Participants were assessed at baseline, 14 and 28 Days. They completed the PainDETECT, WOMAC and POAS questionnaires. Quantitative sensory testing was carried out at three sites (index knee, contralateral knee, ECRB) using standard methods. Cold and heat pain thresholds were tested using a Peltier thermal stimulator and pressure pain using a digital algometer. Stabilometric Physical function was assessed using three timed locomotor function tests (sit-to-stand, walk, stairs).

Results: Participants receiving pregabalin (300mg) exhibited greater reductions in WOMAC Pain scores (P=0.0001) and PainDETECT scores (P=0.0001) at Day 28 compared to the paracetamol group and a greater increase in pressure pain thresholds (reduced tenderness) (P=0.025) at the index knee. There was no significant difference between the groups in cold pain thresholds (P=0.33).

Participants in the pregabalin group completed the physical tests more quickly than the paracetamol group (Sit-to-stand p=0.05, Walk, p=0.001, stair algometer p=0.05).

The pregabalin group also had a significantly increased likelihood of reducing their PainDETECT score below the entry value of 13 compared to the paracetamol group (OR 9.20; P=0.001) but there was no significant difference in the likelihood of reducing their cold pain threshold below the 15°C entry value (OR 2.28; P=0.14).

Conclusions: The group receiving pregabalin 300mg showed greater reductions in pain, reduced features of neuropathic pain and reduced tenderness at the affected knee. Further research is warranted to evaluate pregabalin in this specific patient cohort.

Ayurveda College & P.D. Patil Ayurveda Hospital, Nadiad, India; 6School of Ayurvedic Medicine, Ayurvedic Point, Milan, Italy; 7European Academy of Ayurveda, Birzstein; 8Institute for Social Medicine, Epidemiology and Health Economics, Charité Medical University, Berlin, Germany

Background: Traditional Indian Medicine Ayurveda is used to treat knee osteoarthritis (OA) despite limited evidence.

Objectives: We aimed to evaluate the effectiveness of complex Ayurvedic treatment compared to conventional complex care in knee OA patients.

Methods: According to ACR criteria patients with knee OA were included in a multicenter randomized, controlled trial and treated in 2 hospital outpatient clinics and 2 private outpatient clinics in Germany with 5 physicians and 20 therapists participating. Patients received either Ayurvedic treatment (n=77) or conventional care (n=74) with 15 treatments over 12 weeks. Primary outcome was the change on the European Centre for Osteoarthritis and Rheumatism (WOMAC) Index after 12 weeks (validated German version). Secondary outcomes included the WOMAC subscales; a pain disability index, numeric rating scales for pain and sleep quality, a pain experience scale, a quality-of-life index, a profile of mood index, rescue medication use, and safety issues.

Results: A total of 151 patients (Ayurveda n=77, conventional care n=74) were included. Changes of the WOMAC index from baseline to 12 weeks were more pronounced in the Ayurveda group (mean difference 6.10 [95% CI 52.69;6.6]) than in the conventional group (32.0 [95% CI 21.4;42.6]) resulting in a significant difference between groups (mean difference 0.001). In a clinically relevant effect size (Cohen’s d 0.68 [95% CI 0.35;1.01]). Similar tendencies were observed for all secondary outcomes at week 12. Effects were sustainable at follow-ups after 6 and 12 months.

Conclusions: The results suggest that a complex Ayurvedic treatment might be clinically superior to a complex conventional intervention in the treatment of OA of the knee.

GENOME-WIDE DNA METHYLATION PROFILING OF OSTEARTHRITIS PERIPHERAL BLOOD MONONUCLEAR CELLS REVEALS SLOWED EPIGENETIC AGING AMONG RAPID RADIOGRAPHIC PROGRESSORS: DATA FROM THE OSTEARTHRITIS INITIATIVE (OAI)

A. Rivas 1, M. Jeffreys 1, 2, R. Rheumatology, Immunology, and Allergy, University of Oklahoma Health Sciences Center; 4 Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Oklahoma City, United States

Background: Extensive evidence has correlated epigenetic alterations in articular tissues with both the pathogenesis and progression of human osteoarthritis, but few analyses of blood cell epigenetic patterns have been done in OA.

Objectives: We examined the DNA methylation aging rate in peripheral blood mononuclear cells (PBMCs) at baseline from knee OA patients with rapid radiographic progression compared to well-matched non-progressors enrolled in the Osteoarthritis Initiative (OAI).

Methods: PBMC DNA was obtained from baseline blood draws of 64 OA patients enrolled in the OAI longitudinal study. All patients had baseline symptomatic and radiographic OA. 32 rapidly-progressive OA patients, defined as ≥1.0mm radiographic joint space loss within 24 month follow-up were compared to 32 non-progressive patients. There were no differences in age, sex, race, BMI, baseline K/L grade, or calculated PBMC subset composition between rapid- and non-progressors. DNA methylation was quantified with Illumina HumanMethylation 450k arrays. Preprocessing was performed in GenomeStudio and normalized to baseline characteristics. Epigenetic age was estimated with the algorithm described by Horvath et. al., using 353 age-associated CpG sites. This epigenetic age was correlated to chronological age to calculate epigenetic-chronological age discordance (∆Age) and group differences compared to a Student t-test. ∆Age was correlated with age at death and BMI. Statistical analyses were performed with the Ingenuity Pathway Analysis (IPA) system.

Results: The baseline DNA methylation aging rate in rapidly progressive (RP) knee OA patients was 5.5±1.4 years less than chronological age (p=0.015). 1165 CpG sites were correlated with ∆Age in rapid progressors, corresponding to 755 genes. Ontologic analysis of highly correlated genes showed association of the STAT3 pathway (p=4E-4), Notch signaling (p=1E-3), axonal guidance signaling (p=7E-3), CREB signaling (p=2E-2), NFAT signaling (p=2E-2), and autophagy (p=4E-2) among others. Associated upstream regulators included FGF2 (p=3E-5), SMAD4 (p=9E-4), SMAD5 (p=1E-3), TNF (p=4E-3), and TGFB1 (p=4E-3), among others.

Conclusions: Our data reveal that a decelerated peripheral blood differential DNA methylation age epigenotype is present at baseline in rapidly progressive knee OA patients, but not in nonprogressive knee OA patients. The genes correlated with this methylation age deceleration cluster in pathways previously associated with OA in articular tissues, suggesting that these pathways may systematically epigenetically dysregulated. Our data reinforce the notion that OA is a heterogeneous disease composed of distinct subgroups, and suggests that future epigenetic investigation of immune cell subsets may be beneficial in OA research.

INTRAMUSCULAR CORTICOSTEROID INJECTION VERSUS PLACEBO INJECTION IN HIP OSTEOARTHRITIS: A 12-WEEK BLINDED RANDOMIZED CONTROLLED TRIAL

D. Dorleijn 1, P. Luijsterburg 1, M. Reijman 2, M. Kloppenburg 3, J. Verhaar 2, P. Bindels 1, K. Bos 3, S. Bijma-Zeestrin 4, 1 General Practice, 2 Orthopedics, 3 Rheumatology, UMC Utrecht, Leiden, Netherlands

Background: Several international guidelines recommend intra-articular (IA) corticosteroid injections for patients with hip OA experiencing moderate to severe pain and no responding to oral analgesics. Previous research has shown a systemic effect of an intramuscular (IM) gluteal corticosteroid injection in patients with subacromial impingement shoulder pain. A clinically relevant effect of IM corticosteroid injections could be less complex, alternative treatment for patients’ episodes of increased pain in hip OA.

Objectives: The trial aimed to assess the efficacy of an IM gluteal corticosteroid injection compared to a placebo injection on patients’ reported hip pain severity in patients with hip OA, who were not responding on oral analgesics.

Methods: Patients in primary care or secondary care who met the inclusion criteria, were included. Patients were randomized to receive either an IM gluteal corticosteroid injection on one hip followed by a placebo injection on the other hip or vice versa. Intervention and placebo injections were performed with a standardized technique. Analgesic medication use was recorded at baseline and at every follow-up visit. Primary outcome was a severity of hip pain at 2 weeks, measured with a numerical rating scale (NRS) in rest and during walking (0–10, 0=no pain). Secondary outcomes included hip pain severity (NRS, WOMAC pain, ICOAP, WOMAC function, stiffness (WOMAC stiffness), adverse events, and medical co-interventions at 2, 4, 6, and 12 weeks followed. Statistical analyses were performed based on the intention to treat principle. Linear mixed models with repeated measurements were used to analyze between group differences. The models were adjusted for variables that changed the effect size.

Results: 107 of 422 screened patients were randomized. After informed consent, one randomized patient did not show up at the appointment for baseline measurement and subsequent injection and could, because of lack of data, not be included in the analyses. Finally, 52 patients in the corticosteroid injection group, and 54 in the placebo injection group were included in the analyses. 88% of the patients were female, and 25% were recruited by orthopedic surgeons. Mean age was 64 years (SD 11) and duration of OA was ≥1 year for 70%. At 2 weeks follow-up (table), the corticosteroid injection was statistically significant and clinically relevant associated with hip pain reduction at rest (coefficient -1.3, 95% CI -2.3 to -0.3) compared to placebo. The corticosteroid injection was also associated with significant hip pain reduction at 4, 6 and 12 weeks. Moreover, at almost all follow-up measurements the estimates showed significant differences in favor of the corticosteroid injection on WOMAC pain, function, stiffness and total score, and ICOAP. No significant differences between groups were found for adverse events and medical co-interventions.

Conclusions: An IM gluteal corticosteroid injection was effective in hip pain reduction compared to placebo injection in patients with hip OA at 2 weeks
follow-up. Moreover, the effect of the corticosteroid injection prolonged the entire 12 week follow-up period.

SAT0493 MAINTAINING SUFFICIENT SERUM VITAMIN D LEVELS OVER TWO YEARS IS ASSOCIATED WITH IMPROVED KNEE STRUCTURAL AND SYMPTOMATIC OUTCOMES IN PEOPLE WITH KNEE OSTEOARTHRITIS: A POST HOC ANALYSIS OF THE VIDEO TRIAL

S. Zheng1, X. Jin1, F. Cicuttini2, X. Wang1, Z. Zhu1, A. Włuka2, W. Han1, 1Winzenberg1, B.E. Antony1, D. Aitken1, L. Blizzard 1, G. Jones 1, C. Ding1. 1Menzies Institute for Medical Research, University of Tasmania, Hobart; 2Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia

Objectives: To describe whether maintaining sufficient serum vitamin D levels in people with knee osteoarthritis (OA) and baseline vitamin D insufficiency has an association with change in knee structures and symptoms over two years.

Methods: Participants (n=413, age 63.2%; 50% females) with symptomatic knee OA and vitamin D insufficiency were enrolled in a clinical trial. 340 participants (62.3%; completed the study with 25-hydroxyvitamin D [25(OH)D] measurements at month 0, 3 and 24. Participants were classified as consistently insufficient (serum 25(OH)D <50nmol/l) at month 3 and 24, n=45); fluctuating (25(OH)D >50nmol/l at either point, n=68) and consistently sufficient (25(OH)D >50nmol/l at month 3 and 24, n=228) vitamin D groups. Knee cartilage volume, cartilage defects, bone marrow lesions (BMLs) and erosion-synovitis volume were assessed using MRI at baseline and month 24. Knee symptoms were assessed at baseline, month 3, 6, 12 and 24 using Western Ontario and McMaster Universities Arthritis Index (WOMAC).

Results: The consistently sufficient group had significantly less loss of tibial cartilage volume (β: -2.1%, 95 CI%: -3.3%, 3.9%), less increase in erosion-synovitis volume (β: -2.5mL, 95 CI%: -4.7, -0.2) and less loss of WOMAC physical function (β: -94.2, 95% CI: -183.8, -4.5) compared to the consistently insufficient group in multivariable analyses. In contrast, there were no significant differences in these outcomes between the fluctuating and consistently insignificant groups. Changes in tibiofemoral cartilage defects, BMLs and knee pain were similar between groups.

Table 1. Associations between maintaining sufficient 25-(OH)D levels and changes in cartilage volume and erosion-volume over 24 months in patients with knee osteoarthritis

SAT0494 EARLY TOLL-LIKE RECEPTOR 4 BLOCKADE IMPEDES THE BEHAVIOURAL AND HISTOLOGICAL CHARACTERISTICS OBSERVED IN A MIA-INDUCED ANIMAL MODEL OF OSTEOARTHRITIC PAIN

M.M. García1, D. Pascual1,2, E. Quesada1,3, J.A. Uranga4, C. Goicoechea5,6, 1Pharmacology, Universidad Rey Juan Carlos, Alcorcón; 2Universidad URJC-IOM-CSIC, Madrid- Alcorcón; 3Grupo Nucleósidos, Instituto química médica CSIC, Madrid; 4Historia, Universidad Rey Juan Carlos, Alcorcón; 5Farmacología, Universidad Rey Juan Carlos, Madrid, Spain

Background: Contribution of Toll-Like Receptor 4 (TLR4) to pain sensitisation has been demonstrated to occur under chronic pain conditions. We previously described an antinociceptive effect of TLR4-A1, a TLR4 inhibitor, in two chronic pain conditions, peripheral neuropathic pain and osteoarthritis (OA).

Objectives: The aim of this study was to evaluate TLR4-A1 effect on alldynia and hyperalgesia in OA model, and to evaluate whether this effect is correlated with changes in spinal glial activation.

Methods: Wistar rats weighing 200–250g were used. OA was induced by a single intraarticular injection of 2mg of monosodium iodoacetate (MIA) into the right knee joint of anaesthetised rats. TLR4-A1, 10 mg/kg, was intraperitoneally administered during the first five days post-MIA injection. TLR4-A1 was synthesised by Dr Quesada. Vehicle-treatment (ethanol:saline, 1:9) was administered in the same way. At three weeks (day 21 post-MIA injection), animals were sacrificed for tissue collection. L3-L5 spinal segments were collected and embedded in paraffin wax. Eventually, samples were immune-stained with anti-GFAP or Iba-1 antibodies. Photomicrographs were recorded to make montages of the entire spinal cord at a final magnification of 20x (n=3 per lumbar section). Total number of GFAP or iba-1 positive cells were counted separately in laminas II-III, IV-VI and V-VI.

Results: Intraarticular injection of MIA increased microglial expression (Iba-1 labelling) in the ipsilateral spinal cord compared to the contralateral side. Being the difference statistically significant for the superficial (II-III; +72.25%, P<0.01) and deeper (V-VI, +95.31%, P<0.001) laminae of L3 and for the superficial laminae of L4 (+87.5%; P<0.01). In animals treated with TLR4-A1, Iba-1 labelling in the ipsilateral dorsal horn showed a similar pattern to the contralateral dorsal horn. Pre-treatment with TLR4 blocker prevented microglia activation after MIA-injection in L3 and L4 segments. Intraarticular injection of MIA also increased the number of GFAP-positive activated astrocytes in the ipsilateral spinal cord compared to the contra-lateral side; in this case, statistically significant differences were found for the superficial (I-II; +41.88%, P<0.01) and middle (III-IV; +64.3%, P<0.001) laminae of L3 levels. GFAP in TLR4-A1-treated rats showed a similar pattern for the ipsi- and the contra-lateral sides. That is, TLR4-A1 prevented L3 increased activated astroglia following MIA-injection.

Conclusions: Early toll-like receptor 4 blockade hampers spinal glial activation, which correlates with diminished allodynia and hyperalgesia observed in TLR4-A1-treated animals in a model of MIA-induced OA. Although further studies are needed, TLR4 blockade could be a good option in the treatment of osteoarthritis.

SAT0495 KNEE FUNCTION AND ENTHESITIS IN LONG STANDING OSTEOARTHRITIS, WHAT ULTRASOUND COULD TELL US?

A. Abogamal, H. Aly, S. Ghaneem, H. Saad on behalf of AL-Azhar MSUS school. 1Rheumatology, Alazhar Faculty of Medicine, Cairo, Egypt

Background: The enthesis around the knee including the quadriceps tendon and infrapatellar ligament insertions could be responsible for a significant cause of knee pain functional deterioration in long standing knee osteoarthritis.

Objectives: Ultrasound evaluation of the enthesis at the quadriceps tendon patellar insertion, infrapatellar ligament patellar and tibial insertions in patients with long standing knee osteoarthritis (KOA) and low knee function.

Methods: 410 Patients with KOA attending the outpatient rheumatology clinic of AL-Azhar university hospitals who had met the inclusion criteria: At least 5 years disease duration. Kellegren – Lawrance scale grade III.

Exclusion criteria: Patients with chronic diseases affects the patient function.

Acknowledgements: Franco R and Marquez A for technical support.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.1056
Patients with previous knee surgery, recent trauma, or intraarticular intervention.
Patients with knee effusion, active synovitis, or popliteal cysts.

All patients were subjected to ultrasound assessment in gray scale and Power Doppler was performed using a scanner with a multifrequency 12L linear array transducer (General Electric Systems; LOGIQ-E). Ultrasound techniques were used for all patients included in the study. Knee was assessed for the following items in both sides while Patient lying supine with the knee flexed 40 degrees:

1. Superior pole of the patella — quadriceps tendon enthesis: • Quadriceps tendon thickness >6.1 mm • Suprapatellar bursitis • Superior pole of patella erosion • Superior pole of patella enthesophytes
2. Inferior pole of the patella – proximal patellar ligament enthesis: • Patellar ligament thickness >4 mm • Inferior pole of patella erosion • Inferior pole of patella enthesophytes
3. Tibial tuberosity – distal patellar ligament enthesis • Patellar ligament thickness >4 mm • Infrapatellar bursitis • Tibial tuberosity erosion • Tibial tuberosity enthesophytes.

Knee functional status was assessed using KOOS scale for Pain, other Symptoms, Activities of Daily Living (ADL), Sport and Recreation Function (Sport/Rec) and knee-related Quality of Life (QOL). Low knee function was considered if the patient had score 50 or more in any KOOS scale parameter.

Results: 172 (42%) patients were found with low knee function among them quadriceps enthesis found in 114 (66.3%) patients, at the patellar attachment of infrapatellar ligament in 160 (93%) patients, and enthesis at the tibial attachment of infrapatellar ligament in 44 (26%) patients. Good knee function were found in 238 (58%) patients among them quadriceps enthesis found in 76 (31.9%) patients, at the patellar attachment of infrapatellar ligament in 87 (36.3%) patients, and no enthesis at the tibial attachment of infrapatellar ligament were detected.

Conclusions: Entheses at the quadriceps and infrapatellar ligament represent a common ultrasonographic finding in patients with longstanding KOA, and significantly associated with low knee function.

SUN0498 SAFETY OF DIACEREIN IN PATIENTS WITH OSTEOARTHRITIS – A REAL WORLD EXPERIENCE WITH UNEXPECTED RESULTS

A. Malpica, D. Buitrago-Garcia, C. Mendez, P. Santos-Moreno, L. Villarreal.

Background: Osteoarthritis (OA) is a common joint disorder and may occur in any synovial joint in the body, the condition is common in hands, knees, hips and spine. Diacerein is an antraquinone derivate has shown the inhibition of cytokine interleukine 1-B (1). A Cochrane review published in 2014 showed that diacerein could be effective for this condition, however the most frequent adverse event with this medication was diarrhea compared to placebo RR 3.52 (95% CI 2.42 to 5.11) or other symptomatic slow acting drugs for OA 3.20 (95% CI 1.58 to 6.49) (2).

Objectives: To describe the real-world safety of Diacerein in patients with OA in a specialized center in Bogotá, Colombia.

Methods: We performed a cross-sectional study; patients with confirmed criteria of osteoarthritis and treated on a regular basis with Diacerein were included. Patients were followed during a 16 month period. Adverse events were classified according the Common Terminology Criteria for Adverse Events (CTCAE) of the World Health Organization. Descriptive epidemiology for continuous variables, measure of central tendency and dispersion for qualitative and categorical variables through percentages and averages were calculated, we analyzed bivariated connections with X2 test.

Results: 1278 patients meet inclusion criteria; mean age was 62 years ± 10 years. 88% were female and 12% male, due to our patient's condition 80% of them were polimedicated. 93% of our patients received diacerein in usual dose of 100 mg daily and remaining 7% in a 50 mg day dose. Regarding safety 7.5% (n=96) of our patients developed adverse, the most frequent event was diarrhea with 50%, followed by nausea and abdominal disturbances among others. According to the CTAE classification the events adverse were mild 98% and only 2% severe; that means only 0.075% of total of patients receiving Diacerein had severe AE. On the other hand, correlation between adverse events and polymedication were statistical significant (P=0.000). For this reason we consider that AE such as diarrhea can be attributed more to patients' polymedication than diacerein.

Conclusions: This evidence showed a low proportion of patients with adverse events taking Diacerein; also most of these patients were polymedicated giving as a result a higher risk of having an adverse event. When we compared our results to other studies diarrhea was the most frequent event, followed by nausea, but only a very low proportion of patients were forced to discontinue medication.

It is important to continue following patients that take diacerein in order to report its true safety and effectiveness.

SAT0497 WHAT ARE THE PATIENTS’ EXPERIENCE, NEEDS AND EXPECTATIONS IN HAND OSTEOARTHRITIS? A QUALITATIVE EVALUATION

M.-A. Ofroy, A. Frazier-Mironer, Centre Viggo Petersen, Rheumatology Department, APHP Lariboisière Hospital, Paris, France

Background: The objective of this study was to evaluate the patients’ experience and needs in relationship with HOA, in order to establish a therapeutic education program for HOA patients.

Objectives: As the subject was about descriptive, not quantifiable elements, qualitative methodology was chosen. Patients were submitted to individual semi-directive interviews. Verbatim were analyzes following the grounded theory until saturation of data.

Methods: Twelve HOA patients accepted to participate to the study. There were 10 women and 2 men, aged 45 to 79 years. Body-mass indexes varied from 18.7 to 31.6 kg/m2. Clinical and radiological severity of HOA varied among patients. They provided data on the experience of HOA, which is influenced by clinical and functional signs and the evolution of the disease. Pain and deformity are the main clinical signs, and lead to severe functional impairment. The functional, psychological, social consequences of HOA also have an impact on the patient experience. Patients develop adaptive strategies, mainly recourse to medical management, and pharmaceutical and non-pharmacological therapies. The needs of HOA patients were also explored, and three main ideas emerged. First, they want to be better informed on HOA. Second, they have a feeling of failure of conventional medicine, and often use alternative medicines. Third, the fear of disability with the course of the disease is very strong. They have difficulty accepting pharmacological treatments, but often do not realize the therapeutic nature of non-pharmacological treatments.

Results: The main concerns of HOA patients are: information, non-pharmacological treatments and evolutionary risks. These themes should be included in the development of therapeutic education programs for HOA.

SAT0498 THE PERFORMANCE OF URINARY COLLAGEN TYPE II C-TELOPEPTIDE (UCTX-II) IN KNEE OSTEOARTHRITIS: A META-ANALYSIS

B. Jeremiasson, F.P. Lalebe, W.E. Van Spil. Department of Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht, Netherlands

Background: Among the currently available biochemical markers for osteoarthritis (OA), urinary collagen type II C-telopeptide (uCTX-II) is one of the most frequently investigated markers. Much research has been performed into the performance of uCTX-II, but most of it in relatively small cohort studies. Therefore, we performed a meta-analysis to summarize uCTX-II studies in a quantitative way.

Objectives: To perform a meta-analysis of the performance of uCTX-II as a biomarker for diagnosing knee osteoarthritis (kOA) and its association with radio-
graphic KOA severity. Furthermore, to look for patient and study characteristics that determine uCTX-II performance.

**Methods:** Medline and Embase databases were searched for studies into uCTX-II levels in adult subjects with radiographic KOA according to the Kellgren and Lawrence (K&L) classification system. uCTX-II levels were compared between subjects with KOA K&L ≥ 2 versus healthy control subjects and between subjects with KOA K&L 2 versus K&L 3–4 (i.e. moderate vs severe KOA). Controls were either selected based on lack of knee symptoms, based on K&L score, or were randomly selected from the general population. Differences between KOA subgroups were expressed as standardized mean differences (SMD). Subgroup analyses were performed to compare uCTX-II performance between genders, ethnicities, and large and small studies. Differences between subgroups were considered relevant when SMDs differed >25% between groups.

**Results:** 2035 Studies were screened for eligibility, of which ten studies were included. A moderate pooled SMD of 0.52 (95% CI: 0.40–0.64, P < 0.0001) was found for subjects with KOA K&L ≥ 2 versus controls, based on ten SMDs. For K&L≥2 versus K&L2 a moderate pooled SMD of 0.47 (CI: 0.32–0.63, P < 0.0001) was found, based on five SMDs. No indications for publication bias were identified using funnel plots. Subgroup analyses of the K&L ≥2 versus control comparison showed that uCTX-II performs better in women as compared to men and in Caucasian subjects as compared to other ethnicities. Study size did not influence the pooled SMD. Subgroup analysis was considered infeasible for the K&L 2 versus K&L 3–4 comparison due to a limited number of studies.

**Conclusions:** This is the first meta-analysis of uCTX-II performance in subjects with radiographic KOA. It appeared that uCTX-II levels can distinguish with moderate strength between radiographic KOA subjects and controls. Moreover, uCTX-II levels are consistently increased in severe versus moderate radiographic KOA. Female gender and Caucasian ethnicity were found to enhance uCTX-II performance in distinguishing radiographic KOA from controls. Yet, the number of studies was relatively small and criteria for KOA and control subjects differed between studies.

**SAT0499 | IDENTIFICATION OF BIOCHEMICAL PHENOTYPES IN KNEE OSTEOARTHRITIS: LONGITUDINAL DATA FROM THE FNIH OA BIOMARKER CONSORTIUM**

B. Jeremiasse 1, P.M. Welsing 1, C. Fellows 2, F.P. Lafeber 1, W.E. Van Spil 1, 1Department of Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht, Netherlands; 2School of Veterinary Medicine, University of Surrey, Guildford, United Kingdom

**Background:** It is hypothesized that patients with knee osteoarthritis (OA) can be classified into different phenotypes. Knowledge of these phenotypes may contribute to developing effective targeted treatment strategies.

**Objectives:** To identify different longitudinal phenotypes of knee OA using biochemical markers and to compare these phenotypes with regard to radiographic joint space loss (JSL) and/or pain progression.

**Methods:** Baseline, 1-year, and 2-year biochemical marker data from the FNIH OA Biomarker Consortium were used. This consortium is a nested case-control study of 600 subjects with one symptomatic index knee showing radiographic OA changes of Kellgren and Lawrence grade 1 to 3. Subjects were classified into different subgroups based on clinical, and radiographic parameters (data not shown).

**Conclusions:** Seven longitudinal phenotypes of knee OA could be identified based on biochemical markers representing bone, cartilage and synovial metabolism. These phenotypes showed relevant differences in other characteristics, such as JSL and/or pain progression.

**SAT0500 | SLEEP DISTURBANCE, KNEE INFLAMMATION, AND SYMPTOMS IN KNEE OSTEOARTHRITIS**

C.K. Kwok 1, E. Ashbeck 1, A. Guermazi 2, F.W. Roemer 2, 3, S. Parthasarathy 4, 1Univ. of Arizona Arthritis Center, Univ. of Arizona (UA), Tucson; 2Radiology, Boston Univ., Boston, United States; 3Radiology, Univ. of Erlangen-Nuremberg, Erlangen, Germany; 4UAHS Center for Sleep & Circadian Sciences, UA, Tucson, United States

**Background:** Sleep disturbance has been shown to contribute to systemic inflammation as well as JSL progression, pain, and pain sensitization. The role of sleep disturbance in knee osteoarthritis (OA) has not been established. Sleep disturbance may be an aggravating contributor to and/or a consequence of knee OA symptoms, with inflammation serving as a potential mediator.

**Objectives:** To compare knee symptoms over nine years of follow-up by...
frequency of sleep disturbance at baseline, among participants with or at risk for radiographic knee OA (ROA), and to estimate the association between the presence of inflammation on knee MRI and pain that disturbs sleep among knees that developed ROA.

Methods: Knees from the Osteoarthritis Initiative (OAI) with or at risk for ROA were included in this longitudinal analysis. Self-reported frequency of restless sleep in the past week was assessed using a CES-D Q3 symptom. Knees were assessed annually using the WOMAC. Knees that developed incident ROA (i.e., ≥ 2 Kellgren-Lawrence grade, KLG) through four years of follow-up were assessed for erosion-synovitis on non-contrast-enhanced 3T MRI using the MRI Osteoarthritis Knee Score (MOAKS) from annual clinical visits between four years prior to incident ROA and up to one year after ROA detection. Erosion-synovitis represents a combination of joint effusion and synovial thickening on fluid-sensitive sequences and scored as 0 (normal), 1 (mild), 2 (moderate), or 3 (severe). Annual mean WOMAC total score was estimated using a mixed model with participant and knee treated as random effects, in 5,028 knees at risk for ROA at baseline, and in 3,893 knees with ROA at baseline. Log-binomial regression with generalized estimated equations was used to estimate the association between erosion-synovitis and knee pain in bed that disturbs sleep, adjusted for age, sex, and BMI in a sample of 355 knees with an average of 3.8 MRI assessments.

Results: There was dose-dependent effect, with participants reporting restless sleep 1–2 days, 3–4 days, and 5–7 days in the past week having higher mean WOMAC total scores compared to those who reported 0–1 day of restless sleep (i.e., difference in means: 2.5 [95% CI: 1.3 to 3.8], 5.1 [95% CI: 3.2 to 7.1], and 10.1 [95% CI: 7.6 to 12.6], respectively) among knees with ROA (KLG ≥ 2) at baseline. Differences in average WOMAC total score between groups were relatively persistent over nine years (Figure 1). A similar dose-dependent effect of restless sleep was observed among knees at risk of ROA (i.e., KLG 0 or 1). Among knees that developed incident ROA, those with mild erosion-synovitis had a 52% higher risk of knee pain in bed that disturbs sleep at the same visit (RR=1.52; 95% CI: 1.13 to 2.04), while knees that had moderate/severe erosion-synovitis had more than double the risk of knee pain that disturbs sleep (RR=2.55; 95% CI: 1.67 to 3.47), compared to knees with no MRI-detected erosion-synovitis.

Conclusions: Restless sleep was associated with knee symptoms and disability in a dose-dependent manner, with average levels persistent over nine years of follow-up among knees with and at risk of ROA. Erosion-synovitis was associated with pain that disturbs sleep among knees that developed incident ROA. Sleep disturbance and knee inflammation may be important targets for interventions in knee OA.

SAI0502 A RANDOMIZED, PLACEBO-CONTROLLED, PROOF-OF-CONCEPT EFFICACY STUDY OF A MICROSOMAL PROSTAGLANDIN E SYNTHASE-1 (MPGES1) INHIBITOR AND A PROSTAGLANDIN E RECEPTOR (EP) ANTAGONIST IN THE TREATMENT OF CANINE OSTEOARTHRITIS PAIN

C. Robertson-Plouch 1, J.R. Stille 2, P. Liu 1, S. Malcolm 2, D. Brown 3, M. Warner 4, M.J. Fisher 5, Lilly Research Laboratories; 6The Chorus Group, Eli Lilly and Company, Indianapolis, United States

Background: Inflammation is a known contributor to osteoarthritis (OA) pain in animals and humans. While translation of human treatments to companion dogs is common, translation from companion dogs to humans is less frequent. We present results of a clinical study, in client-owned canines with moderate OA pain, which evaluated the efficacy of 2 molecules targeting the actions of prostaglandin E, either by modulating its production (mPGES1 inhibitor; LYA), or subsequent degradation (EP4 antagonist, LIP).

Objectives: To provide translational and comparative data to inform the potential utility of each of these mechanisms for treatment of chronic OA pain in humans and animals.

Methods: A multicenter, randomized, double-blind, placebo (PBO)- and active-controlled trial in client-owned canine patients with moderate OA pain ≥ 1 hindlimb/forelimb joint. Dogs ≥ 2 years of age with Liverpool Osteoarthritis in Dogs (LOAD) Mobility total score ≥ 13 to ≤ 46 were randomized (1:1:1:1:1 to 2 weeks of LVA (1.5 mg/kg/day), LBV (25 mg/kg/day), carprofen (4.4 mg/kg/day), or PBO. Efficacy versus PBO was assessed by mean change from baseline (CFB) to Week 2 in the Canine Brief Pain Inventory (CBPI) Pain Interference (PI) Score (primary endpoint), and for secondary endpoints: CBPI Pain Severity (PS) and Overall Impression (OI) subscore and LOAD Mobility score. Data were analyzed by mixed-effect model for repeated measures with treatment, time, and interaction of treatment and time as fixed effects, and with baseline score, site, and weight as covariates. Posterior probability of treatments being superior to PBO was calculated with Bayesian methods.

Results: Of 163 dogs randomized, 158 (96.9%) completed the study. Treatment arms were well-balanced for baseline characteristics (mean [standard deviation] age: 9.3 [3.0] years, weight: 54.6% 15–32 kg, 45.4% > 32–50 kg, CBPI PI: 5.1 [2.1]; CBPI PS: 4.2 [1.9]; LOAD Mobility: 24.1 [5.6]). Improvements (CFB) in CBPI PI were observed in all treatment groups after 2 weeks (Table). For LVA,
the probability of superiority to PBO was 80% for CBPI PI and 89% to 96% for secondary endpoints. LYB showed inconsistent separation from PBO across the endpoints, with probability of superiority to PBO 54% to 89%. The separation of carprofen and PBO arms demonstrated assay sensitivity. The incidence of adverse events for LYA (35.9%) was comparable to that of carprofen (25.6%) and the control group (32.6%). For LYB, the incidence was significantly higher versus PBO (59.5%, P<0.01).

**Conclusions:** The study results support an efficacy proof-of-concept signal for the mPGE51 inhibitor mechanism for treatment of chronic OA pain in canine patients.

**Acknowledgements:** We also thank Leijun Hu, Alain Frix, and Claire Smith of Eli Lilly and Company for their contributions to the study.

**Background:** MicroRNAs (miRNAs) are a class of 19–23 nucleotides long non-coding RNAs that post-transcriptionally regulate the activity of target mRNAs. MicroRNAs are involved in cartilage homeostasis and play an important role in the pathogenesis of osteoarthritis (OA). They have been detected in human plasma and in synovial fluid and are considered potential diagnostic biomarkers and therapeutic targets of OA. Balneotherapy is a common non-pharmacological treatment for OA patients. In a previous published prospective single-blind randomized clinical trial in patients with knee OA, we showed that a cycle of mud-bath therapy (MBT) in addition to conventional treatments induced an improvement on pain, functional capacity and quality of life in comparison to standard treatment alone.

**Objectives:** As part of this study we evaluated the whole blood levels of miR-155, 225, 225, 181a, 146a and miR-let-7e, which are involved in the pathogenesis of OA.

**Methods:** Thirty-two patients aged between 50 and 75 years with knee OA defined by the ACR criteria were included for the current analysis, based on the availability of blood sample at basal time and after 2 weeks. Twenty-one patients (MBT group) were daily treated with a combination of daily mud-packs at 42° C and mudbaths in mineral water, at 37° C for 15 min, for a total of 12 applications over a period of 2 weeks, in addition to standard therapy; the other eleven patients (control group) continued their conventional treatment alone.

**Clinical parameters [global pain score by a 0–100 mm Visual Analog Scale (VAS); physical function, total pain score and total stiffness score (WOMAC)] and microRNAs expression were performed at basal time and after 2 weeks.**

**PREDICTIVE ABILITY OF BIOMARKERS LINKED WITH SYNOVITIS FOR FUTURE INCIDENCE OF PAINFUL KNEE OSTEOARTHRITIS IN A COMMUNITY-BASED COHORT OF MIDDLE-AGE WOMEN**

**1 Biomarkers & Research, Nordic Bioscience, Herlev, Denmark; 2 Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford; 3 Department of Twin Research, King’s College London, St. Thomas Hospital, London, United Kingdom**

**Background:** Radiographic knee osteoarthritis (RKOA) is associated with the knee pain. However, more than half of the middle-aged individuals with RKOA will report no concurrent knee pain. Specific matrix metalloproteinases (MMPs) generated protein fragments have been associated with knee synovitis and suggested as specific neo-epitope biomarkers of joint remodelling.

**Objectives:** The aim of the study was to evaluate the association between MMP-derived neo-epitope biomarkers measured in serum, and future incidence of either painful RKOA or RKOA without pain, in a cohort of middle-aged women with no RKOA at baseline.

**Methods:** 585 participants (mean age 53.2, mean BMI 25.1) from the Chingford 1000 Women Study Chingford Women Study had serum biomarker levels of MMP- degraded of CRP (CRPM), collagen type II (C2M) and collagen type III (C3M) measured at year 2 or 3 of the study. All participants had a Kellgren Lawrence (KL) score of 0 in both knees at baseline. Ten years following the recruitment, incidence of RKOA was determined as KL≥2 and painful RKOA was defined as the presence of pain on any number of days in the preceding month in the knee with RKOA. Log-transformed normalised biomarker levels were utilised in separate logistic regression models adjusted for age. Outcomes were defined as either without pain or painful RKOA. Further analyses were performed adjusting for both age and BMI.

**Results:** 24.6% of women developed RKOA during 10 years after the recruitment, but only 8.9% of developed RKOA associated with concurrent knee pain. After adjusting for age, statistically significant positive associations were found between C3M and CRPM and the risk of developing painful RKOA with odds ratio (OR) ≥3.4 (95% confidence interval (CI): 1.4 to 8.2), and OR≥2.5 (95% CI: 1.2, 5.2) respectively. After adjusting for age and BMI, only C3M was positively associated with risk of developing painful RKOA with OR≥3.2 (95% CI: 1.3, 7.8).

**Conclusions:** In a population of middle-aged women without knee osteoarthritis, an MMP generated neo-epitope of collagen III previously linked with knee synovitis (C3M) can independently identify high-risk individuals for developing painful RKOA. These findings indicate that targeting MMP activity may be a promising therapeutic strategy in well-targeted populations.

**SAT0505**

**SELF-REPORTED KNEE INSTABILITY ASSOCIATED WITH PAIN AND ACTIVITY LIMITATIONS PRIOR TO TOTAL KNEE ARTHROPLASTY IN PATIENTS WITH KNEE OSTEOARTHRITIS**

C. Leichtenberg 1, J. D. Mesters 1, J. Dekker 2, 3, R. G. Nielssen 1, T. P. Vliet Viladot 1, M. van der Esch 4, 5, Orthopedics, Leiden University Medical Center, Leiden; 2 Rehabilitation Medicine, Psychiatry, VU University Medical Center; 3 Rehabilitation Research, Reade, Amsterdam, Netherlands

**Background:** Sixty to 80% of the patients with knee osteoarthritis (OA) reported self-reported knee joint instability, which was associated with pain and activity limitations. In the previous randomized control trial described the prevalence of retained self-reported knee joint instability after total knee arthroplasty (TKA) (32%). To better understand self-reported knee joint instability in usual care there is a need to replicate and extend the results.

**Objectives:** The aims of the study were to determine (i) the prevalence of self-reported knee joint instability prior and one year after TKA, (ii) the associations between self-reported knee instability, pain, activity limitations and quality of life prior and one year after TKA, (iii) the course of self-reported knee instability over time and (iv) the associations between retained knee instability, pain, activity limitations and quality of life.

**Methods:** The aim of the study was to determine (i) the prevalence of self-reported knee joint instability prior and one year after TKA, (ii) the associations between self-reported knee instability, pain, activity limitations and quality of life prior and one year after TKA, (iii) the course of self-reported knee instability over time and (iv) the associations between retained knee instability, pain, activity limitations and quality of life.
Methods: Consecutive patients with knee OA undergoing primary TKA, extracted from the Longitudinal Leiden Orthopaedics and Outcomes of OsteoArthritis Study (LOAS Study), were included. Self-reported knee joint instability and the Injury and Osteoarthritis Outcome Score (KOOS) Pain, Activity Daily Living (ADL) and QoL subscales (0–100; worst–best) were assessed by questionnaires prior and one year after surgery. Multivariable regression analyses were performed to determine associations between knee joint instability, pain, activity limitations and quality of life, adjusted for potential confounders including age, sex, comorbidities, physical activity and preoperative frailty.

Results: 982 patients were included of which 649 patients (72%) reported knee joint instability (mean age 67 years (SD8.6), 485 females (70%)) and 187 patients (21%) postoperative knee joint instability. Preoperative knee joint instability was associated with preoperative KOOS Pain (B=-2.7;95% CI -10.9–3.5) and ADL (B=-3.8;95% CI -7.5–0.9), but not QoL (B=0.495; CI -2.1–1.1). In addition, postoperative knee joint instability was associated with postoperative KOOS Pain (B=-13.5;95% CI -17.0–10.0), ADL (B=-15.1;95% CI -18.4–11.6) and QoL (B=-11.0;95% CI -13.5–8.5). Among the patients with preoperative self-reported knee joint instability, 65 patients (25%) retained knee instability and among the patients with no preoperative self-reported knee joint instability, 22 (8%) developed knee instability one year after surgery. Adjusting for baseline scores and potential confounders, retained knee joint instability was associated with postoperative KOOS Pain (B=-19.6;95% CI -30.9–8.3), ADL (B=-16.5;95% CI -27.0–5.9) and QoL (B=-13.0;95% CI -19.7–8.1).

Conclusions: In usual care, knee joint instability is prevalent one year after TKA (21%). Reported knee joint instability is associated with more pain, worse physical function (pre- and postoperatively) and worse QoL postoperatively. Besides, retained knee joint instability was associated with worse pain, physical function and QoL. This emphasizes the importance of further research into the genesis of pre- and postoperative knee joint instability.

LACK OF A CLEAR DISEASE MODIFYING ACTIVITY OF ECOCIBOX IN TREATMENT OF END-STANCE KNEE OSTEOARTHRITIS: A RANDOMIZED OBSERVER BLINDED CLINICAL TRIAL

1Rheumatology and Clinical Immunology, University Medical Centre Utrecht, Utrecht;
2Rheumatology, 3Orthopaedics, Sint Franciscus Gasthuis, Rotterdam, Netherlands

**Background:** Several studies suggest that celecoxib has beneficial effects on degenerated cartilage (1, 2). Together with effects on synovial tissue and bone, celecoxib was postulated to have disease modifying osteoarthritic drug (DMOAD) activity.

**Objectives:** This study evaluated the DMOAD activity of celecoxib, a selective cyclooxygenase 2 (COX-2) inhibitor compared to no treatment and naproxen, treating end-stage knee osteoarthritis (OA), after in vivo exposure using detailed *ex vivo* tissue analyses.

**Methods:** 172 patients with end-stage knee OA were randomized to 4 groups and treated for 4 weeks prior to knee replacement surgery: celecoxib 2dd200mg, naproxen 3dd250mg, celecoxib 2dd200mg stopped 3 days prior to surgery, or no treatment. To determine if treatment had reached the joint, intra-articular COX-2 expression was determined by Western Blot analysis in the celecoxib until surgery group. Intra-articular content was determined by staining and precipitation of glycosaminoglycans (GAGs) with Alcian Blue. Release of newly formed proteoglycans, as a measure of proteoglycan retention, was determined by loss of 35SO2-labeled GAGs in culture medium by precipitation of GAGs and no treatment group, considering these as most extremes. Proteoglycan expression was determined by Western Blot analysis in the celecoxib until surgery group. Intra-articular content was determined by staining and precipitation of glycosaminoglycans (GAGs) with Alcian Blue. Release of newly formed proteoglycans, as a measure of proteoglycan retention, was determined by loss of 35SO2-labeled GAGs.

**Results:** Intra-articular COX-2 expression was significantly decreased in both cartilage and synovial tissue (figure 1) indicating proper in vivo exposure of the treatment. Despite this reduction, no significant effect on proteoglycan release, retention or cartilage expression was found for none of the treatment groups (table 1). Synovial tissue showed only a small decrease in nitric oxide levels in celecoxib treated patients. No clear clinical effects could be observed as indicated by the WOMAC scores.

**Conclusions:** No effect of a 4-week in vivo celecoxib treatment on joint tissue in knee OA patients could be detected, although decreased expression of COX-2 confirmed its intra-articular availability. Effects on synovial inflammatory mediators and clinical outcome were very limited. No adverse effects were found either. As such the previous reported disease modifying effects of celecoxib in *in vitro* and pilot clinical studies could not unambiguously be confirmed in this randomized trial.

life. Obesity is considered to be associated with the incidence and progression of OA, thus weight loss is of paramount importance in OA management.

**Objectives:** To evaluate the efficacy of pharmacological and non-pharmacological therapy of obesity in pts with knee OA.

**Methods:** The study included 50 female pts aged 45–65 years with knee OA, Kellgren-Lawrence stage II–III, and obesity (BMI ≥30kg/m²). Pts form Group 1 (n=25) were administered orlistat at 120 mg x 3 times a day for 6 months along with low-caloric diet and therapeutic physical exercise. Pts from Group 2 (n=25) adhered to life-modifying therapy only, i.e. low-caloric diet and therapeutic physical exercise for 6 month. Anthropometry data (height, body weight, BMI), as well as WOMAC and quality of life EQ-5D scores were assessed at baseline, at 6 and 12 months (i.e. 6 months after discontinuation of therapy) after initiation of treatment in all pts.

**Results:** After 6 months of pharmacological therapy pts from Group 1 achieved significant mean weight loss by 10.07% (p<0.05), while pts from Group 2 with non-pharmacological therapy demonstrated only <1% (0.84%) (p>0.05) weight loss. Pts receiving pharmacological therapy with orlistat demonstrated the following improvements by WOMAC subscales: pain reduction by 52.5% (p<0.05), stiffness reduction by 47.96% (p<0.05), and 51.55% function improvement, while total WOMAC score improved by 51.49% (p<0.05). Respective WOMAC subscale scores in pts from Group 2 were considerably less impressive vs Group 1. Pts from Group 1 demonstrated statistically significant improvement in the quality of life by 52.27% EQ-5D (p<0.05), EQ-5D score remained unchanged only in 2 pts from Group 1 who failed to lose weight. During the following 6 months after discontinuation of orlistat pts from Group 1 regained 5.6% of their body weight (p>0.05) (Fig.1), which was associated with OA worsening OA (deterioration of pain by 42.63% (p<0.05) WOMAC, and total WOMAC score decrease by 23.15%). After 12 months of follow up pts from Group 2 showed body weight loss by 3.5%, and continuing decrease of pain in knee joints by WOMAC pain subscale, reaching 22.3% (p<0.05) as compared to baseline.

**Conclusions:** The results of our study demonstrate significant >10% weight loss in OA pts induced by orlistat therapy. Such a noticeable weight loss was associated with reduced pain intensity, improved function and quality of life in OA pts. Partial regain of body weight during 6 months after discontinuation of orlistat was accomplished by worsening of OA clinical course. Thus, effective maintenance of optimal body weight in OA pts requires longer pharmacotherapy of obesity.

