSE PROGNOSIS IN SYSTEMIC SCLEROSIS PATIENTS WITH ASYMPTOMATIC CARDIAC INVOLVEMENT

H. Iida, H. Hanaoka, T. Kiyokawa, Y. Takakawa, T. Okazaki, H. Yamada, S. Ozaki. Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Cardiac involvement is a manifestation of systemic sclerosis (SSc) that contributes to significant mortality and morbidity. Since many SSc patients with cardiac involvement are asymptomatic and it may progress silently, early diagnosis is still challenging. The perfusion-metabolic mismatch in cardiac scintigraphy indicates functional abnormality due to myocardial injury and has been expected to detect early cardiac involvement in various diseases. However, its clinical utility has been poorly evaluated in patients with SSc.
Objectives: To evaluate clinical utility of perfusion and myocardial fatty acid metabolism mismatch in SSC patients without cardiac failure.

Methods: All patients who visited St. Marianna University Hospital from 2009 to 2015 and performed cardiac scintigraphy using 99mTc and 123I-BMIPP were retrospectively evaluated. Patients who fulfilled American Collage of Rheumatology classification criteria of SSc and systemic lupus erythematosus (SLE) were selected. We subtracted %uptake of metabolism (123I-BMIPP) from that of perfusion (99mTc) on each 17 myocardial segments standardized by American Heart Association. We compared sum of all the scores and each score in 3 coronary artery regions between patients with SSc and SLE. Furthermore, we evaluated incidence of cardiac death or cardiac failure depending on the scores of each coronary artery regions.

Results: Among 177 patients, we analyzed the data in 22 cases with SSc and 23 with SLE. The sum of all mismatch scores was not significantly different between the 2 groups (p=0.05). The mismatch score of left anterior descending coronary artery (LAD) region was significantly higher in SSc than SLE (p=0.05) (Figure 1A). We next divided SSC patients into 2 groups depending on degree of the LAD mismatch score and found the group with low score had higher incidence of cardiac death or cardiac failure (p=0.04) than that with high score (Figure 1B).

Conclusions: The low mismatch score in LAD region of cardiac scintigraphy could be associated with cardiac death or cardiac failure in SSC patients. Since myocardial fibrosis might replace viable cardiomyocytes leading to loss of ventricular volume metabolic mismatch detected by scintigraphy might be less detectable.

FR10392 OPPORTUNISTIC INFECTIONS IN PATIENTS WITH MYOSITIS. A RETROSPECTIVE COHORT STUDY

A. Redondo-Benito 1, A. Curran-Fabregas 2, A. Villar-Gomez 3, E. Trallero-Araguas 4, A. Fernandez-Codina 5, L. Pinal-Fernandez 1, A. Selva-O’Callaghan 1, Internal Medicine; 2Infectious Diseases, Vall d’Hebron General Hospital; 3Pneumology, Vall d’Hebron General Hospital; 4Rheumatology Unit. Internal Medicine Dept., Vall d’Hebron General Hospital; 5Internal Medicine, Vall d’Hebron General Hospital. Universitat Autònoma de Barcelona, Barcelona, Spain

Background: Idiopathic inflammatory myopathies, also known as myositis, are a heterogeneous group of acquired diseases of probable autoimmune origin, characterized by the presence of inflammatory muscle infiltrates. Infectious complications are not uncommon in myositis, and some predisposing factors, such as upper esophageal involvement, calcinosis cutis, ventilatory insufficiency due to diaphragm involvement, calcification cuts, ventilatory insufficiency due to diaphragm involvement, and immunosuppressive drug therapies, seem to be implicated.

Objectives: To describe the prevalence, clinical characteristics, and risk factors for opportunistic infection (OI) in a cohort of patients with inflammatory myopathies, and compare mortality rates between those with and without OIs.

Methods: In total, 204 patients from our myositis cohort were reviewed to identify patients who had experienced an OI during the period 1986–2014. The onset of the myositis and OIs were systematically recorded. Disease activity at the OI diagnosis and cumulative doses of immunosuppressive drugs were analyzed, as well as the specific pathogens involved and affected organs.