**SAT0511 THUMB BASE OSTEOARTHRITIS: ASSOCIATIONS BETWEEN SYNOVITIS ON ULTRASOUND AND PAIN**

S. Ermutlu 1, F. Kroon 2, M. Kortekaas 2, M. Reijnierse 3, M. Kloppenburg 2,4.

1Rheumatology, Uludag University Medical Faculty, Bursa, Turkey; 2Rheumatology; 3Radiology; 4Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

**Background:** Hand osteoarthritis (OA) affects the interphalangeal (IP) joints but also the first carpometacarpal (CMC1) joint in the thumb base. Previous ultrasonography (US) studies of the IP joints have shown that inflammatory and structural features are frequently present and associated with clinical signs and symptoms. Until now, US studies specifically assessing the CMC1 joint have not been performed.

**Objectives:** To investigate associations between inflammatory features, structural damage and pain in CMC1 OA.

**Methods:** Cross-sectional data of 87 hand OA patients participating in the EChography in Hand OA (n=63) and the Etanercept in Hand OA (n=24) study at the Leiden University Medical Center were used in this analysis. Both CMC1 joints were assessed with US for synovial thickening, effusion and power Doppler signal (PDS) on a 0–3 scale by experienced ultrasonographers. Presence of pain upon palpation of the thumb base was assessed by trained research nurses on the same day as the US. Hand radiographs were scored blinded for clinical and US features, according to the Osteoarthritis Research Society International Atlas for osteophytes (0–3), joint space narrowing (JSN, 0–3), sclerosis (0–1) and malalignment (0–1) in the CMC1 joint. Risk ratios (RRs) with 95% confidence intervals (CIs) were calculated using generalized estimating equations to investigate associations between US or radiographic features and thumb base pain on joint level.

**Results:** Of 87 patients (mean age 60.3 years, 82% women, mean BMI 27.2 kg/m²) 174 CMC1 joints were assessed, of which 54 (31%) were painful. The US features synovial thickening, effusion and PDS were found in 26%, 33% and 25% of the joints, respectively. Radiographic features were present in 55% (osteophytes), 79% (JSN), 20% (sclerosis) and 12% (malalignment) of the joints. No associations were seen between inflammatory US features and pain upon palpation of the thumb base (Table). However, osteophytes and sclerosis were associated with more pain (RR 2.5 [95% CI 1.4 to 4.6] for osteophytes grade 3 versus no osteophytes, and RR 2.0 [95% CI 1.3 to 3.2] for sclerosis). Other radiographic features (JSN, malalignment) showed a trend for increased risk of pain on palpation, and for osteophytes and JSN a dose-response relation was apparent.

**Conclusions:** Radiographic features, especially osteophytes and JSN, were prevalent and more frequently present than US inflammatory features in the CMC1 joints of hand OA patients. In contrast to what is known from studies in IP joints, the presence of inflammatory US features was not associated with pain in the thumb base, but structural damage was. These results suggest differences in etiology of pain in thumb base compared to IP OA, with a larger role for structural damage in thumb base OA.

**SAT0512 MRI PROVIDING INSIGHTS IN ASSOCIATION OF SYNOVITIS AND BONE MARROW LESIONS (BMLS) WITH PAIN IN THUMB BASE OSTEOARTHRITIS (OA)**

F. Kroon 1, S. van Beest 1, W. Damman 1, R. Liu 1, M. Reijnierse 2, M. Kloppenburg 1,3, 1Rheumatology; 2Radiology; 3Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

**Background:** Hand OA affects the interphalangeal (IP) and thumb base joints (first carpometacarpal [CMC]1 and scaphotrapeziotrapezoid [STT]). Much is still unknown about the pathophysiology of thumb base OA. Magnetic resonance imaging (MRI) studies have led to new insights in IP OA, but in absence of a scoring system thumb base MRI studies are lacking.

**Objectives:** To investigate the prevalence of MRI synovitis and BMLs in the thumb base, and their association with pain, using the novel OMERACT thumb base OA MRI scoring system (TOMS).

**Methods:** Cross-sectional data of the Hand OSTeoArthritis in Secondary care (HOSTAS) study, including consecutive patients diagnosed by their treating rheumatologist with primary hand OA, were used. Patients with an MRI of the right thumb base at baseline were included in the analysis. MRI were scored by two readers using the TOMS for synovitis and bone marrow lesions (BMLs) in the CMC1 and STT joints (grade 0–3). BMLs were evaluated in the proximal and distal joint parts separately, resulting in a 0–6 and 0–9 sum score for CMC1 and STT, respectively. Pain on palpation of the thumb base was assessed by trained research nurses. Hand radiographs were assessed for presence of osteophytes in the CMC1 and STT joints. Associations between MRI lesions and thumb base tenderness were analysed using logistic regression, presented as odds ratios (ORs) with 95% confidence intervals (CIs), stratified for absence or presence of radiographic osteophytes. For the analyses synovitis and BML scores were
aggregated into a dichotomous total thumb base involvement score (0–1 in both joints vs. ≥2 in at least one joint).

**Results:** 85 out of 202 patients (84% women, mean age 60.1 years) reported pain on palpation in the thumb base. Synovitis was seen in both thumb base joints (CMCJ 42%, STT 37%), although prevalence of grade ≥2 synovitis was low in both joints. MRLs were present in CMCJ 1 and STT in 54 and 53%, respectively, with 18 and 21% having a sum score of 2–3, and 16 and 7% a sum score ≥4. In absence of radiographic osteophytes, presence of synovitis or BMLs in either thumb base joint was not statistically significantly associated with thumb base tenderness (ORs 1.9 [95% CI 0.6–6.4] and 1.5 [0.5–4.3], respectively). However, in absence of synovitis or BMLs, radiographic osteophytes and pain were associated, with increasing ORs when MRI lesions were additionally present (Table). Similar results were found for self-reported thumb base pain (not shown).

**Conclusions:** Synovitis and BMLs are present in the thumb base, although severe MRI lesions were uncommon. Prevalence of synovitis was similar in the CMCJ and STT joints, although higher BML scores were more frequently seen in CMCJ. Radiographic osteophytes seemed more important in predicting thumb base tenderness than MRI inflammation alone. Combined presence of radiographic osteophytes and MRI lesions had a small additive effect. These findings are in contrast to results from IP OA studies, supporting thumb base OA as a distinct hand OA subset. It might also explain why trials investigating intra-articular corticosteroids in thumb base OA have led to equivocal results.

---

**Cluster analysis showed that patients with severe functional impairment had also high rate of co-morbidities to baseline. The reduction of OA functional impairment is an important determinant of 5-year improvement of HSU while burden of co-morbidities was not associated with change in hip and knee OA HSU. This result highlights the importance of reducing functional impairment in clinical management of patients with hip and knee OA, and gives clues for interpretation of medico-economic analyses.

**CAN IMMUNOPHENOTYPING OF SYNOVIAL FLUID CELLS HELP DISTINGUISH BETWEEN PATIENTS WITH OSTEOARTHRITIS?**

**G. Osabova 1, G. Manukyan2, Z. Mikulkova 1, E. Kriegová 1, J. Gallo3, 1Department of Immunology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic; 2Group of Molecular and Cellular Immunology, Institute of Molecular Biology NAS RA, Yerevan, Armenia; 3Department of Orthopaedics, Palacky University, Teaching Hospital Olomouc, Olomouc, Czech Republic**

**Background:** Osteoarthritis (OA) is a leading cause of chronic pain and functional disability in elder people. It is not a homogeneous but diverse group of joint diseases. This could stay behind the therapeutic inconsistency observed in clinical practice caused probably by different diseases and/or different stages of a single disease. The comprehensive immunophenotyping of immune cells and their cell counts in synovial fluid (SF) might therefore advance our understanding of a particular type/stage of OA. This could have diagnostic value as well as provide novel insights into the pathophysiology of OA.

**Objectives:** To characterize immune cells present in SFs from OA patients in different stages of a disease.

**Methods:** We performed immunophenotyping of SFs from 63 patients with OA and 10 SFs from control patients (non-OA) without clinical/radiographic signs of OA using flow cytometry. We were able to characterize the following immune cells in the sampled SFs: T helper lymphocytes (CD3+/CD4+), T cytotoxic lymphocytes (CD3+/CD8+), NK cells (CD3-/CD16-/CD56+), B lymphocytes (CD19+), T regulatory (Treg) cells (CD4+/CD25+/CD127+), mast cells (CD203c+/CD117+), M1+ (CD14+/CD68+/HLA-DR+), and M2-polarized macrophages (CD14+/CD163+/CD206+), and neutrophils (CD15+). The second largest cell population was macrophages. Despite the dominant mixed-polarized (M1-M2) macrophage subpopulations in both the studied groups, SFs from the OA patients displayed a tendency towards greater M1 activity compared to the controls. A markedly increased percentage of neutrophils found in the OA group was associated with their activated state compared to the controls. No difference was found in percentages of B, Treg and mast cells. Despite the similar numbers of NK cells in both the groups, the activation-associated marker CD69 was up-regulated in NK cells from the OA patients. Representative dot-plots (FCS-SSC) of inter-individual variability of the main immune cell populations in synovial fluids from osteoarthritic patients is shown in Figure 1.

**Results:** A comparison between OA and control (non-OA) SFs revealed phenotypic alterations mainly in T cells, NK cells, macrophages, and neutrophils. T cells were the predominant population in the SFs, with CD4+ T lymphocytes being more prevalent than CD8+ T cells in OA (increased CD4/CD8 ratio). The second largest cell population was macrophages. Despite the dominant mixed-polarized (M1-M2) macrophage subpopulations in both the studied groups, SFs from the OA patients displayed a tendency towards greater M1 activity compared to the controls. A markedly increased percentage of neutrophils found in the OA group was associated with their activated state compared to the controls (increased CD11b). No difference was found in percentages of B, Treg and mast cells. Despite the similar numbers of NK cells in both the groups, the activation-associated marker CD69 was up-regulated in NK cells from the OA patients. Representative dot-plots (FCS-SSC) of inter-individual variability of the main immune cell populations in synovial fluids from osteoarthritic patients is shown in Figure 1.

**Figure 1.** Representative dot-plots (FCS-SSC) of inter-individual variability of the main immune cell populations in synovial fluids from osteoarthritic patients.

**Conclusions:** We were able to distinguish between the OA cases and controls...
in terms of their immune cells profiles (i.e. their numbers, activation status etc.). Additionally, we were able to follow specific immune cell patterns inside the OA group. Our study further emphasized the role of immune cells in the pathogenesis of OA. In particular, the results provide evidence suggesting ongoing activation of innate immunity as well as a shift towards T helper lymphocytes in fluids of the patients with OA. Our findings warrant a rational treatment point to be addressed by the future research for clinically useful biomarkers associated with the OA development and progression.

SAT0515 SONOGRAPHIC AND CLINICAL EXAMINATION OF TENDON INVOLVEMENT IN HAND OSTEOARTHRITIS

Background: Persistent tenosynovitis and degenerative tendinosis is associated with pain and can lead to dysfunction and tendon damage. While tenosynovitis is a common finding in rheumatoid arthritis, data on tendon involvement in hand osteoarthritis (HOA) is clearly limited. The clinical assessment of tendons is difficult and not fully standardized, but musculoskeletal ultrasound (MSUS) has been used successfully in inflammatory rheumatic disease as a sensitive method to detect tenosynovitis, tendon damage and osteophytes.

Objectives: To characterize tendon involvement in hand osteoarthritis and compare ultrasound with clinical assessment.

Methods: In this cross-sectional observational study 34 patients with HOA underwent MSUS and clinical examination on the same day. Each flexor and extensor tendon of the hand was scored independently for tenosynovitis and tendon damage (presence-absence) respectively by an expert in MSUS, blinded to the results of the clinical examination. Additionally, osteophytes in the proximal and distal interphalangeal joints of the fingers were assessed. Clinical assessment of tendons for tendon involvement included volar or dorsal pain, crepitus and swelling involving the hand, wrist or forearm during active movement of the tendon against resistance according to the Birmingham consensus criteria, by assessors who were blinded to the results of the MSUS. Conventional radiographs (CR) of the hands were also acquired and evaluated by the Interphalangeal Osteoarthritis Radiographic Simplified score.

Results: The majority of patients (30/34, 88.2%) were female, with a mean age of 69.5±8.5 years and a median of 10 (9–22.5) years disease duration. Clinical examination revealed tendon involvement in 21 (61.8%) patients with a median of 3 (1–11) tendons involved. A total of 20/33 (60.6%) patients exhibited sonographic signs of tendon involvement (tenosynovitis/tendon damage) with a median of 2 (1–12) involved tendons. Tendon damage was found more often on the right hand (p<0.05) while tenosynovitis did not significantly differ. Similarly, no significant difference between male and female patients was found. The extensor digitorum and the extensor carpi ulnaris tendons were the most commonly affected tendons under US. Tenosynovitis was found to be more prevalent among extensor tendons (p<0.001), while tendon damage was demonstrated at a higher frequency in flexor tendons (p<0.05) (Fig. 1). The agreement between MSUS and clinical examination was moderate on the patient level and poor on the level of individual tendons. Osteophytes were found in 96.8% patients using MSUS and in 100% of patients assessed using CR. Osteophytes detected on MSUS or CR showed good agreement (p=0.01, Cronbach’s Alpha=0.66).

Fig. 1 Distribution of tenosynovitis and tendon damage

Conclusions: The findings of our study reveal a high prevalence of tendon involvement in patients with hand OA. Sensitivity of MSUS in detecting tendon involvement coupled with the lack of agreement between clinical examination and MSUS on the level of individual tendons may suggest that while clinical examination is able to identify patients with overall tendon involvement, it does not allow the specific identification of involved tendons.

SAT0516 INFLUENCE OF ETHNICITY ON CLINICAL PAIN IN PATIENTS WITH OSTEOARTHRITIS VERSUS RHEUMATOID ARTHRITIS: CONTRIBUTION OF LEVEL OF EDUCATION AND DEPRESSION

I. Castrejon⁴, J. Chu⁴, J.A. Block⁴, L.A. Bradley⁵, Y. Yazici⁶, N. Shakoor⁴

1. Rheumatology, Rush University Medical Center, Chicago; 2. Clinical Immunology and Rheumatology, University of Alabama, Birmingham; 3. Rheumatology, NYU Hospital for Joint Diseases, New York, United States

Background: The experience of pain is characterized by inter-individual and group variability, with ethnicity being one potential contributing factor. In a systematic review, it was shown how African Americans (AA) demonstrated lower pain tolerance in experimental studies. Pain is the most common and troubling symptom in patients with osteoarthritis (OA) and in patients with rheumatoid arthritis (RA) – maybe reflecting synovitis- but other pain mechanisms are important.

Objectives: To investigate the influence of ethnicity on clinical pain and other outcomes and to identify potential predictors of higher scores for pain in AA and Hispanic patients with OA or RA seen in routine care.

Methods: As part of their clinic visit, all patients complete a multidimensional health assessment questionnaire (MDHAQ) at 2 academic sites. MDHAQ includes 0–10 visual analogue scales (VAS) for pain, physical function, and a patient global evaluation (PATGL), and a depression score between others. The MDHAQ also include demographic data and patients “self-identify” their ethnicity. One random visit with complete questionnaire data for each OA (ICD-9=714.0) and RA (ICD-9=714.10) patient from each site was included in this analysis. Comparison according to patients’ self-reported ethnicity -White, African-American (AA) or Hispanics- were performed using ANOVA and chi-squared. Multiple regression models were performed to identify independent explanatory variables for clinical pain in AA and Hispanics groups versus White.

Results: The study included 402 OA patients and RA 373. There were no differences in age and gender between ethnicity groups in both diagnostic groups. Years of education were highest in the White followed by AA and then Hispanics in both OA and RA. AA and Hispanics showed statistically significantly higher scores for pain (6.6 vs 5.3 in OA, p<0.001; 5.7 vs 4.4 in RA, p<0.001) and lower physical function (3.2 vs 1.9 in OA, P<0.001; 3.2 vs 1.9 in RA, P<0.001) in comparison with Whites in both diagnostic groups. A lower level of education and a higher level of depression predicted greater pain on a MDHAQ in OA in separate models for AA and Hispanic patients and in RA in Hispanic patients (Table).

Conclusions: AA and Hispanic patients had higher level of pain than Whites, but these differences are mainly influenced by level of education and level of depression in OA and RA patients. These results support the biopsychosocial-cultural model of pain in which, ethnic group differences may be determined by multiple mechanisms including socio-cultural as education, and psychological as depression, in addition to biological pathways.

Factors Related to Analgesic Use in Patients with Knee and/or Hip Osteoarthrosis Referred to an Outpatient Center: Results from the Amsterdam Osteoarthritis Cohort

J. Knop1, J. van Tunen2, M. van der Esch1, L.D. Roorda1, J. Dekkers3, M. van der Leeden1,2,3, W.F. Lem5,4,6,1  
1Amsterdam Rehabilitation Research Center, Reade, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands;  
2Department of Sports Science and Clinical Biomechanics, University of Southern Denmark, Odense, Denmark;  
3Department of Rehabilitation Medicine, VU University Medical Center;  
4Jan van Breemen Research Institute, Reade, Center for Rehabilitation and Rheumatology;  
5Department of Rheumatology, VU University Medical Center, Amsterdam, Netherlands

Background: Analgesics are recommended in current guidelines, but non-use or inadequate prescription have been reported in patients with knee and/or hip osteoarthrosis (OA). Furthermore, predictors of analgesic use have not yet been clarified.

Objectives: To (i) describe the use of analgesics; and (ii) determine factors that are related to analgesic use in patients with knee and/or hip OA referred to an outpatient center.

Methods: Data from 656 patients with knee and/or hip OA referred to an outpatient center (Amsterdam Osteoarthritis (AMS-OA) cohort) were used. Self-reported use of analgesic (yes/no) was administered and subdivided into acetaminophen, non-steroidal anti-inflammatory drugs (NSAIDs, including coxibs) and opioids. Logistic regressions were performed to analyze the association between analgesic use and disease-related, predisposing, and enabling factors.

Results: Analgesic use was reported by 62% of the patients, with acetaminophen, NSAIDs and opioid use reported by 50%, 30% and 12%, respectively. Factors related to analgesic use were higher pain scores, longer duration of symptoms, higher radiographic hip OA severity, overweight/obesity, and psychological distress. These factors explained 21% of the variance of analgesic use.

Conclusions: Less than two-thirds of patients with knee and/or hip OA referred to an outpatient center reported analgesic use, which seems to be indicative for under-use. Although multiple, mostly disease-related factors were associated with analgesic use, it remained predominantly unexplained. Our findings may indicate that prescription of analgesics should be guided more dominantly by clinical symptoms, rather than by a grading system. Multiple linear regressions were used to explore associations and OA. Hand grip strength was measured using a hand-held dynamometer, and this large, population-based cohort study, we took advantage of the availability of which may also show a one-way effect of reduced muscle strength on OA. In whether grip strength, as a measure of muscle activity, is related to knee OA, is related to specific radiographic features of hand OA, such as osteophytes, Republic Of

DOI: 10.1136/annrheumdis-2017-eular.2286

Association Between Grip Strength and Hand and Knee Radiographic Osteoarthrisis in Older Adults: Data from the Dong-gu Study

J.-E. Kim1, J.-H. Kang, K.-E. Lee, D.-J. Park, S.-S. Lee1,1  
1Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic Of

Objectives: Although some studies have shown a negative relationship between grip strength and hand osteoarthrosis (OA), little is known about how grip strength is related to specific radiographic features of hand OA, such as osteophytes, joint space narrowing, and erosion. In addition, no reported study has examined whether grip strength, as a measure of muscle activity, is related to knee OA, which may also show a one-way effect of reduced muscle strength on OA. In this large, population-based cohort study, we took advantage of the availability of subjects without hand pain to evaluate the effect of grip strength on OA using a novel, semi-quantitative grading system. We also examined whether grip strength was related to detailed radiographic features of OA.

Methods: Data from 2,251 subjects enrolled in the Dong-gu study, who had no hand and joint pain, were analyzed to investigate the relationship between grip strength and OA. Hand grip strength was measured using a hand-held dynamometer, and radiographs of the hand and knee were scored according to a semi-quantitative grading system. Multiple linear regressions were used to explore associations between grip strength and radiographic features of OA.

Results: Grip strength in men and women was negatively related to hand (both p<0.01) and knee (men, p<0.001; women, p=0.010) OA after adjusting for confounders. Hand (men, p<0.001; women, p=0.001) and knee (both p<0.001) joint space narrowing showed the strongest associations with low grip strength, regardless of sex. Moreover, the severity of joint space osteophytes in women (p<0.001), knee osteophytes in men (p=0.006), hand malalignment (men, p=0.008; women, p=0.041), and subchondral cysts (men, p=0.001; women, p=0.007) was correlated with low grip strength in both sexes.

Conclusions: Among subjects without hand joint pain, low grip strength was associated significantly with hand and knee radiographic OA, regardless of sex. Among all types of OA radiographic damage, low grip strength showed the strongest association with joint space narrowing.

The Value of High-Sensitivity C-Reactive Protein in Hand and Knee Radiographic Osteoarthrisis: Data from the Dong-gu Study

J.-E. Kim1, J.-H. Kang, K.-E. Lee, D.-J. Park, S.-S. Lee1,1  
1Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic Of

Objectives: Due to the inconsistent association between high-sensitivity C-reactive protein (hs-CRP) and osteoarthrisis (OA), we evaluated the relationship between hs-CRP and various radiographic findings in older adults with OA.

Methods: This cross-sectional study recruited 2,400 participants from the population-based Dong-gu cohort. The scores of radiographic features in OA on X-rays of the knees and hands were computed using a semi-quantitative grading system. The hs-CRP levels were measured using a particle-enhanced immunonephelometry assay. Correlations showing the relationship between hs-CRP and radiographic OA were calculated using multiple linear correlation analysis.

Results: The hs-CRP levels were significantly higher in older subjects (p<0.001), with those higher body mass index (BMI) (p<0.001), current smokers (p<0.001), current alcohol drinkers (p=0.012), those who were less physically active (p<0.002), and those with a lower level of education (p<0.036). After adjusting for BMI and other confounders, the total OA scores (knee, p=0.048; hand, p=0.010), erosion scores (knee, p=0.035; hand, p=0.031), and sclerosis (knee, p=0.021; hand, p=0.029) in the knees and hands were all significantly positively correlated with hs-CRP. A significant association was also observed between hs-CRP and the hand malalignment score (p<0.012).

Conclusions: In this large, population-based radiographic study, the hs-CRP level was a significant predictor of radiographic OA. Of the various types of OA radiographic damage, erosion, sclerosis, and malalignment showed significant associations with hs-CRP.

Marked Reduction of Osteoarthrisis Pain with a Hydrogen Sulphide-Releasing Naproxen Derivative

J.L. Wallace1, D. Vaughan2  
1University of Calgary, Calgary, Canada; 2Antibe Therapeutics Inc, Toronto, Canada

Background: Nonsteroidal anti-inflammatory drugs (NSAIDs) remain a mainstay of therapy for osteoarthrosis, but their use is limited by their propensity to cause significant gastrointestinal (GI) bleeding and ulceration. Hydrogen sulfide (H2S) is an endogenous signaling molecule that has been shown to exert protective and pro-healing effects in the GI tract. We developed a series of H2S-releasing NSAIDs, and have now tested the lead drug (ATB-346) in a phase 2a clinical trial in patients with osteoarthritis. ATB-346 is a derivative of naproxen, the most cardiovascular-safe of the NSAID family. Data from a phase 1 clinical trial suggested that ATB-346 was significantly more potent and long-lasting than naproxen in terms of suppressing cyclooxygenase (COX) activity.

Objectives: An open-label phase 2a trial was performed to determine if a low dose of ATB-346 (250 mg; equivolmar to 160 mg naproxen), given once daily, would provide significant pain relief in patients with osteoarthritis. To be admitted to the trial, patients had to exhibit a ≥10 point increase in the WOMAC Visual Analogue Score between the worst score of their current trial and the baseline study entry visit.

Methods: 12 patients with osteoarthritis of the knee who met the inclusion criteria were recruited for the trial (diagnosis of OA ≥2 years; age 40–75; BMI ≤40). The WOMAC subscale pain score (0–20) was the primary endpoint. The patients were off anti-inflammatory medication for 5 days prior to starting this study. After recording the initial WOMAC subscale pain score, they began once daily oral treatment with ATB-346 (250 mg). Pain scores were recorded on the day prior to starting ATB-346 treatment (day `-1`) and on days 4 and 10 of treatment. Blood samples were collected for measurement of COX activity on days `-1`, 4, and 10. Results: ATB-346 was safe and well tolerated. The mean WOMAC subscale pain score the day prior to initiation of treatment was 14.0 ± 0.7. A significant decrease in the WOMAC subscale pain score was observed on day 4 (−4.3±1.0; p<0.01), with an even greater decrease on day 7 (−7.6±1.5; p<0.001). Whole blood COX activity was suppressed by 89% (p<0.01) on the first day of treatment, and continued to be suppressed throughout the study.

Conclusions: The results of this study demonstrate that a low dose of ATB-346, given only once daily, produces a clinically and statistically significant reduction in pain in patients with osteoarthritis, that may exceed what can be achieved with standard doses of naproxen or celecoxib (1,2). The observed suppression and regression of COX activity was consistent with the pain reduction data, supporting the conclusion that ATB-346 is considerably more potent and long-acting than naproxen. Extensive pre-clinical studies have demonstrated that ATB-346 has greatly improved GI profile as compared to naproxen and other commonly used NSAIDs.

SAT0521 INCREASING PHYSICAL ACTIVITY IN OLDER PEOPLE WITH PAIN. PRELIMINARY RESULTS OF THE IPOPPI PILOT TRIAL

J. McBeth1,2, E. Nichols3, E. Healey4, N.E. Foster2,1, E.M. Hay7, T. Pincus4, S. Dent2, C.A. Chew-Graham2, L. Hartshorne3, C. Jinks2 on behalf of the IPOPPI team. 1Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester; 2Research Institute for Primary Care and Health Sciences; 3Keele Clinical Trials Unit, Keele University, Keele; 4Department of Psychology, University of London, London, United Kingdom

Background: Chronic (>3 months) pain is associated with physical inactivity in older adults and walking is an accessible form of physical activity with health benefits. We have developed Increasing Physical Activity in Older People with Pain (iPOPPI), a brief intervention to increase walking.

Objectives: To assess the acceptability and credibility of iPOPPI, and to test the feasibility of key processes, in a pilot randomised, controlled trial.

Methods: Eligible respondents to a screening questionnaire (>65 years; consulted their general practitioner for chronic pain; Chronic Pain Grade score ≥2) collected 7-day accelerometer data before randomisation and at the end of follow-up. Participants were randomised to one of Usual primary care; Pedometer, walking diary, pain toolkit (written pain management information); or iPOPPI comprising week 1 face-to-face Health Care Assistant (HCA) consultation to develop a walking action plan, pedometer, walking diary, pain toolkit (written pain management information); or iPOPPI comprising week 1 face-to-face Health Care Assistant (HCA) consultation to develop a walking action plan, pedometer, walking diary, pain toolkit, discussion of walking behaviour and barriers, goal setting; week 2 follow up face-to-face or telephone (participant preferred) HCA consultation to review progress and goals, relapse prevention strategies; 3–10 weekly motivational prompts (participantpreferred postcard, email or text). A follow-up questionnaire was sent 12 weeks post-randomisation.

Success criteria were: 7% of those screened would be eligible, return an accelerometer and be randomised; follow-up rates ≥75% of those randomised; ≥50% of those in iPOPPI would complete week 1 and 2 intervention sessions; and a median score of ≥5/10 across a four-item acceptability and credibility questionnaire.

Results: Of 2326 people mailed, 1256 (54%) responded and 695 (30%) were eligible. After mailing study information to 425 eligible participants, 161 (38%) agreed to participate, 159 (12% of those mailed) returned an accelerometer and were randomised, 7 withdrew, and 136 (86%) returned a follow-up questionnaire. Of those randomised to iPOPPI 82% completed week 1 and 2 intervention sessions; 32% had a face-to-face week 2 follow-up; 48% preferred postcard motivational prompts, 10% email, 22% text, and 20% had no preference. Median (IQR) acceptability and credibility scores were: “how logical is treatment?” 5 (3, 9.8), “confidence in treatment success” 5.5 (3, 8), “would recommend treatment to friend” 5 (3.3, 9), and “treatment would be successful for another pain problem” 5 (3.7, 8). 152 participants were mailed a follow-up accelerometer and 144 (95%) were returned. 147 (91%) baseline and 117 (81%) follow-up accelerometers had usable data.

Conclusions: This data demonstrate the acceptability and credibility of the iPOPPI intervention, and the feasibility of proposed trial processes. The effectiveness of iPOPPI compared with usual care will be tested in a future main trial.

SAT0522 SEARCHING FOR THE OPTIMAL TIMING FOR PREVENTIVE WEIGHT REDUCTION STRATEGIES FOR KNEE OSTEOARTHRITIS DEVELOPMENT

J. Runhaar1, M. Landsmeer1, M. van Middelkoop1, S.M. Bierma-Zeinstra2.

1General Practice; 2General Practice and Orthopaedics, Erasmus University Medical Center Rotterdam, Rotterdam, Netherlands

Background: We previously showed that middle-aged women free of clinical knee osteoarthritis (OA), but at high-risk for future OA development due to a BMI ≥25 kg/m2). MRI scans of both knees was made on a 1.5 Tesla scanner. All MRIs were scored using the semi-quantitative MRI effect of glucosamine over the control intervention in the different subgroups was estimated using multiple imputation methods, within each original study. Subgroup factors were dichotomized, based on consensus of the OA Trial Bank Steering Committee. A systematic search for published randomized controlled trials on the effectiveness of oral glucosamine in clinical relevant subgroups of hip and knee OA patients based on pain severity, BMI, sex, structural abnormalities and inflammation, using individual patient data from published trials.

Methods: A search was performed to include all published randomized controlled trials on the effectiveness of oral glucosamine in clinical relevant subgroups of hip and knee OA patients based on pain severity, BMI, sex, structural abnormalities and inflammation, using individual patient data from published trials.

Results: A total of 9555 trials were identified, of which 257 were randomized controlled trials on the effectiveness of oral glucosamine in clinical relevant subgroups of hip and knee OA patients. Of these, 95 were included in the meta-analysis. Of these trials, 44 were included in the meta-analysis of patients with knee OA. The effect of glucosamine over the control intervention in the different subgroups was estimated using multiple imputation methods, within each original study. Subgroup factors were dichotomized, based on consensus of the OA Trial Bank Steering Committee. Additional, trial registries were searched for ongoing studies. All authors and institutions of all eligible studies were contacted and asked to share the trial data. All shared trials were assessed for their risk of bias, using the criteria recommended by the Cochrane. Missing data for covariates and outcome measures were imputed, using multiple imputation methods, within each original study. Subgroup factors were dichotomized, based on consensus of the OA Trial Bank Steering Committee. A multilevel regression analysis was performed to evaluate the magnitude of the effect of glucosamine over the control intervention in the different subgroups with the individuals nested within each study. Pain at short-term (3 months)
Estimates pooled differences between glucosamine and placebo on a 0-100 scale and p-values for treatment-subgroup interactions.

## Results

### Conclusions

The majority of industry-led glucosamine studies for osteoarthritis did not wish to share data, challenging optimal use of available data. There is currently no evidence for the use of glucosamine for the treatment of hip or knee osteoarthritis and an absence of support for clinically relevant subgroups of OA patients according to baseline pain severity, BMI, sex, and structural abnormalities.

## SAT0525 | THE EFFICACY OF PELOID THERAPY IN MANAGEMENT OF HAND OSTEOARTHRITIS

M. Aksy Y Kasapoğlu1, L. Altan2, R. Erdıkız3, B. Ökmen Metin1, 1Physical Medicine and Rehabilitation, University of Health Sciences Bursa Yüksek İhtisas Training and Research Hospital; 2Physical Medicine and Rehabilitation, Uludağ University Medical Faculty; 3Ecology and Hydroclimatology, University of Health Sciences Bursa Yüksek İhtisas Training and Research Hospital, Bursa, Turkey

**Background:** Hand osteoarthritis (OA) is associated with pain, reduced grip strength, loss of range of motion (ROM), and joint stiffness, leading to impaired hand function and difficulty in performing daily living activities. Various randomized controlled clinical trials were conducted to assess the efficacy and tolerability of mud-pack therapy in patients with knee OA. Data from these trials support the beneficial effect of mud-pack therapy on pain, function, and quality of life in knee OA. However, to the best of our knowledge, in spite of its significant impact on the activities of daily life, there is a lack of adequate randomized controlled studies on peloid therapy in management of osteoarthritis of the hand.

**Objectives:** To investigate the effects of peloid therapy in the patients with hand OA on pain, functional state, grip strength, and the quality of life.

**Methods:** 53 patients aged 35–75 and 78 years, who had been diagnosed with hand OA were included in the study. Patients were randomized into 2 groups with a random number table. Patients in Group 1 (n=33) underwent peloid therapy over 2 weeks, 5 sessions a week, for a total of 10 sessions and home exercise program. Patients in Group 2 (control, n=30) received only the same home exercise program as in Group 1. Patients were evaluated just before, and 2 and 6 weeks after the start of the study with Visual Analogue Scale (VAS), Australian/Canadian Osteoarthritis Hand Index (AUSCAN) Health Assessment Questionnaire (HAQ), Hand Grip Strength (HGS), Pinch strength (PS).

**Results:** Statistically significant improvements were observed in all parameters assessed at week 2 and week 6 in the Group 1 (p<0.05). Statistically significant differences were observed in HGS scores in the Group 2 at week 2, and in AUSCAN scores at week 6 (p<0.05). Intergroup comparisons of the scores revealed significant differences between the peloid therapy group and control group in VAS, HAQ, AUSCAN, HGS and PS scores at week 2 and week 6 (p<0.05).

**Conclusions:** This study demonstrates that peloid therapy is an effective and confident treatment modality in the management of symptomatic osteoarthritis of the hand and provides effective pain control and improvements in the hand functions, quality of life and grip strength.

**SAT0524 | UTILITY OF TOCILIZUMAB IN CLINICAL MANIFESTATIONS OF EROSIIVE OSTEOARTHRITIS OF HANDS REGIONAL HOSPITAL ISSSTE PUEBLA, MEXICO**

J.M. Sánchez Huerta1, J. Gálvez-Romero2, W. López-Rodriguez3, A. López3, 1Rheumatology; 2ISSSTE, Puebla, Puebla; 3UDLAP Cholula, Puebla, Mexico

**Background:** Erosive osteoarthritis (EOA) is a form of severe involvement of osteoarthritis in the hands, characterized by inflammation of the synovium of the proximal interphalangeal joints and distal joints (DIP); the last ones are the most affected in a symmetrical manner. Inhibition of interleukin 6 (IL-6) in joints with osteoarthritis helps to improve the production of the cartilaginous matrix and microstructures of articular cartilage.

**Objectives:** To know if the application of TCZ is useful for the control of the clinical manifestations of EOA of the hands.

**Methods:** Twenty-four patients with EOA were studied, 18 females and 6 males with ages ranging from 42 to 72 years, with an evolution time of 4 to 30 years. The application of TCZ was intravenous (8 mg/kg of body weight per month). Articular pain in the PIF and distal joints was evaluated by the visual analogue scale (VAS) (0 to 10) and joint pain (0 to 60), morning stiffness (0 to 10), and functional limitation (0–90) by the AUSCAN index.

**Results:** The VAS showed improvement of 30% (0% to 100%). The AUSCAN index showed improved pain (16.2%), morning stiffness (0.6%) and functional limitation (17.5%). Decreased ESR, CRP, and IL-6 levels less than 1.56 to 59.1 pg/ml.

**Conclusions:** IV Tocilizumab is useful for the control of the clinical manifestations of EOA of the hands. More precise studies are needed to evaluate the improvement of the cartilaginous matrix in EOA by TCZ.

**SAT0526 | POSSIBILITY OF CARTILAGE REPAIR WITH PLATELET AUTOLOGOUS PLASMA (PAP)**

L.V. Khimion1, O.A. Burianov2, L.O. Smolina1, H. Havryliuk1, T. Omelchenko3, 1Department of Family Medicine, Shupyk National Medical Academy of Postgraduate Education; 2Traumatology and Orthopedic Department; 3Traumatology and Orthopedic Department, Bogomolets National Medical University, Kyiv, Ukraine

**Background:** The investigations of the platelet-derived biologic agents in osteoarthritis treatment had shown promising but often controversial results.

**Objectives:** To study the efficacy (in clinic & experiment) & safety (in clinic) of the platelet autologous plasma (PAP) in cartilage repair and treatment of early knee OA.

**Methods:** The study was conducted at the Department of Family Medicine and Traumatology and Orthopedic Department and consisted of 2 parts: experimental (20 rabbits with the traumatic damage of the knee cartilages) and clinical (included 146 patients with diagnosed knee OA (radiological stage I-II). Rabbits...
were randomly divided in 4 groups: in 1st and 2nd grs. 10 animals received 3 intra-articular injections of PAP (on 5th, 7th, 14th day after knee trauma) as a control (gr.3) and 4 rabbits received 3 intra-articular injections of 0.9% NaCl at the same days after trauma; histopathology was performed at 45th (1st and 3rd gr.) & at 90th day (2nd and 4th gr.) after trauma. 146 patients - 58 men (39.7%) & 88 women (60.3%), were divided into 2 grs. Gr.1 included 68 patients who consented to receive standard OA treatment and 3 weekly intra-articular injections of PAP (total 2 courses in 12 months) (plasma volume 12–15ml/course, total platelets number per injection 1260±24±22.1±10⁹); Gr.2 consisted of 78 patients with the same diagnosis who received only standard OA treatment (non-steroidal anti-inflammatory drugs, physiotherapy, exercises). Both groups were of comparable age, gender and initial WOMAC data (Gr.1 40.9±0.7 Gr.2 39.7±0.9, p<0.05). WOMAC scale parameters were analyzed before treatment and after 3 weeks; 6 & 12 months after course of treatment in both groups. Results: In all patients who received PAP, significant improvement of joint pain, inflammation and better structure of the knee cartilage after PAP injections comparing with the control group was found (comparing to 4th gr.). Clinical study demonstrated better changes in pain, stiffness and function in 3 weeks after treatment in patients of Gr.1 comparing to Gr.2 (WOMAC had decreased by 35.8% in Gr.2 and by 74.1% in Gr.1), p<0.05. After 6 months of follow-up (before 2 course of PAP treatment), the mean number of OA exacerbations was (0,7±0,02) Gr.1 & (1,6±0,04) Gr.2 (p<0.05) and general WOMAC index in Gr.1 was significantly lower than in Gr.2 (accordingly (22,8±0.3) and (36,5±0,8); p<0.05). In the next 6 months again patients in Gr.1 had less exacerbations (0,51±0,03) then patients in Gr.2 (1,4±0,03),p<0.05; & better WOMAC performance (Gr.1-(17,5±0.8) Gr.2–37,1±0.5 accordingly)p<0.05). Conclusions: 1. Histopathology of the knee cartilage has shown promising results concerning possibility of cartilage repair after trauma and prophylaxis of the early posttraumatic OA after PAP injections in animal model. 2. Repeating intra-articular injections of PAP, added to the standard care in knee OA improves functional activity, reduces pain and number of OA exacerbations in 12 months of follow up. 3. The further studies (both experimental and clinical) are needed to obtain more accurate information and determine the most effective methods of PAP use in OA patients.

SAT0527 ASSESSMENT OF SHORT-TERM EFFECTIVENESS OF FIVE LOCAL TREATMENT MODALITIES IN PATIENTS WITH SYMPTOMATIC KNEE OSTEOARTHRITIS

Background: Inside the therapeutic algorithm of knee osteoarthritis (OA) it is included the Non-Arthroscopic Joint Lavage (NAJL) since around 1934 Burman reported that arthroscopies improved the symptoms. Current medical treatment strategies are aimed at pain reduction and symptom control rather than disease modification (1). The large variety of potentially interventions available has raised the need to assess their effectiveness.

Objectives: To compare the short-term effectiveness among five treatment strategies in patients with symptomatic knee OA.

Methods: An open, controlled, randomized prospective study involving 150 patients of whom 76.7% were females. The average age was 65.3±7.35. Patients had knee OA according to American College of Rheumatology criteria, with Kellgren-Lawrence radiographic grades II-III. They were randomly assigned to five groups of treatment, 1)NAJL (n=30), 2)NAJL+hyaluronic acid (HA) (n=32), 3)NAJL + corticosteroid (CS) (n=32), 4)HA (n=31), and 5)CS (n=25). Evaluations took place at baseline, one and three months. Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Lequesne scores were recorded. Statistical analysis included mixed analysis of variance, with post-hoc comparisons with Sidak’s adjustment, and multiple linear regression (MLR) to identify those possible factors associated to WOMAC total at 3 months.

Results: Regarding WOMAC pain, significative differences were found in NAJL at one month and at 3 months; in NAJL+CS at one month, and at 3 months; in NAJL+HA at one month and 3 months; and in NAJL-CS at one month and 3 months. For WOMAC function, significative differences were found in NAJL at one month and at three months; in NAJL-C at one month; and in HA at 3 months. Regarding WOMAC total, significative differences were found in NAJL at one month (p<0.001) and at 3 months (p<0.001); and in NAJL+CS at one month (p<0.018). For Lequesne, significative differences were found in HA at one month (p<0.003) and at 3 months (p<0.019) versus baseline; and in CS, at one month (p<0.001). The WOMAC function at baseline, NAJL+HA, and infiltration with CS are the variables that show a significant association with WOMAC total at 3 months. The group that received NAJL+HA had poorer outcomes.

Conclusions: One month after treatment, best outcomes were obtained with HA due to the results found in Lequesne scale when comparing HA versus NAJL+HA, and NAJL-CS. Three months after the treatment, the most effective modality treatment was NAJL; since we did find significant differences regarding articular stiffness, physical function and Lequesne scale. The treatment with NAJL+HA appears to be less effective than the other modalities.

SAT0528 MOLECULAR MODIFICATIONS INDUCED BY MUD-BATH THERAPY IN PATIENTS WITH OSTEOARTHRITIS

M. M. Angioni1, A. Denotti2, S. Pinna1, C. Sanna2, A. Fioris1, M. Piga1, A. Loi2, A. Cau1,1 Scienze Mediche e Sanità Pubblica, Università degli Studi di Cagliari, Monserato (CAGLIARI); 2Antiche Terme di Sardara, Sardara (VS), Italy

Background: Mud-bath therapy (MBT) is a non-pharmacological approach commonly used to treat osteoarthritis (OA). Several data indicate that MBT improve patient’s symptoms (1), exerting a beneficial effect on pain and joint function, although the biological mechanisms involved in the therapeutic response are poorly defined.

Objectives: This study aimed to find molecular changes (proteins and mRNA variations) in patients with OA after MBT treatment.

Methods: The study included 39 patients whit primary diffuse osteoarthritis, assigned to receive a cycle of mud-bath therapy over a period of 2 weeks added to usual pharmacologic treatment. Whole blood and serum were collected before and after standard MBT treatment: for each time points two pools of patients sera were analyzed by the direct antigen-labeling technology (RayBio® Biotin Label-based Antibody Array, RayBiotech) obtaining a broad, panoptic view of protein expression. Using this semi-quantitative technique up to 1000 target proteins was simultaneously detected, making this approach ideally suited for proteomic studies. Again, pooled samples of mRNA were used to investigate genes expression and to perform the transcriptomic analysis using an high-resolution array design that contains >6.0 million distinct probes, covering coding and non-coding transcripts (GeneChip® HTA 2.0, Affymetrix).

SAT0529 PROLONGED TNF-INHIBITOR TREATMENT DURATION IS ASSOCIATED WITH LOWER RISK OF HAND OSTEOARTHRITIS PROGRESSION IN PATIENTS WITH RECENT-ONSET RHEUMATOID ARTHRITIS AFTER 10-YEAR FOLLOW-UP

M. Looi 1, F. Kroon 1, S. A. Bergstra 1, J. A. van der Pol 1, W. F. Lems 1, P. J. Kerstens 2, C. F. Allaart 1, M. Kloppenburg 1,4.

1. Department of Rheumatology, VU University Medical Center, Amsterdam; 2. Department of Rheumatology, Westfriesgasthuis, Hoorn; 3. Department of Epidemiology, Leiden University Medical Center, Leiden; 4. Department of Epidemiology, Leiden University Medical Center, Leiden.

BACKGROUND: Increasing evidence indicates involvement of the pro-inflammatory cytokine TNF-α in hand osteoarthritis (OA) pathogenesis. Ten years clinical and radiographic follow-up of the BeSt study, a randomized trial primarily designed to investigate targeted treatment in rheumatoid arthritis (RA) patients, offered the unique opportunity to study the long-term effects of TNF inhibitors (TNFi) on the development and progression of hand OA. The distal interphalangeal joints (IPs) are rarely affected in RA, which allowed to evaluate primary OA separately.

OBJECTIVES: To investigate the effect of TNFi on incidental and progressive radiographic hand OA after 10-year follow-up in recent-onset RA patients.

METHODS: At baseline and 10-year follow-up 262 patients (mean age 52 years, 66% women) were available for radiologic assessment of hand OA. Eighteen interphalangeal joints (IPs) were scored for osteophytes (OP) using the Osteoarthritis Research Society International (OARSI) atlas (0–3; summated score 0–72). Incidental OA was defined as an increase in summated OP score or ≥1 in summated KL score in presence of OA at baseline, and progressive OA as an increase ≥3 in summated OP or KL score in presence of OA at baseline, based on the smallest detectable change. TNFi treatment and disease activity score (DAS) were assessed on standardized visits at a three-monthly interval. Associations between duration of TNFi treatment in months and incidental and progressive OA were analyzed using generalized linear models with Poisson distribution and robust standard errors, while adjusting for age, gender, time averaged DAS, time averaged Sharp-van der Heijde score and hand OA severity at baseline.

RESULTS: Based on the OP score, 126 patients (48%) were classified with OA at baseline in the DPs and 82 patients (31%) in the proximal IPs (PIPs). Incidental OA developed in 33% of patients in DPs and in 42% in PIPs. Progressive OA occurred in 30% of patients in DPs and in 38% in PIPs. Of patients with and without OA at baseline, irrespective of joint location, 63% and 55% were treated with TNFi, with a median treatment duration of 47 and 36 months, respectively. No effect of TNFi treatment duration was seen on incidental hand OA. On progressive hand OA, every month of TNFi treatment resulted in a reduced relative risk (RR) of OA progression in DPs with a RR (95% confidence interval) of 0.987 (0.978–0.996), but not in the PIPs. The results from the analyses with the KL scoring method were comparable to the OP score, as shown in table 1.

CONCLUSIONS: Prolonged TNFi treatment is associated with a reduced relative risk on radiologic hand OA progression in DPs, but not in PIPs, after 10 years. Although the effect sizes are small, these results provide evidence for influence of TNFi in hand OA pathogenesis.