Results: The prevalence of OI in the total cohort, was 6.4%: viruses, 44.4% (varicella-zoster virus, cytomegalovirus); bacteria, 22.2% (Salmonella sp., Mycobacterium tuberculosis, M. chelonae); fungi, 16.7% (Candida albicans, Pneumocystis jirovecii); and parasites, 16.7% (Toxoplamosis gondii, Leishmania spp.) were the pathogens detected. Lung and skin/soft tissues were the organs most commonly affected (27.8%). Overall, 55.6% of OIs developed during the first year after the myositis diagnosis and were significantly associated with administration of high-dose glucocorticoids (p=0.0148). Fever at onset of myositis (p=0.0317), biological therapy (p=0.001) and sequential administration of 4 or more immunosuppressive agents during myositis evolution (p=0.0032) were significantly associated with OI. All-cause mortality in the OI group was 3.69 deaths per 100 patients/year versus 3.40 in the remainder of the cohort (p=0.096).

Conclusions: The prevalence of OI was 6.4% in our myositis cohort. High-dose glucocorticoids at disease onset and severe immunosuppression are implicated in the development of these complications. Mortality did not differ from the remainder of the cohort.

FR10393 PREVALENCE OF MYOSITIS-SPECIFIC ANTIBODIES IN IDIOPATHIC INFLAMMATORY MYOPATHY COMPARED TO DISEASE AND HEALTHY CONTROLS

J.-B. Vuilsteke 1, X. Bossuyt 2, D. Dillaerts 3, K. Poesen 4, K. Claey s5, J. Lenaerts5, R. Westhoven6, D. Blockmans1, P. De Haes7, E. De Langhe6,7, 1Department of General Internal Medicine; 2Department of Laboratory Medicine, University Hospitals Leuven; 3Experimental Laboratory Immunology; 4Laboratory for Molecular Neurobiomarker Research, KU Leuven; 5Department of Neurology; 6Department of Rheumatology, University Hospitals Leuven; 7Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, KU Leuven; 8Department of Dermatology, University Hospitals Leuven, Leuven, Belgium

Background: Myositis-specific autoantibodies (MSA) are increasingly recognized as important diagnostic and prognostic markers in idiopathic inflammatory myopathies (IIM) (polymyositis, dermatomyositis, sporadic inclusion body myositis and necrotizing autoimmune myositis). The prevalence of these MSAs in other systemic autoimmune rheumatic diseases and neuromuscular diseases is unclear.

Objectives: To compare positivity of MSA in a cohort of IIM patients to positivity in healthy controls and different systemic autoimmune rheumatic diseases (SARD) or chronic inflammatory demyelinating polyneuropathy (CIDP).

Methods: A line immunoassay (Myositis 12 IgG DOT for BlueDiver) for IgG autoantibodies against Jo-1, PL-7, PL-12, EJ, SRP, Mi-2, MDA-5, TIF1-Y, HMGCR, SSA/Ro52kD, SAE1/2 and NXP-2 antigens was performed in patients with IIM (n=146), healthy controls (blood donors, n=40) and disease controls (n=200). The disease control group consisted of patients with other SARD (rheumatoid arthritis, RA; systemic sclerosis, Ssc; Sjogren’s syndrome, SJ; and systemic lupus erythematosus, SLE) (n=40 for each disease group) and CIDP (n=40).