SAT0530 CENTRAL SENSITISATION IN HAND OSTEOARTHRITIS: THE ANTERIOR CINGULATE CORTEX IS INVOLVED IN PAIN PROCESSING

M. Russell 1, F. Howe 1, T. Barrick 2, N. Sofat 1.

1. Institute of Infection & Immunology; 2. St George’s, University of London, London, United Kingdom

BACKGROUND: We have previously shown that people suffering with chronic pain in hand OA have activation of central brain pain processing centres localised to the anterior cingulate cortex, insular cortex and thalamus by functional neuroimaging (1) and algometry (2).

OBJECTIVES: We hypothesised that hand OA subjects will have structural differences in 3 pain-processing regions of the brain - the anterior cingulate cortex (ACC), insular cortex and thalamus - based on activation of brain centres we have found previously (1). Our brain neuroimaging work was part of a randomised, placebo-controlled trial to assess the effect on clinical pain outcomes by intervention with centrally-acting analgesic agents: pregabalin or duloxetine.

METHODS: The primary outcome measures for our clinical trial were hand pain numerical rating scale (NRS) and AUSCAN pain after 12 weeks’ treatment. In secondary outcome analyses, participants with hand OA (n=28) underwent T1-weighted MRI of the brain before and after 12 weeks of treatment with pregabalin, duloxetine or placebo therapy. Grey matter brain structure was compared using FreeSurfer regional volumetric analysis and voxel-based morphometry (VBM) to age-matched controls (n=11), and evaluated for volume changes in the ACC, insular cortex and thalamus.

RESULTS: In our clinical trial, we observed clinically significant improvement in pregabalin, duloxetine and placebo treatment groups after 12 weeks (ANOVA p=0.0078). Most notably, pairwise comparisons for pregabalin vs placebo showed significant improvement for NRS pain and AUSCAN pain outcomes in the ITT analysis (p<0.05), but not for duloxetine vs placebo after 12 weeks’ (p>0.05). Both voxel-wise and regional volumetric analyses demonstrated areas of reduced grey matter volume in the ACC of hand OA subjects, relative to control subjects, but not for duloxetine (p<0.05) Figure 1. The structural differences in the ACC persisted following 12 weeks of treatment with pregabalin, duloxetine or placebo therapy (p<0.05). We did not observe structural differences in the insular cortex or thalamus in any of the three groups.

Conclusions: We found that the ACC volume was reduced in participants with hand OA. The ACC is a key pain-processing region of the brain. Changes in ACC grey matter volume have previously been described in other painful conditions, but not hand OA. ACC grey matter volume reduction is thought to represent neural plasticity in chronic pain states. Our data supports the role of central sensitisation in hand OA and provides a rationale for the further investigation of centrally-acting analgesics in its management. Our trial demonstrated improvement in clinical endpoints for pain for pregabalin vs placebo and duloxetine vs placebo, respectively (p<0.05). However, structural differences in the ACC were still evident following 12 weeks of treatment with pregabalin or duloxetine. This may relate to the relatively short duration of treatment in our study. Alternatively, the baseline differences in the ACC may represent irreversible changes. Longitudinal studies with greater follow-up periods are necessary to further investigate this.

MATRIX ASSISTED LASER DESORPTION IONIZATION IMAGING MASS SPECTROMETRY APPLIED TO HUMAN OSTEOARTHRITIS CARTILAGE REVEALS THE INTRA-TISSUE METABOLIC HETEROGENEITY

M. Evève-Mouroux, P. Ransimans, R. Vautrot, O. Manhès, I. Gourmelon, A. Boonen, R. Heeren, B. Cillère-Pastor. 1Division of Imaging Mass Spectrometry, Maastricht Multimodal Molecular Imaging (M4I) Institute. 2Department of Orthopaedic Surgery. 3Caphri Research institute, Maastricht University Medical Center, Maastricht, Netherlands.

Background: Osteoarthritis (OA) is one of the most common diseases, caused by a chronic degenerative disorder of the joint. OA can be related to the metabolic syndrome or metabolic abnormalities being recently defined as a subtype of the disease. Matrix-assisted laser desorption/ionization (MALDI) imaging mass spectrometry (IMS) technology allows for the investigation of the bimolecular distribution of proteins, lipids or metabolites through the in situ analysis of tissue sections. In order to better understand the metabolic OA phenotype, the study of the endogenous metabolic profiles using MALDI-IMS should be considered.

Objectives: The main goal of this study is to apply MALDI-IMS methodology to study the metabolic spatial distribution of cartilage and to reveal intra-tissue and inter-patient heterogeneity.

Methods: Human OA cartilage was obtained from donors undergoing total knee joint replacement. Samples were heat stabilized by a stabilizer system, before being snap frozen. Cartilage punches were sectioned at 12 μm thickness in a cryostat and deposited on indium tin oxide (ITO) glass slides. 9-Aminoacridine (9AA) and N-(1-Naphthyl) Ethylenediamine DihydroChloride (NEDC) matrices were sprayed on the tissues. MALDI-MS profiling and imaging experiments were performed using different mass spectrometers. Data were analyzed by different software dedicated to mass spectrometry.

Results: Results showed that 9AA and NEDC matrices were both able to extract several and different compounds. MALDI-MS/MS profiling and imaging experiments were performed using different mass spectrometers. Data were analyzed by different software dedicated to mass spectrometry.

Conclusions: MALDI-IMS methodology is a useful technique for metabolic profiling of cartilage and could be employed to study OA patient heterogeneity. This fact will be especially relevant for OA patients suffering of metabolic syndrome.

SAT0532

SLEEP QUALITY IN PATIENTS WITH KNEE OSTEOARTHRITIS

M. Sezgin, Y. Eşyalısalı, S. Sevim, H. Ankaraş, G. Sahin. 1Department of Physical Medicine and Rehabilitation; 2Department of Neurology, University Medical Faculty, Mersin; 3Department of Biostatistics and Medical Informatics, Duzce University Medical Faculty, Düzce, Turkey.

Objectives: The aim of this study was to investigate sleep quality in patients with knee osteoarthritis (OA).

Methods: One hundred patients with knee OA and age and gender-matched 75 healthy controls were enrolled into the study. Demographic characteristics of the participants were recorded. All patients were examined by a single physician. The findings were recorded. Knee radiographs of the patients were staged according to the Kellgren-Lawrence grading. In addition, to evaluate the clinical status and quality of life of patients, the MOS Sleep Scale and computerized sleep staging system (DreamLab) were used. The Knee Osteoarthritis Outcome Score (KOOS) was also used. The study was approved by the ethical committee of the hospital.

Results: All scores of MOS sleep scale were significantly lower in patients with knee OA than controls (p<0.001). When MOS outcomes of the patients compared with the controls, sleep quality during sleep period (WSTS) (37.2±35.9, 13.1±19.4 p=0.012 respectively) and number of awakeness (NOAW) (9.2±18.2, 6.2±3.5, p=0.05 respectively) were significantly higher. Sleep efficiency (SE) (84.2±21.1, 96.7±6.4 p=0.009 respectively) was significantly lower in patients with knee OA. There were positive correlations between MOS sleep scale and PSG (sleep latency, sleep onset, sleep efficiency). Regression analysis (Multiple and REM latencies) outcomes of the patients were significantly lower in patients with knee OA. There were significant differences of the patients and controls in the MOS sleep scale scores of patients were negatively related with both NHP (pain, emotional reaction, sleep and social isolation subgroup scores) and WOMAC (total and functional disability subgroup scores) whereas in the REM latency subgroup scores.

Conclusions: The sleep quality of patients with knee OA was worse compared to healthy controls. The poor sleep and sleep quality in knee OA had adversely affected the clinical status and quality of life.

SAT0533

ASSOCIATION OF OSTEOARTHRITIS AND PERIODONTITIS BASED ON THE KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY

M.K. Chung, N. Koo, B.W. Lee, J. Lee, S.-K. Kwok, S.-H. Park, J.H. Ju. Division of Rheumatology, Department of Internal medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of

Background: Osteoarthritis (OA) is a chronic joint disease with complex etiologies characterized by synovial inflammation, subchondral bone remodeling, and the formation of osteophytes, which leads to cartilage deterioration. Periodontitis (PD) is also a chronic inflammatory disease characterized by loss of periodontal ligament and alveolar bone. Recently, the association between OA and metabolic diseases has been proposed, and the association between several systemic diseases such as rheumatoid arthritis, metabolic syndrome and periodontitis has been unveiled.

Objectives: The aim of this study was to investigate the association between OA and PD in South Korea using data from the Korean National Health and Nutrition Examination Survey (KNHANES) during 2010–2014.

Methods: Cross-sectional data of 7,969 adults who completed the KHANES, and participated in both a periodontal examination and a knee imaging were analyzed. OA of knee was defined when a participant had knee arthralgia and showed radiographic change of Kellgren-Lawrence (KL) grade over 1. OA patients were grouped into mild (KL grade 1–2) and severe (KL grade 3–4) OA. The periodontal status was assessed by the Community Periodontal Index. Binary logistic regression analysis was performed according to the OA and PD status, severity of OA, and subgroups (age, gender) adjusting for the socio-demographics, oral health behaviors and status, smoking, and drinking.

Results: Of the 7,969 participants, 1,408 (17.7%) had OA and 2,987 (37.5%) had PD. OA and PD showed no significant association in overall analysis. However, in subgroup analysis, female patients with severe OA were more likely to have PD (adjusted odd ratio (OR) 1.377, P=0.0316); likewise, OR for severe OA in female patient with PD was 1.367. (P=0.054).

Conclusions: Severe OA and PD were associated with each other especially in
female in the Korean population. Further prospective and experimental studies are necessary to identify the impact and mechanisms of association between severe OA and PD in female.

SAT0534 EFFECT OF SUSTAINED-RELEASE SYMPTOMATIC DRUGS ON PROGRESSION OF KNEE JOINT OSTEOARTHRITIS IN PATIENTS WITH LESS THAN 5 YEARS DISEASE DURATION IN A 5-YEAR PROSPECTIVE STUDY

N. Kashkevarova, E. Taskina, L. Alekseeva. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Objectives: To assess the effect of sustained release symptomatic drugs chondroitin sulfate (CS) + glucosamine hydrochloride (GH) on progression of knee OA in pts with <5 years disease duration during the 5year follow-up period (FUP).

Methods: This 5-year study included 52 female-patients with primary knee OA (ACR criteria), disease duration did not exceed 5 yrs (mean age=59±8,9). On each pts the individual file including 200 parameters was filled. Diagnostic modalities used in each patient included plain radiography of knee joints (progression stage was classified using Kellgren J.-Lawrence J. scale), DEXA subchondral portions of the hip and tibia, ultrasound (US) and MRI examination of knee joints. First OA stage was documented in 22 (42,3%)pts, 2-nd - in 24 (46,2%), 3-d- in 6 (11,5%). During 5 years of FUP 31 (60%) pts were administered the combined CS+GH regimen for more than 6 months a year. OA progression was documented based on radiographic criteria.

Results: During the 5 year FUP radiographic progression (upgrade in radiographic stage) of knee OA was documented in 14 pts (Group 1 - with OA progression), while in 38 pts radiographic stage remained unchanged (Group 2 - without progression). Patients from both groups were comparable in terms of age and disease duration (p=0,05). Although, pts from Group 1 with OA progression had more intense knee pain when walking: 60,4±18,3 vs 48,7±17,8mm, p=0,04; and higher BMI values: 34,5±4,6 vs 28,9±4,9 kg/m 2, p=0,001; US-findings based higher rate of synovitis:57,1% vs 18,4%, OR=5,9, 95% CI 1,6–22,5, p=0,009; bone marrow edema in medial tibia aspect 64,3% vs 13,2%, OR=11,9, 95% CI 2,8–50,3, p=0,0006 based on MRI findings. In pts with OA progression DEXA examination identified significantly higher absolute BMD values in the medial condyle of the tibia (0,9 (0,8–1,2) vs 0,8 (0,7–0,8) g/cm 2, p=0,001) as compared to pts from Group 2. Re-examination in Sysrs showed that statistically significant differences between the two groups still remained. Analysis of 5year therapy revealed, that the majority of pts without OA progression (68,4%) were taking combined CS+GH regimens for more than 6 months a year during 5-year FUP, while only 35,7% of pts who progressed (OR=4,3, 95% CI 1,1–16,3, p=0,003) managed to adhere to this regimen. Discriminant analysis showed that 5-year intake of combined CS+GH therapy for more than 6 months a year should be considered as a predictor of decreased risk of disease progression, while on the contrary, such symptoms as synovitis, bone marrow edema, and high BMD values in the medial condyle of the tibia should be viewed as predictors and risk factors for knee OA progression in pts with <5 years disease duration. Based on identified factors and their coefficients the authors designed a model (with area under the ROC curve equal to 0,93), allowing to predict the future course of the disease in an individual patient with high accuracy, i.e. 85,7% sensitivity and 84,2% specificity.

Conclusions: Use of combined CS+GH regimens for more than 6 months a year during 5 years is an important factor, decelerating the progression of knee OA in pts with <5 years disease duration by the factor of 4. While synovitis, bone marrow edema, and high BMD values in the medial condyle of the tibia are responsible for further OA progression on this group of pts.

SAT0535 IMPACT OF THE METABOLIC SYNDROME ON THE PREVALENCE, SEVERITY INCIDENCE AND PROGRESSION OF KNEE OSTEOARTHRITIS

N. Oireo-Villar 1,2, M. Fernandez-Moreno 1,2, E. Cortes-Pereira 1, M.E. Vazquez-Mosquera 1, S. Relaño 1, S. Pertega 3, C. Fernandez-Lopez 1, F.J. Blanco 1, I. Rego-Perez 1, 1Servicio de Reumatología, Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidad da Coruña (UDC), As Xubias, 15006, A Coruña; 2Centro de Investigación Biomédica En Red, Ciber-Bbn, Madrid; 3Unidad de Epidemiología Clínica y Bioestadística, Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidad da Coruña (UDC), As Xubias, 15006; A Coruña, Spain

Background: The contribution of metabolic factors on the development of OA has not been fully elucidated.

Objectives: The aim of this work is to analyze the influence of metabolic syndrome in the rate of radiographic incidence and progression of knee osteoarthritis, as well as its impact on the prevalence and severity of the disease.

Methods: For this work we used data from the Spanish cohort PROCOAC (PROGnostic Cohort of OsteArthritis A Coruña). This cohort consists of subjects that visited the Rheumatology consultations at different time points and comprises 984 subjects at baseline including radiographic knee and hip KL grade, radiographic hand OA status, demographic and clinical parameters, as well as the necessary information to assess the metabolic syndrome at baseline, that is, abdominal circumference (in cm) in addition to at least two of the following parameters: triglycerides above 200mg/dL, low HDL (<35mg/dL), hypertension and increased glucose blood levels (>110 mg/dL). To assess the severity of the disease, the number of affected joints was coded as 0–1 and 2–3, according to the radiographic information of hands, knees and hips. Appropriate statistical analyses including Cox regression models with Kaplan-Meier survival curves and chi-square contingency tables were performed with SPSS v19.

Results: The mean age of subjects was 63.86 [32–88] years and 75.6% were women. A total of 85% had radiographic hand OA and 11.8% suffered metabolic syndrome at baseline. In those OA patients that experienced radiographic knee OA progression over time (any KL increase from KL=2 at baseline) the metabolic syndrome appeared as a significant risk factor (HR=3.68;95CI:1.085–14.520,p-value=0.037) (Figure 1). Similarly, in those subjects that developed incident radiographic knee OA over time (a new-onset KL grade 2), the metabolic syndrome at baseline also appeared as a significant risk factor with an increased magnitude (HR=12.931;95CI:3.037–55.051,p-value<0.001) (Figure 1). In addition, to have contralateral knee OA at baseline (HR=12.937;95CI:5.044–32.673;p-value<0.001) as well as radiographic hand OA (HR=5.671;95CI:0.854–37.649;p-value=0.07) associates with an increased rate of incident knee OA too. In terms of prevalence and severity of the disease, the metabolic syndrome associate with an increased risk of knee OA (OR=1.865;95% CI=1.080–3.220;p-value=0.024) as well as with increased number of affected joints, though in a non-significant manner (OR=1.582;95%CI=0.916–2.733;p=0.098).

Conclusions: The alterations that underlie the metabolic syndrome condition the severity and prevalence of knee osteoarthritis, as well as the rate of incidence and progression of the disease

Background: Opening-wedge high tibial osteotomy (HTO) is primarily indicated in treating varus gonarthrosis. The rationale behind HTO treatment of knee
Influence of meloxicam in orodispensible form on platelet aggregation and von Willebrand factor in patients with osteoarthritis

O.S. Khmel, V.V. Rodionova. Occupational Diseases and Clinical Immunology, State Establishment "Dnipropetrovsk Medical Academy, of Health Ministry of Ukraine", Dnepr, Ukraine

Background: Meloxicam, which selectively inhibits COX-2, can cause inhibition of the biosynthesis of vascular endothelium vaso dilator - prostacyclin, without impacting significantly on production of thromboxane, which promotes vascular dysfunction [1]. Meloxicam on the possibility of thrombotic complications need to be learn more accurately.

Objectives: To investigate the effect of orodispensible form of Meloxicam on platelet aggregation and von Willebrand factor in patients with knee osteoarthritis.

Methods: The study included 24 patients with knee osteoarthritis (OA) of the II stage according to the Kellgren-Lawrence. The control group consisted of 15 healthy individuals. Patients were prescribed the orodispensible form of Meloxicam in dose of 15 mg 1 time per day orally during 10 days. The survey was carried out before and after treatment. Patients had all-clinical studies, questionnaires (visual analogue scale (VAS), WOMAC, Lequesne index (WOMAC), questionnaire Lequesne), optical aggregometry with adenosine diphosphate (ADP), collagen, thrombin and ristocetin for revealing the level of von Willebrand factor.

Results: The result of treatment patients had a significant improvement of overall health and reduction of pain in knee joints according to the VAS (before treatment – 54.5 [50 – 71] mm, after treatment – 27 [18 – 41] mm; p<0.05), WOMAC (before treatment – 143 [109 – 187] points, after treatment – 98 [13–168] points; p<0.05), questionnaire Lequesne (before treatment – 16 [13 – 21] points, after treatment – 12 [9 – 18] points; p<0.05). After treatment patients experienced a significant increase in the degree of platelet aggregation with ADP (before treatment – 52.6 [39.6 – 82.0]% after the treatment – 83.5 [41.2 – 127.2]%); p<0.05), which may indicate a probable increase in the initiation of irreversible aggregation of circulating platelets. The degree of platelet aggregation with collagen also increased (before treatment – 84.5 [71.6 – 89.4]% after treatment – 86.8 [87.9 – 115.4]%); p<0.05), indicating the increased adhesion of platelets to collagen of the vascular endothelium. Before and after treatment, patients remained significantly elevated degree of aggregation with thrombin in comparison with the control group (before treatment – 65.6 [32.11 – 42.26]% after treatment – 78 [62.3 – 92.7%], control group – 37.8 [32.11 – 42.26]%); p<0.05) which may indicate the stimulation of the of the endothelin-1 synthesis with further infringements of procoagulants and anticoagulants. Von Willebrand factor, as an indirect indicator of endothelial damage, was significantly increased after treatment (before treatment – 151.4 [138.9 – 224] after treatment – 245.6 [238.6 – 262.5]%), which may indicate increase of endothelial lesions because of meloxicam with further endothelial dysfunction (p<0.05).

Conclusions: Intake of the orodispensible form of Meloxicam in patients with osteoarthritis can cause an increase of platelet aggregation and level of von Willebrand factor that may contribute to the vascular endothelial dysfunction and increase in risk of thrombosis.

Results: Altogether, 129 patients (12 male) with symptomatic nodal OA were included in this study and followed between April 2012 and January 2017. Out of these patients, 72 had erosive disease. The disease duration (p < 0.01) was significantly higher in patients with erosive compared with non-erosive disease. Pain (p < 0.05) and the number of clinically swollen joints (p < 0.05) were significantly higher in patients with erosive compared with non-erosive disease at baseline. There were significant progression of pain (p < 0.05) and the number of clinically swollen joints (p < 0.01) at the two years follow up. The progression in clinically swollen joint count was about 21% higher in patients with erosive disease.

According to the AUSCAN, patients with erosive compared with non-erosive disease had more pain (p < 0.05) and stiffness (p < 0.01) at baseline. Pain and stiffness, but not function, got worse (p < 0.01) in patients with erosive compared with non-erosive disease at the two years follow up.

US-images of patients with OA showed, as gray-scale synovitis total score (p < 0.001), intensity of PDS (p < 0.01) and number of osteophytes (p < 0.01) were significantly higher in patients with erosive compared with non-erosive disease at baseline.

There were improvements in gray-scale synovitis total score and intensity of PDS in patients with non-erosive disease while patients with erosive disease worsened at the two years follow up. On the other hand, the progression of US-determined osteophyte formation was observed in both groups.

Conclusions: The findings of this study show that pain and number of clinically swollen joints associated with US-detected synovial hypertrophy inflammatory signs and osteophyte formation is more severe in patients with erosive HOA than in patients with non-erosive disease. In addition, osteophyte formation is more likely to progress independent of synovial inflammation.

**SAT0539**

**DIFFERENTIAL PROFILE OF ENDOGENOUS PEPTIDES DETECTED BY TARGETED PROTEOMICS IN HIP AND KNEE CARTILAGE SECRETOMES FROM OSTEOARTHRITIS PATIENTS**

P. Fernandez-Puente, L. Gonzalez-Rodriguez, V. Calamia, L. Lourido, M. Camacho, C. Ruiz-Romero, F.J. Blanco. Grupo de Proteómica-PBR2-ProteoRed/ISCIII-Servicio de Reumatologia, Instituto de Investigación Biomédica de A Coruña (NIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC), A Coruña, Spain

Background: Peptidomics can be defined as the comprehensive, qualitative and quantitative study of all native peptides in a sample in a defined space at a defined time under defined biological conditions. LC-MS/MS targeted proteomics have been used to identify and quantify candidate molecular biomarkers in diverse range of samples, including cells, tissues, serum/plasma, and other types of body fluids.

Objectives: In the present work, we have developed a targeted method to detect a panel of endogenous peptides that were identified as released from human healthy (N) and/or osteoarthritic (OA) hip and knee cartilage. Secretomes were obtained separately from the wounded (WZ) and unwounded (UZ) zones of OA cartilage. The enrichment of endogenous peptides was achieved by ultrafiltration and solid phase extraction (SPE). After peptide extraction, the different peptide profiles of these secretomes were relative quantified by target proteomics.

Methods: Proteins secreted from human articular cartilage (secretomes) were obtained by culture of tissue explants [1]. The enrichment of endogenous peptides was standardized using ultrafiltration procedures and solid phase extraction with reversed phase (C18) resins. A method for the targeted identification and relative quantitation of endogenous peptides by Multiple Reaction Monitoring (MRM)-mass spectrometry was developed employing cartilage secretome samples, and then applied on synovial fluid and serum. The peptides were separated by nano-LC coupled to a 5500 QTRAP mass spectrometer using stable isotope-labeled (SI) peptides as external standards. Peptide identifications were searched using the ProteinPilot program. Data analysis was performed using the Skyline software.

Results: 23 endogenous peptides belonging to 9 proteins related with OA, as Cartilage Oligomeric Matrix Protein (COMP), Cartilage Intermediate Layer Protein (CILP), Prolargin (PRELP), Dermcidin (DDC), Fibronectin (FNC) and Oligo Derived Nocin (GDN) among others, were differentially detected and relatively quantified in the cartilage secretomes. Some of the endogenous peptides belonging to COMP, FNC and GDN were found with a significant high release in the UZ of hip cartilage, however in knee cartilage the release is higher in the WZ. On the other hand, certain peptides belonging to proteins like CILP or PRELP were found to be mostly increased in the UZ of both hip and knee OA cartilages when compared to healthy tissue.

Conclusions: A panel of endogenous peptides has been identified in articular cartilage, which are differentially released between OA and healthy patients, and which could be used as potential biomarkers of disease. A panel of OA-specific peptides may be potential biomarkers to differentiate osteoarthritis from hip and knee. Our targeted proteomics approach would be widely applicable to quantify low abundant peptides of interest in complex biological samples as synovial fluid and serum in order to unravel their putative biomarker value for osteoarthritis.

**THE REDUCTION IN ADRENERGIC AND INFAMMATORY SERUM MARKERS IN OSTEOARTHRITIS PATIENTS AFTER TREATMENT WITH CHONDROTIN SULFATE/GLUCOSAMINE HYDROCHLORIDE AND CELECOXIB IS DIFFERENT ACCORDING TO THE PRESENCE OF BACTERIAL DNA IN BLOOD**

P. Zapater 1, M. Herrero 2, H. Martínez 2, R. Francés 3,4, J. Vergés 3, J.F. Horga 5, 5

1Pharmacology Department, Miguel Hernández University, Alicante; 2Clinical R&D, Boeberica, Barcelona; 3CIBERehd. Instituto de Salud Carlos III. Madrid; 4Medicine Department, Miguel Hernández University, Alicante; 5Osteoarthritis Foundation International (OAFI), Barcelona; 6Pharmacology Department, Miguel Hernández University, Alicante, Spain

Background: Inflammation in osteoarthritis (OA) has been characterized by infiltration of immune cells and secretion of cytokines into synovial tissues. Synovial macrophages production of IL-1beta and TNF-alfa is increased in response to glycopolysaccharide (LPS) and associated molecular patterns (PAMPs) in OA development and/or evolution. Adrenergic activity have been associated with subchondral bone loss and increased osteoclast activity. Also, adrenergic activity is a main modulator of immune response to PAMPs in different settings. However, the relationship between activation of adrenergic and immune system with OA progression and treatment response remains still unknown.

Objectives: To assess the adrenergic and immune activation in OA patients according to the presence of bacterial DNA (bDNA) fragments in blood before and after Chondroitin Sulfate/Glucosamine Hydrochloride (CS/GH) or Celecoxib (CE) treatment.

Methods: Serum samples from patients participants in a 6-month controlled, double blind and randomized clinical trial comparing the analgesic efficacy of CS/GH and CE were analyzed to determine cytokines (IL-2, IL-4, IL-6, IL-8, IL-1beta, catecholamines (noradrenaline, adrenaline and dopamine) and the presence of endotoxin or LPS and bDNA. Results are shown as mean±sd or median with ranges (Q25-Q75).

Results: Serum samples from 12 OA patients (age: 62±8yr; BMI: 31±6kg/m² 86 females; VAS: 73±15; WOMAC: 369±43) treated with CS/GH (50) or CE (50) were analyzed. There were no baseline significant differences between the two treatment groups regarding demographics,clinical and experimental variables. Thirty-four patients (17-CS/GH and 17-CE) showing bDNA in blood had significantly higher levels of noradrenaline compared with patients without bDNA (1993 [1354–3183] vs. 1561 [1174–2193]; p=0.0325). IL-8 positive at baseline). Patients with bDNA at 6 months after treatment showed reduced serum noradrenaline levels compared with those observed in patients with bDNA at baseline (1993 [1354–3183] vs. 1561 [1174–2193]; p=0.0002). After 6 months, both groups of treatment showed a similar reduction in VAS and WOMAC score (pain assessment) and serum adrenaline levels independent of presence or absence of bDNA (Table 1). Thirty-three patients showed bDNA presence at the end of the study (23 negative and 10 positive at baseline). Patients with bDNA at 6 months after treatment showed reduced serum noradrenaline levels compared with those observed in patients with bDNA at baseline (1993 [1354–3183] vs. 1561 [1174–2193]; p=0.0325). IL-8 was significantly reduced after 6 months of treatment only in patients without bDNA. There were no significant differences between baseline and 6 months samples in the other experimental variables.

Conclusions: OA patients show bDNA fragments in blood associated to higher noradrenaline levels. Six month treatment with CS/GH or CE reduces significantly and in a similar fashion the pain intensity and adrenaline levels. IL-8 levels were reduced in patients with presence of bDNA fragments in blood. Systemic adrenergic and inflammatory activity in OA patients is influenced by the presence of PAMPs as bDNA in blood and this may be a factor to take into consideration to evaluate the severity, evolution and response to treatments.

SAT0541 INHIBITING αV3 INTEGRIN AND CD47 SIGNALING AMELIORATES THE PROGRESSION OF OSTEOARTHRITIS
Q. Wang 1, K. Chuma 2, R. Mao 1, H. Wong 1, W.H. Robinson 1, 2, Medicine, 1:Stanford University, Stanford, United States
Background: Osteoarthritis is leading cause of disability, and its prevalence is rising due to aging population and obesity epidemic. Despite the substantial morbidity and health costs attributed to osteoarthritis, no treatment has been approved to prevent or slow disease progression, largely because the underlying pathogenic mechanisms remain elusive. Both integrin αV3 and the integrin-associated receptor CD47 are considered important therapeutic targets for a number of diseases, but the potential involvement of these receptors in osteoarthritis remains unclear.

Objectives: Our study aimed at assessing the role of integrin αV3 and the integrin-associated receptor CD47 signaling pathways in the pathogenesis of osteoarthritis, and identifying potential targets for disease-modifying therapy.

Methods: We performed transcriptomic and proteomic analyses of human and murine osteoarthritic tissues to examine the involvement of integrin αV3 and CD47 with osteoarthritis. Further, we evaluated the effects of genetic deficiency in and pharmacological modulations of integrin αV3 subunits, CD47, and their downstream signaling molecules Fyn and FAK on the degenerative meniscus (DMM) mouse model. Additionally, we used microPET/CT imaging of the DMM mouse model to assess the ligand-binding capacities of integrin αV3 and CD47 in osteoarthritic joints. Finally, we carried out multiple in vitro assays to determine how integrin αV3 and CD47 signaling might become activated in osteoarthritis, and what the molecular consequences of such activation might be.

Results: Our transcriptomic and proteomic analyses revealed the involvement of dysregulated integrin αV3 and CD47 signaling in osteoarthritis. Data from investigations of genetically deficient mice and pharmacological modulations showed that αV3, CD47, Fyn, and FAK are crucial to the pathogenesis of arthritis. We detected elevated ligand-binding capacities of integrin αV3 and CD47 in osteoarthritic joints by microPET/CT imaging of mice subjected to DMM. Our in vitro studies demonstrated that chondrocyte breakdown products, derived from the articular cartilage of individuals with osteoarthritis, induced αV3/CD47-dependent expression of inflammatory and degradative mediators, and revealed that the signaling network involved the Ras-CRAF-MEK-ERK pathways.

Conclusions: Our findings identify a central role of deregulated αV3 and CD47 signaling in the pathogenesis of osteoarthritis, and provide a rationale for targeting these signaling pathways as a disease-modifying therapy.

SAT0542 SUBCLINICAL CRYSTAL ARTHROPATHY MIGHT INFLUENCE FUNCTIONAL DISABILITY IN PATIENTS WITH KNEE OSTEOARTHRITIS? AN EGYPTIAN CROSS SECTIONAL STUDY
R. H. A. Mohammed, Department of Rheumatology and Rehabilitation, MD, FRCP, FACR, School OF MEDICINE, Cairo University Hospitals, Cairo, Egypt

Background: Osteoarthritis is a complex slowly progressive degenerative disease that affects joint components. Concomitant articular crystal deposits are able to stimulate an inflammatory response in OA through stimulation of the innate immune system.

Objectives: Assess the contribution of sonographically detected crystal deposits to pain severity and functional disability in patients with knee OA (WOMAC score)

Methods: Single-center cross sectional study. Adult patients diagnosed with knee OA diagnosed in accordance with ACR criteria from the Department of Rheumatology and Rehabilitation, Kasr Alainy School of Medicine, Cairo University were recruited. Clinical assessment of pain and functional status in patients with knee OA was measured using Western Ontario and McMaster Universities Arthritis Index score. The Logic p5 ultrasound machine (GE) with linear array probe (8–13 MHz). Examination of the articular and periarticular structures was performed by a trained rheumatologist according to the standard EULAR guidelines for exam of the knee. Serum uric acid was investigated, and plain radiography was done for comparison.

Results: 53 patients (44 females 83% & 9 males 17%) were included, aged mean 53.5 years ± 8.3 SD, disease duration 42.5 months ± 49.5 SD, body mass index mean 34.9±3.3 SD. Crystal deposits were sono-graphically diagnosed in 73 knees (68.9%). Monosodium urate deposits found in 33 knees (31.1%) and Calcium Pyrophosphate Dihydrate deposits were diagnosed in 67 knees (63.2%). Pain, stiffness and disability scores were significantly higher in OA knees with crystal deposition as compared to those without (p<0.05) that in fact resistant to conventional analgesics, chondro-protectives and physiotherapy demanding the ongoing use of NSAIDs.

SAT0543 CLINICAL PREDICTORS AND RADILOGIC EVIDENCES OF OCCULT CRYSTAL DEPOSITION DISEASE WITH KNEE OSTEOARTHRITIS
R. H. A. Mohammed. Department of Rheumatology, Rehabilitation and Clinical Immunology, MD, FRCP, FACR, School of Medicine, Cairo University Hospitals, Cairo, Egypt

Background: Osteoarthritis is a slowly progressive degenerative disorder that affects joint components. Concomitant articular crystal deposits are able to stimulate an inflammatory response in OA through stimulation of the innate immune system.

Objectives: Assess the contribution of sonographically detected crystal deposits to pain severity and functional disability in patients with knee OA (WOMAC score)

Methods: Single-center cross sectional study. Adult patients diagnosed with knee OA diagnosed in accordance with ACR criteria from the Department of Rheumatology and Rehabilitation, Kasr Alainy School of Medicine, Cairo University were recruited. Clinical assessment of pain and functional status in patients with knee OA was measured using Western Ontario and McMaster Universities Arthritis Index score. The Logic p5 ultrasound machine (GE) with linear array probe (8–13 MHz). Examination of the articular and periarticular structures was performed by a trained rheumatologist according to the standard EULAR guidelines for exam of the knee. Serum uric acid was investigated, and plain radiography was done for comparison.

Results: 53 patients (44 females 83% & 9 males 17%) were included, aged mean 53.5 years ± 8.3 SD, disease duration 42.5 months ± 49.5 SD, body mass index mean 34.9±3.3 SD. Crystal deposits were sono-graphically diagnosed in 73 knees (68.9%). Monosodium urate deposits found in 33 knees (31.1%) and Calcium Pyrophosphate Dihydrate deposits were diagnosed in 67 knees (63.2%). Pain, stiffness and disability scores were significantly higher in OA knees with crystal deposition as compared to those without (p<0.05) that in fact resistant to conventional analgesics, chondro-protectives and physiotherapy demanding the ongoing use of NSAIDs.

53.5 years ± 8.3 SD, disease duration 42.5 months ± 49.5 SD. Crystal deposits were sono-graphically diagnosed in 73 knees with normal serum uric acid values (68.9%—MSU in 31.1%, CPPD in 63.7%), a picture of mixed deposits in 5.7%). Plain radiography revealed chondrocalcinosis in 3 patients only. Regression analysis models and Forest Plot test revealed a 4.1 fold incidence of crystal deposition in patients with sonographic bursitis than those without (OR=4.13, Cl=1.5–11.2, p=0.01) and a 3.2 fold incidence of crystal deposition in patients with sonographic effusion than those without (OR=3.16, Cl=1.34–7.44, p=0.01).

Conclusions: The study concluded a number of clinical as well as radiographic associates that might be considered as predictors of silent CDD in patients with knee OA as diagnosed by ultrasonography, the most commonly reported clinical associates were bursitis and effusion.

SAT0544 | SUBGROUPS IN RADIOGRAPHIC FEATURES IN PATIENTS WITH HIP OSTEOARTHRITIS: RESULTS OF THE AMS-OA COHORT

R.A.M. Poux 1,2, M. van der Esch 1, M. van der Leeden 1,3, D. Reiding 4, L.D. Roorda 5, J. Dekker 5, W.F. Lems 6, 7, 1 Amsterdam Rehabilitation Research Center, Reade, Center for Rehabilitation and Rheumatology; 2 Faculty of Behavioural and Movement Sciences, VU University; 3 Department of Rehabilitation Medicine, VU University Medical Center; 4 Department of Radiology, Reade, Center for Rehabilitation and Rheumatology; 5 Rehabilitation Medicine; 6 Department of Rheumatology, VU University Medical Center; 7 Jan van Breemen Research Institute, Reade, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands.

Background: Radiographic features are important in diagnosing hip osteoarthritis (OA). In daily practice, only the anterior-posterior view is visualized but not the false profile view. Since we assessed radiographic features in both types of radiographic hip images in the AMS-OA cohort, we were able to examine the differences in radiographic features in two regions of the hip (superior-lateral and central-axial region).

Objectives: (i) To describe the presence of radiographic features in patients with hip OA; and (ii) to determine whether radiographic features differ between the superior-lateral and central-axial region of the hip.

Methods: Data from 97 patients with bilateral hip pain and a Kellgren and Lawrence score of >1 of the Amsterdam Osteoarthritis (AMS-OA) cohort of patients with knee and/or hip OA were used. Standard radiographic images were examined of patients in an erect position, both with an anterior-posterior view and with a false profile view, which is an oblique lateral view of the hip. Radiographic images were scored by an experienced radiologist (DR) and an independent researcher (ME). Consensus between two raters was achieved for each score. Four radiographic features were scored: presence of joint space narrowing, osteophytes, sclerosis and cysts. All joint features were scored separately for the superior-lateral and the central-axial region of the hip. A Fisher’s exact test was performed for testing the significance of the differences between the two regions of the hip.

Results: Table 1 shows the frequencies of radiographic features (joint space narrowing, osteophytes, sclerosis and cysts) in the superior-lateral and the central-axial region of the left and right hip joint of patients with hip OA. Significant differences between the two regions were found for osteophytes, sclerosis and cysts with the highest frequency of these features in the superior-lateral region of the hip.

Conclusions: In our cohort we found as expected, that joint space narrowing of the hips was the most frequent feature (>-80% in both the superior-lateral and central-axial region). Moreover, osteophytes, sclerosis and cysts were more frequently present in the superior-lateral region. Our findings indicate that hip OA may exist of two subgroups with differences in radiographic features (i.e., superior-lateral and central-axial). Future research should confirm these results and focus on possible associations with biomechanical and physical function variables.

SAT0545 | PREDICTIVE FACTORS FOR RESPONSE TO ULTRASOUND-GUIDED INTRA-ARTICULAR GLUCOCORTICOIDS IN KNEE OSTEOARTHRITIS

S. Sliman 1, A. Aissoug 2, S. Aoudiane 1, H. Bounee 1, M.M. Makhloufi 1, A. Ladjouze-Rezig 3, 1 Medicine, University of Batna 2; 2 Private practice, Batna; 3 Medicine, University of Algiers 1, Algiers, Algeria

Objectives: To investigate predictive factors for good outcome of ultrasound-intra-articular glucocorticoids in knee osteoarthritis (OA).

Methods: We conducted a prospective monocenter cohort study including 116 patients with knee OA, after failure to standard treatments, with pain >4 (numerical rating scale NRS 0–10). Patients received an ultrasound-guided injection of 40 mg triamcinolone acetonide in their most painful knee. We exhaustively collected demographic and clinical data at inclusion, as well as lab, radiographs and ultrasound parameters of the included knees. WOMAC score was calculated at inclusion and after 4 weeks. Responders were defined as patients with at least 40% improvement of their WOMAC score. Univariate analysis was performed in order to select possible predictive factors, and stepwise multiple logistic regression analyses were conducted to identify predictors of response.

Results: Among the 116 patients, 101 were females. Median age was 64 years (40–85) and mean duration of the disease was 14.1±14.8 years. Mean BMI was 29.9±3.8 Kg/m2. Mean NRS of pain was 8.4±1.2 and mean WOMAC was 73.3±11.8 at inclusion. 70.0% of the knees were grade 3 or 4 of Kellgren-Lawrence. 98% of patients expressed ultrasound synovial effusion and/or hypertrophy at inclusion. After 4 weeks, 61.2% of patients were responders. Regression analysis showed that patients with a BMI <30 Kg/m2 (OR=0.38, 95% CI 0.16–0.89) and an ESR <20 mm (OR=0.27, 95% CI 0.08–0.90) were more likely to respond to ultrasound-guided glucocorticoids injection. Having both predictive factors of good response increases the response rate to 72.5%, whereas having no predictive factor decreases the response rate to 25.0%.

Conclusions: Our study is the largest study evaluating predictive factors of response for intra-articular glucocorticoids injections in knee OA. Also, it is the first study of predictive factors for ultrasound-guided injections. Patients with high BMIs and high ESR seem less likely to respond to intra-articular injections.

TOTAL OSTEOPHYTE SCORE IS A BIOMARKER OF CURRENT AND PERSISTENT PAIN IN KNEE OSTEOARTHRITIS SUBJECTS

S. Feng, M.C. Levesque. AbbVie Inc., Worcester, MA, United States

Background: X-ray and magnetic resonance imaging (MRI) demonstrated associations between osteophyte severity and current pain in knee osteoarthritis (OA) patients. Persistent pain over 5 years was also associated with x-ray osteophyte severity. A biomarker to identify knee OA subjects with persistent pain may reduce placebo response rates in clinical trials.

Objectives: To determine whether the total knee osteophyte score (TKOS), as measured by MRI Osteoarthritis Knee Score (MOAKS), is a biomarker of current and persistent pain severity in knee OA subjects.

Methods: Knee OA subjects from the Foundation for the National Institutes of Health Biomarker Consortium were longitudinally assessed over 4 years and categorized as pain and x-ray progressors (n=194), x-ray-only progressors (n=103), pain-only progressors (n=103), and non-progressors (n=200). Knee osteophyte severity was scored at baseline by MOAKS at 12 positions across the knee and summed to obtain the TKOS. TKOS was summarized as means and SDs in the 4 progression groups; each progression group TKOS was compared with the non-progression group using Wilcoxon rank sum tests (Table 1). The longitudinal Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain scores were plotted and tested with a linear mixed model, by high and low TKOS status, defined as above and below the TKOS median of 6 (Figure 1). Subjects with persistent pain were defined based on WOMAC pain scores at 4 out of 5 time points higher than the thresholds listed in Table 2; at each threshold, mean differences in TKOS were tested using analysis of variance among those with and without persistent pain.

Results: The distribution of baseline TKOS differed by progression group, with the highest TKOS among pain and x-ray progressors (Table 1). In all 4 progression groups, baseline WOMAC pain scores were higher in subjects with high (>6) versus low (<6) baseline TKOS status (p=0.0001, 0.0383, 0.0035, and 0.0466, respectively). The difference in WOMAC pain scores between TKOS high and low subgroups was constant over time (Figure 1; solid curves above and parallel to dashed curves with TKOS effect always significant [P<0.01] in all 4 progression groups), but the TKOS-Time interaction term in the longitudinal mixed model was not statistically significant, indicating that the pain difference between the TKOS high and low subgroups did not change over time. TKOS was highly associated with persistent pain, with TKOS high at all thresholds (Table 2).

Conclusions: TKOS is a candidate biomarker for current and persistent pain in knee OA patients and may be a predictive biomarker for reduced placebo response rates in clinical trials.

DOI: 10.1136/annrheumdis-2017-eular.5095

THE INFLUENCE OF OSTEOARTHRITIS ON CLINICAL, LABORATORY AND ULTRASOUND PARAMETERS OF PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

T. Serban1,2, I. Satulu3, O. Vutcanu2, M. Milicescu1,2, C.M. Mihai1,2, M. Bojnic1,2, Internal Medicine and Rheumatology; Carol Davila University of Medicine and Pharmacy; Clinical Hospital “Cantacuzino” Clinical Hospital, Bucharest, Romania;2Rheumatology, Kalmar County Hospital, Kalmar, Sweden

Background: Osteoarthritis (OA) and rheumatoid arthritis (RA) are not infrequent in the general population. The two pathologic entities can overlap and the presence of OA can interfere with the evaluation of patients with RA.

Objectives: This study aims to evaluate the possible impact of OA on the clinical, laboratory and ultrasound parameters currently evaluated in patients with early RA (ERA).

Methods: We have evaluated the data obtained from patients with ERA referred to our Early Arthritis Research Center (EARC). Only data from patients who fulfilled EULAR/ACR 2010 criteria for RA (1) and had a symptom duration of less than 12 months were analyzed. 43 patients were diagnosed with ERA in the EARC between 2012 and 2016 and were enrolled in this study. Patients were evaluated at baseline and after 12 months. All patients underwent clinical examination, laboratory tests and ultrasound (US) examination. For the US examination we have calculated the score proposed by Naredo et al. considering that this simplified US score includes the evaluation of the hand and knee. (2) Results: There was a clear predominance of women (62.8%). The mean age was 55.47±13.71 years. At baseline, 21 patients (48.8%) were diagnosed with OA. 15 patients (34.9%) presented hand OA and 9 patients (20.9%) presented knee OA. Hand OA didn't influence the values of DAS28, SDAI, patient's and physician's visual analogue scale (VAS) or ultrasound scores (p>0.05). For patients with knee OA, significantly higher values for DAS28 were observed at baseline (p=0.018) and were maintained significantly higher after 12 months of observation (p=0.031). All the other parameters were not influenced by the presence of knee OA (p>0.05). The median value and interquartile range for lab tests and for disease activity indices are shown in Table 1.

</tr>
</tbody>
</table>

Conclusions: Significantly higher values of DAS28 were observed in patients with ERA who associated knee OA, while the values of SDAI were not influenced, suggesting that SDAI may be superior to DAS28 in evaluating patients with ERA and knee OA. Not the same tendency was observed in patients with ERA who associated knee OA, while the values of SDAI were not influenced, not the values of ultrasound scores were not influenced by the presence of OA.

PLASMA CGRP CONCENTRATIONS WERE NOT ASSOCIATED WITH PATIENT OA SYMPTOMS OR RESPONSE TO GALCANEZUMAB, A MONOCLONAL ANTIbody AGAINST CGRP

1Neuroscience/Pain, Eli Lilly and Company, Indianapolis, United States; 2Eli Lilly and Company, Windlesham, United Kingdom; 3Eli Lilly and Company, Indianapolis, United States; 4Eli Lilly and Company, Sesto Fiorentino, Italy; 5Xenon Pharmaceuticals Inc, Burnaby, Canada; 3Eli Lilly and Company, Indianapolis, United States; 4Eli Lilly and Company, Sesto Fiorentino, Italy

Background: The safety and efficacy of galcanezumab, a monoclonal antibody against calcitonin gene-related peptide (CGRP), currently in phase 3 clinical trials for the prevention of episodic cluster headache, is supported by evidence in patients with chronic primary headache and experimental headache models.2 Subsequently, there has been significant interest in the potential role of CGRP in the pathogenesis of patients with OA.3,4 Previous studies have demonstrated the association between OA and CGRP expression,5,6 which suggests that CGRP may be involved in the pathogenesis of OA.

Objectives: To compare plasma CGRP levels in patients with OA who had OA symptoms or responded to galcanezumab treatment with those who did not.

Methods: This was a post-hoc analysis of all patients with OA who participated in phase 2 and 3 clinical trials of galcanezumab. Plasmatic CGRP was measured at baseline in 249 patients with OA who underwent clinical trials at 5 academic centers in the United States. The patients were divided into two groups: responders and non-responders. Response was defined as a ≥50% reduction in pain scores at the end of the treatment period. CGRP levels were compared with repeated measures ANOVA with Bonferroni post-hoc testing.

Results: The mean change in plasma CGRP concentrations from baseline did not differ significantly between responders and non-responders (−0.0001 versus −0.0015, respectively, p=0.82). The mean change in plasma CGRP concentrations did not differ significantly between patients with OA symptoms and those without OA symptoms (−0.0002 versus −0.0014, respectively, p=0.34).

Conclusions: These findings suggest that plasma CGRP concentrations are not associated with OA symptoms or response to galcanezumab, a monoclonal antibody against CGRP.
directed against CGRP were assessed in a phase 2 clinical trial NCT02192190 in patients with moderate to severe osteoarthritis (OA) knee pain. Patients were randomized to placebo, galcanezumab (5, 25, 120 and 300 mg subcutaneously every 4 weeks, at weeks 0 and 4) or celecoxib (200 mg once daily) for 16 weeks in a 2:1:1:1:1:1 ratio. The study was terminated after an interim analysis due to ineffectiveness for pain outcomes.

**Objectives:** This study assessed the correlation of baseline plasma CGRP concentrations with signs, symptoms and radiographic severity of OA, and response to galcanezumab and celecoxib treatments.

**Methods:** Plasma samples were collected at baseline and weeks 4, 8, 12 and 16 and analyzed for CGRP. CGRP concentrations were determined by a validated high sensitivity (HS) assay. Correlation of baseline CGRP levels to WOMAC scores, PGA and radiographic Kellgren-Lawrence (K-L) grades were assessed using Spearman’s correlation and Wilcoxon test. Patients were stratified into high vs low baseline by baseline CGRP concentrations and post-treatment changes from baseline WOMAC scores evaluated by mixed effect model repeated measures for each subset.

**Results:** At the interim analysis, baseline plasma CGRP samples were available for 262 patients with 54 patients providing samples at study termination through the week 8 visit. The median CGRP concentration at baseline was 1.07 pg/ml, range <0.78 to 33.91, and 31% of patients were below the level of quantitation (BLQ, <0.78 pg/ml). Median baseline CGRP levels were 1.0 pg/ml for K-L grade 2 (N=178), and 1.2 pg/ml for K-L grade 3 (N=84) (p=0.06). Correlations of WOMAC or PGA scores with baseline CGRP levels were all <0.01 (no significant correlations). In OA patients receiving galcanezumab 300mg SC at week 0 and week 4, those with high baseline CGRP levels demonstrated a 14mm improvement in WOMAC Pain response at week 12 (95% CI 0, 29mm). The pain response to galcanezumab 300mg did not reach the magnitude of celecoxib response and no effects were seen at 5–120mg doses. Celecoxib treatment had larger pain reduction among patients with high baseline CGRP compared to low baseline CGRP levels. Treatment with celecoxib did not alter plasma CGRP concentrations.

**Conclusions:** At baseline, CGRP levels in OA patients were not associated with WOMAC or PGA scores. There was a modest association to radiographic K-L grade. Subgroup analyses of patients with high (<median) CGRP levels at baseline suggested a potential response to galcanezumab for the highest dose, 300mg, but not lower doses. Celecoxib response was greater in those with higher CGRP levels. However, interpretation was limited by small sample sizes at the latter time points. Further studies may determine if enriching the OA population for higher CGRP levels at baseline, or if increased or longer dosing of galcanezumab would improve pain responses or if CGRP blockade is relevant in relieving OA knee pain.

**DOI:** 10.1136/annrheumdis-2017-eular.2155
75.0±13.8, WOMAC pain score was 16.±3.6. Eighty-two patients of 161 (50.9%) had neuropathic pain. When diabetics were excluded (n=58), the proportion of patients with neuropathic pain reduced to 45.6%. The most frequently described pain characteristic was sensation of electric shock (58.4%). Mean total WOMAC and physical function subscale was significantly higher in neuropathic pain group compared to non-neuropathic pain group (Table 1). In KOA patients, the serum and SF concentrations of midkine significantly correlated with the baseline thickness of the cartilage on the medial condyle (r=0.41, p<0.05) but not on the lateral condyle of the femur (r=0.12 and 0.15 respectively, p>0.05). Patients with elevated serum and SF midkine (defined as midkine level more than the mean±2 standard deviation of healthy controls’ level) had a twofold increased risk of radiological progression with MSUS (age, sex and BMI adjusted RR 2.4 and 2.6, 95% CI respectively). With elevated serum and SF midkine levels, there was no increased risk of radiological progression detected with plain radiography in KOA Patients (age, sex and BMI adjusted RR 1.3 and 1.6, 95% CI respectively).

Conclusions: Osteoarthritis patients who have significantly elevated serum and synovial levels of midkine that were obviously associated with radiological progression of knee osteoarthritis.

SAT0551 INCREASED SERUM AND SYNOVIAL LEVELS OF MIDKINE ARE ASSOCIATED WITH RADILOGICAL PROGRESSION IN KNEE OSTEOARTHRITIS PATIENTS

W.A. Hassan 1, A.I. Mansour 2. 1Rheumatology and Rehabilitation; 2Clinical and Chemical Pathology, Benha university, Benha, Egypt

Background: Midkine is a heparin-binding growth factor that plays an important role in mesoderm remodeling as in chondrogenesis and adipocyte formation. There is an increased expression of midkine in damaged tissues and it is believed to have functional antagonism, as it helps in tissue repair and survival while, on the other hand it can enhance inflammatory reactions resulting in more tissue injury [1].

Objectives: This study aimed to determine serum and synovial fluid (SF) levels of midkine in patients with primary knee osteoarthritis (KOA) and to examine the relationship between these levels with the clinical and functional parameters as well as radiological progression of KOA.

Methods: We measured midkine in the serum (n=52) and SF samples (n=23) from 52 KOA patients as well as in the serum from 20 healthy control (n=20). In the patients, numerical rating scale of pain (NRPSP), body mass index (BMI) and The Western Ontario Mc Master scale (WOMAC) were recorded. Graded plain radiographs using Thomas score, and musculoskeletal ultrasound examination (MSUS) of both knees were performed at baseline and after 24 months to assess radiological progression [2,3]. Radiological progression was considered if there is an increase in the Thomas grading score or MSUS transition to a higher grade at the 24 months follow up period compared to baseline evaluation.

Results: Serum and SF midkine levels were significantly increased in KOA patients (mean ± SD 80.79±31.8 pg/mL and 216.31±94.93 pg/mL respectively) compared to serum level in the healthy controls (mean ± SD 65.1±47.6 pg/mL, p<0.05 and p=0.001 respectively). In KOA patients, the serum and SF midkine levels were significantly increased in KOA patients (mean ± SD 80.79±31.8 pg/mL and 216.31±94.93 pg/mL respectively) compared to serum level in the healthy controls (mean ± SD 65.1±47.6 pg/mL, p<0.05 and p=0.001 respectively). In KOA patients, the serum and SF midkine levels were significantly increased in KOA patients (mean ± SD 80.79±31.8 pg/mL and 216.31±94.93 pg/mL respectively) compared to serum level in the healthy controls (mean ± SD 65.1±47.6 pg/mL, p<0.05 and p=0.001 respectively). In KOA patients, the serum and SF midkine levels were significantly increased in KOA patients (mean ± SD 80.79±31.8 pg/mL and 216.31±94.93 pg/mL respectively) compared to serum level in the healthy controls (mean ± SD 65.1±47.6 pg/mL, p<0.05 and p=0.001 respectively).

Conclusions: Osteoarthritis patients who have significantly elevated serum and synovial levels of midkine that were obviously associated with radiological progression of knee osteoarthritis.

**SAT0553 DETECTION OF SERUM LEVEL CHANGES OF MATRIX METALLOPROTEINASE-13 AND INTER LEUKIN-1 BETA DURING REMISSION AND FLARE-UPS OF PRIMARY OSTEOARTHRITIS OF THE KNEES**

Y. Hussein Gazar, H. Bassioumi. Alazhar University Hospital, Cairo, Egypt

**Background:** The diagnosis of osteoarthritis is currently based on radiographic criteria (eg, joint space width) and clinical symptoms (eg, pain and loss of function). The evaluation of new disease-modifying osteoarthritis drugs (DMOADs) is performed on the same basis, since the regulatory bodies currently require evidence for an impact on radiographic joint space narrowing (JSN) and an impact on symptoms. However, the limitations of radiography have led to the research into alternative parameters for monitoring osteoarthritis that could serve as biomarkers in drug development.

**Objectives:** Detection the serum level of MMP-13 and IL-1 beta in OA of the knee during remission and exacerbation and if these Biomarkers can be validated as gold biomarkers in assessing OA progression and drug development in OA treatment.

**Methods:** This study was performed on 60 patients with knee osteoarthritis, 18 males (30%) and 42 females (70%), all diagnosed as osteoarthritis of one or both knees. Their ages ranged from (40-65) years. The duration of their disease ranged from one to 15 years. The control groups were 8 males (32%) and 17 females (68%). Their ages ranged from (40-65) years. The patients were allowed to continue on the medications that they have been on during the study.

**Results:** Among 50 patients with knee OA, 32 patients had flare-ups (during one year follow-up) showing the statistically significantly highest mean IL-1 beta & MMP13 level.

**Conclusions:**

- There is a potential role for IL1 beta and MMP 13 biomarkers in assessing the development in osteoarthritis.
- IL 1 beta and MMP 13 were found to be correlated positively in patients with knee OA this correlation sounded right as the expression of MMP 13 depends on the presence of IL 1 beta.
- Although most medications groups failed to lower the level of IL 1 beta and MMP 13 yet there was a numerical difference in favor of Diacerein and NSAID.
- Patients on both Diacerein and NSAID had the lowerest rate of flare ups.
- It is recommended that the early measurement of biomarkers may detect cases to progress and thus stronger treatment may be given for these groups.

**SAT0554 INVESTIGATION OF SELECTED BIOCHEMICAL MARKERS IN KNEE OSTEOARTHRITIS COHORT**

Y. Luo1, Y. Hei1, A.S. Siebuhr2, S. Hoelt1, D. Felson2, M. Karstad1, A.-C. Bay-Jensen1, Biomarkers & Research, Nordic Bioscience, Herlev, Denmark; 2Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, United States

**Background:** Osteoarthritis (OA) is a major cause of functional impairment and disability among the elderly. There is an unmet need for the development of biomarkers for identifying patients with high risk for OA and for monitoring drug efficacy. Specific and sensitive biochemical markers revealing the turnover of bone, cartilage, and synovial tissue may be useful for investigation and monitoring of OA.

**Objectives:** To investigate a targeted set of five biochemical markers, which reflect cartilage turnover, for their ability to evaluate the prevalence of radiographic and symptomatic knee osteoarthrosis (OA) in a study from the cross-sectional Framingham OA cohort (FOA).

**Methods:** The subjects from the community-based FOA cohort were divided up based on a terminology proposed by the FNIH-OAI consortium. Two main groups were defined: subjects with radiographic knee OA (ROKA, n=80) and a group with no radiographic OA (NROKA, n=136). The presence of ROA as any Kellgren-Lawrence (KL) grade ≥3 or the ROKA group were further divided into two groups; those with persistent symptoms of a joint (ROKA+S, n=30) and those without (ROKA-, n=50).

- IL-1 beta was negatively associated with the level of Roa and persisted in the ROKA+ group. It is recommended that the early measurement of biomarkers may detect cases to progress and thus stronger treatment may be given for these groups.

- The subjects of this study provide two major findings: 1) aggrecan degradation is not just aggrecan degradation and different neo-epitopes have distinct clinical relevance; 2) CRPM is a candidate biomarker of disease activity and for patient profiling. This data suggest a reference for interpretation of OA subject biomarker data in future human studies.

**SAT0555 MRI-DETECTED KNEE OSTEOARTHRY: NATURAL HISTORY AND STRUCTURAL RISK FACTORS AFFECTING CHANGE**

Z. Zhu1, W. Han2, S. Zheng2, T. Winzenberg2, F. Cicuttini1, C. Ding2, G. Jones2 on behalf of Musculoskeletal Unit, Menzies Institute for Medical Research. 12779, Hobart, Australia; 2Macquarie University, 12779, Hobart; Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia

**Background:** Although magnetic resonance imaging (MRI) has been proved to be far more sensitive than conventional radiographs to detect OP, the natural history of MRI-detected OP in older adults has not yet been described, and it is unclear whether knee structural abnormalities, including cartilage defects, cartilage volume, bone marrow lesions (BMLs), meniscal extrusion, infrapatellar fat pad (IPFP), and effusion-synovitis, can predict osteoarthritis change.

**Objectives:** To describe the natural history of knee MRI-detected OP, and to determine if knee structural risk factors are associated with change of MRI-detected OP in a longitudinal study of older adults.

**Table 2. Odds ratios of OA in the substudy. Values in bold represent associations p < 0.05.**
Methods: A total of 1000 patients with severe infection were included, 75% of whom were biologic-naïve. The baseline characteristics of both groups were compared. The outcome measure was the rate of serious infections during repeat cycles of RTX. Results: The rate of serious infections was 9.5% in RTX-naïve patients and 12.5% in repeat cycles. Conclusions: Repeat cycles are effective for maintenance but may lead to hypogammaglobulinaemia. Low IgG autoimmunity is not associated with increased OPs over time.

Results: 550 patients were female, median age (IQR) at RTX initiation 58 (46–68) years and median disease duration (IQR) 7.9 (3.4–15.0) years. 506 (72%) had RA, 94 (13%) SLE, 49 (7%) AAV, 14 (2%) DM, 5 (1%) APS, 6 (1%) SSc and 26 (4%) other CTD. 364 (52%) were biologic-naïve and 515 (74%) were on concomitant DMARDs. Total follow-up: 2940 patient-years (PY), 284 serious infections were recorded in 179 patients (9.7/100 PY); 88 cases within 12 months of cycle 1 (C1). In MVA, previous severe infection (OR 10.7, 95% CI 5.8–19.5), low IgG (OR 3.6, 95% CI 1.5–8.6), previous cancer (OR 2.9, 95% CI 1.2–6.6) and chronic lung disease (OR 1.7, 95% CI 0.9–3.1) increased the odds of a severe infection within 12 months of C1. A diagnosis of CTD was associated with lower risk (OR 0.5, 95% CI 0.2–0.9). Low IgG at RTX initiation was predicted by older age, previous cancer, RA diagnosis, previous severe infection and previous treatment with cyclophosphamide. In C1-C3, higher rate of change in IgA and IgG levels were associated with serious infections (Figure 1). Overall, only 7% of the patients required Ig replacement in this cohort.

Conclusions: Knee MRI-detected OP in adults is common and, in contrast to radiographs, is likely to progress over a relatively short period. Progression can be predicted by structural risk factors suggesting they are a consequence of these abnormalities.

RISK FACTORS FOR SEVERE INFECTION AND RATIONALE FOR IMMUNOGLOBULIN MONITORING DURING RITUXIMAB TREATMENT IN AUTOIMMUNE RHEUMATIC DISEASES

M.Y. Md Yusof1,2, E.M. Vital1,2, D. McEneny3, E.M. Hensor1,2, S. Das1, M.H. Buch1,2, P. Emery1,2, S. Savic1,2.*Rheumatology, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; 2NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; 3Institute of Population Health, University of Manchester, Manchester, United Kingdom

Background: Rituximab (RTX) has been used in the treatment of various autoimmune rheumatic diseases (AIRDs) for over a decade. Repeat cycles are effective for maintenance but may lead to hypogammaglobulinemia. Low IgG at baseline has been associated with post-treatment infection rate but may be confounded by other clinical variables and fully adjusted models with method for handling missing data have not been presented. Importance of post-treatment infection and IgG subclasses being associated with increased risk of post-treatment infection. Further analysis including predictors of serious infections in repeat cycles is in progress and will be used to develop guidelines for safety monitoring of rituximab.

CHIKUNGUNYA OUTBREAK IN BRAZIL: DEMOGRAPHIC AND CLINICAL CHARACTERIZATION OF 732 PATIENTS – CHIKBRASIL COHORT

A.L. Duarte1, C.D.L. Marques1, P.R. Santos1, A. Ranzolin2, N.G. Cavalcanti1, R.S. Gonçalves3, A.T. Dantas1, M.S. Luna1, C.A. Andrada1, L.F. Rocha Junior1, M.R. Freitas3, P.R. Melo1, L.D. Valadares4, C.A. da Fonte4, M.L.D. Valadares4, E. Freire5, A.K.G. Melo5, M.M. Medeiros6, M.C. Bezerra6, V.B. Marques6, R.A. Océa7. 1Internal Medicine, Universidade Federal de Pernambuco; 2Rheumatology, Hospital Getulio Vargas, Recife; 3Rheumatology, Universidade Federal da Paraíba, João Pessoa; 4Rheumatology, Universidade Federal de Pernambuco; 5Rheumatology, Hospital Universitário Pedro II, Rio de Janeiro; 6Rheumatology, Universidade Federal do Ceará, Fortaleza; 7Rheumatology, Universidade Federal de Sergipe, Aracaju, Brazil

Background: Chikungunya Fever (CF) is a disease characterized by acute febrile arthritis and caused by a mosquito-transmitted alphavirus. Considering the wide distribution of the vector, the presence of imported cases from 2010 and Brazilian population’s susceptibility, there was a dispersal and establishment of Chikungunya virus (CHIKV) throughout the country. Since 2014, the CF has achieved a large proportion of the Brazilian population and has been responsible for the development of chronic joint symptoms in thousands of people.

Objectives: To describe the demographic, clinical and serological characteristics of patients from specialized Rheumatology services from northeastern Brazil, in a large, multicenter cohort.

Methods: Data from 732 patients in a prospective, multicenter, observational cohort conducted in six research rheumatology centers were analyzed. Patients
18 years or older who fulfilled the clinical and epidemiological Health Ministry criteria for case definition of CF were included in the study, from April to December 2016.

Results: From 732 patients included, 83.1% were women. The mean age was 54.1 (± 13.4) years; 92.4% lived in urban area and 58.6% had only primary education. The most common comorbidities were hypertension (43.8%), hyperlipidemia (25.3%) and diabetes mellitus (13.7%). Prior rheumatologic disease was observed in 16.4% patients, being the most frequent rheumatoid arthritis (32.5%), osteoarthritis (32.5%) and spondyloarthritis (11.7%). Arthritis was the most frequent symptom referred by all patients; fever and fatigue were also common manifestations, being referred by 95.3% and 97.1% of patients, respectively. Arthritis occurred in 84.3%. The most frequent joint pattern involvement was polyarticular (67.8%) and the additive (84.0%). At the first appointment with the rheumatologist, 75.9% had been or were under corticosteroids, frequently with an average dose of prednisone (8.8 mg) or equivalent; was observed an median of 8 painful joints (IQR 4–21) and arthritis was found in 73.6% patients, with an median of 2 swollen joints (IQR 0–5). The median score of patient global assessment at the time of the initial evaluation was 6 (IQR 4–6) using a 10 points visual analogue scale. After resting stiffness was referred by 86.0%, with 56.8% of these longer than 30 minutes. The most commonly prescribed medications were corticosteroids (58.3%) and hydroxychloroquine (59.1%). The serological tests for CHIKV were positive for IgM in 97.1% and for IgG in 71.7% of patients.

Conclusions: This is the first descriptive study of a cohort Brazilian patients with CF, as an expression of care of patients when compared to those described in the literature. Most of the features of patients in our cohort were similar to the results described in studies/cohorts published.

SAT0558 Concordance between Clinical-Epidemiological Criteria and Chikungunya Fever Serology

Background: The first autochthonous reports of Chikungunya fever (CF) in Brasil was confirmed in 2014, and by December 2016, there were 263,980 probable cases of CF; 55.03% confirmed. According to recommendations of the Ministry of Health (MH) of Brasil, in an established epidemic situation, the diagnosis of CF should be made by applying clinical and epidemiological criteria. There is no indication for the serology for Chikungunya virus (CHIKV) in the acute phase, except in atypical or complicated clinical situations, which may generate doubts in clinical practice about the correct diagnosis of these patients.

Objectives: The objective of this study was to evaluate the concordance of the clinical and epidemiological criteria with the serology results for CF in a cohort of patients with CF.

Methods: The multicenter cohort CHIKBRASIL from the Northeast of Brasil has enrolled CF patients with joint manifestations since April 2016, using as inclusion criteria the presence of fever and arthralgia/arthritus in a patient residing or who had visited an endemic or epidemic area within 15 days prior to the onset of symptoms. In the present study, we evaluated patients in which IgM and/or IgG serology was performed, regardless of the results. For the analysis of agreement with the criteria, the most characteristic symptoms of CF were used individually (fever, arthralgia/arthritus or exanthema) and three models of association of symptoms were created: fever and arthralgia (2) fever and arthritis (3) fever and arthritis/arthritus, and exanthema. The sensitivity (SENS), specificity (SPEC), positive predictive value (PPV) and negative predictive value (NPV) of the criteria were also assessed, with the serology result considered the gold standard.

Results: A total of 143 patients were evaluated, 119 (83.2%) of which were female, with a mean age of 53.89 years (± 13.5); 52.4% of the cases were in the subordinate phase of the disease (15 days to 3 months) and 42.7% were in the chronic phase (over 3 months). The IgM positivity was observed in 95.1% of cases and IgG in 71.67%. The concordance rate between the IgM serology of CHIKV and the clinical criteria (fever and arthralgia) was over 80% for any of the symptoms/symptoms model analyzed, as well as the SENS and PPV of the symptoms/symptoms model, which was over 95% in all situations evaluated. The concordance rate for IgG serology ranged from 51.9 to 72.1%. Model 1 presented the highest agreement with the result of positive combined serology.

Conclusions: During an epidemic situation, the criteria and epidemiological criteria shows high agreement with the serology result, regardless of the combination of symptoms presented, with high sensitivity and positive predictive value.

SAT0559 Septic Arthritis in Coventry in the UK: 5 Year Data

A. Vivekananthan1, I. Kahlon1, M. Ai1, A. Metcalfe2, S. Dubey1.

Rheumatology & Orthopaedics Hospitals Coventry and Warwickshire, CV2 2DX, United Kingdom

Background: Septic arthritis (SA) is a serious condition associated with significant morbidity and prolonged hospital stay, posing a large economic burden to healthcare systems. It affects 2–10 people per 100,000 and there has been a suggestion that the incidence is increasing due to iatrogenic causes [1]. Our local secondary centre, University Hospitals Coventry and Warwickshire NHS Trust (UHCW NHS Trust), provides care to Coventry and Rugby covering an estimated population of 550,000.

Objectives: To investigate the incidence of native joint SA in the adult population in a secondary care hospital in the UK. To investigate whether immunosuppression contributes significantly to the burden of SA.

Methods: Patients were retrospectively identified on the basis of the International Classification of Diseases (ICD)-10 coding generated following discharge from hospital for all patients between 2007–11. Exclusion criteria included paediatric patients, diabetic foot, prosthesis joint infections and those who on review were not thought to have SA. The data was analysed using Excel. Formal ethical approval was obtained via the research and development department within the UHCV NHS Trust.

Results: A total of 189 admissions were coded as SA. Of these, 103 were excluded (n=74 not thought to have SA on review of the notes, n=26 paediatric patients and n=3 prostatic joints). Therefore, there were 86 adult admissions for 64 patients with SA. The mean age of these patients was 53.4 years, with the majority of them being males (n=43, 67.2%). The majority of patients had co-morbidities (n=44, 65.7%), with hypertension (n=10, 14.9%) and type 2 diabetes (n=10, 14.9%) being the most prevalent. Joint aspirates were performed on 63.2% (n=56) of admissions and blood cultures on 70.8% (n=63) of admissions. Staphylococcus aureus was the most commonly cultured microbe (n=54, 64.2%) and blood and (42.9%, n=3). The knee was the commonest joint involved (n=31, 46.3%). Other commonly affected joints included the small joints of the hands (n=9, 13.4%) and shoulderacroametocavicularternosttloartic joints (n=9, 13.4%). Interestingly, 23 (35.9%) of the patients were immunocompromised. Of these, 4 patients had a diagnosis of rheumatoid arthritis (RA) and were on steroid treatment alone (n=2), or in combination with disease-modifying anti-rheumatic drugs (n=2). A total of 11 patients had a pre-existing rheumatological diagnosis of which RA was the most common condition (n=6). Two of these patients were not on immunosuppressants. The 5-year mortality was significant at 23.7% (n=19).

Conclusions: Our local data showed the incidence of SA to be approximately 3 per 100,000, which is in keeping with proposed figures. Our cohort highlighted that those with pre-existing co-morbidities or those who were immunocompromised were at greatest risk. An ageing population with multiple co-morbidities means the incidence of SA is set to rise. Greater emphasis therefore needs to be placed on improving awareness and optimising treatment.

SAT0560 Coexistence of Septic and Crystal-induced Arthritis: A Diagnostic Challenge

Background: Septic arthritis (SA) is a rheumatologic emergency as joint destruction occurs rapidly and can lead to significant morbidity and mortality. Accurate diagnosis can be particularly challenging in patients with underlying inflammatory joint disease. Crystal-induced arthritis (CA) is a risk factor for its appearance. When both conditions appear simultaneously, CA may mask diagnosis of infection and delay the antibiotic treatment.

Objectives: To describe the characteristics of patients with concurrent septic and CA.

Methods: Retrospective analysis of patients with coexistence of septic and CA attended between 1985 and 2015 in a university hospital with a reference area of 850,000 inhabitants. We collect demographic, clinical, laboratory and imaging data as well as patient medical treatment, complications and evolution records. All patients had positive bacterial culture (blood and/or joint fluid) and crystals in synovial fluid.

Results: A total of 123 patients with SA were identified. 20.3% (n=25) of them had concomitant CA, with mean age of 67 years (SD 14), 17 (68%) males and 8 (32%) females. Risk factors were: diabetes (24%), diuretic drugs (24%), chronic renal failure (16%) -2 of them undergoing hemodialysis and 4 kidney
transplant patients with immunosuppressive treatment. In only 2 cases there was a previous arthrocentesis. The mean diagnostic delay was 14 days (SD 13) (data available in 14 cases). The most commonly affected joint was the knee (48%), followed by the foot (20%) and the hip (12%). In 2 cases several joints were involved at the same time. In synovial fluid cytological studies, the most frequently identified crystals were: urate (60%), calcium pyrophosphate (20%) and hydroxyapatite (8%). In 32% of cases gram staining was positive, but 88% of patients had a positive joint fluid culture, with the most commonly identified germs being methicillin-sensitive S. aureus (48%), methicillin-resistant S. aureus (MRSA) (12%) and M. tuberculosis (12%). 32% of patients presented positive blood cultures (12% with negative synovial fluid culture), although 48% of patients had fever at the time of diagnosis. It should be noted that 48% had radiological baseline damage. Surgical debridement was performed in 32% of patients. Evolution was successful in 56% of patients; although intercurrent complications were present in 40% who required oxygen 8%, one case due to acute pulmonary edema and the other because of septic shock.

Conclusions: Coexistence of infectious and CA represents a diagnostic challenge and requires a high suspicion index. It usually appears in elderly patients with comorbidities. Gout was the most prevalent CA. S. aureus was the most commonly causative pathogen, with a high rate of MRSA infection. If it's treated early the evolution is usually favorable, which makes synovial fluid microbiological study imperative.

**SAT0562** | CHIKUNGUNYA FEVER IN PATIENTS WITH PRIOR RHUematic DISEASES: IS IT MORE SEVERE?

Background: Chikungunya fever (CF) is an infectious disease caused by a RNA virus and its transmission occurs by the inoculation of the virus by the female bite of Aedes aegypti mosquito. In Brazil, where the vector is endemic, the virus rapidly disseminated and there was an epidemic, especially in the Northeast region of the country with 263,980 notified cases in 2016. It is known that CF may have a chronic course with arthritic symptoms, however there is not consistent data in the medical literature on CF evolution in patients with prior rheumatic diseases.

Objectives: To assess whether there is any difference in the characteristics of arthritic manifestations of CF in patients with prior inflammatory rheumatic diseases (IRD), non-inflammatory rheumatic diseases (NIRD) and controls (patients with no diagnosed prior rheumatic diseases).

Methods: Cross-sectional study using a database from CHIKBRASIL cohort. Patients enrolled had clinical and epidemiological characteristics of CF and were classified in three groups: IRD (rheumatoid arthritis, axial spondyloarthritis and systemic lupus erythematosus), NIRD (fibromyalgia and osteoarthritis) and controls (no prior rheumatic diseases).

Results: In a total of 150 patients were enrolled. There were 55 patients with IRD, 40 patients with NIRD and 55 controls, paired by age and sex. There were no differences in acute phase symptoms in the groups. There was a more frequent occurrence of arthritis in patients with IRD compared to NIRD (p=0.001) and to controls (p=0.002). In 89.1% of the patients with IRD there was an underlying disease exacerbation and 74% described an expressive worsening of symptoms compared to the period prior to infection. Patients with IRD had an increase in the current dose of corticosteroids (median 10mg, IQR 10–20) compared to previous dose used (median 8mg, IQR 5–10) after the onset of CF (p=0.0007). Importantly, there was more methotrexate prescription (23.5%) in IRD group, compared to NIRD group (0, p=0.001) and to controls (3.7%, p=0.003).

Conclusions: Patients with IRD and CF presented significantly more arthritis compared to NIRD or to controls. CF seems to induce underlying rheumatologic disease exacerbation in patients with inflammatory disease and a more aggressive therapeutic approach might be necessary in this group of patients.

**SAT0561** | USEFULNESS OF POLYMERASE CHAIN REACTION FOR DIAGNOSING WHIPPLE'S DISEASE IN RHUMATOLOGY

Background: No consensus exists about the combination of clinical, laboratory, and radiological findings that warrant tests for Whipple's disease.

Objectives: The primary aim of this multicentre retrospective study was to determine when patients evaluated for rheumatological symptoms should undergo T. whipplei PCR testing. Secondary aims were to describe the clinical patterns and treatments used, to determine the diagnostic yield of PCR testing, and to assess whether centres with higher numbers of tests also had a larger number of Whipple's disease diagnoses.

Methods: In a retrospective observational study done in five hospitals, we assessed the clinical and radiological signs that prompted T. whipplei PCR testing between 2010 and 2014, the proportion of patients diagnosed with Whipple's disease, the number of tests performed and the number of diagnoses according to the number of tests, the patterns of Whipple's disease, and the treatments used.

Results: At least one PCR test was performed in each of 267 patients. Rheumatic signs were peripheral arthralgia (n=239, 89%), peripheral arthritis (n=173, 65%), and inflammatory back pain (n=65, 25%). The main extra-articular signs were constitutional symptoms (n=41, 11, 41%), diarrheaoa (n=70, 26, 5%), fever (n=53, 20%), lymphadenopathy (n=14, 5, 3%), and neurological signs (n=11, 4, 2%). Whipple's disease was diagnosed in 13 patients (4,9%). The main samples tested and the more frequently positive tests in the centres with diagnoses of Whipple's disease were saliva and stool. In the centres with no diagnoses of Whipple's disease, arthritis was less common, whereas constitutional symptoms, fever, and lymphadenopathy were more common. 11 patients with Whipple's disease had the annual incidence ranged across centres from 0 to 36.1/100000 inhabitants. The group patients with Whipple's disease had a higher proportion of males, older age, and greater frequency of arthritids.

Conclusions: Males aged 40–75 years with unexplained intermittent seronegative peripheral polyarthritis, including those without constitutional symptoms, should have T. whipplei PCR tests on saliva, stool and, if possible, joint fluid.

SAT0564 SUBLINGUAL VACCINE: NEW CHALLENGE IN THE PREVENTION OF RECURRENT INFECTIONS IN AUTOIMMUNE DISEASES

K. Llano Hernández 1, S. Sanchez Ramón 1, J. Ochoa Grullón 1, P. Macarron 2, C. Morado 2, C. Martínez-Prada 2, A. Rodríguez De La Peña 1, E. Rodríguez Frias 1, M. Nuñez Beltran 1, B. Fernández 2, J.A. Joker 2, G. Candelas 2.

1Immunology; 2Rheumatology, Madrid Clinic Hospital, Madrid, Spain

Background: Disease-modifying antirheumatic drugs (DMARDs) and new biologicals have improved the prognosis of systemic autoimmune diseases (SAD), but recurrences increase the risk of recurrence with tetracyclic antidepressants (RRTI) and urinary tract (RUTI) infections. Given the rising of antibiotic resistance, the search for new strategies for the prevention of recurrent infections is a priority.

Objectives: The purpose of this study was to evaluate the clinical benefit of the sublingual polybacterial vaccines on infections’ rates in SAD patients.

Methods: A retrospective observational study on a cohort of SAD patients on active immunosuppression with RRTI and RUTI was conducted. Patients were treated with multibacterial sublingual vaccine formulations either for RRTI (Staphylococcus spp., S. pneumoniae, K. pneumoniae, M. catarrhalis, H. influenzae), or/and RUTI (K. pneumoniae, E. coli, E. faecalis, P. vulgaris) (Bactek/Uromune® ImmuneL. SL Madrid, Spain) for 3-months period and clinical follow-up at 6- and 12-months. We monitored the frequency of infections, the intensity and severity of infections during follow-up. Immunological evaluation was performed, including: Serum immunoglobulin levels, IgG subclasses, specific antibodies’ production: anti-pneumococcal, anti-Typhi polysaccharide and anti-tetanus toxoid antibodies, and B and T cell phenotype.

Results: A total of 50 patients were evaluated, and 34 were eligible at 12-months. The mean age of the patients was 58±13 years, 31 women (91.7%) and 9 men (8.3%). All patients were positive for at least one of the following: 21 (67.6%) with systemic lupus erythematosus (SLE), 8.2% (n=5) mixed connective tissue disease, 2.94% (n=1) ankylosing spondylitis, 2.94% (n=1) psoriatic arthritis, 2.94% (n=1) SLE/RA, 2.94% (n=1) discoid LE/Sjogren, 2.94% (n=1) adult onset Still disease, 2.94% (n=1) sarcoidosis, 2.94% (n=1) SLE-like. All patients showed a significant decrease in RRTI (3.15±2.66 vs 0.46±1.07, p<0.01) and RUTI (1.85±2.49 vs 0.35±1.06, p<0.01) frequency and use of antibiotics at 6-months of vaccine, except one with sarcoidosis. 23 of 34 patients (67.6%) disclosed defects on specific antibody production to polysaccharide and protein immunization. Three patients with antibody production deficit and protein immunization. Three patients with antibody production deficit and protein immunization. Three patients with antibody production deficit and protein immunization.

Conclusions: Mucosal vaccination in immunosuppressed patients due to SAD with recurrent infections resulted in lower rates of RRTIs and RUTIs with subsequent improvement in their quality of life. Our preliminary results need to be validated in controlled trials.

SAT0565 THE FREQUENCY OF SEPTIC ARTHRITIS AFTER ARTHROCENTESIS AND INTRA ARTICULAR GLUCOCORTICOID INJECTION IS LOW

S.K. Petersen, R.A. Andreassen, I.M.J. Hansen. Rheumatology, Odense University Hospital, Svendborg Hospital, Svendborg, Denmark

Background: Intraarticular (IA) procedures have both diagnostic and therapeutic purposes in patients with arthritis. The therapeutic benefit of IA glucocorticoids (GC) injection in patients with rheumatoid arthritis (RA) 23.52% (n=8) with systemic lupus erythematosus (SLE), 8.2% (n=5) mixed connective tissue disease, 2.94% (n=1) ankylosing spondylitis, 2.94% (n=1) psoriatic arthritis, 2.94% (n=1) SLE/RA, 2.94% (n=1) discoid LE/Sjogren, 2.94% (n=1) adult onset Still disease, 2.94% (n=1) sarcoidosis, 2.94% (n=1) SLE-like. All patients showed a significant decrease in RRTI (3.15±2.66 vs 0.46±1.07, p<0.01) and RUTI (1.85±2.49 vs 0.35±1.06, p<0.01) frequency and use of antibiotics at 6-months of vaccine, except one with sarcoidosis. 23 of 34 patients (67.6%) disclosed defects on specific antibody production to polysaccharide and protein immunization. Three patients with antibody production deficit and protein immunization. Three patients with antibody production deficit and protein immunization.

Conclusions: Mucosal vaccination in immunosuppressed patients due to SAD with recurrent infections resulted in lower rates of RRTIs and RUTIs with subsequent improvement in their quality of life. Our preliminary results need to be validated in controlled trials.

SAT0566 ELECTRONEUROGRAPHIC FINDINGS IN PATIENTS WITH SUBACUTE/CHRONIC ARTICULAR SYMPTOMS OF CHIKUNGUYA FEVER AND NEUROPATHIC COMPLAINTS – PRELIMINARY RESULTS

L.F. da Rocha Jr 1,2, H.D. de Lima 1, R.M. Correia 1, M.R.D.A. Freitas 1, P.R.S. de Melo 1, A.G.L. de Mattos 1, A.F.R. de Oliveira 1, C.D.L. Marques 1, A.L.B.P. Duarte 1, O. Lima 1, A. Ranzolin 1, Instituto de Medicina Integral Professor Fernando Figureira, Hospital Das Clínicas de Pernambuco, Recife, Brazil

Background: The mechanisms of nonarticular pain associated with Chikungunya virus (CHIKV) infection are still poorly understood. Many patients that progress to Subacute/Chronic phases have neuropathic pain (NP) besides the articular symptoms. The NP is associated with a less favorable outcome, with greater impact on quality of life and lower efficacy of treatment. The NP can reflect a dysfunction of the nervous system, rather than a neurological lesion induced by CHIKV, but the pathophysiology of the neural dysfunction is not completely understood. There are no studies evaluating the electroneurographic findings in patients with CHIKV infection and neuropathic symptoms.

Objectives: To evaluate the results of electroneuography (ENoG) of patients with Chikunguya Fever (CF) and neuropathic symptoms.

Methods: Patients with diagnosis of CF (clinical and epidemiological) and symptoms of paresthesias underwent EMG of upper and lower limbs. The electrodiagnostic evaluation consisted of nerve conduction study of median, ulnar, tibial, fibular, sural and plantar nerves. Clinical and epidemiological data were also recorded.

Results: The sample was composed by 18 patients (82.3% females) with mean age of 56 (±9.8) years. The mean duration of symptoms of CF at the time of the ENoG was 23.8 (±10.8) weeks and the average of tender and swollen joints (including ankle and foot) was 29.6 (±21.5) and 9 (±9.9), respectively. The mean score of visual analogic scale (VAS) for pain was 4.4 (±2.4) and for fatigue was 5.9 (±2.3). Nine patients (50%) had pain in 10. No patient presented axial pain and the number of painful joints was higher in upper (19.4±13.9) compared to lower limbs (10.2±8.4). Only 3 patients reported unspecific paresthesias prior to the onset of arbovirus and worsening after CF. However, these 3 patients had normal ENoG. Six patients had diabetes. Mononeuropathy was the most frequent result occurring in 12 subjects (67%). Bilateral mononeuropathy of median nerve (at carpal tunnel) was found in 11 patients and one subject had median neuropathy just on the left hand. Other mononeuropathies were also present: bilateral tibial nerve in 4, bilateral plantar nerve in 2 and bilateral fibular nerve in 1 patient. Distal axonal polyneuropathy was present in 8 cases (6 sensory and 2 sensorimotor); 5 of these were diabetic. The ENoG was normal in 4 cases. Ten patients were in use of prednisone (mean dose 11.4mg/d) and just 6 were using antineuropathic agents.

Conclusions: Our preliminary results indicate that the ENoG is altered in most patients with chronic articular manifestations of CF and associated paresthesias. Mononeuropathy is the most frequent finding, even in the chronic phase of the disease when the nonarticular edema is not common. Further clinical studies with a larger number of patients and follow-up tests will be needed to confirm our data.

SAT0567 IMPACT OF CHIKUNGUNYA FEVER ON FUNCTIONAL STATUS AND QUALITY OF LIFE – A PROSPECTIVE COHORT STUDY OF BRAZILIAN PATIENTS

L.F. da Rocha Jr1,2, M.R.D.A. Freitas1, A.G.L. de Mattoes1, H.D. de Lima1, R.M. Correia1, F.G.T. Vieira1, A.L.B.P. Duarte2, C.D.L. Marques2, W.L.M. de Oliveira1, P.R.S. de Melo1, A. Ranzolin3,4,5, Instituto de Medicina Integral Professore Fernando Figueira,6 Hospital Das Clínicas de Pernambuco, Recife, Brazil

Background: An epidemic of Chikungunya Fever (CF) spread throughout South America in 2014. The acute manifestation of CF typically consists of febrile arthritis. The burden of the chronic articular manifestations remains a public health issue affecting activities of daily life. There is a very important impact on quality of life in patients affected by CF, even at chronic phase. The long-term functional status may also be affected by CF.

Objectives: To evaluate longitudinality the disability, Health Related Quality of Life (HRQOL) and functional status of patients with CF and analyze the clinical and epidemiological factors associated with different outcomes.

Methods: Patients with clinical and demographic diagnosis of CF and persistent articular symptoms were evaluated in a cohort study between May 2016 and December 2016. HRQOL was rated by Short Form-12 (SF-12) and the Global Functional Status (GFS). Data were divided per weeks after disease onset and were analysed (Spearmans’s correlation coefficient and Mann-Whitney test).

Results: Sixty-five patients (58 females), mean age of 51.3 (±13.3) years were assessed. As expected, a significant correlation between pain related scores and Physical Health Component Score (PCS), HAQ and GFS was found (p<0.05). Edema and morning stiffness correlated with PCS, HAQ and GFS status from 4 to 20 weeks after disease onset (p<0.05). There was improvement in scores of all instruments used from 4–8 weeks of disease to 12–16 weeks of disease (table 1). The worst indices of PCS, Mental Health Composite Scale Score (MCS) and GFS were scored in the first month, mean scores of 30.07±7.77, 38.13±8.54 and 3.15±1.07 respectively. Higher HAQ values were demonstrated between 4 and 8 weeks after disease onset (mean score 1.87±0.82).

Conclusions: We demonstrated the impact of CF on HRQOL and Functional Status of patients. The SF-12 Health Survey, HAQ and GFS are influenced mostly by patients pain and worsening of this status are more prominent in the first 8 weeks of disease. Further clinical studies of the impact of CF on quality of life and functional studies are needed.

SAT0568 RHEUMATOLOGICAL MANIFESTATIONS IN A SERIES OF PATIENTS WITH CHIKUNGUNYA FEVER

A.M. Sagap Duran1,2, A.M. Beron1,2, S. Sagap Duran3, C. Coral Cristado4, G. Medina5, G. Nasswetter6, D. Dubinsky7, Rheumatology, Hospital Universitario Japones, Santa Cruz, Bolivia, Plurinatal State Of;
2Rheumatology, Clinical Hospital “Jose de San Martin”; University of Buenos Aires, CABA, Argentina

Background: Chikungunya fever is characterised by a high probability of persistent rheumatological manifestations, producing a negative impact in the work, social and economic fields.

Objectives: To determine the frequency and type of rheumatologic involvement in the subacute and chronic phase of Chikungunya fever.

Methods: Descriptive, cross-sectional study. We included patients ≥ 16 years old with Chikungunya infection (real time PCR, IgM or IgG for Chikungunya) who consulted consecutively for rheumatic symptoms/signs from March 2015 to March 2016. According to the time of evolution, the disease was divided in 2 Phases: acute (<10 days of duration) and subacute/chronic (>11 days).

Results: Two hundred and two patients were evaluated, 80 were excluded due to negative serology for Chikungunya. 122 were included: 107 (88%) female, mean age 52.52±13.19 years, and time of evolution of 116.66±91.61 days. Acute phase, 122 patients: fever 85 (69.67%), rash and pruritus 54 (44.26%), tenosynovitis 23 (18.8%), polyarthralgies 100 (82%) and arthritis 56 (45.90%). Chronic phase. 122 patients: 71 (58%) patients had a chronic persistent rheumatologic manifestations and 51 (42%) presented remission of symptoms but all of them presented subsequent recurrence in an 91±40 days. NARC in 33 patients (27%) and AR in 89 (73%), with no significant differences in age and time of evolution was observed.

NARC: 14 (42.4%) exacerbation of previous osteoarthritis pain, 9 (27.3%) developed fibromyalgia and 10 (30.3%) had localized soft tissue pain.

Conclusions: The frequency of rheumatological manifestations post Chikungunya fever in our sample was high, and can trigger ARC. Patients presenting new immunological manifestations in an endemic area for Chikungunya fever should have a serologic test performed. This series of patients must be evaluated with long-term studies to define their evolution, under the possibility of developing definite autoimmune disease or remission.

SAT0569 OUTCOME OF PATIENTS WITH SYSTEMIC RHEUMATIC DISEASES ADMITTED IN INTENSIVE CARE UNIT: A PROGNOSTIC STUDY OF 98 PATIENTS

A. Malejczyk-Picard1, H. Hivernat1, N. Marits1, G.-J. Fuzibet2, G. Bernardin3, V. Queyrel1,1, Internal medicine department;2Intensive care unit, Centre Hospitalier Universitaire de Nice, Nice, France

Background: Systemic rheumatic diseases (SRD) are a rare and heterogeneous group of diseases, associated with a high mortality rate due to the natural evolution of the disease and/or consequences of their specific treatments (infections, toxicity).

Objectives: To describe the clinical features, outcomes and prognostic factors for patients with SRD admitted to the intensive care unit (ICU).

Results: Ninety-eight patients (57% women; median age, 57 years [19–81years]) accounted for 108 admissions. Connective tissue disease (primarily systemic lupus erythematosus) and systemic vasculitides (mainly ANCA-associated vasculitides) represented respectively 55% and 30% of SRD. For nineteen patients, diagnosis of SRD was made at admission. Reasons for admission were: SRD exacerbations (43%), isolated infections (34%), SRD exacerbations associated with infections (12%) or other (11%). Respiratory failure was the most common organ dysfunction. Mechanical ventilation was necessary for 43 patients (44%), vasoactive drugs for 47 (48%) and extra-renal replacement therapy for 38 (39%). The ICU mortality rate was 30% and 37% one year after admission. Infection was the main cause of death (69%). The factors significantly associated with mortality in the ICU were (multivariate analysis): diabetes, cardiovascular diseases and immunosuppressive treatments on admission. At 1 year of follow-up, additional risk factors were: number of organ dysfunction at ICU admission and mechanical ventilation. It is to be noted that at 1 year of follow-up, diabetes was not anymore a prognostic factor.