Results: 50% of 146 patients with IIM tested positive for an MSA (table 1), compared to 3.5% of 200 disease controls (table 1). 1 SSC patient was positive for Jo-1, 1 CIDP patient was positive for PL12, 2 SSc patients were positive for TIF1-Y and a RA patient was positive for SAE1/2 and Mi-2. 10 AU MSA detected 68 (47%) 7 (3,5%) 0 (0%) Jo-1 28 (19%) 1 (0,4%) 0 (0%) PL12 3 (2%) 1 (0,4%) 0 (0%) PL7 1 (1%) 0 (0%) 0 (0%) EJ 2 (1%) 0 (0%) 0 (0%) Mi-2 7 (5%) 0 (0%) 0 (0%) MDA-5 7 (5%) 0 (0%) 0 (0%) SRP 3 (2%) 0 (0%) 0 (0%) HMGCR 7 (5%) 0 (0%) 0 (0%) SAE1/2 3 (2%) 2 (0,8%) 0 (0%) TIF1-gamma 3 (2%) 2 (0,8%) 0 (0%) NXP2 5 (3%) 1 (0,4%) 0 (0%) SAE1/2 and NXP2 4 (3%) 0 (0%) 0 (0%) Jo-1 + EJ 1 1 CIDP patient was positive for PL12, 2 SSc patients were positive for TIF1-Y and a RA patient was positive for SAE1/2 and Mi-2.

Conclusions: MSA positivity in patients with a clinical non-IIM diagnosis (other SARD or CIDP) is infrequent compared to positivity in the IIM group. For MSA positivity in patients with a clinical non-IIM diagnosis (other SARD or CIDP) is infrequent compared to positivity in the IIM group. For MSA positivity in patients with a clinical non-IIM diagnosis (other SARD or CIDP) is infrequent compared to positivity in the IIM group. For MSA positivity in patients with a clinical non-IIM diagnosis (other SARD or CIDP) is infrequent compared to positivity in the IIM group. For MSA positivity in patients with a clinical non-IIM diagnosis (other SARD or CIDP) is infrequent compared to positivity in the IIM group.

FR0394 NEUROPATHIC PAIN IS ASSOCIATED WITH SKIN THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS
J. Sousa-Neto1, M. Cerqueira2, D. Santos-Faria1, J. Leite Silva1, C. Alonso1, P. Teixeira, Rheumatology, Hospital Conde de Berliandos, ULSAM, Ponte de Lima, Portugal

Background: Systemic Sclerosis (SSc) is a connective tissue disorder characterized by fibrosis of skin and internal organs, vasculopathy and systemic inflammation. To date, few studies assessed pain in SSc patients, (1) namely the neuropathic component. Data is also scarce on defining possible neuropathic pain (NP) predictors in these patients.

Objectives: To determine if patients with SSc have a higher prevalence of NP compared with a group of age and sex matched controls and study possible associations between NP and SSc clinical variables.

Methods: The study evaluated patients diagnosed with SSc fulfilling the SSc classification criteria of the American College of Rheumatology (ACR), older than 18 years old and followed up at our Rheumatology Unit. Forty-eight patients with mean age of 56.98±12.73 years and mean disease duration of 9.77±6.12 years were included. Comparison group comprised 45 age and sex matched controls. Patients and controls were consecutively evaluated at our Unit and NP in 4 questions questionnaire (DN4) was used for assessing the presence of NP. In SSc patients, skin involvement was also evaluated clinically by the modified Rodnan skin thickness score (mRSS) ranging from 0 to 51. Hand mobility (HAMIS) and relevant clinical variables were also calculated and relevant clinical variables associations between NP and SSc clinical variables.

Results: In our study, prevalence of NP assessed by DN4 was significantly higher in SSc patients compared to controls (56.2% versus 13.3%, p<0.001). In addition to age and sex, presence of diabetes (p=0.041) was also similar in both groups. In SSc group, patients with and without NP showed some statistically significant differences (table 1).

</table>

Multivariate logistic regression revealed that only mean mRSS (odds ratio [OR] =1.90, 95% confidence interval [CI] 1.01 to 3.55, p=0.045) was independently associated with the presence of NP.

Conclusions: To the best of our knowledge, this is the first study evaluating the prevalence of NP in SSc patients in comparison with age and sex matched controls. NP was significantly more prevalent in patients with SSc. Skin thickness assessed by mRSS was independently associated with the presence of NP.

FR0336 LEVELS PENTRAOXIN 3 AND C1Q IN SYSTEMIC SCLEROSIS: ASSOCIATION WITH PULMONARY ARTERIAL HYPERTENSION AND CLINICAL FINDINGS
R. Cevik1, K. Nas1, T. Bozan1, A. Ekinci2, A. Kamanli2, I. Tekeoglu2, M.O. Ayyildiz4.