Conclusions: Patients with SRD admitted to the ICU have a severe prognosis. Causes of mortality are mainly infections. Our study points out the importance of vaccination and developing new therapeutic strategies. Diagnosis of SRD in the ICU is not rare and should be systematically considered on admission. Prognostic factors of mortality in the ICU were patient comorbidities and immunosuppressive treatments on admission.

SAT0570  | AN IGNORED DISEASE IN ADULTS: ACUTE RHEUMATIC FEVER
B. Biltik 1, O. Kucukcakih 2, N. Karahan Yesil 2, H. Yesil 2, S. Ertan 2
1Rheumatology, Ankara Research and Education Hospital; 2Rheumatology, Yildirim Beyazit University, Ankara, Turkey

Background: Acute rheumatic fever (ARF) is a delayed, inflammatory sequela of pharyngitis secondary to Group A Streptococcus infection. ARF remains one of the important causes of cardiovascular morbidity and mortality in developing countries. Although it is mainly known as a childhood disease, it is also encountered in adult clinics in developing countries.

Objectives: To investigate the clinical and laboratory characteristics of patients who were diagnosed with ARF in two rheumatology outpatient clinics from June 2015 to January 2017.

Methods: The data of 20 patients (12 female; median age 29.5 (21–40) years) were evaluated. The diagnosis of ARF was based on the 2015 Jones criteria. The data collected included patient age, gender, arthralgia, arthritis, erythema marginatum (EM), subcutaneous nodules (SN), ECG/ Doppler transthoracic echocardiography/TH, and other rare findings. The erythrocyte sedimentation rate (ESR), antistreptolysin O (ASO) and CRP levels of the patients and the drugs initiated were also recorded. Anti-streptolysin O (ASO) test or throat culture were used for the evidence of preceding Streptococcal infection. Patients with post-streptococcal reactive arthritis were differentiated and excluded by clinically. Patients with positive rheumatoid factor or anti-CCP were also excluded. Joint fluid examination was done to exclude septic arthritis in patients with monarthrosis.

Results: All patients were referred to rheumatology for arthralgia or arthritis. Patients were taking some sort of nonsteroidal antiinflammatory (NSAI) drugs before evaluation. The median follow-up time was 9 months (6–18). Sixteen out of 20 patients had mono-, oligo- or polyarthritis (25%, 25% and 30%, respectively). Knees and ankles were the most common involved joints. The median duration of arthritis was 1 week (1–50 weeks). Six out 20 patients had subclinical carditis (30%). Nine out 20 patients had a history of ARF attack previously. Three patients had chronic rheumatic mitral valve thickening without any severe insufficiency. EM and SN were observed in 15% and 60% of patients, respectively. Chorea was diagnosed in one patient. NSAI drugs were given to all patients with maximum dosages. High dose salicylate therapy were not given to patients due to intolerance or side effects. Nine patients were given prednisolone therapy (5–20 mg/d). The median duration of prednisolone therapy was 2 weeks (0–6 weeks). Sulfasalazine was given to two patients for the prolonged arthritis. All patients received secondary prophylaxis with penicillin.

Conclusions: ARF should be considered in the differential diagnosis of arthritides in young adults in developing countries. ARF in adults seems to be resistant to classical NSAI drugs. Our data show that steroid therapy can be given safely instead of salicylates in carditis or arthritis.

SAT0571  | PERFORMING SEPTIC ARTHRITIS DIAGNOSIS IN SCENARIOS WHERE SYNOVIAL FLUID IS NOT AVAILABLE: MULTIVARIATE LOGISTIC REGRESSION ANALYSIS
C.A. Guillen-Astete 1, G.A. Gabilondo-Alvarez 2, 1Rheumatology Department; 2Microbiology, Ramon y Cajal University Hospital, Madrid, Spain

Background: In order to establish the diagnosis of septic arthritis (SA) it is necessary to demonstrate the presence of bacteria into the synovial fluid. However, clinicians should act according to its suspicious when the differential diagnosis included this possibility even when the microbiologic study of the synovial fluid in unavailable by any cause (small joints, lack of training or logistic deficiencies).

Objectives: The purpose of our study is to determine the relative weight of other clinical or analytical variables that should be useful in these scenarios.

Methods: A retrospective multivariate logistic regression analysis about the registries of monarthrosis assessed in our unit between 2013 and 2016. There were included only registries with cases of synovial joints with all parameters of interest available. The binary response variable was the microbiological demonstration of septic arthritis (culture/Gram stain of synovial fluid or tissue).

Explanatory variables were age (stratified in < 30, 30–39, 40–49, 50–59, 60–69 and > 70 years old), gender, temperature above of 37.9°C, recount of neutrophils in peripheral blood sample, measure of procalcitonin (PCT), and measure of C reactive protein (CRP). Synovial fluid study, although was available in almost all cases was deliberately omitted for purpose of this study. The logistic regression analysis variables were selected from the forward model strategy.

Results: There were included 449 registries. One hundred an sixteen of them were SA. The fixed model showed a Chi-square=226.64 with 5 degrees of freedom and a P<0.0001. Explanatory variable gender was excluded from the forward model strategy due to its lack of impact on the binary response variable. The Odds Ratio for PCT, PCT >1.3 ng/dL, age, neutrophils recount and body temperature were 1.0175, 8.1588, 0.5135, 1.0001 and 3.4147, respectively. The model showed a sensitivity of 68.1%, specificity of 94.8%, PPV of 82.2% and NPV of 89.5%. The following table shows the full results of the logistic regression analysis: Standard error, Wald index, p value and R coefficients.

Conclusions: Previous studies have demonstrated the usefulness of PCT measure for the diagnosis of SA however all of them have been based on joints which synovial fluid is quite easy to obtain for further analysis. Present study allows laying the ground for creation of future diagnostic models based on five clinical variables that could be useful on scenarios where the assessment by joint puncture is not available.

SAT0572  | LEVELS OF SERUM PROCALCITONINE AS DIAGNOSIS DISCERNING TOOL BETWEEN GOUT AND SEPTIC ARTHRITIS
C.A. Guillen-Astete, M. Terán-Tinedo. Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain

Background: In a previous study we demonstrated the potential usefulness of the procalcitonine serum measure in order to diagnose septic arthritis. This utility is quite important on the differential diagnosis of knee arthritis in patients with known gout or other inflammatory joint disease which can express as a monarthrosis.

Objectives: Due to that, this study aims to determine sensibility, specificity, positive predictor value and negative predictor value of procalcitonine serum measure (PCT) in patients with knee arthritis for the diagnosis of septic arthritis.

Methods: We reviewed the registries of patients who consulted due to knee acute monoarthrosis between 2013 and 2015 in which a PCT was obtained. Registries were grouped according to the final diagnosis (gouty arthritis only (group I) and septic arthritis with or without gout (group II). Based on a previous study, PCT value of 1.47 ng/mL was considered the cut point. Validation tests were applied fixed to demographic and clinical specific scenarios.

Results: Registries of 121 patients with gout and 47 patients with septic arthritis (SA) were included. From the 47 patients with SA, 9 were previously diagnosed by gout. All diagnosed were based on guidelines and clinical recommendations for SA and gout (Coakley et al. Rheumatology, 2006 and Zhang et al. Ann Rheum Dis, 2006).

Using the cut point of 1.47 ng/mL, test validation results were as follows: sensibility of 87.2%, specificity of 92.5%, PPV of 82.0% and NPV of 94.9%. Excluding patients with less than 48 hours of onset, there were 44 registries of patients with SA and 83 with gout. In this scenario the results of the validation tests were as follows: Sensibility of 93.1%, specificity of 96.3%, PPV of 93.1% and NPV of 96.38%. Excluding all patients with body temperature above 37.5°C there remained 11 with SA and 61 with gout. In this scenario the results of the validation tests were as follows: Sensibility of 72.7%, specificity of 95.1%, PPV of 66.6% and NPV of 96.2%.

Conclusions: This is the first study aimed to validate previous observations about the usefulness of PCT determination in patients with acute knee monoarthrosis. Although the global results in the validation test are a bit inferior that our original observations in a shorter pilot study in terms of sensibility, the NPV remains over 95% in scenarios where the differential diagnosis could be harder to establish such as recent onset flares or cases without an associated febrile syndrome.

**SAT0573** SOCIODEMOGRAPHIC, CLINICAL CHARACTERISTICS AND JOINT INVOLVEMENT OF A CHIKUNGUNYA EPIDEMIC IN COLOMBIA

J.C. Rueda1, J.-I. Angarita1, A.M. Santos1, E.-L. Saldarriaga1, I. Pelaez-Ballestas2, E. Couto-Luvie1, J. Londono3, 1 Reumatología, Universidad de la Sabana, Chia, Colombia; 2Reumatología, Hospital General de México, México, Mexico; 3Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá, Colombia

**Background:** During 2014 and 2015 a chikungunya epidemic took place in Colombia concurrently with a COPCORD study across the country.

**Objectives:** To describe the clinical characteristics of CHIKV infection in 6 different cities in Colombia and determine the most frequently associated clinical picture with CHIKV.

**Methods:** World Health Organization criteria was used to identify CHIKV patients. A complete characterization and confirmation was established with CHIKV immunoglobulin G and IgM serology. Four possible scenarios were established: patients who met or not the criteria for probable case, and patients who met or not the criteria for confirmed case. 

**Results:** A total of 604 patients with MSK symptoms were evaluated in 6 different cities. The sociodemographic, clinical characteristics and joint involvement of the studied population is depicted in tables 1 and 2. Sensibility and specificity of the WHO criteria were 56.2% and 91.1% respectively (PPV: 83.3%, NPV: 74.4%).

**Conclusions:** Our study revealed a good performance of IgG and regular performance of IgM for the diagnosis of CHIKV in a cohort of CHIKV patients from Colombia’s epidemic. Cut off points for both IgG and IgM were measured for future reference.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.1886

**SAT0574** PERFORMANCE OF IMMUNOglobulin M AND G (IgM AND IgG) ANTIBODIES AGAINST CHIKUNGUNYA VIRUS (CHIKV) BY ENZYME-LINKED IMMUNOSORBENT (ELISA) TECHNIQUE

J.C. Rueda1, J.-I. Angarita1, A.M. Santos1, E.-L. Saldarriaga1, I. Pelaez-Ballestas2, P. López-Morales1, J. Londono3, 1 Reumatología, Universidad de la Sabana, Chia, Colombia; 2Reumatología, Hospital General de México, México, Mexico; 3Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá, Colombia

**Background:** CHIKV is suspected based on epidemiological and clinical criteria, however confirmation of the disease is only achieved by laboratory tests.

**Methods:** IgM and IgG antibodies against CHIKV were measured by ELISA (Abcam® ab177835 and ab177835 anti-chikungunya virus IgM and IgG human ELISA kit, Cambridge, UK) technique in 604 patients with CHIKV suspicion. A typical case of CHIKV with high sensitivity and specificity obtained from a previous study was used as gold standard for diagnosis of CHIKV. Since CHIKV epidemic of 2014–2015 was the first to be reported in our country (Colombia), no second measurements of IgG were needed to confirmed infection.

**Results:** Cut off point for IgG was 14.3 SU and for IgM was 11.2 SU. Mean values for IgG was 36.7 SU (±22.7) in patients with CHIKV and 8.6 SU (SD: 6.3) for IgM. Statistical significance was obtained for both IgG and IgM (p<0.0001) when comparing patients with and without CHIKV. Receiver operating characteristic (ROC) curves showed and area under the curve (AUC) of 0.81 for IgG and 0.65 for IgM (figure 1).

**Conclusions:** Our study reviewed a good performance of IgG and regular performance of IgM for the diagnosis of CHIKV in a cohort of CHIKV patients from Colombia’s epidemic. Cut off points for both IgG and IgM were measured for future reference.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.1879
mg/L; SD±8.4). Association alleles of HLA-A, and DR are depicted in table 1. No association was found with HLA-B alleles.

CHIKV: chikungunya virus infection; CI: confidence interval 95%; Cp: Bonferroni corrected p value.

Conclusions: Our study demonstrated the alleles A*28 and A*27 were associated with resistance to CHIKV, and alleles A*68, DRB1*01, DRB1*04 and DRB1*13 were to be associated with susceptibility to CHIKV. No association was found in any HLA-B alleles.

Disclosure of Interest: None declared

**SAT0576** IMPROVED CLINICAL SCENARIO FOR CHIKUNGUNYA DIAGNOSIS

Background: The World Health Organization (WHO) criteria for chikungunya virus (CHIKV) infection are a diagnostic possibility, and the criteria are considered highly sensitive and specific. In order to test the performance of the new criteria and improve sensitivity in diagnosing and treating CHIKV patients, a new clinical scenario was developed with the agreement of CHIKV criteria according to WHO). Patients from outpatient and inpatient departments were recruited irrespective of the duration of anti-tuberculosis therapy.

Methods: We included patients who had active tuberculosis as per World Health Organization (WHO) 2010 criteria. Patients with chronic illnesses were excluded. A detailed history, examination, and appropriate investigations (blood, urine, serological and radiological) of the 100 consecutive patients fulfilling the inclusion criteria were recorded.

Results: Mean age of patients was 32.16±12.93 years. Male to female ratio was 43.57. Mean duration of disease was 6.85±8.33 months. Of the 100 patients, 60 (60%) had pulmonary tuberculosis. Pleural tuberculosis presenting as pleural effusion was seen in 17 (17%) patients. Abdominal tuberculosis was seen in 9 (9%), tuberculous lymphadenopathy in 8 (8%) and pott's spine in 4 (4%). Eye tuberculosis and tubercular breast lump were seen in 1 patient each. 83 (83%) patients had first episode of tuberculosis while the other 17 (17%) patients had second episode of tuberculosis. 74 (74%) patients were on category 1 antituberculosis treatment (ATT), while 23 (23%) were on category 2 ATT and 3 (3%) were on modified ATT. Mean duration of ATT was 1.79±1.34 months. Fibromyalgia was classified in 21 (21%) patients, polyarthralgia was seen in 9 (9%), pott's spine in 7 (7%), osteomyelitis in 4 (4%) and scleritis in 2 (2%) patients. Uveitis, tenosynovitis, erythema induratum, subcutaneous abscess and dactylitis was seen in 1 (1%) each. Rheumatological manifestations as septic arthritis, DILE, poncer's arthritis, tendinopathy, amyloidosis, gout, erythema nodosum and myositis were not seen in any patient. In 21 patients who had fibromyalgia, 11 patients developed fibromyalgia with 2nd episode of tuberculosis amounting to 60.75% patients.

Conclusions: This is the first prospective study to look at the musculoskeletal manifestations of tuberculosis. Patients with active tuberculosis were found to have various rheumatological manifestations.

**SAT0577** LEFLUNOMIDE INHIBITS THE APOTOPSIS OF HUMAN EBRYONIC LUNG FIBROBLASTS INFECTED BY HUMAN CYTOMEGALOVIRUS

O. Ren 1, H. Zeng 1, 2, Department of Pediatric Allergy, Immunology and Rheumatology; 1Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children’s Medical Center, Guangzhou, China

Background: The immunomodulatory drug leflunomide (LEF) is frequently used for treating human cytomegalovirus (HCMV), but its antiviral mechanism is still unclear.

Objectives: In this study, we investigated the effects of the active LEF metabolite AT71726 on the HCMV lifecycle in human embryonic lung fibroblasts. We clarified the mechanism of LEF antiviral infection, and provide a new way to treat immune dysfunction patients with HCMV infection.

Methods: The experiment was divided into four groups: the control group, the HCMV group, the ganciclovir + HCMV group as well as the LEF + HCMV group. The treated cell line was infected with HCMV, and was then treated by staining with fluorescein isothiocyanate (FITC) and propidium iodide. Statistical significance was determined by paired t-test using SPSS software.

Results: The results of the study showed that cell proliferation was significantly inhibited by HCMV at 24 hours and 48 hours. With increasing HCMV concentration, the value-added inhibition of the cells was significantly decreased compared with the control group, and was statistically significant (P<0.01). Ganciclovir can increase proliferation of cell-sorted into HCMV: compared with the control group it was statistically significant (P<0.05). Meanwhile, with LEF treatment cell proliferation was significantly improved at 24 hours and 48 hours, with statistical significance (P<0.05). The apoptosis rate of human embryonic lung fibroblasts infected with HCMV increased significantly at 24 hours, 48 hours and 72 hours, and as time goes on the apoptosis rate increases statistically significantly (P<0.01) compared with the control group. The apoptosis rate of the HCMV infection group decreased by adding LEF and was statistically significant (P<0.05).

Conclusions: This study shows that LEF is an exciting new drug for cytomegalovirus infection. LEF significantly inhibited HCMV infection-induced apoptosis and proliferation, playing an important role in the treatment of patients infected by HCMV. In this study we explored the potential usefulness of LEF for...
cytomegalovirus infection and found it to be a cost-effective new treatment for cytomegalovirus infection that deserves further study.

**SAT0579** LOW DOSE IL-2 RESTORES IMBALANCE BETWEEN TH17 AND REGULATORY T CELLS IN PATIENTS WITH CONNECTIVE DISEASE COMBINED EBV/CMV VIREMIA

O. Wang, C. Wang. Rheumatology, The second hospital of Shanxi medical university, TaiYuan, China

Background: DMARDs are the most important medicine in treatment of autoimmune disease. However, excessive using DMARDs lead to decrease immune function, which increasing opportunistic infection, such as EBV, CMV viremia. Recent study show the imbalance between T help cell 17 (Th17) and regulatory T cell (Treg cell) is a pivotal cause of autoimmune disease and correction of this imbalance to be a potential therapy. So whether low dose IL-2 restores the balance of Th17/Treg and improve immune function?

Objectives: To investigate the effect of low-dose IL-2 on Treg and effector lymphocyte subsets in patients with connective tissue disease (CTD) combined EBV or CMV viremia.

Methods: Clinical records of 70 CTD patients combined EBV or CMV viremia, hospitalized from May 2012 to January 2017 in the second Hospital of Shanxi medical university (Group infection), were analyzed. The group includes 21 patients who received rhl-2 after infected CMV or EBV, and 12 continue receiving DMARDs. As control, we selected 70 health persons (Group health) whose age matched with group infection, 70 naïve CTD patients with no treatment (Group treatment-naïve), and 70 CTD without viremia patients having glucocorticoid and DMARDs medical history (Group Treatment-DMARDs). The two groups’ underlying diseases are matched with the Group infection. The absolute numbers and proportions of peripheral lymphocytes (T cells, B cells, NK cells, the total number of the three cells, CD4+ T cells, CD8+ T cells), and CD4+ T cell subsets (CD4+Th1, CD4+Th2, Th17, Treg cells and Th17/Th2, Th17/Treg) were examined by flow cytometry.

Results: 1. The absolute count of Treg cells in the Group treatment-naïve was significantly low and Th17/Treg was notably increase compared with the Group health (P<0.05). The peripheral lymphocytes and Treg cells are notable low (P<0.05) and Th17/Treg was significantly increase (P<0.05) in the Group treatment-DMARDs compared with the Group treatment-naïve.
2. The peripheral lymphocytes, CD4+ T cells subsets except Treg cells and Th1Th2, Th17/Treg were significantly decrease in the Group infection compared with the Group treatment-DMARDs (P<0.05). While the absolute count of Treg cell was no different between the two groups.
3. After the course of rhl-2 treatment, there were significantly increase of the peripheral lymphocytes and CD4+ T cells subsets (P<0.01). Th17/Treg was significantly low after treatment. Compared with the patients who continue receiving DMARDs, all lymphocyte subsets had a rising trend in patients receiving rhl-2 treatment.

Conclusions: The decrease of Treg cell number and imbalance of Th17/Treg may contribute to the pathogenesis of CTD. Excessive using glucocorticoid and DMARDs may aggravate the imbalance on the other hand, these medicines decrease immune function, which leads to EBV and CMV viremia. Over the treatment of rhl-2, immune function was improved and there was a more significant increase in the absolute count of T reg cells than Th17, and a consequently restore the balance of Th17/Treg.

**SAT0580** OSTEARTICULAR TUBERCULOSIS: A RETROSPECTIVE STUDY OF 119 CASES

R. Sonia, S. Boussaid, I. Abdelkafi, S. Hela, C. Ilhem, E. Mohamed. Rheumatology, la Rabita, Tunisia, Tunisia

Background: Bone and joint involvement in tuberculosis is uncommon. While osteoarticular tuberculosis most commonly occurs in the vertebral column, less frequently affected sites are the hip, knee and sacroiliac joints. The multiform form of skeletal tuberculosis is exceptional.

Objectives: To evaluate the clinical and diagnostic features of osteoarticular tuberculosis.

Methods: We reviewed the files of all patients admitted to our department from 2000 to 2016 to search for diagnosis of osteoarticular tuberculosis.

Results: We identified 119 patients (52 men, 67 female), having osteoarticular tuberculosis lesions. Mean age was 43 years [21–82]. Diagnosis delay was 4 months. Pain, low-grade fever and loss of weight were the most common presenting symptoms. All the patients consulted because of pain. The spine was involved in 81 patients. Peripheral osteoarticular tuberculosis was diagnostic in 38 cases, mainly in the knee (21 cases). Five patients have a multifocal involvement of the osteoarticular tuberculosis. The tuberculin skin test was positive in 75% of the cases. The diagnosis of spondylodiscitis was provided by CT-scan and/or magnetic resonance imaging. Paraspinal and epidural abscesses has been reported in 11 cases. Bacteriological and/or pathological diagnosis was made in 72 cases (60.5%). The QuantiFeron test was done in 7 cases and was positive. The antibiotic treatment led to recovery in all cases. Tree patients have presented neurological signs.

Conclusions: Our results were similar to those of the literature. Elderly population was, as expected, at risk. The diagnosis can be delayed especially in negative investigations. Therefore it is recommendable to do a very large screening tests especially in endemic areas.

**SAT0582** CHAGAS’ DISEASE IN PATIENTS WITH AUTOIMMUNE DISEASES RECEIVING IMMUNOSUPPRESSIVE THERAPY.

ANALYSIS OF 48 CASES

S. Retamozo1,2, J.M. Haye Salinas3, A. Alvarellos2, V. Sauvant2, F. Caeiro2, J.P.Caeiro2, V. Carballo4, M. Medina5, O. Salomone3, R. Albertini6, F. Merschon7, F. Bonisconti8, A. Sanchez8, T. Alvarados8, M. chelonae, M.chelonae

Rheumatology, The second hospital of Shanxi medical university, TaiYuan, China

Background: DMARDs are the most important medicine in treatment of autoimmune disease. However, excessive using DMARDs lead to decrease immune function, which increasing opportunistic infection, such as EBV, CMV viremia. Recent study show the imbalance between T help cell 17 (Th17) and regulatory T cell (Treg cell) is a pivotal cause of autoimmune disease and correction of this imbalance to be a potential therapy. So whether low dose IL-2 restores the balance of Th17/Treg and improve immune function?

Objectives: To identify the risk factors of the development and exacerbation of NTM infection in patients with rheumatic diseases.

Methods: Among 7013 patients with rheumatic diseases visiting Toho University Ohashi Medical Center and Tokyo Medical Center, 20 patients were enrolled in this study by fulfilling the diagnostic criteria of NTM infection by The Japanese Society for Tuberculosis and The Japanese Respiratory Society, and being followed-up for more than 1 year. The medical records of enrolled patients were retrospectively reviewed.

Results: Eleven patients with rheumatoid arthritis, 4 patients with vasculitis, 3 patients with SJögren's syndrome and 1 patient with dermatomyositis and systemic lupus erythematosus for each were enrolled in this study. Mycobacterium avium complex (MAC) was detected in 13 patients, M. chelonae in 2 patients, M. abscessus and M.Kansasii in 1 patient each, and undetermined mycobacterium in 5 patients. Notably, bronchiectasis was the predominant pulmonary complication observed in 13 patients, and intestinal lung disease was observed in 5 patients. Although 7 patients experienced the exacerbation of NTM during the observation period, immunological state on NTM diagnosis including peripheral blood leucocyte (median 5.8×10³ versus 7.0×10³/μL; p=0.72), lymphocyte (median 1.3×10³ versus 1.1×10³/μL; p=0.10) and the serum IgG level (median 1379 mg/dL versus 1207 mg/dL; p=0.20) were within normal ranges and comparable between ever and never exacerbation patients, respectively, as well as the treatments for rheumatic diseases such as glucocorticoids and biological agents.

Conclusions: NTM infection in patients with rheumatic diseases develops based on the dysfunction of pulmonary barrier rather than the systemic immunosuppression.

**SAT0581** NON-TUBERCULOUS MYCOBACTERIAL (NTM) INFECTION IN PATIENTS WITH RHEUMATIC DISEASES: POSSIBLE IMPORTANCE OF PULMONARY BARRIER FUNCTION RATHER THAN SYSTEMIC IMMUNE STATE IN THE DEVELOPMENT AND EXACERBATION OF NTM INFECTION

S. Takenaka1, H. Kameda1, T. Ogura1, H. Oshima2, K. Izumi3, A. Hirata1, H. Ito1, Y. Fujisawa1 on behalf of Department of Connective Tissue Diseases, National Tokyo Medical Center.

Rheumatology, Toho University Ohashi Medical Center;
1Rheumatology, Tokyo University Medical Center;
2Rheumatology, Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

Objectives: To identify the risk factors of the development and exacerbation of NTM infection in patients with rheumatic diseases.

Methods: Among 7013 patients with rheumatic diseases visiting Toho University Ohashi Medical Center and Tokyo Medical Center, 20 patients were enrolled in this study by fulfilling the diagnostic criteria of NTM infection. We identified the patients who were receiving DMARDs [DMARDs] and biological drugs [BD]; 2) had confirmed or were positive for NTM infection in patients with rheumatic diseases.

Results: We identified 13 patients (from our Units and 35 from the literature search) fulfilled the inclusion criteria. There were 41 (85.4%) women, mean age of 57±15 years. The decrease of Treg cell number and imbalance of Th17/Treg was significantly increased in patients receiving DMARDs and biological drugs compared with patients not receiving DMARDs.

Conclusions: The decrease of Treg cell number and imbalance of Th17/Treg may contribute to the pathogenesis of CTD. Excessive using glucocorticoid and DMARDs may aggravate the imbalance on the other hand, these medicines decrease immune function, which leads to EBV and CMV viremia. Over the treatment of rhl-2, immune function was improved and there was a more significant increase in the absolute count of Treg cells than Th17, and a consequently restore the balance of Th17/Treg.

SAT0583 | LATERAL EPICONDYLITIS: WHAT IS NEW? DIAGNOSTIC, IMAGING AND TREATMENT. A SYSTEMATIC LITERATURE REVIEW

A. Pieren1, M. Dougados2, P. Le Gouix3, M. Lavelie2, C. Roux2, A. Moltò2, C. Vial4, J. Gueydon2, S. Cuny2, V. Deloche2, J. Berthou2, A. Boudier1, C. Vial1

1 Rheumatology, Hospital la Paz, Madrid, Spain; 2 Rheumatology, Hôpital Civil; 3 Rheumatology, Calmels Ambroisie-Park, Paris, France; 4 Rheumatology, Hôpital Civil

Background: Lateral epicondylitis or tennis elbow is an extremely frequent disease, secondary to intratendinous degeneration of the common carp extensor tendon. However, diagnosis and therapeutic management are still a challenge for the rheumatologist.

Objectives: To determine the available evidence regarding the diagnostic, imaging and treatment of epicondylitis.

Methods: A systematic review literature was performed using PUBMED. Only controlled trials, systematic literature reviews and meta-analysis were selected (Jan 1990 to May 2016). The MESH search words were “tennis elbow”, “lateral epicondylitis” or “tennis elbow tendinopathy”. Diagnostic imaging” and “therapeutics.

Results: 1314 potential articles were screened; 7 articles of clinical diagnosis, 21 of imaging and 18 of treatment were finally selected.

Diagnostic: No controlled trials were found about the diagnosis of the epicondylitis. The clinical tests employed in the retrieved clinical trials were based upon the experts’ recommendations: lateral epicondyle palpation, resisted extension of the carpe and resisted extension of the 3rd and 4th fingers.

Imaging: Among the 21 articles identified, 1 article concerning plain Xray, 1 about scintigraphy, 10 of US and 10 of MRI were selected. One clinical trial, found plain Xrays were not helpful for the initial diagnosis. Ultrasound was found to be sensitive (84–100%) and specific (38–100%) tool for the diagnosis, in one meta-analysis. Ten studies, within a systematic review, showed MRI was reported to be as sensitive (90–100%) as the ultrasound, with a greater specificity (83–100%). In addition, MRI showed better reliability (0.41–0.53 vs 0.73–1.00). An MRI was therefore considered as a good complementary tool between the observed physical and symptoms, severity and involvement of other structures. On the contrary, no data was found to support the use of imaging tests for follow-up.

Treatment: Among the 18 articles, 9 articles (within 4 systematic review and 5 randomized clinical trials) about pharmacological treatment, 10 about the non-pharmacologic approach and 1 about surgery were selected. Corticoids injections were found to be effective in one meta-analysis at short-term and preferably for acute epicondylitis (Pain reduction at 1–3 weeks +1.18 (95% CI 0.27–2.09), 4–8 +1.30 (95% CI 0.55–2.04), 12–24 +0.38 (95% CI 0.85–0.08). Similar results were found for NSAIDs. Five prospective randomized clinical trials showed braces and carpal extension splints were reported to improve pain at rest and during exercise, in short term. Physical therapy was reported to be efficacious in pain and function too, in a systematic review. Therapies like rich platelet plasma show braces and carpal extension splints were reported to improve pain at rest and during exercise, in short term. Physical therapy was reported to be efficacious in pain and function too, in a systematic review. Therapies like rich platelet plasma showed a good agreement between for subscapular tendinosis (accu-

SAT0584 | THE ROLE OF MRI INTERPRETATION IN PATIENTS WITH ROTATOR CUFF DISEASE

S. Albina1, A.-M. Ramazan2, E.V. Ionescu3, M.G. Iliescu 3.

1. Rheumatology, Clinical Hospital of Rehabilitation, Cluj-Napoca; 2Department of Radiology, Emergency County Clinical Hospital “Sf Apostol Andrei”; 3Faculty of Medicine, Ovidius University, Constanța, Romania

Background: Shoulder pain is a common musculoskeletal complaint, roughly equal in incidence to neck pain (1). The shoulder pain syndrome has a prevalence to 47% in general population (2) and an incidence to 87–100,000 persons per 100,000 people per year (3,4). The identification of the cause of shoulder pain is very important because of the variability of the treatment. Patients with rotator cuff injuries should be managed with the appropriate pain relief and physical therapy (5). MRI is the imaging modality of choice for evaluating rotator cuff abnormalities. We aimed to determine whether there was agreement among radiologists in the diagnosis and treatment of rotator cuff disorders.

Objectives: To determine whether there was agreement among radiologists in the diagnosis and treatment of rotator cuff disorders. To assess the concordance between two radiologists in the diagnosis and treatment of rotator cuff disorders.

Methods: A systematic review of the literature was performed using PUBMED. Only controlled trials, systematic literature reviews and meta-analysis were selected (Jan 1990 to May 2016). The MESH search words were “infiltration”, “arthrocentesis” or “joint puncture” and “shoulder” or “knee” or “dabigatran” or its brand names.

Results: 12 articles (including 4 systematic reviews and 8 individual clinical studies) were included in the analysis. Among the 18 articles, 9 articles (within 4 systematic review and 5 randomized clinical trials) showed a good agreement between for subscapular tendinosis (accuracy=98%, Kappa=0.79, p=0.000) and perfect compatibility (accuracy=100%, Kappa=1, p=0.000) for terrs minor tendinosis. The poorest concordance between readers was in impingement syndrome (comparing=55%, Kappa=0.11, p=0.05).

Conclusions: The MRI examination is significant in rotator cuff disease only when the radiologist is overtrained for shoulder, otherwise the technique is unsusal and doubtful in clinical practice.

SAT0585 | IS IT SAFE TO PERFORM JOINT PUNCTURES IN PATIENTS TREATED WITH DABIGATRAN?

C.A. Guillen-Astete, J.R. Quinones-Torres. Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain

Background: The introduction of new oral anticoagulants provides us with a new therapeutic intervention and secondary prevention opportunity in stroke patients previously not well controlled with acenocoumarol due to not compliance or other issues.

As with other anticoagulants or even antiplatelet agents, the attending doctor may hesitate to perform a joint puncture in patients receiving such treatments. The purpose of this study is to describe the four-year cumulative experience of joint and peri-articular punctures in patients receiving dabigatran, a new oral anticoagulant recently introduced in our country.

Methods: We performed a systematic review of the records of patients who underwent a knee joint aspiration or periaricular joint puncture for diagnostic or therapeutic purposes and who were under treatment with dabigatran between the years 2012 and 2016.

For this purpose we conducted an search for electronic records within that period, using the search terms: "infiltration", "arthrocentesis" or "joint puncture" and "shoulder" or "knee" and "dabigatran" or it's brand names.
Follow up visits in either primary care (HORUS® Application) or emergency settings (CAJAL® Application) were analyzed, regardless of the main complain at admission, and the data was collected from this records.

**Results:** Between 2012 and 2016, 68 joint knee punctures and 49 periaricular shoulder punctures were performed in dabigatran patients. Of the 117 procedures, 73 (66.6%) were performed by attending physicians in Traumatology, 9 (7.8%) in Rheumatology, 10 (8.5%) in Neurology or Physical Medicine and Rehabilitation, and the rest by internal medicine residents. Of the 68 knee arthrocentesis, in 48 (70.5%) of the cases synovial fluid collection and infiltration were performed, while in the rest only infiltration was needed. Of the 49 shoulder punctures, in 12 (24.4%) a bursocentesis was performed while in the rest only an infiltration was done. 16 knee and 17 shoulder punctures (23.5% and 34.6%) were ultrasound assisted procedures. Among the patients with knee puncture, 11 (16.1%) came back before 15 days due to procedure related symptoms. Of these, 9 did so because of persistence of the main symptom or persistent pain and 2 because of increased pain. These two patients were studied sonographically and one of them had a hematoma that was treated conservatively. In the group of patients with shoulder puncture, 7 (14.2%) came back before the first 15 days and in all of them the cause was persistence of the main symptom. None of the patients required admission at the hospital. None of the patients with ecography-assisted procedures came back before the first 15 days. No patient consulted due to bleeding after the first fifteen days. (There were no hemorrhagic cases which lasted 15 days). The outcome of the procedure was not influenced by the person performing it (attending vs resident), however, all the ecdochiagnostic procedures were performed by an attending.

**Conclusions:** Although it is a small population, this is to the best of our knowledge the first published series of dabigatran anticoagulated patients who underwent a large joint or periarticular puncture. We can conclude that this type of punctures are safe in patients with this characteristics. On the other hand, there is evidence that ecography-assisted procedures are more effective in this group of patients.

**SCHOOL BAGS WEIGHT ARE NOT ASSOCIATED WITH LOW BACK PAIN IN SCHOOLCHILDREN IN CAMEROON**  
F. Kemta Legloa, M.S. Doualla, H. Namme Luma. Service de Médecine Interne, Douala General Hospital, Douala, Cameroon

**Background:** Data are mixed on the role of school bags in the occurrence of low back pain in pupils.

**Objectives:** Thus, we carried out this study with the aim to determine if the school bags were a factor associated with low back pain in Cameroon schoolchildren.

**Methods:** We performed a cross-sectional study between December 2015 and April 2016 in 10 primary schools of the city of Douala, Cameroon. A questionnaire was submitted to the students of these different schools. Informed and signed consent of their parents were obtained. Sociodemographic and clinical data were collected, as well as the weight of each school bags. A p < 0.05 was significant.

**Results:** We included 1070 pupils (543 boys, 532 girls). The mean age was 11.1 years (8–16 years). BMI was normal in 928 children (86.5%). The prevalence of low back pain was 12.3% (132 children: 81 girls and 51 boys). Sixteen children had already met a physician for low back pain. The mean weight of the school bag was 4.9±1.9 kg, with 369 children (57.7%) with a school bags weight > 15% of their body weight in private schools compared with 56 (12.9%) in public schools. We had 99 children with low back pain with a school bag weight >10% of their body weight (Table 1). We didn’t find any relationship between low back pain and the weight of the school bag, regardless of gender, BMI, age of pain, type of school, distance from home to school, way of transportation, and age (p > 0.05). However, the exception was found in girls aged from 8 to 10 years with a school bag weight > 15% of their body weight (p < 0.05). Furthermore, in univariate analysis, factors associated with low back pain were (p < 0.05): age, history of low back pain in at least one parent, competitive sport, a bad seated position on school benches. In multivariate analysis, factors associated with low back pain were female, competitive sport, and low back pain in at least one parent (Table 2).

**HEALTHCARE WORKERS ARE NOT MORE AT RISK TO LOW BACK PAIN THAN OTHER OCCUPATIONS**  
F. Kemta Legloa, M.S. Doualla, H.B. Ngahane Mbatchou, A.S. Mkoh, H. Namme Luma. Service de Médecine Interne, Douala General Hospital, Douala, Cameroon

**Background:** Low back pain is common among healthcare workers but is it more frequent than in other occupations?

**Objectives:** In order to answer this question, we carried out this study with the aim to determine if healthcare workers was more at risk for low back pain than other occupations.

**Methods:** We performed a survey on all permanent workers (n=584) of the Douala General Hospital in Cameroon from January to May 2016. Socio-demographic characteristics of workers (distinction with different occupations – healthcare workers, administrative workers, technical workers) and the main features of low back pain were collected. A p < 0.05 was significant.

**Results:** Of the 584 questionnaires distributed, 474 responses were obtained (81.1%). We excluded 27 for incomplete data. 447 were retained for the final analysis: 296 healthcare workers, 79 administrative workers, and 72 technical workers. The mean age was 40±10 years (22–66 years) and 258 (57.7%) were female. Mean BMI was 27±4.9 kg/m² with 103 (23%) obese.

At the end of the study, 252 (56.4%) workers described low back pain, including 170 (57.4%) healthcare workers, 44 (55.7) administrative workers and 38 (52.7) technical workers. There was no significant difference between the different groups (p > 0.05). Same for sex (p=0.9). The overall independent risk factors associated with low back pain were: seniority in their current position (OR 4.97, 95% CI 1.80–13.68, p=0.002), office chair quality (OR 3.06, 95% CI 1.29–7.26,
The aim of this study is to examine the effect of therapeutic education on fears and beliefs in chronic low back pain.

Methods: A prospective, comparative study was conducted with two groups of 50 patients each one having chronic low back pain. Both groups had benefited from the same physical rehabilitation program. The second group concurrently attended therapeutic education sessions.

Objectives: To assess the effectiveness of therapeutic education in reducing fears and beliefs among chronic low back pain patients.

Results: The initial evaluation of apprehension-avoidance showed a high FABQ score in both groups. Despite differences in initial scores, the intervention group showed a significant decrease in FABQ scores compared to the control group.

Conclusions: Therapeutic education significantly reduces fears and beliefs in chronic low back pain patients.

EFFECT OF INTERFERENTIAL CURRENT THERAPY IN PATIENTS WITH SUBACROMIAL IMPINGEMENT SYNDROME: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY

T. Nazligul, P. Akpinar, I. Aktas, F. Unlu Ozkan, H. Cagliyan. Department of Physical Medicine and Rehabilitation, Fatih Sultan Mehmet Education and Research Hospital, Istanbul, Turkey

Background: Shoulder pain is one of the most common types of musculoskeletal pain in the adult population. Subacromial impingement syndrome (SIS) has been reported to be the most frequent etiologic factor for shoulder pain (1). A conservative approach using non-steroid anti-inflammatory drugs (NSAID), subacromial injections, exercise, and several physical therapy agents is recommended as the first step treatment for SIS (2). Although interferential current (IFC) is a common electrotherapeutic modality used to treat musculoskeletal pain, there isn’t any randomized controlled trial investigating its clinical efficacy on SIS (3).

Objectives: To investigate the effectiveness of IFC treatment in patients with SIS.

Methods: In this double blind, placebo controlled study, patients with shoulder pain, who had been diagnosed SIS according to clinical evaluation and subacromial injection test were randomly assigned to the IFC or placebo groups. Exercise, cryotherapy, and NSAID were applied to all the groups. Daily 20 min per session, 5 days per week, for 2 weeks. 10 sessions IFC with alternative method were applied to the IFC group while sham IFC therapy were applied to the placebo group with the same protocol. Visual analog scale (VAS), Constant Murley Scale (CMS) and Shoulder Disability Questionnaire (SDQ) were used for evaluation at baseline, post-treatment and 1 month post-treatment.

Results: A total of 60 patients were completed the study; 26 (43.3%) were male and mean age was 50.02±9.10 years. There was not a significant difference in demographic and clinical data of the patients between the IFC (n=30) and placebo (n=30) groups (p>0.05). Significant improvement in all parameters was observed on post-treatment and 1 month post-treatment evaluations compared to baseline evaluations in both groups (p<0.01). Comparison of the VAS, CMS and SDQ scores between the two groups did not show significant difference either pre-treatment or post-treatment (p>0.05).

Conclusions: This study showed that IFC treatment does not provide additional benefit to NSAID, cryotherapy and exercise program in the treatment of SIS. Further studies are needed to investigate the long-term effects of IFC therapy.

GENDER-SPECIFIC ASSOCIATIONS BETWEEN FAT MASS AND MUSCULOSKELETAL PAIN IN COMMUNITY RESIDENTS: A 3-YEAR LONGITUDINAL STUDY

K.M. Son1, N.H. Cho2, S.H. Lim3, H.A. Kim3. 1Department of rheumatology, Hallym University Dongtan Sacred Heart Hospital; 2Ajou University school of Medicine; 3Hallym University Sacred Heart Hospital, Gyeonggi-Do, Korea, Republic Of

Background: Increase in fat mass is correlated with musculoskeletal pain in general population.

Objectives: In this study, we sought to delineate the prospective relationship between body mass parameters and the musculoskeletal pain in Korean community residents.

Methods: In the Korean Health and Genome Study, 1,325 participants (mean age 60.2 years, 56.2% women) who completed pain questionnaires and underwent dual x-ray absorptiometry to calculate body composition had 3 year follow-up data on pain. Pain was categorized according to number of pain regions. After 3 years of follow-up, subjects were classified into the following: 1) no pain both at baseline and at 3 years (no pain), 2) any pain (one, two or more, or widespread regions) at baseline and no pain at 3 years (transient pain), 3) no pain at baseline and any pain at 3 years (new pain) 4) any pain both at baseline and at 3 years (persistent pain), 1) and 2) were grouped as no/persistent pain group (no pain) and 3) and 4) as new/persistent pain group (pain).

Results: Female gender and obesity were significant factors associated with the persistence or development of pain. Total fat mass and fat: muscle mass ratio were significantly correlated with development of pain. Odds ratios for persistent pain were significantly increased in subjects in the highest quartile of fat mass ratio after adjustment among female subjects only. Among normal weight subjects, those without metabolic syndrome were less likely to belong to the pain group, especially among women.

Conclusions: The association of fat mass and pain was only significant among females.

musculoskeletal system disorders. Local inflammation could be the major cause of night pain, and using a deep diathermic modality might be contradictory.

Objectives: Investigation of the effectiveness of short wave diathermy SWD treatment in patient with SIS and to emphasize the significance of night pain (NP) status on treatment response.

Methods: In this double-blind, randomized placebo controlled trial, 57 patients aged between 35 to 65 years, diagnosed as SIS were classified into two groups as night pain positive NP(+) (n=28) and night pain negative NP(-) (n=29). Both groups were randomly assigned to SWD treatment NP(+) n=14, NP(-) n=14 and sham NP(+) n=15, NP(-) n=14 subgroups. Exercise, cold pack application and a moderate anti-inflammatory drug treatment were applied to all groups. 27.12 MHz continuous SWD (daily 20 min per session, 5 days per week, for 2 weeks, 10 sessions) was applied to the treatment groups while sham SWD was applied to the sham groups with the same protocol. Rest, activity and night visual analog scale (VAS), Constant (Murley) Score (CS) and Shoulder Disability Questionnaire (SDQ) were used for evaluation of patients at 2 weeks before the treatment, 1 month and 2 months after the treatment.

Results: There were no statistical differences between the SWD treatment and sham groups in all outcome parameters except for the Constant pain scores in NP(+) group. In NP(-) group, SWD treatment improved the parameters of pain strength, total scores of CS, and SDQ compared to sham group at 1 month. SWD treatment was superior to sham for all parameters except for the Constant daily living activity scores at 2 months.

Conclusions: In conclusion, addition of 27.12 MHz continuous SWD treatment to chronic treatment improves long term benefits when compared to sham SWD in terms of rest and activity VAS scores, Constant-Murley scores, and SDQ scores in SIS patients without night pain. However, there was no convincing evidence that SWD treatment is of additional benefit in SIS patients with NP. Therefore, night pain as a symptom should be regarded in the selection of treatment modalities in order to use the deep heat effectively in the management of SIS.

SAT0596 EFFICACY OF EPIDURAL STEROID INJECTION IN LUMBAR SPINAL STENOSIS IS NOT RELATED TO THE DEGREE OF SEVERITY BY MRI
E.S. Elsayad1, M.A. Mortada1
1Department of Radiology, College of Medicine of Baghdad, BAGHDAD, Iraq

Background: Lumbar spinal stenosis (LSS) is a common degenerative disease. Treatment modalities for LSS vary and include medication, exercise, interventional techniques, and surgical intervention. The lumbar epidural steroid injection has been used for the treatment of LSS with variable results. The relationship between severity of lumbar spinal stenosis and efficacy of lumbar epidural steroid injection is still undetermined.

Objectives: The aim of our study was to determine the relationship between the severity of LSS using MRI grading system and the response to lumbar epidural steroid injection.

Methods: Thirty patients with degenerative LSS were enrolled in this prospective study. All subjects underwent lumbar spine MRI (T2-weighted axial images). LSS was graded using MRI grading system (grade 1 - mild stenosis with separation of at least 2 – moderate stenosis with some cauda equina aggregated; grade 3 – severe stenosis with none of the cauda equina separated). All fluoroscopy guided transforaminal epidural steroid injections (FG- TFESI) were performed in the procedure room. Outcome measures were obtained using the visual analogue scale (VAS) for both back and leg pain, Oswestry disability index (ODI), Roland 5-point pain scale, walking tolerance and patient’s satisfaction scale at 2 and 8 weeks post-treatment.