Background: Systemic sclerosis (SSc) is an autoimmune rheumatic disease with unknown etiology that characterized fibrosis and vascular endothelial damage with obliteration of the microvasculature caused from exaggerated synergy of collagen and extracellular matrix deposition in skin and internal organs. Pentraxin 3 (PTX3) accepted as a vascular inflammatory marker which secreted in early stage of endothelial dysfunction.

Objectives: In this study, we aimed to investigate plasma PTX3 and serum complement C1q levels and their relations with cytokines and pulmonary arterial pressure in SSc.

Methods: Fifty nine patients diagnosed with SSc and 28 subjects without inflammatory rheumatic disease recruited to the study. Plasma PTX3 and serum TNF-α, IL-1α, IL-4, IL-10, INF-γ, TGF-β and complement C1q measured in both groups. Clinical findings and pulmonary arterial pressure of the SSc patients assessed.

Results: Ages of fifty nine with SSc (54 female and 5 male) and 28 control subjects (23 female and 5 male) were 48,47±12.74 and 43,07±13,71 respectively. PTX3 (IL-1α and IL-4 levels) were increased in SSc patients. There were no differentiations between limited and diffuse cutaneous SSc subgroups in terms of PTX3, cytokines and C1q levels. Plasma PTX3 and serum IL-1α levels found decreased only limited cutaneous SSc subgroup comparing controls. According to the immunosuppressive drugs use; PTX3 levels found decreased in using group and TNF-α ve IL-1α levels found decreased in not using group comparing controls. Significant positive association found between PTX3 and C1q and all cytokines except TGF-β.

Conclusions: PTX3 suggested to be used in the pathogenesis and assessment of disease treatment efficacy of SSc, because of found decreased in SSc patients especially in limited cutaneous and immunosuppressive drugs using subgroups. Associations between C1q, and PTX3 and pulmonary artery pressure highlighted possible roles of both parameters in development of pulmonary hypertension. It is possible to develop preventive treatment strategies with better understanding of these associations. Advanced studies should be carried out for clarifying this condition.

FR0395 INCIDENCE OF MYOSITIS-SPECIFIC AUTOANTIBODY (MSA) SPECIFICITIES IN SSc REFERRED TO NEW ZEALAND (NZ) MEDICAL LABORATORIES
J. O’donnell1,2, P. Keating1, M. van Voorthuizen1, J. Liu1, I. Chua1, A. Soepnel2, E. Gumbley2, M. Spellberger1,1. Immunology Section, Canterbury Health Labs, New Zealand. Christchurch,2 Waikato Hospital Laboratory, Waikato Hospital, Hamilton, New Zealand

Background: Idiopathic inflammatory myopathies can be classified by clinico-pathological phenotype into four major groups: overlap myositis (OM), dermatomyositis (DM), polymyositis (PM) and inclusion body myositis (IBM). The different phenotypes associate with distinct MSA specificities although a variable percentage within each group are seronegative and the majority of IBM patients are seronegative. No commercial assay for the IBM associated specificity, n.lA is available. In NZ testing for MSA is restricted to two laboratories: Waikato Hospital (WHL) and Canterbury Health Laboratories (CHL). Both laboratories use the commercial Euroimmun Euroline assay. In addition CHL has developed an ELISA for anti HMGCR autoantibodies and receives referrals from throughout NZ.

Objectives: To define the incidence and specificities of MSA in serum samples referred for testing in New Zealand.

Methods: For the period 3 November 2015 to 2 November 2016 each laboratory information system (LIS) was interrogated for requests for MSA. For the purposes of this report positive results were grouped into the specificities associated with each of the defined clinicopathological phenotypes.