Results: Thirty LSS patients treated with FG- TFESI, who were completely followed up, were included in this study, the injection rate was one injection per patient. The patients were followed at 2 weeks and 8 weeks. Fifty-six percent of patients at 2 weeks and 70% at 8 weeks had a successful outcome, reporting at least a 50% reduction between pre-injection and post-injection visual analogue pain scores.Roland 5 point pain scale showed pain reduction in 50% of patients by (25%) at 2 weeks and in 70% of patients by50% pain reduction at 8 weeks. Oswestry low back pain disability questionnaire (ODI) scores showed statistically significant improvement from initial scores to 2 weeks and from 2 weeks in 70% of patients. Walking tolerance showed improvement at 2 weeks in 50% of patients and at 8 weeks in 70% of patients. The outcome was statistically significant even in severe stenotic patients when comparing initial scores of moderate and severe stenosis at 2 weeks and 8 weeks scores in walking tolerance (P<0.006), Back VAS (P=0.717), Leg VAS (P=0.139), ODI (P=0.139), and Roland (P=0.001).

Conclusions: FG-LESI may reduce pain and improve walking tolerance in the short term for the treatment of patients with LSS for a period of 8 weeks. The outcome does not seem to correlate with the degree of lumbar spinal stenosis. Patients with severe LSS may have the same chance to get benefits from FG-LESI as patients with moderate LSS.

SAT0597 RELATIONSHIP BETWEEN LUMBAR DISC HERNIATION AND BENIGN JOINT HYPERMOBILITY SYNDROME
M.R. Albeer1, F.K. Abd alrazaq2, M.H. Alosami2
1Radiology, College of Medicine of Baghdad; 2Medicine, Baghdad Teaching Hospital; 3Medicine, College of Medicine of Baghdad, BAGHDAD, Iraq

Background: Benign joint hypermobility syndrome (BJHS) can present with a wide variety of musculoskeletal problems. Benign joint hypermobility syndrome (BJHS) is a hereditary disorder characterized by the presence of musculoskeletal symptoms in persons with generalized joint laxity in the absence of systemic rheumatologic disease (1–3). Lumbar disc herniation (LDH) is a common cause of low back pain. On the other hand, low back pain may be a presenting symptom in patients with BJHS.

Objectives: to evaluate relationship between Lumbar disc herniation and BJHS.

Methods: The study included 100 patients diagnosed with LDH depending on history, clinical examination and MRI findings and another 100 healthy control participants. All, patients and healthy controls were assessed for BJHS using the revised (Brighton 1998) criteria.

Results: The mean age was (35.4±8.9) year and (33.72±8.3) for patients and controls respectively, there were 43 males and 57 females in each group. The mean BMI was (27.6±4.6) kg/m2 in patients and (28.3±4.6) in controls. No significant differences found between the groups regarding the age, sex and BMI in all comparisons (Pvalue<0.05). The mean Beighton score was significantly higher among patients in comparison to controls; t(23.1±6.2) versus (1.2±1.3) in controls group; on the other hand major and minor criteria were significantly more prevalent among patients rather than controls, in all comparisons (Pvalue<0.05). BJHS was more prevalent among patients rather than controls, 55% of the patients had BJHS compared to 21% of controls, the odds ratio was (4.6) and (Pvalue<0.05). BJHS was more prevalent among females compared to males, from the total number of all participants, BJHS was present in 76 participants, and of them 47 were females versus 29 males, (Pvalue<0.05).

It had been significantly found that subjects with BJHS in both groups (patients and controls) were relatively shorter than those without BJHS, Pvalue<0.05. The correlation analysis of BJHS with the MRI findings of LDH in patients group showed no significant differences among patients with and without BJHS, in all comparisons Pvalue>0.05.

Conclusions: BJHS is more prevalent among patients with LDH. There is no significant relationship between presence of BJHS in LDH patients and MRI findings.

SAT0598 EVALUATION OF THE QUALITY OF SEXUAL LIFE DURING CHRONIC LOW BACK PAIN
I. Haddada1, M. Brahem1, H. Hachi1, S. Ben Hammouda1, M. Maroua1, M. Juririm1, M. Younes2, M. Rahman, Tahar Sahal Hospital Mahdia, mahdia, Tunisia

Background: Sexual life has an important role in preserving the good quality of life of patients and their partners. Chronic low back pain (CLBP) as well as other musculoskeletal diseases, can affect all life activities including sexual function.

Objectives: The aim of this study is to assess the impact of chronic low back pain on sexual life and to identify the associated factors.

Methods: It’s a study of 144 patients suffering from chronic low back pain, during a period of nine months (from February to October 2016).We have specifically studied the relationship between chronic low back pain and sexual quality of life, using the Sexual Quotient (QS) (a validated questionnaire), which consists in 10 questions, each of them from 0 to 10, to have a final score rated from 0 to 100.

Results: The average age of our patients was 53.8±10.7 years (23–79 years), with a female predominance in 64% of cases. The mean visual analogue scale for pain was 4.72 (1–9).

The average duration of low back pain was 6.5 years. The average score of the mean Dallas score, the segmental results were as follows: 53.1% of impact on daily activities, 47.6% of impact on work/leisure ratio, 45% of impact on anxiety/depression ratio and 33.4% of impact on sociability.

In our study, 57.2% of cases were under analgesic treatment, 85.5% were under...
non-steroidal anti-inflammatory drugs, 20% had at least one local corticosteroid infiltration, 34% had functional rehabilitation and 4% had surgical treatment. Regarding sexual dysfunction, 34.5% of our patients didn’t have any sexual activity. 2.1% had a catastrophic sexual life (score < 20), 9% had a disappointing sexual life (score between 20 and 40), 20% had an average sexual life (score between 40 and 60), 17.9% had a satisfying sexual life (score between 60 and 80), while only 13.1% had a very fulfilling sexual life (score between 80 and 100. We showed that the alteration of the sexual quotient in our patients is more marked when the age of the patients is more advanced. But we didn’t found a significant correlation with the duration of the disease, the mean visual analogue scale for pain and the functional scores of Quebec and Dallas.

**Conclusions:** Our study suggests that sexuality is profoundly disrupted in chronic low back pain. The advanced age is proved to be correlated with the deterioration of the sexual life. So, sexuality must be taken into account in the management of patients with chronic low back pain.

**LOW BACK PAIN IN MEDICAL STUDENTS LINKED TO POOR SLEEP QUALITY: RESULTS FROM THE PAX-I STUDY**

**N.R. Ziade** 1, F. Fayad 1, B. Badra 3, 1Rheumatology, Hotel Dieu de France; 2Rheumatology; 3Medicine, St. Joseph University, Beirut, Lebanon

**Background:** Low Back Pain (LBP) is a major public health problem and is classified by the Global Burden of Disease Study among the ten diseases most responsible for Disability-Adjusted Life Years worldwide. All ages may be affected, mostly young adults, with a prevalence going up to 50%. Medical students may be particularly vulnerable due to sedentary lifestyle and high stress levels.

**Objectives:** The primary objective is to evaluate the prevalence of LBP in Lebanese medical students. The secondary objective is to identify predictive factors associated with LBP and to identify prevalence and components of inflammatory back pain (IBP).

**Methods:** PAX-I is a cross-sectional study, completed at the St-Joseph University of Beirut from April to June 2016. All students from the first to the sixth year of medicine were invited to fill a questionnaire about their demographic data, lifestyle habits, Patient Health Questionnaire for Depression and Anxiety (PHQ24) and LBP characteristics, including components of IBP as per ASAS criteria. Student test and ANOVA were used for quantitative variables, chi-square test was used for qualitative variables and logistic regression was used to identify predictive factors for low back pain. Analysis were performed on IBM SPSS Statistics 23.

**Results:** Response rate was 51.3% (258/502). Mean age was 20.86 years (SD 1.92). 54.3% were women. 76.7% drank caffeine. 66.3% had a regular sports activity and 9.7% were smokers. 38% had the habit of walking while studying. 46% were satisfied with their quality of sleep. Mean PHQ24 score was 7.17 and increased with the years of studies (p 0.045). 55.8% of students reported a LBP event during the past year, with a mean number of 3.6 episodes per year. 91% of these students had LBP while studying, with high reported intensity (5.18±10). 62.5% reported LBP after exercise. 80% had episodes of less than one month and 7% of more than three months duration. 12% had IBP according to the ASAS criteria (Details of IBP in Figure 1).

**Predictive factors for LBP in univariate analysis were:** smoking (p 0.040), alcohol consumption (p 0.005), caffeine consumption (p 0.041), telewaching (p 0.042) –positive association-, and number of hours of sleep (p 0.011) and satisfaction with sleep quality–negative association– (p 0.017). Satisfaction with sleep quality remained the only significant association in multivariate analysis (p 0.014).

**Conclusions:** LBP is a frequent problem among medical students with high intensity, especially when studying, and a high recurrence rate. The main predictive factor was poor satisfaction with sleep quality. A significant percentage fulfills IBP criteria by auto-questionnaire and should benefit from further investigation.

**USEFULNESS OF VERTEBROPLASTY IN VERTEBRAL FRACTURES WITH PERSISTANT BACK PAIN. A REPORT OF 64 VERTEBRAL AUGMENTATION FROM A UNIVERSITY HOSPITAL**

O. Fernandez-Berrizbeitia 1, M. González-de-Varay-Sanzo 2, A. López-Medina 2, M. García-Vivar 2, E. Ruiz-Lucea 1, I. Torre-Salabert 1, A. Inxaurbe-Pellejero 1, J. Blanco-Madrigal 2, E. Guerrero-Basterretxea 1, I. Calvo-Zorrilla 2, O. Ibanezgoitia-Barrena 1, C. Pérez-Velasquez 2, L. Estopifán-Fortea 1, C. Gómez-Aranjo 1, N. Rivera-Garcia 1, M. Allande-López-Linares 1, A. Bilbao-González 2, E. Galindez-Aguirregoyoka 2, 1Rheumatology; 2Radiodiagnostic; 3Research, Basurto University Hospital, Bilbao, Spain

**Background:** Management options for patients with persistent back pain after a vertebral fracture include vertebral augmentation, but its use is controversial.

**Objectives:** Our aim was to evaluate the clinical efficacy and complications of consecutive vertebroplasties performed in our Hospital in a 12 years period.

**Methods:** Retrospective study of vertebroplasties performed at a University Hospital in the last 12 years (April 2004 to April 2016). The duration of follow-up was more than 12 months. Epidemiological variables, indications, time elapsed, efficacy and complications of the procedure were collected. The indication of vertebroplasties in fractures was pain refractory to usual symptomatic treatment in these pathologies: osteoporosis, trauma, leukemia/lymphoma, metastasis and hemangioma. Efficacy was assessed at 6 and 12 months with a simple verbal scale according to the pain response (improvement/non-improvement). Patients who died before 12 months period were excluded for the that parameter. A comparative study of the efficacy between a)cause of fracture, b)location, c)time elapsed, d)access route and e)complication was performed. For the descriptive analysis we used frequencies and percentages in the case of qualitative variables, and mean and standard deviation (SD) or median and interquartile range for quantitative variables. Chi-square test or Fisher's exact test was used in for qualitative variables, and Wilcoxon's non-parametric test for evolution time.

**Results:** Efficacy and complications of the procedure were collected. Indication of vertebroplasties in fractures was pain refractory to usual symptomatic treatment in these pathologies: osteoporosis, trauma, leukemia/lymphoma, metastasis and hemangioma. Efficacy was assessed at 6 and 12 months with a simple verbal scale according to the pain response (improvement/non-improvement). Patients who died before 12 months period were excluded for the that parameter. A comparative study of the efficacy between a)cause of fracture, b)location, c)time elapsed, d)access route and e)complication was performed. For the descriptive analysis we used frequencies and percentages in the case of qualitative variables, and mean and standard deviation (SD) or median and interquartile range for quantitative variables. Chi-square test or Fisher's exact test was used in for qualitative variables, and Wilcoxon's non-parametric test for evolution time.

**Statistical analysis was performed with the SAS System for Windows V 9.2.**

**Results:** 66 vertebroplasties were performed in 44 patients (75% female/25% male). 80% were satisfied with their quality of sleep. Mean PHQ24 score was 7.17 and increased with the years of studies (p 0.045). 55.8% of students reported a LBP event during the past year, with a mean number of 3.6 episodes per year. 91% of these students had LBP while studying, with high reported intensity (5.18±10). 62.5% reported LBP after exercise. 80% had episodes of less than one month and 7% of more than three months duration. 12% had IBP according to the ASAS criteria (Details of IBP in Figure 1).

**Predictive factors for LBP in univariate analysis were:** smoking (p 0.040), alcohol consumption (p 0.005), caffeine consumption (p 0.041), television watching (p 0.042) –positive association-, and number of hours of sleep (p 0.011) and satisfaction with sleep quality–negative association– (p 0.017). Satisfaction with sleep quality remained the only significant association in multivariate analysis (p 0.014).

**Conclusions:** LBP is a frequent problem among medical students with high intensity, especially when studying, and a high recurrence rate. The main predictive factor was poor satisfaction with sleep quality. A significant percentage fulfills IBP criteria by auto-questionnaire and should benefit from further investigation.

TREATMENT OF CARPAL TUNNEL SYNDROME (CTS) WITH ESWT: A SHAM CONTROLLED DOUBLE BLINDED RANDOMISED STUDY

Ö. Karatas 1, S. Cata 2, E.A. Gökmén 3, N. Samanci 4.

Objectives: The aim of this study was to investigate the efficacy of extracorporeal shock wave therapy (ESWT) in the treatment of CTS.

Methods: 49 hand with the diagnosis of CTS were included in the study. Patients were randomised in ESWT (n=29 hands) and sham (n=20 hands) groups. Patients were randomly allocated to receive 1 session per week for 3 weeks of either sham or active ESWT. All patients were prescribed with tendon and nerve gliding exercises and hand-wrist splint which used night. Patients were evaluated before the treatment, and at the end of the first week, first month and third month after the last ESWT treatment session with Boston Scale (symptom severity and functional capacity), Visual Analogue Scale (VAS) for pain and paresthesia assessment, for muscle strength: hand gross grasp and electromyographic variables (P<0.05). In both groups, there was no statistically significant difference between groups in all clinical and electrophysiological parameters.

Conclusions: Although ESWT was effective in symptoms in CTS but this efficacy isn’t superior to placebo. Our results indicated that ESWT was effective in pain and clinical variables in CTS. Wider and high-quality studies are needed to further demonstrate the effectiveness of ESWT in treatment of CTS.

MANAGEMENT OF EPICONDYLITIS WITH SINGLE LOCAL INJECTION OF SODIUM HYALURONATE

R. Petrella, A. Cogliano, A. Decruze. Western University, London, Canada

Background: Lateral elbow epicondylitis, also known as tennis elbow, is a common musculoskeletal condition causing pain and functional impairment in daily activities.1 It affects between 40–50% of recreational tennis players at some time during their career.2 Hyaluronate (SH) is a natural biological substance which has proven to be effective to improve pain and function in osteoarthritic patients with low incidence of side effects.3 Similarly, the administration of periarticular injections of SH can be an alternative approach to treat chronic epicondylitis.4

Objectives: To evaluate the efficacy and safety of a single percutaneous injection with SH in the treatment of chronic epicondylitis.

Methods: A single-site, and placebo-controlled trial was conducted in patients with chronic epicondylitis. Patients’ condition was assessed at baseline and afterwards they were randomized 1:1 to receive a single 2.5ml injection of SH (manufactured by Tedec Meiji Farma SA) or placebo (saline) at the point of maximal pain at the lateral epicondyle. Additionally, standard of care (RICE: Rest, Ice, Compression and Elevation) was prescribed to both groups. Efficacy assessments were done at days 30 and 90 and included VAS (0–10cm) pain at rest and assessment of grip strength, patient global satisfaction, patient assessment of normal function and physician global assessment of elbow injury (all measured using 5-point categorical scale). Adverse events were recorded for safety purposes.

Results: A total of 60 patients were included and completed the study procedures. Both groups were homogeneous at baseline. A statistically significant reduction from baseline in VAS pain at rest and after grip testing was observed at 30 and 90 days in both treatment groups (p<0.05). Besides, inter-group comparison showed statistically significant differences in favour of SH group at 30 and 90 days (p<0.05). This was associated with significantly greater grip strength, patient global satisfaction and assessment of normal elbow function in SH group vs placebo (p<0.05). Improvement of elbow injury assessed by the physician was also statistically greater in patients treated with SH compared to placebo (p<0.05). No adverse events were recorded.

Conclusions: A single local injection of SH administered to patients with epicondylitis was significantly superior to placebo improving pain at rest and after grip testing, through all the study follow up period. The treatment was highly satisfactory for both physicians and patients and there were no safety concerns.

AN INNOVATIVE TREATMENT MODALITY FOR ACUTE ILIO-TIBIAL BAND SYNDROME IN RUNNERS: LOCAL HYALURONATE + BOTULINUM TOXIN IN A PROSPECTIVE COHORT OF 45 ATHLETES

R. Petrella, A. Decruze, J. Decaria. Western University, London, Canada

Background: Iliotibial band syndrome (ITBS) is the most common cause of lateral knee pain in runners.5 It is an overuse injury that results from repetitive friction of the iliotibial band (ITB) over the lateral femoral condyle. Initial treatment includes activity modification, nonsteroidal anti-inflammatory medication, taping, stretching exercise and in severe cases, a corticosteroid injection.6 Treatment of symptoms and return to activity are variable and can be intractable.

Objectives: To evaluate the efficacy and safety on pain and return to activity of a single injection of ITBS with combination hyaluronate and Botulinum toxin in 45 runners.

Methods: 45 runners with at least grade 2 ITBS underwent baseline investigations including pain following symptom-limited treadmill running test during which pain was recorded on a visual analogue scale (VAS 0–100) every minute. Runners then had injection in the area where the iliotibial band crosses the lateral femoral condyle with 2.5 ml combination hyaluronate (750–1300 kDa) with 40 U Botulinum toxin. Additionally, standard of care (RICE: Rest, Ice, Compression and Elevation) and stretching was prescribed but participants were instructed not to use NSAIDS or taping. The same pain VAS measures as well as peak exercise time, patient global satisfaction and patient assessment of normal running function (all measured using 5-point categorical scale) were repeated after 2, 7, 14 and 30 days. The primary outcome was peak pain during symptom-limited treadmill running.

Adverse events were recorded for safety purposes.

Results: 45 consecutive runners with acute (within 7 days) ITBS were included and completed the study procedures. A statistically significant reduction from baseline in VAS peak treadmill exercise was observed at all time points (p<0.05). This was associated with significantly longer exercise time at 7, 14 and 30 days. Patient global satisfaction was increased progressively after 7, 14 and 30 days and assessment of normal running function was described in >75% at 14 days. No serious adverse were reported. 3 subjects described transient (~24 hours) weakness in knee extension and 2 subjects described mild pain at the time and location of injection.

Conclusions: A single local injection of combination hyaluronate + Botulinum toxin for ITBS in runners improved pain and exercise time with treadmill running by 7 days post treatment and continued to 30 days. This treatment was satisfactory to runners and resulted in few, limited adverse events.

**SAT0604** AUTOLOGOUS BLOOD AND CORTICOSTEROID LOCAL INJECTION IN TREATMENT OF PLANTAR FASCIITIS (RANDOMIZED, CONTROLLED MULTICENTER CLINICAL TRIAL)

A. Karimzadeh, S.A. Raeesadat, S. Farhani, L. Sedighipour. Physical Medicine & Rehabilitation Research Center, Tehran, Iran, Islamic Republic Of

Background: Plantar fasciitis is the most common cause of heel pain. Local injection modalities are among treatment options in patients with resistant pain.

Objectives: The aim of the present study was to evaluate the effect of local autologous blood compared with corticosteroid local injection in treatment of plantar fasciitis.

Methods: In this randomized controlled multicenter study, 36 patients with chronic plantar fasciitis were recruited. Patients were allocated randomly into 3 treatment groups: local autologous blood, local corticosteroid injection and control groups receiving no injection. Patients were assessed with Visual Analogue Scale (VAS), Pressure Pain Threshold (PPT) and Plantar Fasciitis Pain/Disability Scale (PFPS) before treatment, 4 and 12 weeks post therapy.

Results: Variables of pain and function improved significantly in both corticosteroid and autologous blood groups compared to control group. At 4 weeks following treatment, patients in corticosteroid group had significantly lower levels of pain than patients in autologous blood and control groups (higher PPT level, lower PFPS and VAS). After 12 weeks of treatment both corticosteroid and autologous blood groups had lower average levels of pain than control group. The corticosteroid group showed an early sharp and then more gradual improvement in pain scores but autologous blood group had steady gradual drop in pain.

Conclusions: Autologous blood and corticosteroid local injection both can be considered as effective methods in the treatment of chronic plantar fasciitis. These treatments decrease pain and improve function significantly compared to control group.

**SAT0605** LOCAL PROGESTERONE INJECTION: NEW OPTION FOR MANAGEMENT OF CARPAL TUNNEL SYNDROME

S.A. Raeesadat1, L. Sedighipour1, S. Shahrarami1,2.1 Physical Medicine & Rehabilitation Research Center; 2Physical medicine and rehabilitation research center, Tehran, Iran, Islamic Republic Of

Background: A number of studies, have demonstrated the neuroprotective effects of progesterone and its influence on the recovery after neural injury. Few studies investigated the efficacy of local progesterone in Carpal Tunnel Syndrome.

Objectives: The objective of this study was to compare the long term effects of progesterone versus corticosteroid local injections in patients with mild and moderate carpal tunnel syndrome.

Methods: In this randomized clinical trial, 78 hands with Carpal Tunnel Syndrome were assigned to two groups. Patients were treated with a single local injection of triamcinolone acetonide in one group and single local injection of hydroxyprogesterone in the other group. Variables including pain (based on Visual Analogue Scale), symptom severity and functional status (based on Bostone/Levine symptom severity and functional status scale) and nerve conduction study were evaluated before and 6 months after the treatments.

Results: All outcome measures including pain, functional scales and electrophysiologic findings improved in both corticosteroid and progesterone groups and there were no meaningful differences between two groups regarding mentioned variables. However, functional outcome was significantly better in progesterone compared to corticosteroid group at 6 month follow up (P<0.04).

Conclusions: The study demonstrated the efficacy of progesterone local injection in mild and moderate CTS at long term follow up. Furthermore, local progesterone can be superior to corticosteroid injection for relieving symptoms and improving functional and electrophysiologic findings at long term follow up.

**SAT0606** IS THE LEVEL OF PHYSICAL ACTIVITY AN IMPORTANT FACTOR FOR LOW BACK PAIN AMONG STUDENTS OF UNIVERSITY?

V. Akduman1, E. Mete1, I. Demirbukten1, G. Ogren2.1 Physiotherapy and Rehabilitation; 2Nutrition and Dietetic, Marmara University, Istanbul, Turkey

Background: Back pain is a major global health problem, causing greater disability worldwide than any other condition. Regular physical activity is widely believed to have important health benefits, such as improving quality of life and mobility, and reducing disabilities. Conversely, lack of physical activity is considered a risk factor for increasing chronic diseases, functional dependence and mortality. Patients with low back pain (LBP) often report disability to perform daily activities. Also, decreased physical activity level can lead to low back pain.

Objectives: The aim of the study was to determine whether increasing the level of physical activity affects the low back pain or not in the population of university students.

Methods: The cross-sectional study included 350 students (181 females and 169 males) with a mean age of 19.8±1.9 years. LBP was determined using the validated Oswestry Disability Index (ODI). ODI consist of ten items and are completed in reference to the patient’s functional status “today”. Physical activity level was evaluated by the short form of the International Physical Activity Questionnaire (IPAQ). IPAQ is a scale to be recorded at different levels of physical activity time in the last week. IPAQ is a scale to be recorded at different levels of physical activity time in the last week. Individuals whose score is lower than 600 MET are described as inactive (IPAQ 1), between 600–1500 MET (IPAQ 2) are described as moderately active and higher than 3000 MET (IPAQ 3) as described as active. For the statistical analyzing we used spearman correlation test.

Results: According to the short form of IPAQ, 14.8% percent of students were found inactive, 48.1% percent of students were found minimal inactive and 37.1 percent of students were found active. The total score of Oswestry disability index was found 6.2±5.0. There was a significant difference between the Oswestry disability index score of inactive, minimally active and active groups (p=0.02). In addition to this, between the Oswestry disability index and total score of IPAQ was found a weak correlation in the negative direction (p<0.01; r=-0.184). Between the IPAQ3 and Oswestry disability index and total score of IPAQ was found a weak correlation in the negative direction (p<0.05; r=-0.190). And also between IPAQ3, which means moderate intensity activity, and Oswestry disability index was found a significant but weak correlation in the negative direction (p=0.01; r=-0.157). Between Oswestry disability index and sedentary activity and walking was not found any significant correlation (p<0.05).

Conclusions: According to our study, increasing the level of physical activity may reduce low back pain. Especially vigorous and moderate intensity activity can be effective in prevention from low back pain. For reducing of low back pain, sedentary activity and walking did not have any significant effect in our study. Therefore, the level of physical activity should be increased at the young age to prevent of low back pain which is a major health problem.

**SAT0607** DISCOVERY OF A SMALL MOLECULE INHIBITOR OF THE WNT PATHWAY (SM04755) AS A POTENTIAL TOPICAL TREATMENT FOR TENDINOPATHY

V. Deshmukh, T. Seo, M. Ibanez, J. Stewart, B. Hoflinena, Y. Yazici, Samumed, LLC, San Diego, CA, United States

Background: Tendinopathy is an inflammatory and degenerative disorder caused by injuries or overuse. It can progress to a chronic condition with failed healing, tendon fibrosis and micro-tears that lead to pain and sometimes rupture. Current therapeutic options focus mainly on pain relief rather than treatment of underlying disease. The Wnt/β-catenin pathway is upregulated in tendinopathy and has an important role in inflammation, fibrosis and tenocyte differentiation.

Objectives: SM04755, a novel, topical Wnt pathway inhibitor, was evaluated in preclinical studies to determine its potential to inhibit inflammation, reduce fibrosis and increase tenocyte differentiation, thereby promoting tendon healing.

Methods: Anti-inflammatory activity was measured by the reducing activity of ELISA in lipopolysaccharides (LPS) and anti-CD3/anti-CD28 stimulated peripheral blood mononuclear cells (PBMCs). Differentiation of human mesenchymal stem cells (mMSCs) and rat tendon derived stem cells (rTDSCs) into tenocytes was measured by high-throughput qPCR for tenocyte markers scleraxis A (SCXA), tenomodulin and tenasin C. Pharmacokinetics were evaluated following topical application in rats. In vivo efficacy of SM04755 was evaluated in a single injection, collagenase-induced acute rodent tendinopathy model and a chronic, multiple injection, failed healing model, by scoring histological indicators of tendon health. Inflammation was measured by chemokine ligand 1 (CCL1) levels in plasma by ELISA and pro-inflammatory markers (IL-6, TNF-α, IL-1β, IFN-γ, IL-8) in the tendon by qPCR. Tendon regeneration and healing were evaluated by qPCR based gene expression of tenocyte differentiation markers SCXα, tenomodulin and tenasin C. Type V/VI collagen ratio and polarized light microscopy using Sirius Red staining. Pain in the rodent model was measured by force distribution with an incapacitance meter.

Results: SM04755 potentely inhibited cytokine secretion in LPS and anti-CD3/anti-CD28 stimulated PBMCs (EC50<500nM). SM04755 induced expression of tenocyte markers in differentiated mMSCs and rTDSCs (EC50<200nM). A single topical application of SM04755 resulted in tendon concentrations >EC50 for up to 24hrs, with minimal systemic exposure or toxicity. In both the acute and failed healing tendinopathy models, SM04755 (10mg/ml) treatment improved tendon morphology (Figure A), significantly increased mean tendon health
score (p < 0.01), decreased plasma levels of CXCL1 (p < 0.05) and reduced gene expression of pro-inflammatory markers (IL-6, TNF-a, IL-1β, INF-g, IL-8; p < 0.05) compared to vehicle. SM04755 treatment promoted tendon regeneration measured as increased expression of tenocyte markers (p < 0.05), increased Type I/Type III collagen ratio (Figure B; p < 0.01) and Sirus Red stained collagen fibers in tendon compared to vehicle. SM04755 treatment increased wet weight, weight bearing on the affected limb (p < 0.01), at multiple time points (Figure C), indicating reduced pain in the rodent model.

Figure. SM04755 inhibited inflammation, promoted tendon healing and reduced pain in a rat collagenase-induced tendinopathy model

Conclusions: Topical SM04755, a Wnt pathway inhibitor, reduced inflammation, promoted tendon regeneration and healing, and reduced pain compared to vehicle in rodent tendinopathy models. SM04755 is a potential treatment for tendinopathy.

Clinical studies are in progress.

SAT0608 RELATION BETWEEN SCAPULAR MUSCLE ENDURANCE, MUSCLE STRENGTH, PAIN AND FUNCTION IN PATIENTS WITH ROTATOR CUFF LESION

U. Sozlu, S. Basar, U. Kanallì, Z. B. Alakan, Gazi University, Ankara, Turkey

Background: Rotator cuff lesion (RCL) is an term that encompasses a spectrum of shoulder conditions including: subacromial impingement syndrome (SIS), partial and full thickness rotator cuff tears (RCT) and calcific tendinitis. Symptoms include pain, limited motion, muscle weakness and functional disability.

Objectives: To investigate the relationship between scapular muscle endurance (SME), muscle strength, pain and function in patients with shoulder RCL.

Methods: This study was conducted on 53 patients in shoulder RCL and 23 healthy controls. SME was measured as isometric based on the exercise developed by Sahrmann. Strength was measured as dynamometer. Activity, night and rest pain levels were evaluated by visual analog scale. Functional activity status was assessed by the Functional Impairment Test-Head, and Neck/Shoulder/Arm (FIT-HaNSA).

Results: Consecutive non selected patients, ≥50 years-old with high vascular risk according to European Guidelines on Cardiovascular Disease Prevention, and without signs or symptoms of GCA, were included. Ultrasonography of carotid artery: Carotid ultrasound examinations were performed on a Mylab Seven (Esaote Medical Systems, Italy) with a 4–13 MHz linear-array. The system employed dedicated software radiofrequency-tracking technology to obtain IMT (QIMTM).

Ultrasonography of temporal superficial artery: A color Doppler ultrasound (CDU) and grey scale measure of the IMT/halo sign in the branches of both TA was performed by a second experienced sonographer. A Mylab Twice equipment (Esaote, Geneve, Italy) was used, with a 22 MHz frequency for grey scale and a 12.5 MHz for CDU, with a color gain of 51 and a PRF of 2 kHz. The sonographer was blind to the clinical data and carotid ultrasound IMT measurements. Examination videos were stored for reliability and an intra-reader was performed months after the examination.

Statistical analysis: Descriptive frequencies, Student’s t-test, Cronbach’s alpha and Spearman correlations was used.

Results: Forty patients were studied, 28 men (70%), with a mean age of 70.6 ± 9 years. Three patients were active smoker and 27 ex-smokers, Arterial hypertension was present in 39 (97.5%), dyslipidemia in 34 (85%) and diabetes in 19 (47.5%). The mean erythrocyte sedimentation rate was 13.6 ± 11.0. Eighty carotids were studied, 50 had plaques and 30 did not with an IMT ranged from 0.526 to 1.480 mm. The mean values of TA related with the carotid IMT was presented in the table: the increase in the carotid IMT is associated with an increase in the IMT of the TA with a weak Spearman correlation (p<0.012 and frontal branches 0.228 p=0.048).

Patients with a final GCA diagnosis (n=22)

</tbody>
</table>

From reliability a Cronbach’s alpha of 0.900 and 0.876 were achieved for parietal and frontal branches respectively. Some patients had a TA IMT that can be interpreted as halo sign: 18 (45%) patients and 32 (26.6%) TA branches if we choose a cutoff ≥ 0.30 mm of IMT/halo sign; 4 (10%) patients and 7 (4.4%) TA branches if the cutoff were > 0.34 mm.

Conclusions: The atherosclerotic disease can produce false-positive GCA diagnosis. Carotid IMT > 0.9 mm is associated with halo sign in TA. The IMT cutoff value for the diagnosis of GCA should be established.

Diagnoses and imaging procedures
SAT0610 | TEMPORAL ARTERY ULTRASOUND IN THE DIAGNOSIS OF GIANT CELL ARTERITIS IN A COHORT WITH ELEVATED CLINICAL IMPRESSION

P.V. Estrada 1, D. Reina 1, V. Navarro 1, D. Roig 1, D. Cerdà 2, V. Torrente 1, S. Heredia 1, H. Corominas 1, 1Rheumatology; 2Hospital Moisés Broggi-Hospital General de l’hopitalat. Consorci Sanitari Integral. Sant Joan Despi, Barcelona, Barcelona, Spain

Background: Giant cell arteritis (GCA) is the most frequent vasculitis in adulthood. The delay in diagnosis sets back treatment and can lead to serious consequences. Diagnosis is complex, and is followed by the classification criteria according to the American College of Rheumatology (ACR). This is an increasing interest on the utility of temporal artery ultrasound (TAUS) as a tool to evaluate inflammation on the vessel wall.

Objectives: to evaluate the utility of TAUS in GCA.

Methods: During 2016, 120 TAUS were carried out in 60 patients with clinical suspicion for GCA. The TAUS was carried to completion by rheumatologist with experience. The symptoms that lead to a TAUS was either one or more of these clinical scenarios: 1) cranial symptoms (recent onset headache, mandibular claudication, visual disturbances) 2) polyarticular syndrome 3) toxic or febrile unspecific syndrome 4) vertebrobasilar (VB) stroke. Demographic and laboratory data were collected, and a follow-up was done to learn the final diagnosis. As for TAUS, the “halo” sign was considered positive if an anechoic image surrounded the vessel was present, and measured >0.30 mm in both, longitudinal and transverse cuts. Other more unspecific signs as stenosis or occlusion were also registered. A temporal artery biopsy was performed whenever the physicians considered necessary, based on clinical criteria, every case in no more than 30 days.

Results: Fifty-two percent were women, mean age 76±7.8 years old. Mean laboratory parameters: eritrosedimentation rate 85±41.9 mm/h, C-reactive protein 77±80 mg/L, Haemoglobin 11.4±2.2 g/L, white blood count 10,228±3,520, platelet count 310,603±123,918. The symptoms that motivated requesting the TAUS were: cranial symptoms (62.2%), toxic, unspecific, febrile syndrome (44%), polyarticular syndrome (30%), VB stroke (5%). A temporal artery biopsy was carried out in 45% of patients (N=27); it was positive in 40.7%, negative in 40.7% and unspecific (given it reported an inflammatory histologic pattern, but without the characteristic giant cells) in 18.5%. From all 60 patients in whom a TAUS was performed, 36% were diagnosed with GCA, based on ACR criteria.

Patients with a final GCA diagnosis (n=22)

SAT0611 | INTIMA-MEDIA THICKNESS REFERENCE RANGES DEPICTING HALO SIGN FOR THE DIAGNOSIS OF LARGE VESSEL GIANT CELL ARTERITIS BY ULTRASOUND

M. Milchert, M. Brzosko. Department of Rheumatology Internal Medicine and Geriatrics, Pomeranian Medical University, Szczecin, Poland

Background: Color duplex ultrasonography (CDU) is most promising tool for the assessment of large vessel giant cell arteritis (LV-GCA). There is a need to define ultrasound findings consistent with the diagnosis of GCA.

Objectives: We aimed to score intima-media thickness (IMT) reference ranges for LV-GCA in polish patients.

Methods: 214 patients suspected for GCA and evaluated with CDU were included in the study and followed up for min 9 months. Large vessel CDU, together with arthritis/non-arthritis categorization, were performed before or within 1 week after treatment initiation by a single physician. Vasculitis was defined as hypoechogenic homogenous, increase of IMT with distorted wall structure resulting in no clear intima-media structure, over long distance (not limited only to the place of arterial bifurcations). ROC curves were calculated.

Results: GCA was diagnosed in 81 patients, polymyalgia rheumatica (PMR) in 131 (characteristics – Table 1). Extracranial LV-GCA was diagnosed in 43 patients: axillary vasculitis in 23 patients, common carotid artery (CCA) — 24, subclavian — 18, superficial femoral — 11, brachial (all spreading per continuum from axillary artery) — 8. In 93 remaining patients other diagnosis was confirmed, and they served as non-GCA/PMR controls. Mean IMT in LV-GCA was significantly higher versus controls and isolated PMR (Fig. 1). IMT in GCA was not significantly influenced by gender, hypertension and smoking in contrast with IMT in controls. Proposed cut off values for IMT depicting vasculitis in GCA patients are presented in Table 2. 100% specificity for vasculitis (vs GCA without large vessel vasculitis) was reached with axillary IMT of 1.06 mm (62% sens.), subclavian — 1.35 mm (38% sens.), superficial femoral — 1.55 mm (60% sens.), CCA — 1.27 mm (22% sens.).

</table>

The sensitivity and specificity for TAUS was 80% and 94% respectively, with a positive predictive value of 88.9% and a negative predictive value of 89.2%.

Conclusions: We demonstrated that cut off values may discriminate between GCA and its mimics as well as between presence and lack of vasculitis in different arteries in GCA.

SAT0612 | THE USE OF 18F-FDG-PET IN THE DIAGNOSIS OF POLYMYALGIA RHEUMATICA (PMR) – A PROSPECTIVE STUDY OF 99 PATIENTS SUSPECTED OF PMR

L. Henckaerts 1, O. Gheyens 2, S. Vanderschueren 1, K. Goffin 2, D. Blockmans 1. 1General Internal Medicine; 2Nuclear Medicine Department, University Hospital Gasthuisberg, Leuven, Belgium, Leuven, Belgium

Background: Previous studies have shown that the majority of patients with polymyalgia rheumatica (PMR) have increased fluorodeoxyglucose (FDG)-uptake around the shoulders, hips and processes of the cervical and lumbar spine on positron emission tomography (PET) (1). The specificity of these findings for PMR is not known.

Objectives: To determine the specificity and sensitivity of FDG-PET findings for the diagnosis of PMR.

Methods: A prospective monocentric study in a tertiary care centre. All patients underwent FDG-PET scanning before treatment with glucocorticoids was started. The clinical suspicion of PMR was quantified by the treating physician on a scale from 1 to 5. FDG-uptake was scored visually in 12 articular regions (cervical spine, processes, lumbar spinous processes, left and right sternoclavicular joint, left and right ischial tuberosity, left and right greater trochanter, left and right hip and left and right shoulder) (score 0–2) and a total skeletal score was calculated reflecting the FDG-uptake in these 12 articular regions. ROC analysis was performed to determine the optimal clinical and total skeletal score for diagnosing PMR. The golden standard for a diagnosis of PMR was the judgment of an experienced clinician after at least six months of follow-up.

Results: 99 consecutive patients with a possible clinical diagnosis of PMR were included in this study. Sixty-seven patients were finally diagnosed with PMR while 32 patients got another diagnosis. A clinical score of 4 or more had a sensitivity
Conclusions: Our results demonstrate that patients with gout and aHU without clinically evident cardiovascular disease have a high prevalence of subclinical atherosclerosis. Disease duration and levels of uric acid are independent factors related with increased cIMT in gout and aHU respectively. These results support the importance of screening for CV risk and to include carotid ultrasound in CV prevention strategies in these patients.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.6363

SAT0613 HIGH PREVALENCE OF SUBCLINICAL ATHEROSCLEROSIS IN GOUT AND ASYMPTOMATIC HYPERURICEMIA: A STUDY BASED ON CAROTID ULTRASOUND

1 Division of Neuroscience; 2 Division of Musculoskeletal and Rheumatic Diseases; 3 Rheumatology Department, Instituto Nacional de Rehabilitación; 4 Rheumatology Department, Instituto Nacional de Cardiología Ignacio Chavez; 5 Epidemiology and Social Medicine Department, Instituto Nacional de Rehabilitación, Ciudad de México, Mexico

Background: Accelerated atherosclerosis is known in gout. Hyperuricemia is considered an independent risk factor for cardiovascular (CV) disease. Evidence supporting both proatherogenic and prothrombotic states in HU is also published

Conclusions: To determine the prevalence of increased cIMT, as sign of subclinical atherosclerosis, by an automated US method, and the associated risk factors in patients with gout and asymptomatic hyperuricemia (aHU)

Methods: 138 patients with gout, 105 with aHU and 99 age and sex matched healthy controls were enrolled. For all patients were recorded: clinical history, disease duration, smoking, ischemic heart disease, comorbidities (diabetes mellitus, high blood pressure, dyslipidemia, renal insufficiency, obesity), and current therapy. ESR and serum CRP, total and HDL cholesterol, triglycerides, glucose, creatinine and uric acid were recorded. Patients with history of CV and cerebrovascular events or autoimmune diseases were excluded.

Results: A total of 684 common carotids were assessed. The prevalence of increased cIMT was 47.1%, 47.6% and 1% in patients with gout, aHU, and control group, respectively. The final adjusted logistic regression for patients with gout showed that time of disease progression (OR =0.79, 95% CI 0.66–0.95) and previous smoking (OR =0.32, 95% CI, 0.10–0.97) were associated with cIMT detected abnormalities in aHU. No significant correlation was found with the other variables. No differences in US findings were found between gout and aHU (p=0.936). There was a significant difference in cIMT in gout versus control (p=0.0001) and aHU versus control (p=0.0001).

Conclusions: To compare the ultrasound-detected abnormalities namely double contour sign (DCS) and hyperechoic aggregates (HAGs) at knee and first metatarsophalangeal (1st MTP) joint verses six sites (knee joint, 1st MTP joint, radiocarpal joint, patellar tendon and triceps tendon) in patients of gout.

Methods: Forty seven gout and fifty controls (serum uric acid >7mg/dl) with age more than 18 years were included in this study. DCS was looked for at three articular cartilage sites (first metatarsal, tibiotalar and femoral condyle) whereas HAGs were looked for at one joint site (radiocarpal joint) and two tendon sites (patellar tendon and triceps tendon).

Results: We found sensitivity, specificity, positive predictive value, negative predictive value and positive likelihood ratio of two joint areas (knee and 1st MTP) ultrasound findings for gout were 87.2%, 84%, 83.7%, 85.6% and 5.5 respectively. Similar sensitivity, specificity, positive predictive value, negative predictive value and positive likelihood ratio were observed with 6 sites ultrasound findings. Amongst controls 17.5% were found to have these abnormal ultrasound findings by both two joint area and 6 sites exams.

Conclusions: Screening of two joint areas (knee and 1st MTP) has similar sensitivity, specificity and positive likelihood ratio as compared to six sites in diagnosing gout. While utilizing lesser time in examination.

DOI: 10.1136/annrheumdis-2017-eular.1680
Background: Articular involvement is a frequent and invalidating manifestation in patients also affected by Systemic Lupus Erythematosus (SLE) ranging from arthralgia to erosive arthritis. Bone erosions are far less common in SLE but require a different management and may display a distinct pathogenesis. Musculoskeletal ultrasonography (MSUS) has proven useful in the assessment of inflammatory arthritis [1] and it is now known that MSUS is more sensitive than radiography in detecting bone erosions.

Objectives: We aimed at analyzing, in a large monocentric cohort of SLE patients who suffered from arthritis, the relationship between 31 polymorphisms in 18 genes previously associated with SLE or other autoimmune/inflammatory arthritis [1] and the presence of bone erosions detected by MSUS.

Methods: Consecutive SLE patients who complained arthritic involvement (defined by 1997 ACR criteria, i.e., ≥ 2 joints with tenderness, swelling or effusion) were enrolled. Patients RF+ve and/or anti-CFP+ve were excluded. Thirty-one SNPs (AID; myositis: n=20; SjS: n=21; rheumatoid arthritis RA n=36; systemic sclerosis SSC n=39; and 77 healthy control samples). Prototype MSUS Erosions (yes/no) 15/80 15.8

Results: Clinical and laboratory features of the 95 enrolled patients are described in table.

The presence of MSUS-detected erosions was demonstrated in 15/95 (15.8%) patients, with a mean±SD of 0.44±1.34. Bone erosions were more frequently observed at iliac metacarpophalangeal joint of the hands (29.4%), followed by the V metatarsophalangeal joint of the feet (16.1%). An association was found between anti-dsDNA and the presence of bone erosions (P=0.009, Fisher’s exact test); indeed, all the 15 patients (100%) with bone erosions were anti-dsDNA positive vs 54/80 (67.5%) of those without erosions. After Bonferroni correction, IL-23R rs11803505 was found to be associated with the presence of MSUS-detected bone erosions both at genotypic (P<0.045) and at the allelic level [P<0.022, OR=8.27 (95% CI 1.02–66.90)]. The association of bone erosions with anti-dsDNA and the presence of bone erosions (P=0.009, Fisher’s exact test); indeed, all the 15 patients (100%) with bone erosions were anti-dsDNA positive vs 54/80 (67.5%) of those without erosions. After Bonferroni correction, IL-23R rs11803505 was found to be associated with the presence of MSUS-detected bone erosions both at genotypic (P<0.045) and at the allelic level [P<0.022, OR=8.27 (95% CI 1.02–66.90)]. The association of bone erosions with anti-dsDNA and the presence of bone erosions (P=0.009, Fisher’s exact test); indeed, all the 15 patients (100%) with bone erosions were anti-dsDNA positive vs 54/80 (67.5%) of those without erosions. After Bonferroni correction, IL-23R rs11803505 was found to be associated with the presence of MSUS-detected bone erosions both at genotypic (P<0.045) and at the allelic level [P<0.022, OR=8.27 (95% CI 1.02–66.90)]. The association of bone erosions with anti-dsDNA and the presence of bone erosions (P=0.009, Fisher’s exact test); indeed, all the 15 patients (100%) with bone erosions were anti-dsDNA positive vs 54/80 (67.5%) of those without erosions. After Bonferroni correction, IL-23R rs11803505 was found to be associated with the presence of MSUS-detected bone erosions both at genotypic (P<0.045) and at the allelic level [P<0.022, OR=8.27 (95% CI 1.02–66.90)].

Conclusions: Our study is the first reporting a contribution of IL-23R gene to detecting bone erosions. As none of the traditional AABs has sufficient sensitivity to achieve diagnosis of SLE, current testing is based on measuring multiple AAB assays either in parallel or serial. We have recently identified novel AABs in SLE, which hold promise for improving diagnostic testing of SLE [1]. We have developed quantitative ELISA-prototypes for five new AABs, which were tested in combination with traditional AABs.

Objectives: The objectives of this study were to evaluate the diagnostic value of novel AABs and to screen for an optimized combination of novel and traditional AABs using logistic regression to increase the diagnostic accuracy of SLE testing.

Methods: Serum samples were obtained from 156 SLE patients with European ancestry at the rheumatology department of the Heinrich-Heine University (Düsseldorf, Germany), and Hannover Medical School (Hannover, Germany). SLE samples were compared against 126 samples from autoimmune diseases (AID; myositis: n=20; Sjögren’s syndrome (SjS): n=31; rheumatoid arthritis (RA) n=36; systemic sclerosis (SSc) n=39); and 77 healthy control samples. Prototype AID was based on five novel antibodies described in [1]. Traditional diagnostic AABs were measured using IVD ELISAs and included: SSA/Ro60, SSA/Ro52, La/SSB, Sm, RNP, dsDNA, Sc70, CENPB, Jo-1, CCP, phospholipid and dsDNA. Optimized marker combinations of new and traditional markers were tested using logistic regression and receiver operating curve analysis (ROC).