FR0397 EVALUATION OF VITAMIN B12 DEFICIENCY AND ASSOCIATED FACTORS IN PATIENTS WITH SYSTEMIC SCLEROSIS
D. Tas Kilic1, A. Sarı2, B. Armagan2, A. Erden1, L. Kilic2, M. Kilincakaya3, T. Turhan4, A. Akdogan4, S. Karahmetoglu4,1. Department of Internal Medicine, Numune Education and Research Hospital; 2Department of Internal Medicine Division of Rheumatology, Hacettepe University Faculty of Medicine; 3Department of Biochemistry, Numune Education and Research Hospital, Ankara, Turkey

Background: Vitamin B12 (Vit B12) deficiency is a common condition, which can be manifested with non-specific clinical features or with neurological and/or haematological abnormalities in severe cases. In systemic sclerosis (SSc)
to the ENMC classification, non-specific myositis was the most frequent finding on muscle biopsy (n=5/15, 30% vs. n=1/24, 4% in the non-axial group, p<0.05) and dermatomyositis (DM) pattern tended to be less frequent in axial-IM patients (3/12 20% vs. 11/24, 46%, p=0.10).

Most of the patients (75%) had also extra muscular involvement including acrosclerosis (45%), interstitial lung disease (35%), sclerodactyly (30%), telangiectasia (25%), digital tip ulcers (10%), sclerodermy (5%). By contrast, no patient had polyarthritis (vs. 20% in the controls, p<0.05). DM rash was hardly threefold less frequent in axial IM patients (15% vs. 42%, p<0.05).

Auto-antibodies associated with scleromyositis were the most frequent in axial-IM patients (30%, 25% ant-PM/Scl, 10% anti-RA, 15% anti-Scl-70). One patient (5%) had cancer within the 3 years before or after IM diagnosis (NS vs. controls).

Thus, most frequent diagnosis in axial-IM patients were scleromyositis (35% vs. 5% in the controls, p<0.05) and inclusion body myositis (20% vs. 2.6% in the controls, p<0.05). DM was twofold less frequent than in control (10% vs. 41%, p<0.05). Other IM subtypes were not statistically different from the control groups. Except with patients diagnosed of sIBM, all axial IM-patients received corticosteroids with another immunomodulatory drugs (median number 2, range 1–5). Half of the axial-IM patients received intravenous immunoglobulin. After a mean follow up of 68.4±3.76 months all patients had improvement, including in axial weakness, except in patients with sIBM. One patient died from ischemic cardiomyopathy.

Conclusions: In IM, camptocormia and dropped head syndrome are associated with late onset scleromyositis and sIBM with delayed diagnosis.

**FR10399**

**EFFICACY OF AN INTENSIVE 24-WEEK PHYSIOTHERAPY PROGRAMME IN PATIENTS WITH SYSTEMIC SCLEROSIS - PRELIMINARY DATA FROM A SINGLE-CENTER CONTROLLED STUDY**

M. Spirtovic1,2, H. Smucrova1, S. Oreska1, H. Storkanova1, P. Cesak2, A. Rathouska1, O. Ruzickova1, H. Mann1, K. Pavalek1, L. Senoff1, J. Vencovsky1, R. Becvar1, M. Tomcik1, 1Department of Rheumatology, Charles University, Institute of Rheumatology; 2Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

**Background:** Involvement of skin and musculoskeletal system in systemic sclerosis (SSc) leads to loss of function, disability and reduced quality of life. Data on efficacy of non-pharmacologic care in SSc is very limited due to variety in studied interventions/outcomes.

**Objectives:** To address the limitations of existing studies, and evaluate the effect of a controlled, long-term (24-week intervention, 24-week follow-up), intensive 1h physiotherapy + 0.5h occupational therapy twice weekly, and home-exercise for 0.5h 5x weekly), tailored physiotherapy programme on function/impairment of hands/faces, and quality of life/disability in cohorts with a substantial number of SSc patients.