Results: When comparing 156 SLE patients with 203 control samples, the area under the curve (AUC) of the five novel SEL ELISAs ranged from 0.63 to 0.75. A cut-off was set at a specificity of 95% and yielded a sensitivity ranging from 13.5% to 21.2% for the five novel AABs. Sensitivity and specificity of novel ELISAs was comparable to traditional ELISAs, which was in this cohort for anti-dsDNA 35% and 97%, anti-Sm 15% and 97%, and anti-RiboP 26% and 97%. A logistic regression model was used to combine the results of multiple tests. Compared to a logistic regression with traditional assays, a logistic regression with novel assays achieved higher sensitivity by pertaining high specificity. The logistic regression model based on a multivariable IVD assay with ten extracted nuclear antigens (ENA) yielded an AUC of 0.87 and a sensitivity of 58% at a specificity of 95%. By contrast, the optimal combination of traditional and novel ELISAs achieved an AUC of 0.92 and a sensitivity of 75% at a specificity of 95%.

Conclusions: This study demonstrates the feasibility of test results of novel and traditional AABs using logistic regression to increase the diagnostic accuracy for SLE. Further studies are required to assess the impact of different ethnicities on marker selection and algorithm performance.

References:

specificity of 85%, positive predictive value of 86%, negative predictive value of 89% and diagnostic odds ratio of 51. UTS was positive in 2 patients with HIV infection and one patient with sarcoidosis. Patients with pSS had significantly higher UTS than patients with systemic diseases (median UTS 27 vs. 10, p<0.001) and patients of the various subgroups (p<0.05; Fig).

Figure: UTS in patient (sub)groups. *p<0.001, **p<0.05. Black horizontal lines indicate median values. The intermittent horizontal line shows the cut-off point. The intermittent black vertical line separates the two major patient groups (pSS vs. systemic diseases) from the subgroups of patients with sarcoidosis, amyloidosis, HIV and HCV infection.

Conclusions: This pilot study indicates that SGUS has a high diagnostic accuracy to discriminate pSS from associated systemic diseases with salivary gland involvement. A minority of HIV and sarcoidosis patients, however, may show SGUS findings mimicking pSS.

SAT0619 ANKLE EVALUATION IN ACTIVE RHEUMATOID ARTHRITIS BY ULTRASOUND: A CROSS SECTIONAL STUDY

A.M. Elsamam1, E.S. Mostafa2, A.R. Radwan1, 3
1Rheumatology, Sohag University Faculty of Medicine; 2Rheumatology, Qena faculty of medicine, Sohag, Egypt

Background: Ankle joint evaluation is underestimated in many clinical and sonographic scores used for evaluation and follow-up of rheumatoid arthritis (RA) patients. Moreover, sonographic scores which included the ankle joint had no agreement on examination parameters. More effort is needed to detect the value of the ankle joint examination in RA and also a description of the earliest and the most frequent ultrasonographic signs that should be considered in ankle assessment (1).

Objectives: detection of ankle affection by ultrasound (US) in active RA and correlated findings with disease duration, DAS28-ESR 28 score and rheumatoid factor (RF).

Methods: 126 ankle joints and tendons of 63 active RA patients, aged above 18 years old were included in the study. US examination was done to the tibiotalar and talonavicular joints for synovitis and/or effusion on Greyscale (GS) mode and power doppler (PD). The anterior, lateral and posterior ankle tendons were examined for tenosynovitis and tendinosis.

Results: The mean age and ± standard deviation were 35.1±8.3 with the female-to-male ratio 2:1. The mean disease duration was 22.7±6.6 months. The mean DAS28-ESR 28 score was 3.05±0.66. The most frequent pathologies detected were tenosynovitis of the flexor, extensor or peroneal tendons (found in 30.2% of the affected ankles); followed by synovitis of the tibiotalar and talonavicular joints (18.3%); next was erosion (8.7%) and lastly tendinosis (4%). The earliest sonographic signs were tenosynovitis, followed by synovitis, erosion, and lastly tendinosis.

Conclusions: It can be stated that ankle evaluation should be considered more in RA assessment. The tibial anterior and posterior tendons, the tibiotalar and talonavicular joints were the commonest and most frequent sites to be involved in the ankle. Tenosynovitis appears earlier than synovitis. DAS28-ESR score was correlated to synovitis and tenosynovitis but not to erosion. Bilaterality and erosion were correlated with disease duration. RF positivity has a positive correlation with positive US findings in the ankle region.

SAT0620 POTENTIAL ROLE OF METACARPOPHALANGEAL JOINTS ULTRASOUND IN THE DIFFERENTIAL DIAGNOSIS BETWEEN EARLY RHEUMATOID ARTHRITIS AND EARLY SPONDYLOARTHITIS

A. Batticciotto, G. Prato, M. Antivalle, M.C. Ditto, M.C. Gerardi, R. Talotta, F. Atzeni, P. Sarzi-Puttini. Rheumatology Department, ASST-Fatebenefratelli–Sacco, “L. Sacco” University Hospital, Milan, Italy

Background: Several studies have demonstrated that musculoskeletal ultrasound (MSUS) is more sensitive in diagnosing arthritis when compared to clinical examination; although, as underlined in a recent review, still remains controversial whether it can improve substantial discriminatory value in an early arthritis (EA) setting. (1) in 2011 Gutierrez M. et al. published preliminary data on high frequency of perionen extension tendon inflammation in Psoriatic arthritis (PsA) patients, suggesting a relevant potential role for US in differential diagnosis between Rheumatoid Arthritis (RA) and PsA at metacarpophalangeal (MCP) joints level and recommending additional research in order to confirm these data (2).

Objectives: To compare MSUS findings between early RA and early Spondyloarthritis (SpA) patients at MCP joints level.

Methods: From a consenting cohort of EA patients presenting to our Rheuma-
VASCULARIZATION IN RHEUMATOID ARTHRITIS

QUANTITATIVE DOPPLER SCORING SYSTEMS FOR THE ASSESSMENT OF SYNOVIAL PATHOLOGICAL VASCULARIZATION IN RHEUMATOID ARTHRITIS

E. Naredo1,2, I. M. Rutigliano2, I. Janta1, C. Scirocco5, L. Valor4, F. Figus4, L. Carrero2, J. Garrido2, A. Iagrocco2, P. Department of Rheumatology, Hospital General Universitario Gregorio Marañon; 2Department of Rheumatology, Hospital Universitario Fundación Jiménez Díaz; 3Autonoma University of Madrid, Madrid, Spain; 4Department of Social Psychology and Methodology. Faculty of Psychology, Autonoma University of Madrid, Madrid, Spain; 5Department Scienze Cliniche e Biologiche, Università degli Studi di Torino, Turin, Italy

Objectives: To compare power Doppler (PD) vs colour Doppler (CD) semiquantitative and quantitative scoring of synovial vascularization (RA) and to evaluate the relationship between semiquantitative and quantitative scores in patients with rheumatoid arthritis (RA).

Methods: One hundred RA patients underwent B-mode, PD, and CD assessments of 12 joints at two European centres. Each joint with synovial hypertrophy detected on B-mode was semiquantitatively scored (0–3) for PD (SPD score) and CD (SCD score) synovial signal. PD and CD synovial signal were also quantitatively scored (0–100%) (PDQ and QCD scores, respectively) using a software for counting the colour fraction.

Results: We found SH in 184 joints. SPD and SCD agreed in 92.3% (95% CI: 88.4–96.2%) of paired scores, with Kendall rank correlation coefficient tau=0.95. Significant differences were between marginal distributions of SPD and SCD were not found (p=0.565). PDQ and QCD scores were highly correlated (Pearson’s coefficient=0.70) but Bland-Altman plot showed insufficient agreement, being the QCD scores systematically slightly higher than the QPD scores. The distribution of QPD and QCD values between SPD and SCD scores, respectively, showed significant differences between grade 0 and grade 1 (p<0.001), and grade 2 and grade 3 (p=0.042 and p=0.007, respectively) but not between grade 1 and 2 (p=0.154 and p=0.150, respectively). Significance: SPD and SCD scores were concordant and QPD and QCD scores highly correlated although were not concordant. There was consistency between SPD and SCD moderate and severe scores and QPD and QCD scores. There was an overlapping between SPD and SCD mild and moderate scores regarding PDQ and QCD scores.

SAT0623

CORRELATIONS BETWEEN CLINICAL, ULTRASOUND AND DISEASE ACTIVITY SCORES OF PERIPHERAL ENHESITIS IN SPONDYLOARTHRITIS (SPA)

A. Haddouche, S. Haid, S. Bencheikh, S. Slimani, A. Abdessemed, N. Brahim, A. Ladouze. Medicine, University of Algiers 2, Algiers, Algeria

Objectives: To look for correlations between clinical, ultrasound (US) and disease activity scores of peripheral enthesitis in an SPA cohort.

Methods: A prospective study of all SpA patients seen at EHS Ben Aoun, over a period from January 2015 to April 2016. Seventeen enthesal sites were assessed bilaterally: insertions of supra-spinatus, infra-spinatus, sub-scapular, medial and lateral epicondylar, triceps brachialis, gluteus minimus and midius, quadriapital, proximal and distal insertion (patellar ligament, medial and lateral collateral ligament), Achilles tendon and plantar aponeurosis. Peripheral enthesitis was assessed by the following clinical scores: Enthesitis Peripheral Score (PES= Sum of symptomatic peripheral entheses sites on clinical examination), Visual Analog Scale of peripheral enthesitis (VAS), Spondylarthritides Research Consortium of Canada score (SPARCC) as well as the following US enthesitis scores: Acute Enthesitis score (Sum of acute enthesitis US scores for each site), Global Enthesitis score (Sum of acute and chronic US scores of entheses), Doppler signal Enthesitis score (Sum of Doppler signal scores less than 2mm from cortical bone for each site), Madrid Sonography Enthesitis Index (MASEI), Simplified Echographic Score (SES) with assesss only the Achilles
tendon and the plantar aponeurosis. Correlations between clinical, activity and US scores were investigated by SSPSS software.

**Results:** A total of 208 patients were included. At examination 88.9% had an active disease and 64.4% of SpA were taking NSAIDs. 62.40 entheses were assessed clinically and with US. A positive correlation was found between activity scores and two clinical scores (RAMRIS and SPARCC). A good correlation was found between Activity scores and all US scores on one hand and with SPARCC scores and PES scores on the other hand. For US and clinical correlations, only Doppler scores was positively correlated with 2 clinical scores (SPARCC and PES scores), Acute Enthesitis score was correlated with the PES scores. No correlation was found between clinical scores and MASEI or SES scores. No correlation was found with the mean enthesitis VAS scores.

**Conclusions:** All US enthesitis scores were correlated with disease activity scores but those correlated with the clinical symptoms and not with its intensity were: Acute Enthesitis Scores, Global Enthesitis Scores and especially Doppler signal Enthesis Scores.

**Disclosure of Interest:** None declared

**DOi:** 10.1136/annrheumdis-2017-eular.1968
showed that joint inflammation is common in ochronotic patients, associated in some cases with peripheral enthesis involvement confirming previously published data (1). The prevalence and the characteristics of the inflammatory manifestations should be further studied in larger cohorts of patients as they could play an important role in the joint damage process in these patients and provide a rationale for the use of new drugs.

SAT0526 METACARPOPHALANGEAL JOINT SWELLING IN PSORIATIC ARTHRITIS: WHAT DOES IT MEAN?

C. Macia 1, S. Falcao 2, M. Gutiérrez 3, J. Medina 4, H.B. Hammer 5, E. De Miguel 6, 7

Rheumatology, Hospital Universitario Severo Ochoa, Madrid, Spain; 2 Rheumatology, Chronic Diseases Study Center (CEDOC), NOVA Medical School, UNL, Lisboa, Portugal; 3 Rheumatology, Division of Musculoskeletal and Rheumatic Disorders, Instituto Nacional de Rehabilitación, Mexico City, Mexico; 4 Rheumatology, Hospital Clínico Universitario, Valladolid, Spain; 5 Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; 6 Rheumatology, Hospital Universitario la Paz, Madrid, Spain

Background: Clinical metacarpophalangeal joint (MCPj) swelling is a frequent finding in psoriatic arthritis (PsA). It is assumed to be caused by intra-articular synovitis (IAS). However, ultrasound (US) have also demonstrated in PsA peritenon inflammation of the extensor digitorum tendon (PTI). To date the data about the significance of this two lesions (IAS and PTI) in MCPj swelling are sparse.

Objectives: Our objective was to explore PTI and IAS as the cause of clinical MCPj swelling in PsA patients.

Methods: 27 consecutive non selected PsA patients, fulfilling CASPAR criteria, with clinical involvement of at least one 2nd to 5th MCPj were included. A MyLab 70 XVG machine, Easote, Genova, Italy, with a greyscale (GS) 13 MHz probe, and a 7.1 MHz power Doppler (PD) frequency (PRF 750 Hz, Gain 60) was used. Videos (3–5 sec) of each MCPj 2nd to 5th of both hands in transversal and longitudinal views were obtained for central reader analysis, scoring US as presence or absence in GS and PD of: 1) PTI (defined as an hypoechoic swelling of the soft tissue surrounding the extensor tendon at MCPj level with or without PD) and 2) IAS (OMERACT definition). US pathology for each joint and lesion was defined as at least three of five central readers having the same score. SPSS analysis was performed for frequencies, percentage of agreement and Cohen's Kappa test.

Results: 27 PsA patients with a mean (SD) age of 56 (11) years and disease duration 10% (17) months were included. Isolated peripheral involvement was present in 21 patients (78%) and 6 (22%) had both axial and peripheral affection. Mean (SD) CRP level was 8.3 (8.2) mg/l and ESR 21.9 (19.3) mm. The mean DAS28 ESR was 3.88 (1.23). Psoriasis involvement included skin and nails in 15 (55.5%) of the patients.

Conclusions: Our study identifies two different US lesions (IAS and PTI) causing clinical joint swelling. PTI is near as frequent as IAS as a cause of MCPj swelling, and future studies are necessary to explore the added value of assessing PTI for prognosis or treatment.

SAT0627 MUSCLE BIOPSY: MASTER ROLE IN DIFFERENTIAL DIAGNOSIS IN PATIENTS WITH SUSPECTED MYOPATHY

Background: The muscle biopsy may be a fundamental technique in the suspicion of myopathy, with high specificity to distinguish between normal or abnormal muscle tissue. It is associated with clinical and laboratory findings, the muscle biopsy has an important role to a more accurate diagnosis.

Objectives: To evaluate the usefulness and safety of muscle biopsies performed in a Rheumatology Unit in patients with suspected myopathy.

Methods: Retrospective analysis of the clinical charts of patients submitted to muscle biopsy between January 2010 and December 2016 at our Rheumatology Unit. Demographic, clinical, laboratory, electromyographic and histological data were collected. The histological study was performed in a Neuropathology Specialized Unit.

Results: A total of 46 patients, 19 men and 27 women, with a mean age of 53.3±11 years, were evaluated. Clinical manifestations included muscle weakness, myalgia and decreased muscle strength. Most patients also had increased muscle enzymes, particularly creatine kinase, but in a patient with generalized muscle atrophy, muscle enzymes were overall diminished. Of the 46 biopsies, 12 (26.1%) did not show alterations, 8 (17.4%) showed nonspecific alterations and only 1 biopsy was not conclusive because the sample was inadequate. In 4 patients, the histological features did not present specific characteristics of a myopathy, but revealed a preferential atrophy of type 2 fibbers, usually associated with prolonged corticosteroïd therapy. Among the others, 9 (19.6%) were compatible with inflammatory myopathies, namely polymyositis (6), dermatomyositis (1), inclusion body myopathy (1), and localized nodular myositis (1). In the latter case, the patient had a different clinical presentation, with intermittent episodes of pain, oedema and flushing of different muscle groups. In addition, 5 metabolic myopathies (2 McArdle’s diseases and 3 non-specific metabolic disorders), 2 muscular dystrophies (1 Becker’s muscular dystrophy and 1 dystrophinopathy), 1 suspected case of myotonic dystrophy and 1 myopathy associated with statins use were diagnosed. In a patient with muscle weakness and prior diagnosis of systemic vasculitis, the histology showed a chronic inflammatory process with no specific alterations. In the patient with overall decrease in muscle enzymes, the biopsy revealed neurogenic atrophy, without inflammatory infiltrates. Overall, the results of electromyography (EMG) did not correlate with the histological findings, because EMG identified alterations both in cases with histologically compatible inflammatory myopathies and in cases without histological pathology. On the other hand, EMG did not reveal any changes in some of the metabolic myopathies. Muscle biopsies were performed mainly in the deltoid muscle. There were no relevant immediate or late complications with this technique.

Conclusions: Although muscle biopsy is an invasive technique, it is a safe technique and allows the differential diagnosis between the various myopathies, which is fundamental to an appropriate treatment.

SAT0628 INCREASE OF CORTICAL MICRO-CHANNELS (COMICS) AS A NEW FEATURE OF STRUCTURAL DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Werner 1, 2, D. Simon 1, M. Engbrecht 1, F. Steimmel 1, A. Berlin 1, J. Haschka 1, M. Rennow 4, T. Buder 5, J. Rech 1, K. Engelke 1, A.J. Hueber 1, G. Schett 1, A. Kleyer 1.

1 Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätshiln Krankenhaus Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen; 2 Rheumatologie & Nephrologie, Städtisches Klinikum Dresden, Dresden, Germany; 3 St.Vincent Hospital, Medical Department, Academic Teaching Hospital of Medical University of Vienna, Vienna, Austria; 4Department of Trauma and Orthopedic Surgery, Friedrich-Alexander-University Erlangen-Nuremberg; 5 Institute of Anatomy, Friedrich-Alexander-University Erlangen-Nürnberg (FAU); 6 Institute of Medical Physics, Friedrich-Alexander-University Erlangen-Nuremberg Erlangen, Germany

Background: Bone damage in rheumatoid arthritis (RA) typically emerges at certain anatomical hotspots corresponding to the so-called "bare area", an intra-articular region between the cartilage and the insertion site of the joint capsule (1,2). We hypothesized that this region exhibits certain micro-anatomical properties, which facilitates the emergence of bone erosions.

Conclusions: Our study identifies two different US lesions (IAS and PTI) causing clinical joint swelling. PTI is near as frequent as IAS as a cause of MCPj swelling, and future studies are necessary to explore the added value of assessing PTI for prognosis or treatment.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.05069
OBJECTIVES: To find the micro-structural correlate of the origin of bone erosions in the bare area of the human joint

METHODS: Bare areas of human joints were analyzed for early microstructural changes by in-vivo high-resolution peripheral computed tomography (HR-pQCT). First, bare areas were exactly defined by scanning 6 cadaveric hands for localization of the bone lesions found in the cadaveric hand by HR-pQCT were additionally by super-resolution ex vivo micro-CT (μCT40). Then, number and distribution of the type of bare area bone loss found in cadaveric study were analyzed in a cohort of 105 healthy individuals and 107 anti-citrullinated peptide (ACPA) positive RA patients with similar sex and age distribution.

RESULTS: HR-pQCT combined with adaptive thresholding allowed the definition of a new type of bone lesions in the bare areas of the human joint termed ‘COMIC’ standing for ‘cortical micro-channel’. Their existence in the bare area was additionally validated by micro-CT (μCT40) in 1 RA patients. RA patients showed significantly (p<0.001) more CoMiCs (112.9±54.7/joint) than healthy individuals (75.2±41.9/joint) with 20-49 years old RA patients exhibiting similar CoMiC numbers as observed in over 65 years old healthy individuals. Importantly, CoMiCs were found in RA patients already very early in their disease course with enrichment in the erosion-prone radial side of the joint.

Conclusions: CoMiCs represent a new structural feature of the joint, which is characteristic for the bone of the bare area. COMICs at low level are found in young healthy individuals but then they significantly increase with age, and particularly with RA. COMICs develop much earlier and much more pronounced in RA patients than in healthy individuals and therefore represent an interesting new early indicator for erosion development in ACPA positive RA patients.

SAT0629
ELECTRODIAGNOSTIC VS ULTRASONOGRAPHY: WHICH ONE IS BETTER TO CONFIRM DIAGNOSIS OF ULNAR NEUROPATHY AT ELBOW?

S.M. Rayegani1, E. Loni2, S.A. Raeesadad2, E. Kargozar3, S. Rahimi Dehghan1. 1Physical Medicine and Rehabilitation Research Center, Shahid Beheshti University of Medical Sciences; 2Rafiedeh rehabilitation Hospital, University of Social Welfare and Rehabilitation Sciences; 3Physical Medicine and Rehabilitation Research Center, ShahidBeheshti University of Medical Sciences;

Background: Ulnar neuropathy at the elbow is the second most common compression neuropathy preceded by carpal tunnel syndrome. Although this diagnosis has been traditionally confirmed by electrodiagnosis (EDX), ultrasonography (US) is a re-emerging alternative method which can also evaluate the cubital zone anatomy. This study determines the maximum amount of US sensitivity and specificity by assessing different sonographic parameters and evaluates consistency and diagnostic value of the best US method in compare with EDX.

Methods: We included 66 participants (32 elbows of patient and 34 normal elbows) and performed physical exam, US and EDX for both groups. Patients were classified into four severity grades using EDX criteria. The parameters of US were cross sectional area (CSA) of ulnar nerve at three levels: medial epicondyle (CSA med), 2cm distal (CSA dist) and 2cm proximal (CSA prox) to the motor in young healthy individuals would be able to evaluate consistency between CSA med and severity grade (p-value=0.034) and the second correlation was between CSA med and CSA dist with a cross-elbow nerve conduction velocity (NCV) (p-value=0.01 and 0.02, respectively). Finally we assessed US diagnostic value as it showed AU-ROC =0.871, that means a very good coverage for an alternative diagnostic method. Also our results showed specificity of 80% and sensitivity of 84% for US in the CSA med cut-off point <9mm² for diagnosis of ulnar nerve entrapment at elbow.

Conclusions: Based on these results we can conclude that US is a highly sensitive and specific method to diagnose ulnar neuropathy at elbow and can be used as an alternative and complementary method in diagnosis of ulnar neuropathy at elbow in particular when EDX is not available. However it could not be still a definitive and substitute mutually exclusive method to EDX in diagnosis of ulnar neuropathy.

SAT0630 EXTRACARTILAGEOUS MUSCULOSKELETAL INVOLVEMENT IN JUVENILE IDIOPATHIC ARTHRITIS: CLINICAL AND ULTRASONOGRAPHIC FINDINGS

V. Ravagnan1, F. Llicciardi2, D. Montin2, F. Santarelli3, S. Martino4, C. Cirone2

1Internal Medicine, ASST MANTOVA - C. Poma Hospital, Mantova;
2Immunology and Rheumatology Unit, Regina Margherita Children Hospital Città della salute e della Scienza; 3Immunology and Rheumatology Unity, Regina Margherita Children Hospital, Città della salute e della Scienza; 4Immunology/Rheumatology Unity, Regina Margherita Children Hospital Città della salute e della Scienza;

Background: In Juvenile Idiopathic arthritis (JIA), musculoskeletal ultrasound (USUS) has been proven to be more sensitive than clinical evaluation in detecting articular synovitis. Nevertheless, many studies report a variable percentage of clinically active joints, that are judged normal by ultrasound examination. In absence of a feasible and reliable gold standard for pediatric synovitis (histology or MRI), this point may weaken the confidence in ultrasound, that is nevertheless perceived as an interesting tool, in the management of JIA.

Objectives: This preliminary study investigates the possibility that sometimes the clinically detected synovitis could be missed by ultrasound, because of its extra-articular localization.

Methods: 43 consecutive children affected by JIA underwent separated clinical and USUS assessment, in the same day. Patients were followed up in a pediatric Rheumatology Unit. The following clinical data were collected: age, sex, disease duration, subset of JIA, ongoing therapy, previous therapy, disease activity. By USUS, the synovitis was investigated bilaterally, both in gray scale and power Doppler, in the MCP and subtalar joints, wrists, knees, ankles, in the flexor and extensor tendons of the wrist and hand, in the anterior, medial and lateral tendons of the ankle, in the synovial bursae of knee and ankle. The possible involvement of the entheses was also investigated. The definition of ultrasonographic synovitis was based on the preliminary OMERACT definitions of synovitis in children. The inter and intra observer reproducibility of the MSUS examination was tested, independently, both between two operators and through a second assessment of the stored images.

Results: 43 children affected by JIA were recruited, in the outpatient clinic of the Regina Margherita Pediatric Hospital of Torino, Italy. They were 9 boys and 34 girls, median age 7.7 (IQR 5.5–10.1), 27 oligoarticular, 11 polyarticular, 4 psoriatic arthritis, 1 undifferentiated arthritis. The median disease duration was 44 months (IQR: 20.5–61.5), 20 patients in remission, 23 with active disease. 774 joints, 1548 synovial sheaths, 430 entheses and 258 synovial bursae were assessed. The physical examination detected inflammation in 54 joints, 33 tendons, 0 entheses,
0 bursae. Ultrasound abnormalities were found in 62 joints, 73 tendons, 8 bursae, 0 entheses. Overall physical examination and US showed good concordance even if MSUS was more sensitive especially in detecting extra-articular locations.

**Conclusions:** If the extra-articular locations of synovitis are taken in consideration during the ultrasound examination, there is a good sensitivity of MSUS and a better diagnostic clinical skill than the clinical examination. Between clinical and MSUS assessment of JIA, MSUS seems more accurate than physical assessment in detecting the exact position of the inflamed synovial membrane in each anatomical location (joint, synovial sheath, synovial bursa). It could be helpful not only for better addressing the injective procedures, but also for a global quantification of the synovitis (both intra and extra-articular), even if the exact clinical meaning of these ultrasound findings is still unknown, in terms of response to treatments and prognosis.

### SAT0632

#### IMPACT OF LUMBAR SPINE MORPHOLOGY (SCOLIOSIS) ON EARLY Spondylodiscitis Pattern (THE IMPALA-DESIR STUDY)

M. Voinir-Hertz 1, G. Carvalj Alegría 2, F. Garrigues 2, A. Simon 3, A. Feydi 4, T. Marraud 1, A. Saura 4 on behalf of DESIR. 1 Rheumatology, 1 University Hospital Inselspital Berne, Switzerland; 2 Reumaklinik Augsburg, Augsburg, Germany; 3 Philpott-Sawyer Arthritis Bone Disease Unit, University of Birmingham, Birmingham, United Kingdom; 4 Radiology, 4 Radiology, 4 Radiology, Leiden University Medical Center, Leiden, Netherlands; 5 Rheumatology, 5 CHU Nancy, Nancy, France; 6 Rheumatology, 6 CHU Creteil, Creteil, France

**Objectives:** To evaluate the impact of scoliosis on both clinical presentation and lumbar imaging of early inflammatory back pain suggestive of spondyloarthritis.

**Methods:** The DESIR cohort is a prospective longitudinal cohort study of adults aged 18–50 with inflammatory back pain (IBP) >3 months, <3 years. Baseline lumbar X-Rays of patients included in DESIR cohort were read by two central blinded reader (and a rheumatologist spine specialist in case of discrepancy) for presence or not of scoliosis (defined as a Cobb angle >10° and a Nash Moe grade >1). Associations between scoliosis and baseline clinical variables, presence of X-Rays (New York) and MRI (ASAS and MORPHO proposal definition) sacroiliitis, presence of spinal signs of spondylarthropathy (mSASSS, BASRI-total, SPARCC scores), presence of spinal degenerative MRI signs on X-rays (yes or no) and MRI (presence of Modic abnormalities, Pfirrmann score, Canal stenosis, Extrusion, High intensity zone Facet osteoarthritis) according to central reading (two readers) and axSpA diagnostic confidence (according to local clinician’s confidence on a 0–10 visual analogical scale) were assessed by univariate analysis using the chi-square test (or Fisher’s exact test where appropriate) and the Mann-Whitney test. Adjustment for multiple testing was performed according to Bonferroni method.

**Results:** 675 patients (47.1% men, mean age of 33.6 years, 89.6% had lumbar pain, 63% fulfilling ASAS criteria) were studied. The mean Cobb angle was 3.2° (± 4.8) and 49/675 (7.3%) patients had lumbar scoliosis. The only significant difference was the lumberosal sagittal balance. Indeed, scoliotic patients had greater lumbar lordosis (57.8° versus 50.9°; p < 0.001) than non-scoliotic. About MRI findings, spinal degenerative manifestations were very scarce in both groups. The major part of degenerative changes was in the two last lumbar discs and vertebrae, without significant difference between scoliotic and non-scoliotic patients.

**Conclusions:** Scoliotic patients with inflammatory back pain suggestive of spondyloarthropathy do not have more lumbar degenerative lesions than non-scoliotic patients, nor difference of clinical presentation, but they have greater lumbar lordosis.

#### INTER-OBSERVER AND INTRA-OBSERVER RELIABILITY OF THE OMERACT ULTRASONOGRAPHIC (US) CRITERIA FOR THE DIAGNOSIS OF CALCIUM PYROPHOSPHATE DEPOSITION DISEASE (CPPD) AT THE METACARPAL, PHALANGEAL, CARPAL, WRIST, ACROMION-CLAVICULAR (AC) AND HIP JOINTS

G. Filippou 1, C.A. Scirè 2, N. Damjanov 3, A. Adinolfi 4, G. Bruyn 5, G. Carrara 6, T. Cazenave 6, M.-A. D’Agostino 7, A. Delle Sedie 8, M.E. Diaz Cortes 9, M. Voirin-Hertz 1, G. Carvajal Alegria 10, M. Groesbeek 11, M. Mouterde 12, R. Piccirillo 13, S. Serban 14, L. Terslev 15, V. Vlad 16, F. Vreju 17, P. Zufferey 18, S. Bellavia 19, F. Garrigues 20, A. Simon 20, A. Feydi 21, T. Marraud 21, A. Saura 22 on behalf of OMERACT. 1 Rheumatology, MC Groep, Lelystad, Netherlands; 29University of Turin, Turin, Italy; 3University of Ioannina, Ioannina, Greece; 27Lausanne University Hospital, Lausanne, Switzerland; 28University of Ioannina, Ioannina, Greece; 21Internal Medicine; 23Immanuel Krankenhaus Berlin, Berlin, Germany; 22Immanuel Krankenhaus Berlin, Berlin, Germany; 24Center for Rheumatology and Spine Diseases, Rigshospitalet, Copenhagen, Denmark; 25St. Maria Hospital, Bucharest, Romania; 26University of Medicine and Pharmacy, Cluj, Romania; 27Lausanne University Hospital, Lausanne, Switzerland; 28University of Ioannina, Ioannina, Greece; 24University of Turin, Turin, Italy

**Background:** The OMERACT US subtask force “US in CPPD” recently created the definitions for US identification of crystal deposits in joints and tests the reliability at the knee [1].

**Objectives:** To assess the inter/intra-observer reliability of US on detecting CPPD using the OMERACT criteria at the AC joint, hip labrum (HL), hyaline cartilage (HC) of the acetabulum (MC) and femoral head.

**Methods:** The OMERACT criteria for CPPD were used for the exercise [1] using a 2 steps approach. First, the panel of experts gave a dichotomous score (presence/absence of CPPD) of 120 images of the sites included, using a web probes were used.

**Results:** Reliability values of static exercise were high for all sites, demonstrating that definitions were clear. The results of the second step are presented in table 1. On live scanning, the TFCC resulted the most reliable site for CPPD assessment, followed by AC. Other sites demonstrated lower kappa values and thus are not reliable for CPPD assessment.

**Conclusions:** TFCC of the wrist is the most reliable site for CPPD. By adding these results to the previous [2], we confirm that the OMERACT definitions for CPPD can be applied reliably at the knee (meniscus and HC), TFCC and AC, usually the most involved sites in CPPD. In the next step of the OMERACT subtask force will be to test these findings in a longitudinal observational study.

### SAT0633

#### NOT A REPLACEMENT BUT A POSSIBLE SUBSTITUTION: DETECTION OF SACROILIITIS ON MAGNETIC RESONANCE ENTEROGRAPHY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

L. Ergen 1, R. Ergelen 2, A.U. Ünsal 3, Z. Erkorkut 4, Z. Yalçınkaya 4, N. İnan 3, I. İmeryüz 1, D. Direksenel 1, G. Ekniz 2, P. Atagündüz 2, 1Internal Medicine; 2Radiology; 3Rheumatology; 4Gastroenterology, Marmara University School of Medicine, Istanbul, Turkey

**Background:** MR Enterography (MRE), a part of the diagnosis in patients with inflammatory bowel disease (IBD), is increasingly used to exclude Crohn’s Disease (CD) in SpA patients with diarrhea. Two important retrospective studies 1,2, on IBD
suggest that acute and structural findings of sacroilitis can be evaluated on MRE. But, it needs to be verified whether it really correlates with sacroiliac MRI.

**Objectives:** We aimed to determine whether assessment of sacroilitis on MRE correlates with magnetic resonance imaging (MRI) of sacroiliac (SI) joint.

**Methods:** MREs used for screening of IBD in Axial SpA patients with chronic diarrhoea and routine semi-coronal SI joint MR images were screened for the presence of acute inflammatory lesions and structural changes of the SI joint by the same radiologist in a blinded fashion to time and diagnosis. Firstly, MRE images and then MR images were evaluated on two separate occasions. Only patients with two imaging modalities with a maximum time distance of a month were evaluated.

**Results:** Forty-four patients with MRE imaging were included. Two MRE studies were excluded because of low resolution. Of those 11 patients (26%) had active inflammatory lesions involving mostly both SI joints and 3 had accompanying chronic structural changes. Ten patients (24%) in the MRE group had chronic structural changes, only. In the remaining 20 (47%) MRE evaluated patients SI joint were not affected. Twenty-five axSpA patients had both MRE and SI joint MRI performed within a month. In 19 cases, out of 25 with both modalities the finding “no sacroilitis” overlapped. An additional four patients had acute inflammatory lesions on both investigations. In only two patients either MRE or SI joint MRI had acute inflammatory lesions. In general, chronic structural changes overlapped in both modalities as well; Fourteen out of 25 patients with no changes and eight with chronic changes overlapped in both examinations. Both modalities differ in only three patients; Chronic changes was present in two patients in SI joint MRI and one patient in MRE only.

**Conclusions:** In SpA patients with chronic diarrhoea a present MRE may substitute a conventional semi-coronal MRI of the SI joints and may hence decrease diagnostic expenses. Evaluation of MRE for the acute inflammatory and chronic structural changes of the SI joints may also have a place in the diagnostic flow in IBD patients referred by the gastroenterology clinics, as well.

MUSCULOSKELETAL ULTRASOUND IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISM POST-CHIKUNGUNYA

I. Monjo Henry 1, F. De la Calle 2, E. Trigo 2, E. Fernández 1, D. Benavent 1, E. De Miguel 1, A. Balas 1, 1Rheumatology, Hospital la Paz; 2Tropical Diseases and Travel Unit, Hospital la Paz-Carlos III, Madrid, Spain

**Background:** Since 2013, Chikungunya fever (CHIK) has become a re-emerging disease, with an important number of cases imported in Europe, mainly from South America. At chronic stage (after third month) it can develop a chronic inflammatory rheumatism (CIR), in some cases indistinguishable from rheumatoid arthritis (RA) or spondyloarthropathy (SpA)

**Objectives:** The aim of this study was to investigate the ultrasound (US) alteration in patients with persistent arthralgia at chronic stage of CHIK.

**Methods:** Observational study of patients with persistent arthralgias at the chronic stage of CHIK. We designed a protocol of derivation patients from the Tropical Diseases Unit to the Rheumatology Department which included patients had persistent arthritis after 6 weeks who did not respond to steroids, presence of bone erosion or any diagnosis doubt. In the basic rheumatological visit, we made the clinical history, physical examination, blood analysis, X-ray and US examination. A Mylab Twice equipment (Esaote, Genova, Italy) was used, with a 5–13 MHz frequency for grey scale and 5–12.5 MHz for Power Doppler (PD). Wrist, metacarpophalangeal (MCP), interphalangeal (IP), knee, ankle and metatarsophalangeal joint were assessed and also enthesis if symptomatic. Three patterns of post-CHIK CIR were defined: 1) Post-CHIK RA (if meet RA ACR/EULAR 2010 criteria), 2) post-CHIK Spondylosis (SpA criteria) and 3) post-CHIK undifferentiated arthritis (arthritis without meeting the previous criteria). Post-CHIK musculoskeletal disorders were defined as chronic polyarthritis without objective physical signs of inflammation (without arthritis, tenosynovitis or enthesis).

**Results:** 93 patients were included. 78,3% women, mean age of 46.0±13.65 years. 6 patients (10.2%) were derived to the Rheumatology Department, 5 women and 1 man. In one rheumatoid factor and anti-cyclic citrullinated peptide antibodies were detected. HLA B27 and antinuclear antibodies were negative in all patients. The physical and US data of these patients are shown in the table. 5 of these patients were diagnosed with post-CHIK CIR: 1) post-CHIK RA, 1 non-radiographic axial SpA with peripheral affection (arthritis and enthesis) and 3 patients with post-CHIK undifferentiated arthritis. The other patient was diagnosed with post-CHIK musculoskeletal disorder. All 59 patients received NSAIDs and steroids. In addition, post-CHIK CIR received methotrexate (2 patients) and sulfasalazine (1 patient), all with improvement. In the full cohort, only 5.9% of patients had arthralgias prior to CHIK infection, vs. 33.3% in the post-CHIK CIR (p=0.081). 3 patients (5.08%) had a family history of arthritis, all in the post-CHIK CIR.

**Conclusions:** Arthralgias are a frequent symptom even at chronic stage of CHIK. Sometimes it is true arthritis and in others cases edema. For this reason US is very useful in doubtful cases. In our cohort, patients that developed post-CHIK CIR were more frequently women, with a higher percentage of family history of arthritis. To the best of our knowledge, this is the first US study in patients with post-CHIK CIR.

DESCRIPTIVE ANALYSIS OF THE QUANTICAP STUDY: A MULTICENTRIC PROSPECTIVE STUDY FOR THE VALIDATION OF QUANTITATIVE AND QUALITATIVE PARAMETERS OF NAILFOLD CAPILLAROSCOPY

I. Castelvi 1, P. Reyner 2, Z. Martinez 4, M. Moreno 5, M.S. Gelman 6, V. Ortiz-Santamaria 1, S. Ordoñez 8, P. Sando 5, S. Heredia 10, X. Juanelo 11, H. Corominas 12, 1Rheumatology, Hospital Universitari de la Santa Creu i Sant Pau; 2Rheumatology, Hospital Universitari Dr. Josep Trueta, Girona; 3Hospital de Santa Caterina, SALT; 4Rheumatology, Hospital Universitari Mutua de Terrassa, Terrassa; 5Rheumatology, Corporación Sanitaria Parc Taulí, Sabadell; 6Rheumatology, Fundació Althaia, MANRESA; 7Rheumatology, Hospital General de Granollers, Granollers; 8Rheumatology, Hospital Universitari Arnau de Vilanova, LLEIDA; 9Rheumatology, Hospital General Parc Santitari Sant Joan de Despo, Sant Boi de Llobregat; 10Rheumatology, Hospital Comarcal Sant Joan Despi-Moises Broggi, Sant Joan Despi; 11Rheumatology, Hospital Universitari de Bellvitge, Hospital de Llobregat, Spain

**Background:** Nailfold capillaroscopy (NC) is a useful tool to study Raynaud’s phenomenon (RP) and other diseases. Different findings and patterns has been described however there is currently no work that validates the qualitative and quantitative NC findings.

**Objectives:** To describe the morphological and metrological findings of NC in patients with RP and autoimmune diseases.

2-Describe the morphological and metrological findings of CP in patients with RP and autoimmune diseases.

3) Describe the morphological and metrological findings of NC in patients with RP and other autoimmune diseases.

4) Describe the morphological and metrological findings of CP in patients with RP and autoimmune diseases.

**Methods:** Observational study performed in 10 hospitals by rheumatologists with experience in NC. Patients with diffuse systemic sclerosis (dSSc), limited systemic sclerosis (SSc), dermatomyositis (DM), polymyositis (PM), systemic lupus erythematosus (SLE) Primary Sjögren’s syndrome (PSS), rheumatoid arthritis (RA), primary RP and a control group without RP or rheumatological condition were collected.A video NC 200x magnification were made in all patients. 8 Fingers in each hand were analyzed to find: megacapillary and thrombosis, haemorrhages, tortuosity, dermatoangiitis, haemorrhages, thrombosis and destructuration. Also we analyzed the diameter of the afferent and efferent loop, the capillary apex, the capillary diameter and density/mm. The following variables were also collected: sex, age, years of evolution of the disease and RP, history of digital ulcers or medication for
RP, smoking and presence of hypertension or diabetes. To compare qualitative variables, the test used was Chi-square or Fisher’s test. To compare quantitative vs qualitative variables Student’s T test was used. Significance was considered for those values with p-value <0.05.

Results: Between May 2014 to December 2016 images of 406 patients were collected: 24 dSSc, 41 sSSc, 19 DM, 14 PM, 40 SLE, 39 PSS, 37 RA, 44 PRP and 145 controls. C 84.5% were women, the age of the sample were 51.32±15.21 years. 28.9% had a history of smoking and 21.1% and 5.5% of hypertension or diabetes, respectively. Excluding the cases of dSSc, ISSc, PRP and the 145 controls, the presence of RP was observed in 18/152 (11.84%). The inter-observer reliability exercise study in JIA patients as the final 3rd phase of the process. The definitions were tested in four joints (wrist, 2nd MCP, knee and ankle) of JIA patients divided in four age groups following standardized image acquisition and machine setting protocol. Statistics program R (version 3.3.0) was used for the statistical analyses. For intra-rater agreement Cohen kappa values and for inter-rater agreement prevalence and bias adjusted kappa (PABAK) were calculated if needed.

Results: Reliability exercise included 20 JIA patients (distributed in equal numbers by age groups), 14 observers, 4 joints/observer, 3 observers/joint, 360 intra- and 360 inter-observer tests. A 0–3 semi-quantitative B-mode and color power/Doppler US definitions for synovial components and grading were agreed (presented in Figure 1).

Conclusions: The proposed synovitis grading for children showed to be reliable why the next step should be to test sensitivity to change in order to possibly be used as an outcome tool in clinical trials.

SAT0637 ULTRASOUND ASSESSMENT OF SKIN THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS: CORRELATION WITH CLINICAL FEATURES

J. Sousa-News 1, M. Cerqueira 1, D. Santos-Faria 1, J. Leite Silva 1, A. Raposo 2, C. Alonso 1, F. Teixeira 1, 1Rheumatology, Hospital Conde de Berliandos, ULSAM, Ponte de Lima, 2Rheumatology, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal

Background: Although modified Rodnan skin score (mRSS) is the most widely used measure for assessment of skin involvement in Systemic Sclerosis (SSc), ultrasound (US) of skin thickness seems to be a promising complementary tool.

Objectives: To compare skin thickness measured by US of a defined anatomical point between SSc patients and age and sex matched controls. To compare, among patients, US measurements of skin thickness with local and total mRSS and other specific clinical variables.

Methods: Forty-eight SSc patients and 45 age and sex matched controls were evaluated in a cross-sectional study at our Rheumatology Unit. SSc patients had a mean age of 56.98±12.73 years and mean disease duration of 9.77±6.12 years; 42 patients had limited cutaneous disease. For comparison between groups, mean skin thickness (mST) of combined right side was used. Patients' local and total mRSS were also assessed.

Conclusions: mST was found to have face and content validity for detecting synovitis in juvenile idiopathic arthritis (JIA) with higher sensitivity than clinical examination. In order to test validity and improve the applicability of US in JIA, the OMERACT US pediatric subtask force recently published preliminary definitions for the sonographic features of synovitis in children.

Background: Ultrasound (US) was found to have face and content validity for detecting synovitis in juvenile idiopathic arthritis (JIA) with higher sensitivity than clinical examination. In order to test validity and improve the applicability of US in JIA, the OMERACT US pediatric subtask force recently published preliminary definitions for the sonographic features of synovitis in children.

Objectives: Aim of this study was to confirm and improve B-mode and color power/Doppler (PD) US definitions for synovial components and grading in children, by using an image and patient based exercise.

Methods: The definitions were confirmed and modified in a multi-step process. In the 1st step, definitions were developed in multi-round Delphi web based consensus process were performed. Participants would need to reach >80% of agreement on a Likert scale from 1–5 (1 strongly disagree, 2 disagree, 3 neutral, 4 agree, 5 strongly agree). In the 2nd step, in a face to face meeting, a subgroup of these experts revised the definitions for final wording and performed intra- and inter-observer reliability exercise study in JIA patients as the final 3rd phase of the process. The definitions were tested in four joints (wrist, 2nd MCP, knee and ankle) of JIA patients divided in four age groups following standardized image acquisition and machine setting protocol. Statistics program R (version 3.3.0) was used for the statistical analyses. For intra-rater agreement Cohen kappa values and for inter-rater agreement prevalence and bias adjusted kappa (PABAK) were calculated if needed.

Results: Between May 2014 to December 2016 images of 406 patients were collected: 24 dSSc, 41 sSSc, 19 DM, 14 PM, 40 SLE, 39 PSS, 37 RA, 44 PRP and 145 controls. C 84.5% were women, the age of the sample were 51.32±15.21 years. 28.9% had a history of smoking and 21.1% and 5.5% of hypertension or diabetes, respectively. Excluding the cases of dSSc, ISSc, PRP and the 145 controls, the presence of RP was observed in 18/152 (11.84%). The inter-observer reliability exercise study in JIA patients as the final 3rd phase of the process. The definitions were tested in four joints (wrist, 2nd MCP, knee and ankle) of JIA patients divided in four age groups following standardized image acquisition and machine setting protocol. Statistics program R (version 3.3.0) was used for the statistical analyses. For intra-rater agreement Cohen kappa values and for inter-rater agreement prevalence and bias adjusted kappa (PABAK) were calculated if needed.

Results: Reliability exercise included 20 JIA patients (distributed in equal numbers by age groups), 14 observers, 4 joints/observer, 3 observers/joint, 360 intra- and 360 inter-observer tests. A 0–3 semi-quantitative B-mode and color power/Doppler US definitions for synovial components and grading were agreed (presented in Figure 1).

Conclusions: The proposed synovitis grading for children showed to be reliable why the next step should be to test sensitivity to change in order to possibly be used as an outcome tool in clinical trials.