**Methods:** All patients fulfilled ACR/EULAR 2013 criteria, had skin involvement of hands/mouth, and were consecutively recruited from 2014 to 2016 at the Institute of Rheumatology in Prague. Both groups received educational materials and instructions for home exercise at baseline, however, only intervention group underwent the intensive physiotherapy programme. At months 3,6,12 all patients were assessed by a physician (physical examination, mRSS-Modified Rodman’s skin score, EUSTAR SSc activity score, Medsger SSc severity score), and a physiotherapist blinded to intervention [validated measurements (dFTP-digital footprint area, grip strength, goniometry, dFTP using Baseline dynamometer); tests (HAMIS-Hand Mobility In Scleroderma)], patients filled out patient reported outcomes/questionnaires (CHFS-Cochin Hand Function Scale, MHISS-Mouth Handicap in SSc Scale, HQA, SHAQ, SF-36) and provided blood for routine laboratory analysis and biobanking. Normality of data was tested, inter-group analysis was performed with 2-way ANOVA, and intra-group analysis by Friedman’s test with Dunn’s post hoc test.

**Results:** 25 SSc patients (22 female/3 male, 14 limited cutaneous (lc)SSc/11 diffuse cutaneous (dc)SSc, median of age 54.0 and disease duration 7.0 years, with 30% in the intervention group (IG) and 29 patients into the control group (CG) (25 female/4 male, 16 lcSSc/15 dcSSc, median of age 49.0 and disease duration 5.0 years, mRSS 11). Compared to observed statistically significant deterioration in CG over the period of m0-m6, we found statistically significant improvement in dFTP, grip strength, HAMIS, inter-incisor and inter-lip
Efficacy of Intravenous Immunoglobulin Therapy in Refractory Dysphagia in Patients with Idiopathic Inflammatory Myopathies

Objectives: To assess the efficacy and safety of intravenous immunoglobulins (IVIg) as therapy of refractory dysphagia (1) in patients affected with PM/DM who have received conventional treatments for at least three months. These are the extended data of a previous abstract entitled “Improvement of refractory dysphagia (1) in patients affected with PM/DM who received IVIg standard dose (2 g/kg in a day) every two months for 3 cycles. In all patients, MMT12 score was 4.45±0.35. Following IVIg therapy we observed a significant improvement of EAT score after the first dose (9±8, p=0.006) with a further reduction after the second dose (7±4, p=0.007) and stability after the third one (7±3, p=0.008). An improvement of pharyngeal muscle propulsation, with a significant resolution of solid stasis and a partial resolution of liquid stasis were observed. In addition, MMT12 score progressively improved after each dose, increasing at 4.65±0.16 after the third dose (p<0.001). Notwithstanding, the third IVIg dose, three patients reported the steroids and the remaining 12 were treated with a significant lower dose of 5 mg/day of prednisone (p=0.04).

Conclusions: According to literature, our findings provided evidence that IgG-induced a meaningful improvement of dysphagia, also having a steroid-sparing effect. An improvement of muscle strength was also detected. Although further studies of larger cohort of patients and a longer follow-up time are needed, our findings corroborate the utility of IgG in the treatment of more resistant idiopathic inflammatory myositis related dysphagia.

Systemic Sclerosis

M. Pestaña Fernández, M. Rubio Rivás, C. Tolosa Villella, A. Guíllen del Castillo, D. Colunga Argüelles, L. Triapeli Martínez, V. Fonollosa Pía, C.P. Simeón Aznar on behalf of RESCLE, Internal Medicine Department, Hospital Universitario de Navarra, Pamplona; Internal Medicine Department, Corporación Sanitaria Universitaria Parc Taulí, Sabadell; Autoimmune Diseases Unit, Internal Medicine Department, Hospital Vall d’Hebron, Barcelona; Internal Medicine Department, Hospital Universitario Central de Asturias; Internal Medicine Department, Hospital de Cabrerizos, Oviedo, Spain

Background: In most patients with SSC, the onset is in the form of Raynaud’s phenomenon (RP), but in a few is in the form of visceral or musculoskeletal involvement or skin sclerosis. Several risk factors are related to poor outcome in patients with SSC, but never before has the mode of onset been described as one of them.

Objectives: To assess the mode of onset as prognostic factor in patients with SSC.

Methods: A retrospective and multicentre cohort study including 1625 patients with SSC, based on the National Spanish Scleroderma Registry (RESCLE) which includes 28 referral centres.

Results: RP, puffy hands, arthralgia/arthritis, skin sclerosis, interstitial lung disease (ILD), pulmonary arterial hypertension (PAH) and esophageal hypomotility where (p<0.01) stopped clinical modes of onset.

Conclusions: The cohort was split up in two groups: 1342 patients (83%) presented as RP and 283 (17%) presented as non-RP (see graphic below) Non-RP patients where younger at onset of disease (44.7±15.6 vs 49±15.6 years, p<0.001). showed higher percentage of diffuse subtype (36% vs 19%, p<0.001), developed more visceral involvement during the course of the illness and where more frequently anti-RNAPIII positive (29 vs 10%, p<0.001). Overall mortality was 16% in patients presented as RP vs 23% in non-RP patients (p=0.003). Few differences where noted among causes of death related to SSC, but other mortality was observed in RP group due to SSc-RV (19% vs 8.1%, p=0.05) and due to ILD in non-RP group (24% vs 8.3%, p=0.002).

Survival of patients with RP at onset was better at anytime than those with a non-RP onset: 0.97 vs. 0.89 at 5 years, 0.93 vs. 0.82 at 10 years, 0.83 vs. 0.63 at 20 years and 0.71 vs. 0.51 at 30 years from onset (p<0.001).
Conclusions: The mode of onset can be considered as independent prognostic factor, and specifically non-RP onset can be considered as a risk factor related to poorer outcome and RP onset and arthralgias can be considered as protector factors.

FR10404 | THE EFFECT OF A HOME-BASED OROFACIAL EXERCISE PROGRAM ON ORAL APERTURE OF SYSTEMIC SCLEROSIS PATIENTS

N. Czudan Coskun1, I. Turk2, V. Ciftci3, D. Aslan Tas2, M.C. Dogan3, I. Unal4
1Department of Physical Therapy and Rehabilitation, Division of Rheumatology; 2Department of Internal Medicine, Division of Rheumatology, Cukurova University Faculty of Medicine; 3Department of Pediatric Dentistry, Cukurova University Faculty of Medicine; 4Department of Biostatistics, Cukurova University Faculty of Medicine, Adana, Turkey

Background: Microstomia is one of the major problems that causes multiple dysfunctions and affects quality of life in systemic sclerosis (SSc).

Objectives: The purpose of this study is to evaluate the effect of a home-based orofacial exercise program on the oral aperture (OA) of SSc patients.

Methods: In this study, patients with systemic sclerosis (SSc) fulfilled the American College of Rheumatology (ACR) 2013 criteria with an OA of <40mm were included in the study. Patients were randomly divided into two groups. Group 1 was given oral augmentation and mouth stretching exercises with combination of strengthening exercise to masseter muscle twice a day for one month in addition to oral hygiene care advice; followed by no activity but oral hygiene care for the next four months. Group 2 received oral hygiene care advice for the first one month followed by the same orofacial exercise program twice a day for the next four weeks.

Results: A total of 52 patients were included in the study. Twenty-seven patients were assigned to group 1 (mean age 53.70±9.79 years; 90.4% female) and twenty-five to group 2 (mean age 50.68±11.93 years; 96.0% female). A total of 28 patients (group 1, n=18; group 2, n=10) completed the study. After four weeks period, OA increased in group 1 (P<0.001), whereas no change was observed in group 2 (P=0.906). At the end of 2 months the intragroup analysis showed no additional increase in group 1 (P=0.283), but a statistically significant increase in group 2, regarding the measurement of OA (P<0.010). We didn’t find any statistically significant difference between OA measurements of the groups 1 and 2 at the end of the trial (P=0.830).

Conclusions: The results of this pilot study suggested that an intervention of combined home-based orofacial exercise program might improve oral aperture of SSc patients. Future studies with longer follow-up period and higher number of patients are needed to observe the long-term benefits of the presented home-based exercise program.