**Clinical Activity, Ultrasound Assessment and Drug Monitoring in Rheumatoid Arthritis Patients Receiving Anti-TNFα Therapy with Extended Interval of Administration**

J.M. Senabre Gallego 1, J. Rosas Gómez de Salazar 1, M. Marco Mingot 1, A. Narango 1, F. Linares-Tello 1, A. Pons 1, X. Barber-Vallet 1, G. Santos-Soler 1, E. Salas-Heredia 1, C. Cano 1, M. Lorente 1, J.A. García Gómez 2, J. Molina 2 on behalf of Asociación para la Investigación en enfermedades del Sistema Inflamatorio (AIRE-MB).

**Rheumatology; Laboratory, Hospital Marina Baixa, Villajoyosa (Alicante); 2Rheumatology, Hospital Dr. Negrín, Las Palmas de Gran Canaria; 3Centro de Investigación Operativa, Universidad Miguel Hernández, Elche, Spain.**

**Objectives:** To assess clinical activity, ultrasound synovitis and drug levels in rheumatoid arthritis (RA) patients receiving anti-TNFα therapy with extended interval of administration (EIA).

**Methods:** Prospective observational study. Population: RA patients, in clinical remission, receiving adalimumab (ADL) or etanercept (ETN) with EIA. Clinical activity was assessed by DAS28-ESR, DAS28-CRP, DASAI and SDAI scores at each visit. Twelve-joint ultrasound assessment (elbows, wrists, 2nd and 3rd metacarpophalangeal joints, knees and ankles) was performed evaluating synovitis through B-mode (BM) and Color Doppler signal (CD). A BM and CD score was calculated summing the highest score from each joint to a maximum of 36 points. We consider positive score ≥1 point. Serum drug levels were measured using Promonitor® ELISA kits (Progenika Biopharma, Spain).

**Results:** A total of 39 patients less than or equal to 62 years of age were included since February 2011 to December 2016. One patient was excluded due to blindness violation and 2 patients never received anti-TNFα due to low drug levels. 31 patients were women (82%) and the mean age was 61 (39–81) years. Most patients were RF positive (87%) and ACPA positive (74%). 22 patients were with ADL treatment and 16 with ETN. 32 patients reduced anti-TNFα: 20 (62%) and CDAD (5%) and 7 patients were with low-dose CS (18%). Mean time to response to ETN 4,61 (2,74 3,59 (2,9) 3,03 (0,84) and to rituximab 12 (20.3%) tocilizumab (74.7%) of whom 47 (79.7%) on combination with csDMARD therapy, 4 (5.7%) were biologic naive. 42 (63.6%) of bioprepared patients had a DAS28 >3.2 and were eligible for a change in their biologic however, only 17 of these patients had US-confirmed synovitis, 21 had evidence of osteoarthritis (OA), 1 tenosynovitis and 3 had no abnormalities. All biologic naive patients had a DAS28-CRP >5.1 before US however, 3 had US-confirmed synovitis and 1 had OA. Of bioprepared, 13/66 (19.4%) patients, including 4 with DAS-28 >3.2 but US-confirmed synovitis, had a new biologic started. 3 rituximab patients (including one with re-treatment) had a new biologic (tacrolimus) treatment. Concomitant treatment was needed in 13 (24.2%) patients. Metabolic (35.3%) and US scan findings 4 with US synovitis/tenosynovitis, had no change in their treatment. 2 (3.0%) patients self-discontinued treatment.

**Conclusions:** By identifying lack of inflammatory synovitis in biologic eligible patients US reduced the unnecessary and costly change of biologics. US also detected subclinical synovitis warranting modification of their treatment.

**Diagnosis and Imaging in Spondyloarthritis**

K. Fujikawa 1, Y. Endo 1, A. Mizokami 2, M. Mine 2, A. Kawakami 3

1Rheumatology, Japan Community Healthcare Organization, Ishaya General Hospital; 2Rheumatology, Suga Orthopedic Hospital, Isahaya; 3Department of Immunology and Rheumatology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan

**Objectives:** To evaluate the diagnostic utility of detecting enthesitis by ultrasound in patients with peripheral spondyloarthritis (SpA).

**Methods:** A single-center cohort study was performed in patients with symptoms suggestive of peripheral SpA (inflammatory back pain, arthritis of the lower limbs, tenderness of the entheses and dactylitis). Patients with only axial symptoms in the absence of peripheral symptoms were excluded. Fourteen sites of entheses (both sides of lateral epicondyle, quadriceps tendon insertion into the patella, patellar ligament insertion into the patella and tibial tuberosity, medial and lateral femoral condyles, and Achilles tendon) were assessed at baseline by ultrasound. Ultrasound assessment was made by Japan College of Rheumatology (JCR)-registered sonographers. Furthermore, articular synovitis and tenosynovitis of both hands were scored by two experienced rheumatologists using Clinical, laboratory, CRP, HLA typing, radiological (X-ray and MRI of sacroiliac joint) findings and SpA classification criteria (Amor's, ESSG and ASAS) were also evaluated. The gold standard was the diagnosis made by the JCR-certified rheumatologists during a six-month follow-up period.

**Results:** Between April 2014 and November 2016, one hundred-thirty six patients were consecutively enrolled. A definite diagnosis was obtained in 112 patients (72 SpA and 40 non-SpA). Diagnosis was not made in the remaining 24 patients. Seventy-two SpA patients (62 with undifferentiated SpA, 6 with psoriatic arthritis, 2 with reactive arthritis, 1 with spondyloarthropathy associated with another disease) and 40 non-SpA patients were investigated in this study. In ultrasound findings, SpA patients showed power Doppler (PD) signals of the articular synovitis (57%), tendon sheath synovium (71%) and enthesis (94%). A PD signal for at least one enthesis sites was the most useful finding for differentiation of SpA from non-SpA (sensitivity 96.1%, specificity 78.6%; positive likelihood ratio 6.3) regarding ultrasound findings. In logistic regression analysis, fulfillment of peripheral ASAS criteria, that of Amor’s criteria, and presence of PD signals at least one enthesis sites were independent variables to the contribution of diagnosis of SpA (Figure 1).

**Diagnosis Utility of Detecting Enthesitis by Ultrasound in Peripheral Spondyloarthritis**

**ULTRASONOGRAPHY AND INTRA-ARTICULAR INJECTION THERAPY IN EARLY RHEUMATOID ARTHRITIS: RESULTS FROM THE RANDOMISED ARCTIC TRIAL**

L.B. Nordberg1, S. Lillegraven1, A.-B. Aga1, I.C. Olsen1, E. Lie1, H.B. Hammer1, T. Uhlig1, D. van der Heijde2, T.K. Kvien1, E.A. Haavardsholm1 on behalf of the ARCTIC study group. Diakonhjemmet Hospital, Oslo, Norway; 2Leiden University medical center, Leiden, Netherlands

**Background:** Intra-articular (i.a.) corticosteroid injections are in many countries an integral part of rheumatoid arthritis (RA) treatment. Ultrasonography (US) is increasingly used in the management of RA as a tool to select joints for i.a. injections. How selection of joints based on US information affects distribution of injections has not been previously studied. US can detect joints with subclinical inflammation, however, it is unknown whether there is any added value of injecting these joints.

**Objectives:** We aimed to explore how US information influences the selection of joints for corticosteroid injection therapy. Additionally, we wanted to examine the efficacy of injecting joints with subclinical inflammation detected by US in terms of reduction of subclinical inflammation and prevention of clinical synovitis.

**Methods:** In the ARCTIC trial, DMARD-naive RA patients fulfilling the 2010 ACR/EULAR criteria were randomised 1:1 to follow-up with or without US.[1] In both arms the same DMARD treatment strategy was applied, and clinically swollen joints were treated with i.a. steroids when indicated. In the US arm, clinicians could also inject non-swollen joints with PD activity. Patients were assessed at 13 visits during the first 2 years of follow-up and injections could be performed at all visits. Distribution of injections in patients followed with and without US was assessed. The proportion of patients with any injection was compared between arms using logistic regression, adjusted for gender. In addition, we examined the effect of injections in clinically non-swollen joints with PD ≥ 0.3 by injecting (PD ≥ 0.3) vs non-injection (PD < 0.3) comparing clinical joint swelling and estimated mean change in PD activity at the next visit in injected versus non-injected joints. We used logistic and linear mixed model with random intercept by patient in order to adjust for within-patient dependencies.

**Results:** 230 patients were included (US arm 118, conventional arm 112). Mean (SD) age was 50.6 (13.3)/52.3 (14.1) years, 71/51% were females and mean (SD) baseline DAS was 3.5 (1.2)/3.4 (1.2) in the US/conventional arms. [1] More injections occurred in the US arm than in the conventional arm (770 vs 548), especially in intercarpal (58 vs 5) and MTP joints (200 vs 104) (Table 1). In the US arm, 193 joints were clinically non-swollen, but had PD score ≥2. Of these, 77 joints were injected. 72/77 injected joints (93.5%) remained non-swollen at next visit compared to 88/116 non-injected joints (75.9%), with an odds ratio of 3.97 (CI: 1.25–12.57, p=0.019, NNT:6). Estimated mean (SE) reduction of PD activity was 2.3 (0.1) compared to 2.0 (0.1) versus non-injected joints (p<0.001).

**Conclusions:** Our study shows that follow-up with US may lead to an increased number of joint injections with a different distribution of injected joints compared to follow-up without US. Joints with subclinical inflammation were more likely to remain non-swollen at next visit if injected. However, as the number of joints needed to treat one swollen joint was six, the clinical relevance of injecting joints with subclinical inflammation may be questionable.

VALUE OF POWER DOPPLER ULTRASOUNDOGRAPHY FOR PREDICTION OF TREATMENT FOR RHEUMATOID ARTHRITIS (RA) IN EARLY ARTHRITIS DURING THE FIRST 12 MONTHS OF FOLLOW-UP

L. Mayordomo 1, L.M. Velloso 1, C. Jurado 2, P. González-Moreno 3, C. Gomez-Cano 1, J.L. Marenco 1, C. Almeida 4, 1 Rheumatology Department; 2 Radiology Dp, Hospital Universitario Valme; 3 Rheumatology Department, HVZ; 4 Research and Statistics Dp, Hospital Universitario Valme, SEVILLA, Spain

Background: There is a short window of opportunity for early diagnosis and treatment of rheumatoid arthritis, that may be critical for achieving remission and a low rate of radiographic progression. High resolution power doppler ultrasonography (PDUS) is helpful in early detection of synovitis and may help to select patients that will need early establishment of treatment for RA.

Objectives: To study whether the presence of basal power doppler signal in patients with early arthritis in a clinical basis treatment decision could predict the risk of receive treatment for AR at 3 and 12 months of follow-up.

Methods: We studied the presence of ultrasonographic Power Doppler (PD) signal on 28 joints (shoulders, elbows, wrists, MCPs, knees) and 44 joints (28 joints and in addition hips, Tarsus, ankles and MTPs), with a mid-range equipment GE L5, in 70 patients with suspected early arthritis. The patients were included with at least one of the following inclusion criteria: a) Swelling in 2 or more joints b) pain in MCPs, MTPs and/or the wrists c) morning stiffness of more than 30 minutes with <12 months duration of the symptoms. Clinical treatment decision was not offered to basal power doppler results. Statistical study: Chi-square, Fisher exact test, p univariate and Odds Ratio calculation.

Results: The presence of basal power doppler signal in ≥1 joints of 44 (PD44) at baseline shows statistically significant association with treatment with oral steroids (p=0.001, OR 6.6 (1.9–22.1), but not sulfasalazine (SSZ) (p=0.145) at 3 months. The presence of basal power doppler signal in 28 joints (PD28) was significantly associated to esteroids (p=0.003, OR 10.3 (2.2–49.9), at 12 months. The presence of at least one joint with power doppler signal in 12 months duration of the symptoms. Clinical treatment decision was not offered to basal power doppler results. Statistical study: Chi-square, Fisher exact test, p univariate and Odds Ratio calculation.

Conclusions: Power doppler ultrasonography in at least one joint of 44 (PD44) may predict the patients that will need esteroids, any DMARD, MTX and SSZ teraphy in early arthritis at 3 and 12 months of follow-up. PD28 may predict the patients that will need esteroids, any DMARD, MTX and SSZ teraphy in early arthritis at 12 months, but may only predict the need of esteroids and MTX at three months.

IS ANKLE INVOLVEMENT IMPORTANT IN RHEUMATOID ARTHRITIS?

L. Enache, C. Mogosan, C. Popescu, G. Gutoiu, C. Codreanu. Rheumatology, Clinical Center of Rheumatic Disease, Bucharest, Romania

Background: The ankles may be affected by rheumatoid ankles (RA). In daily evaluation of RA patients, the ankles are often neglected by clinical examinations, while composite activity scores do not include them.

Objectives: The aim of the study is to assess the inflammatory lesions in RA ankles, regarding frequency and possible correlation with activity disease.

Methods: The study included 76 RA patients fulfilling the 2010 ACR/EULAR classification criteria. In every patient we recorded clinical ankle involvement (ankle swelling and/or tenderness on physical examination); both ankles were evaluated by gray scale (GS) and Power Doppler (PD) ultrasound examination, signal (PD28). In each ankle we assessed: tibial anterior joint (TT); tibialis anterior (TA) tendon; extensor halluc (EH) and extensor digitorum (ED) tendons; talo-navicular joint (TN); bimalis posterior (TP) tendon; flexor digitorum (FD) and flexor halluc (FH) tendons; peroneus brevis (PB) and longus (PL) tendons; Achilles tendon (AT); subtalar joints (ST); posterior, lateral, medial recesses; planatar fascia (PL). We recorded the following abnormalities: synovitis, tenosynovitis, bursitis, entesopathy and rupture. Activity scores (DAS28, DAS44, SDAI), inflammatory markers (ESR, CRP), serology (FR, ACPR) and HAQ were also assessed.

Results: The mean age was 57.2±14.2 years; 88% were women; mean disease duration was 12.2±9.2 years; 56.6% had symptomatic ankles; 61.6% had undergone ankle arthroscopy. The most frequent ultrasound pathology encountered was ST synovitis (56.6%), followed by TT synovitis (48.7%), TN synovitis (38.2%), TP tenosynovitis (30.3%), PL tenosynovitis (15.8%). Ultrasound abnormalities were recorded in 93% of the symptomatic ankle patients and in 56% of the asymptomatic ankle patients (p=0.008). Overall, 43% had positive PD signals, but the prevalence of positive PD signals was significantly higher in symptomatic ankle patients than in asymptomatic ankle patients (60.5% compared to 21.2%, p=0.011). Statistically significant correlations were found between ultrasound inflammatory pathology (synovitis and tenosynovitis), activity disease markers and quality of life (Table 1).

Conclusions: Musculoskeletal ultrasound detected a high prevalence of inflammatory abnormalities in rheumatoid ankles, both in symptomatic and asymptomatic patients, while power Doppler signal was present mostly in symptomatic patients. The ultrasound pathology was highly correlated with activity disease markers and quality of life.

MAGNETIC RESONANCE IMAGING AND HISTOPATHOLOGICAL CORRELATION IN DERMATOMYOSITIS

M.V. Collado 1, J.C. Millisenda 2, X. Tomás 3, A.I. García 2, M. Faruch 2, J.M. Grau 2 on behalf of Muscle Research Unit, Internal Medicine Service, Hospital Clínic de Barcelona, Universidad de Barcelona and CIBERER, 1 Rheumatology, Instituto de Investigaciones Médicas Alfredo Lanari (UBA), Buenos Aires, Argentina; 2Internal Medicine; 3Radiology, Hospital Clinic de Barcelona, Barcelona, Spain; 4Radiology, CHU Toulouse Purpan, Toulouse, France

Background: Dermatomyositis represents one of the major forms among the inflammatory myopathies (IM). Although the muscle biopsy remains the definitive test, MRI has been used to detect unique patterns of muscle involvement. To date, no studies have compared MRI with muscle pathology in naïve DM.

Objectives: To compare the patterns of muscle MRI with muscle pathology.

Methods: All the patients enrolled in the Hospital Clinic de Barcelona (HCB) from January 2009 to December 2016 with an available MRI, performed just before muscle biopsy were included. The HCB ethics committee approved this study, and written informed consent was obtained from each participant.

MRI findings were classified according to the classical clinical and histologic features. Patients were prospectively collected.

Conclusions: Magnetic resonance imaging and histopathological correlation in dermatomyositis.
COMPARISON OF US, CT, X-RAY AND MRI EFFICACY FOR LASER DOPPLER IMAGING: AN OBJECTIVE OUTCOME

M. Eliseev

Background: Moscow, Russian Federation

V. A. Nasonova Research Institute of Rheumatology,

Objectives: of disease regression in pts receiving urate-lowering therapy is not sufficiently to identify affected joints and surrounding tissues (tophi, erosions and synovitis) computed tomography (CT), and X-ray are the alternative diagnostic modalities used. Dose of allopurinol administered in all pts was adjusted by titration starting from 300–600 mg/day, 9 (45%) pts had to take 600 mg/day and more. At baseline US examination detected periarticular tophi in 3 (14%) pts, MRI - in 6 (28%) pts, CT in 3 (14%), X-ray - 1 (5%) pts, after one year - by US in 4 (9%) pts and MRI - 3 (14%) pts, CT in 2 (9%), X-ray - 1 (5%) pts. At baseline intraosseous tophi were detected only by CT and X-ray in 18 (81%) and 2 (9%) pts respectively, and in 17 (77%) and 3 (14%) pts respectively. At baseline erosions were detected in 19 (86%) pts by MRI, in 11 (50%) pts - by US, in 14 (65%) pts - by CT, and in 9 pts (41%) - by X-ray, after one year in 14 (64%) pts by MRI, 10 (45%) pts by US, 12 (54%) pts by CT, 8 (36%) pts by X-ray. At baseline synovitis was reliably diagnosed by MRI and US: in 15 (68%) pts and 7 (33%) pts, after one year in 2 (9%) pts and 3 (14%) pts respectively.

Conclusions: MRI and US, as for synovitis, erosions and tophi dynamics, are comparable, at that for erosions MRI is more accurate. CT is the most informative approach to monitor intraosseous tophi regression. X-ray is low- informative modality for sequential assessment of gout.

SAT0647 | LASER DOPPLER IMAGING: AN OBJECTIVE OUTCOME MEASURE FOR ASSESSMENT OF CUTANEOUS LUPUS ERYTHEMATOUS

M.Y. Md Yusof1,2, J. Britton3, E.M. Hensor1,4, M. Goodfield2, M. Wittmann2, P. Emery2,3, E.M. Vital1,2, 1Rheumatology, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; 2NIHR Leeds Musculoskeletal Biomedical Research Unit; 3Medical Physics Department, Leeds Teaching Hospitals NHS Trust; 4NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

Background: Cutaneous lupus erythematosus (CLE) is the most common manifestation of SLE and may occur without systemic features. Skin disease is particularly heterogeneous, rendering assessment of activity difficult. Laser Doppler imaging (LDI) is a non-invasive imaging tool that monitors blood perfusion in dermal tissue. It has been shown to correlate with inflammation in psoriasis but no study has been undertaken in CLE.

Objectives: To evaluate validity of LDI against the gold standard of histology from skin biopsy as well as other clinical tools including the Revised Cutaneous Lupus Erythematosus Disease Area and Severity Index (RCLASI) and Visual Analogue Scale (VAS) scoring of photographs.

Methods: A prospective observational study was conducted in consecutive patients with CLE flare at a single centre. Disease activity was assessed using RCLASI and measured using a high resolution LDI system (Morin Instruments) by JB and YY, both blinded to clinical assessment. Relative difference to the non-lesion area was calculated and expressed in perfusion unit (PU). Skin biopsy was obtained in those who consented and scored as 0=non-active, 1=mild activity and 2=active. Photographs were taken on the same day and were later assessed by a dermatologist and a rheumatologist who were blinded to LDI results using a 100mm VAS. The agreement of VAS between both clinicians was analysed using Bland-Altman limits of agreement (LOA) and the correlation between histology and LDI, RCLASI and VAS were analysed using Kendall’s Tau-a.

Results: 20 patients were studied (19 female, median age 47.2 (range 21–62) years, 6 smokers, 2 CLE only, 14 (70%) ANA positive at the time of the scan). The distribution of CLE type were: acute CLE=7, subacute CLE=6 and chronic CLE=7. The agreement between the VAS scores of the two clinicians was fair; mean difference 7.8 (95% CI LOA -26 to 41) mm versus average. In 10 patients with skin biopsy, the correlation with histology was better for LDI (τ=0.56) than RCLASI [0.09; difference (90% CI) 0.64 (0.10, 1.19)] or VAS [0.16; 0.71 (0.13, 1.29)] (figure 1). One patient who was deemed to have a subacute CLE flare based on clinical assessment indeed had a negative histology and a low PU. Conclusions: In this preliminary analysis, assessment of blood perfusion to dermal tissue using LDI provides a valid quantitative and objective measure of inflammation in cutaneous lupus. The findings from LDI also had a better correlation with histology than skin biopsy compared to currently used clinical tools. Further validation and longitudinal analysis including assessment of responsiveness to therapy will provide further evidence on the usefulness of LDI in clinical practice and trials.

SA6046 | COMPARISON OF US, CT, X-RAY AND MRI EFFICACY FOR SEQUENTIAL ASSESSMENT OF CHRONIC GOUT MANIFESTATIONS

Background: Ultrasonography (US), magnetic resonance imaging (MRI), computed tomography (CT), and X-ray are the alternative diagnostic modalities used to identify affected joints and surrounding tissues (tophi, erosions and synovitis) in gout patients, but the potential of each method for sequential assessment of disease regresses in pts receiving urate-lowering therapy is not sufficiently studied. One patient who was deemed to have a subacute CLE flare based on clinical assessment indeed had a negative histology and a low PU. Conclusions: In this preliminary analysis, assessment of blood perfusion to dermal tissue using LDI provides a valid quantitative and objective measure of inflammation in cutaneous lupus. The findings from LDI also had a better correlation with histology than skin biopsy compared to currently used clinical tools. Further validation and longitudinal analysis including assessment of responsiveness to therapy will provide further evidence on the usefulness of LDI in clinical practice and trials.

ULTRASOUND FINDINGS IN SYMPTOMATIC AND ASYMPTOMATIC JOINTS IN PATIENTS WITH GOUT

M.M. Basaric, G. Rudanovic, N. Damjanov, M. Radak Perovic. Institut of rheumatology, Belgrade, Serbia

Objectives: To determine sensitivity and specificity of ultrasound (US) findings for gout, “double contours” (DC) and hyperechogenic aggregates (HAGs) of symptomatic and asymptomatic joints in patients with gout.

Methods: This prospective study included 69 persons (34 patients with primary gout and 35 healthy subjects). Including criteria for patients with gout were: age ≥18 years; diagnosis of primary gout; absence of acute gout attacks during the study tests; the absence of any other inflammatory and infectious joint disease, and secondary gout. The research included: demography and medical history, Physical and US examination covered following structures: 138 radiocarpal joint, 276 patellar and triceps tendon and 414 articular cartilages (first metatarsal, talar and femoral condyle).

Results: Both groups were compatible for age and gender. In the gout group 124 (30%) symptomatic and 284 (70%) asymptomatic joints were found and in healthy group all joints was asymptomatic. The sensitivity of the DC for symptomatic joint was 56 to 84% and specificity also was very high 91% to 94% as well as positive and negative predictive value (69 - 86% and 38 - 71%). Sensitivity of DC finding for the asymptomatic joints was 42 to 73% and specificity was 91 to 94%, with also high positive and negative predictive value (69 - 89% and 44 - 62%). The specificity of the HAGs for both symptomatic and asymptomatic joints was very high 99% but sensitivity of HAGs symptomatic structures was moderate (41 do 56%), while its sensitivity for asymptomatic structures was low (18 to 34%), table 1.

DC - “double contours”; HAGs - hyperechogenic aggregates; PPV - positive predictive values; NPV - negative predictive values.

Conclusions: Ultrasound examination of symptomatic and asymptomatic joints in patients with gout equally observed structural changes characteristic of gout. The finding of “double contours” in the symptomatic and asymptomatic joints has a very high sensitivity and specificity. Consequently, future research should be focused on the ultrasound examination of asymptomatic joints in patients with gout.

CHANGES IN CARTILAGE QUALITY (dGEMRIC) FOLLOWING KNEE JOINT DISTRACTION OR HIGH Tibial OSTEOTOMY: A TWO-YEAR FOLLOW-UP

N. Besselink 1, S. Mastbergen 1, K. Vinken 1, L. Bartels 2, A. Concepcion 1, A.K. Marinissen 1, F. Laebele 1. Rheumatology and Clinical Immunology; 1Image Sciences Institute, University Medical Centre Utrecht, Utrecht, Netherlands

Background: Since abnormal loading can cause onset and progression of OA, unloading the affected compartment of an osteoarthritic knee, should slow down OA progression, or even enable joint repair. High tibial osteotomy (HTO) is a well-known unloading approach for treating unilateral compartment osteoarthritis (OA) with mechanical axis deviation. Transient unloading using knee joint distraction (KJD) has demonstrated a progressive decrease in pain, normalization of function, and an increase in walking distance. 1 Although both treatments show indications of joint repair, there is limited information about the actual quality of the regenerated tissue.

Objectives: To evaluate the change in quality of the repaired cartilaginous tissue using dGEMRIC after KJD or HTO treatment.

Methods: 40 patients (20 with KJD, and 20 with HTO), treated for medial tibiofemoral OA, are included in this study. Radiographic changes, clinical changes, and changes in cartilage quality are evaluated after one and two years follow-up. Joint space width (JSW) is evaluated on weight-bearing radiographs. Clinical improvement is evaluated by Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Visual Analogue Scale (VAS) pain score. In order to evaluate the quality of the (newly formed) cartilaginous tissue, quantitative MRI analysis, in the form of Delayed gadolinium enhance Magnetic Resonance Imaging of cartilage (dGEMRIC) is performed.

Results: A significantly increased medial (± 1.15 mm, p < 0.000), minimal (± 0.93 mm, p < 0.000) and mean (± 0.79 mm, p < 0.000) JSW one year after KJD, sustaining up until 2 years, was demonstrated (medial (± 0.99 mm, p < 0.000), minimal (± 0.04 mm, p < 0.000), mean JSW (± 0.68 mm, p < 0.027)). Similarly, medial (± 0.69 mm, p < 0.017) and minimal (± 0.32 mm, p < 0.023) JSW were significantly increased one year after HTO, sustaining up until 2 years (medial: ± 1.03 mm, p < 0.000, minimal: ± 0.72 mm, p < 0.015), after which mean JSW (± 0.46 mm, p < 0.030) is also significantly increased. Both interventions led to clinical improvement, observed as an increase in WOMAC after one year (KJD: ± 33.89. p < 0.000, HTO: ± 33.74. p < 0.000) and two years (KJD: ± 32.52. p < 0.000, HTO: ± 24.15. p < 0.002), and a decrease in VAS Pain, after one year (KJD: ± 30.79. p < 0.001, HTO: ± 41.89. p < 0.000) and two years (KJD: ± 30.50. p < 0.004, HTO: ± 34.64. p < 0.000). However, no statistically significant changes in cartilage quality were found after KJD or HTO, not in the medial and lateral compartments of the tibiofemoral joint, nor in the separate ROIs (see figure 1).

Conclusions: Treatment of medial compartmental OA by either HTO or KJD leads to alleviation of pain and recovery of function, achieved one year after either intervention, and maintained for another year. Within the first year after treatment, KJD shows a statistically significantly higher increase in WOMAC as compared to HTO. Both treatments led to a statistically significant increase in JSW after one and two years, postponing the natural osteoarthritis progression rate. No statistically significant change in the quality of newly formed cartilaginous tissue could be detected by dGEMRIC.

18F]-FLUORO-PEG-FOLATE PET: A NOVEL IMAGING TECHNIQUE TO VISUALIZE RHEUMATOID ARTHRITIS

N. Verweij 1, S. Bruijnien 1, Y. Gent 1, M. Huisman 2, G. Jansen 1, C. Moolhuijzen 2, Q. Chen 2, P. Low 3, A. Windhorst 4, A. Lammertse 2, O. Hoekstra 2, A. Voskuyl 1, C. van der Laken 1, 1Dept. of Rheumatology, Amsterdam Rheumatology and Immunology Center - location VU University Medical Center; 2Dept. of Radiology & Nuclear Medicine, VU University Medical Center, Amsterdam, Netherlands; 3Dept. of Chemistry, Purdue University, West Lafayette, United States

Background: Imaging arthritis activity in rheumatoid arthritis (RA) patients using PET macrophage tracers holds promise for both early diagnostics and monitoring response to therapy (1,2). Previously, (R)-[18F]CPK11195 has been used, but this macrophage tracer is limited due to high background uptake, especially in bone and bone marrow. Recently, a novel macrophage tracer, [18F]fluoro-PEG-folate,
was developed, which showed excellent targeting of the folate receptor beta on activated macrophages in synovial tissue in a preclinical arthritis rat model (3).

Objectives: To assess the value of [18F]fluoro-PEG-folate PET-CT for imaging inflamed joints in patients with clinically active RA.

Methods: Nine RA patients with at least two clinically inflamed hand joints were included. PET-CT scans (120 min after injection with 370 MBq of [18F]fluoro-PEG-folate) were acquired at 2 time points: baseline (T0) and 3 months (T3) after initiation of methotrexate (MTX) or infliximab (IFX) treatment. PEM PET images were analyzed semi-quantitatively using a region of interest (ROI) analysis approach. Outcome parameters were calculated based on visually marked uptake and SUVs were calculated. The area under the curve (AUC) was calculated for each ROI.

Results: No side effects were observed, and the high uptake in inflamed joints was confirmed in all patients. The AUC was significantly higher in inflamed joints compared to non-inflamed joints.

Conclusions: PEM PET with [18F]fluoro-PEG-folate PET-CT provides a promising imaging approach to assess early arthritis inflammation.

SAT0653 | QUANTITATIVE ASSESSMENT OF INTERSTITIAL LUNG DISEASE IN SJÖGREN SYNDROME: A PILOT STUDY

Background: The interstitial lung disease (ILD) is the most frequent form of lung damage in Sjögren’s syndrome (SS). The diagnosis is still nowadays challenging: the absence of a specific functional test, the presence of non-specific radiological images, the chest CT is the gold standard. Semiquantitative (SQCT) assessment (such Taouli or Goh visual scores) could estimate ILD severity or burdened by relevant inter-rater variability. Quantitative chest CT (QCT) is a promising method to assess primary or secondary ILD, but there are not studies focused on SS-ILD.

Objectives: Herein we designed a study to evaluate if QCT indexes may assess differences in SS-ILD.

Methods: We conducted a multicenter, cross-sectional, and retrospective study, identifying subjects affected of SS (per modified American-European consensus criteria) with a thorax CT ordered by local physician by any reason. We enrolled 52 cases, divided in two cohorts according to the presence/absence of ILD on CT. A centralized SQCT assessment was carried out to calculate both Goh and Taouli scores. A DICOM-viewer open-source software (Horos) was used to analyse, blindly and anonymously, all CT images and to calculate QCT indexes (pulmonary function tests; total lung volume; functional, standard deviation, mean total lung attenuation). QCT indexes and SQCT scores were compared using the Spearman rank and Mann-Whitney tests. ROC curves were calculated to assess the sensibility and specificity of the QCT indexes to detect ILD.

Results: Median age was 50.5 (95% CI 51.6–51.7) years, 52.2% were female, 9 cases had ILD, and 41 were not affected - patients not assessable. The disease duration (tilt CT thorax) have a median of 21 (95% CI 6 – 42.4) months. 42.3% have secondary SS and 57.7% a primary SS. All QCT scores, except pSdev (105.6 (IQR 101.4 - 122.95) vs 96.4 (IQR 92.38 to 104.94), p=0.006; pSdev (149.4 (IQR 149.0 - 194.2) vs 146.0 (IQR 144.0 to 196.0), p=0.101), TurkT 7.62, IQR 7.09 to 9.01 vs 6.45, IQR 6.04 to 8.71, p<0.001; sensitivity 88.89% (95% CI 51.8–99.7), specificity 65.85% (95% CI 49.4–79.9), p<0.001. The correlation coefficients for QCT and Goh and Taouli’s score ranges around 0.4.

Conclusions: QCT indexes identify some differences between SS-ILD and those not. These parameters could be useful both to improve imaging diagnosis and also the decision to treat those cases. This innovative tool might open up a potential research area to be developed in SS. Moreover, the operator independence of QCT makes it a time-saving method extremely suitable for multi-centre trials. Our pilot study have some handicaps: small sample, low number of events, different reasons for CT performance, no smoking identification, and biological differences between primary and secondary SS. However, it could be point out that GTC could be a useful tool to identify and quantify ILD in SS, and further data are needed to ascertain this hypothesis.

SAT0655 | EARLY ENDOTHELIAL DAMAGE IN PATIENTS WITH RAYNAUD’S PHENOMENON

R. Quattrocchi 1,2, F. Ingegnoli 1,2, T. Schioppo 1, S. Griffini 1,2, E. Groveti 1,2, M.O. Borghi 1, M. Cugno 1,5, P.L. Meroni 1,2,3,6.

Background: Endothelial dysfunction is highly prevalent in Raynaud’s phenomenon (RP). Among Raynaud’s phenotypes, patients with capillaroscopic abnormal pattern (CPA) are at higher risk of cardiovascular and cerebrovascular events. However, the role of endothelial dysfunction in early phase of Raynaud’s disease is unknown.

Objectives: To evaluate the difference of plasma levels of tissue-type plasminogen activator (t-PA) and von Willebrand factor (vWF) in primary Raynaud’s disease (PRD) and secondary RP divided in CPA and capillaroscopic normal pattern (CNP).

Methods: A cross-sectional study was conducted in the period 2013–2015. PRD and secondary RP patients were included in the study by means of the recruitment of consecutive patients attending the Rheumatology Unit of the University of Parma. Baseline demographic, clinical and laboratory characteristics were evaluated. Plasma levels of t-PA and vWF were evaluated by ELISA technique. The differences among the groups were evaluated by means of the non-parametric Mann-Whitney U test and the χ2 test. The normality of the data was evaluated by using the Shapiro-Wilk test and the Q-Q plot. A significance level of p<0.05 was used for all statistical analysis.

Results: A total of 309 patients with primary RP and 80 patients with secondary RP were included in the study. The mean age of the patients was 43 ± 13 years and 75% were female. The most common RP phenotype was PRD (95%). Primary RP included 134 patients with secondary RP included 175 patients. The mean age of the patients with CPA was 40 ± 13 years and 73% were female. The differences in age and sex between the CPA group and the CNP group were not statistically significant. The serum levels of t-PA and vWF were statistically significantly higher in the CPA group than in the CNP group (p=0.005 and p=0.004, respectively). The differences between the CPA group and the CNP group were statistically significant for both primary RP and secondary RP (p=0.001 and p=0.001, respectively). The serum levels of t-PA and vWF were statistically significantly higher in the CPA group than in the CNP group (p=0.005 and p=0.004, respectively).

Conclusions: Our study demonstrated that the serum levels of t-PA and vWF were higher in CPA than in CNP group. These findings suggest that endothelial damage is present in CPA patients and may be a marker of early vessel damage.

SAT0654 | THE RECALL SURVEY: DIFFERENCES OF ULTRASOUND EXAMINATION BETWEEN EARLY VS LONG LASTING RHEUMATOID ARTHRITIS PATIENTS IN CLINICAL REMISSION

Background: Ultrasound (US) examination is able to show subclinical synovitis and bone involvement in patients with RA in clinical remission (CR).

Objectives: To investigate the differences of US examination of US small joints of hands, feet and wrists in pts with very early (ERA, <1y) vs early (ERA, <3y duration) vs long lasting RA (LRA, > 7 y duration) in clinical remission (CR).

Methods: In 2015 an educational event (RECALL survey) focused on the added value of US in RA was held in 22 Italian centers. In each center, the local rheumatologists provided RA pts to be examined by US. Pts signed an informed consent and a brief history of them was collected by the local rheumatologists (previous and current therapy, DAS28, HAQ score). Bilateral US examinations of wrists, metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints were performed by rheumatologists expert in US, to assess synovitis (joint effusion, synovial proliferation, and power Doppler (PD) signal), and bone erosions, using a Logiq E R7, General Electrics, with a 4.2–13 MHz linear probe.

All US findings were scored using a 4 degree semiquantitative scoring system.

Results: Eighty-eight pts were classified as VERA, 183 as ERA and 165 as LRA. LRA usage was not different among the three groups of pts. LRA pts were older (p<0.001), had longer disease remission before US examination (p<0.001) and had an higher prevalence of female sex (p<0.01). Table 1 reports the differences of US examination between VERA vs ERA vs LRA patients. LRA pts had more erosions at MTP and wrists with no differences at MCP joints. Synovial hyperthrophy and PD signal had the same degree in the two groups of patients. LRA pts had more MTP joints with effusion with lower degree as compared to patients with ERA and VERA (see table 1).

<td>59</td>
</tr>
<tr>
<td>% of pts with MTP joints effusion &gt;1</td>
<td>25</td>
<td>21</td>
<td>12</td>
</tr>
</tbody>
</table>

Conclusions: At US examination VERA, ERA and LRA pts in CR have the same degree of synovial hyperplasia and PD signal despite the differences of duration of CR. Higher degree of erosive disease (at wrist and MTP joints), lower degree of MTP effusion and higher prevalence of joint effusion at MTP joints were present among LRA vs ERA and VERA pts.

SAT0656  OPTICAL IMAGING OF PHAGOCYTE MIGRATION REPRESENTS A NOVEL METHOD TO DETERMINE DISEASE ACTIVITY IN CIA

S. Gran1, L. Honold2, O. Feither1, S. Zenerk1, S. Hermann2, M. Schäfers2, T. Vogl1, J. Roth1, 1Institute of Immunology; 2European Institute for Molecular Imaging, Münster, Germany

Background: Recruitment and migration of phagocytes to the site of inflammation are key events in the onset of inflammation. Albeit crucial for pathogen elimination, tissue repair and restoration of tissue homeostasis, dysregulated phagocyte infiltration can also cause severe inflammatory disorders. Therefore, targeting and modulation of phagocyte infiltration represents a promising new approach to fight inflammatory disorders and diseases, such as rheumatoid arthritis. Additionally, non-invasive tracking of phagocyte migration to the site of inflammation could contribute to scientific knowledge as well as the repertoire of diagnostic strategies in clinical use.

Objectives: The aim of this study was to establish a fluorescence reflectance imaging (FRI) based system to visualize and analyze migration properties of different cell populations in inflammatory disease models, like experimental arthritis, in vivo.

Methods: Immortalized murine myeloid progenitor ER-HoxB8 cells were differentiated to neutrophils or monocytes (1). Cells were labeled with the membrane-selective fluorescent dyes DOR (2) or DID, respectively. We analyzed viability and functionality of stained cells in vitro and investigated their ability to migrate to sites of inflammation in vivo in several mouse models - particularly in a collagen-induced arthritis (CIA) mouse model - via fluorescence reflectance imaging (FRI).

Using CRISPR-Cas9 technology we introduced targeted gene deletions for main adhesion molecules.

Results: Differentiated ER-HoxB8 cells could effectively be labeled with DOR or DID. Labeling of monocytes or neutrophils did not affect cellular viability or functionality in vitro. Subsequent in vivo imaging experiments allowed the visualization of migrated labeled phagocytes in different murine disease models, thereby cells could be detected at sites of inflammation with high sensitivity and specificity. In a leucocyte recruitment during the early stages of arthritis, Correlation of labeled cells could even be associated closely to disease score and disease severity. Thus, the detection of immigration of labeled cells might also give hints about new inflammatory spots that are about to settle up before they can be detected macroscopically. Furthermore, differential cell labeling allowed direct quantitative comparison of differences in migration rates of wildtype and CD18 or CD49d knockout cells in vivo.

Conclusions: Specific and distinguishable labeling of diverse cell types allows in vivo tracking and subsequent quantification of migrated cells within the same animal. Targeted gene deletion allows analysis of molecular mechanisms relevant for leucocyte recruitment during different stages of arthritis. Correlation of the amount of immigrated cells to disease severity offers new opportunities to non-invasively detect and monitor inflammatory sites in vivo.

elasticity was attached to the transducer during the elastostenography. The inlet of the carpal tunnel at the scaphoidprocess level and the proximal portion of the inlet carpal tunnel were scanned in a transverse plane. The cross-sectional area (CSA) and the elasticity of the median nerve, which was measured as the acoustic coupler/median nerve strain ratio, were evaluated. The measurements were Power Doppler (PD) scans of the average strain ratio was used for analysis.

Results: We analyzed 342 hands in 177 RA patients (139 female, mean age: 63.5±11.6 years) and 158 hands in 81 non-RA (68 female, mean age: 71.5±14 years) finally. There were no significant differences in the cross-sectional area of median nerve (left: 8.9 vs 8.7 mm², p=0.91, right: 8.2 vs 8.4 mm², p=0.62) or the circumference of median nerve (left: 13.1 vs 13.4 mm, p=0.41, right: 13.7 vs 13.7 mm, p=0.95) within carpal tunnel between RA group and non-RA group. Strain ratio within carpal tunnel in RA group was higher than that of non-RA group (left: 2.6 vs 2.1, p=0.002, right: 2.7 vs 2.2, p=0.003). There were no significant differences in the cross-sectional area of median nerve (left: 7.5 vs 8.1 mm², p=0.07, right: 8.8 vs 8.3 mm², p=0.6), the circumference of median nerve (left: 13.1 vs 13.5 mm, p=0.3, right: 13.7 vs 13.9 mm, p=0.71) and strain ratio (left: 2.1 vs 2.0, p=0.88, right: 2.3 vs 2.1, p=0.01) at the entrance of the carpal tunnel between RA group and non-RA group.

Conclusions: Real-time Elastosonography showed the stiffness of the median nerve with RA patients without any symptoms of CTS was higher than controls. It suggests that inflammation of flexor tenosynovitis and wrist joint may generate fibrotic change of median nerve in patients with RA.

SAT0659 COMPARISON BETWEEN EIGHT DIFFERENT ULTRASONOGRAPHIC SCORES AND ASSESSMENT IN RHEUMATOID ARTHRITIS - A CROSS-SECTIONAL STUDY

S. Hussain1,2, P. Sivakumaran1,2, L. Attopoe1, C. Curtin1, 1University College London Medical School, 2Department of Rheumatology, University College London Hospitals NHS Foundation Trust, London, United Kingdom

Background: Rheumatoid arthritis (RA) is a chronic inflammatory condition associated with well-recognised inflammatory joint features, which are amenable to ultrasound (US) examination. The implementation of US scoring systems in addition to clinical examination could help standardise the way RA is monitored; however, due to variation in local availability of US and sonographer expertise, different scoring systems have been used in clinical practice (1). Despite significant research progress in supporting the role of US in RA, there is no consensus as different scoring systems have been used in clinical practice (1). Despite significant research progress in supporting the role of US in RA, there is no consensus as different scoring systems have been used in clinical practice (1).

Methods: We performed a cross-sectional study of 224 RA patients stratified based on their DAS-28 scores and assessed using eight preselected US examination protocols including 22, 18, 16, 14, 10, 8 and two different combinations of 4 joints, respectively. Student T, Mann-Whitney U and Kuskal-Wallis tests were employed for analysis of clinical, laboratory and US parameters in the RA patient groups. (P < 0.05 was considered significant). Spearman’s coefficients were used to correlate permutations of pairs of US scores, and US and DAS-28 scores.

Results: We found a significant difference between different US hand scores and their ability to detect the presence of active and chronic inflammation in RA patients. The DAS-28 scores correlated very well (R=0.89–1, P < 0.05) with the total Power Doppler (PD) scores generated by all US protocols irrespective of patients’ disease activity. Simplified US scores missed information on presence of erosions (P < 0.05), but were equivalent to the extensive 22 joint score in appreciating the amount of chronic and active inflammation compared to the extensive 22 joint score (P=0.15, P=0.11, respectively).

Conclusions: SAT0660 SAFETY, FEASIBILITY AND TOLERABILITY OF PERFORMING CONSECUTIVE MINIMAL INVASIVE ULTRASOUND-GUIDED SYNOVIAL BIOPSY PROCEDURES ON THE SAME WRIST IN A PROSPECTIVE RHEUMATOID ARTHRITIS STUDY

S.A. Just1, C. Nielsen2, E.K. Heibo1, H.D. Schroder3, I.M.J. Hansen4, T. Barrington5, H.M. Lindegaard1, 1Rheumatology; 2Clinical Immunology; 3Clinical Pathology, Odense University Hospital, Odense; 4Medical, Svendborg Hospital, Odense University Hospital, Svendborg, Denmark

Background: Studies on synovial tissue retrieved using the minimal invasive ultrasound-guided synovial biopsy (USG-SB) method have led to major advances in the understanding of Rheumatoid Arthritis (RA). The method is now used in multicenter RA studies and recommended in the phases of RA drug development. Only to biopsy disease active joints at start and end of a study, can lead to biopsies being retrieved from different joints. This can make interpretation of the changes in the synovial tissue and gene-expression profile difficult, as synovial histology patterns can vary between joints. We here present an approach where we biopsy the wrist with disease activity at presentation and the same wrist after six month of disease duration. We use the same biopsy site, as it is the joint most commonly involved in the upper extremity in RA. The joint is easily accessible for USG-SB and therefore ideal to use to follow disease activity/treatment response/biomarker change in prospective RA studies.

Objectives: To assess the safety, tolerability and feasibility to perform repeated synovial biopsies from the same wrist, using a minimally invasive USG-SB technique in patients suffering from RA.

Methods: Patients with newly diagnosed untreated RA or longstanding (>5 years) RA and at least one clinically swollen wrist, underwent x-ray, magnetic resonance imaging (MRI) and ultrasound examination of the affected wrist and hand on the day of the biopsy. This was repeated 6 months later, where the second biopsy from the same wrist was taken. EULAR guidelines for RA treatment were followed in the 6 months between biopsies. Patient-reported outcomes (PRO) included a standard questionnaire given to all patients on the day of the biopsy as well as 2 weeks after the biopsy. Tolerability and the patient-reported willingness to repeat the procedure was assessed using the 5-point Likert scale.

Results: 38 RA patients (22 early, 16 longstanding) underwent USG-SB procedure at inclusion and after 6 months. One patient was excluded and did not have second biopsy due to diagnosis of Osteoporosis. All patients have undergone first biopsy and at present time and 50% second biopsy. At the EULAR congress complete data will be presented. At present time, at both first and second biopsy no worsening in PRO of the biopsied joints was reported 2w after the biopsy, as compared before the biopsy. No infection, hemorrhage, nerve or tendon damage has currently been observed. One patient developed a tenosynovitis after biopsy (the CPPD patient), successfully treated with glucocorticoid injection. 10% of the patients were somewhat or very unlikely to have another biopsy procedure after the first procedure, and 6% after the second. All included RA patients accepted to have a second biopsy. Detailed data on differences in tolerability between early untreated RA patients versus patients with longstanding RA, will be presented at the conference.

Conclusions: To our knowledge, we are the first, to demonstrate that retrieving synovial tissue using the USG-SB method on the same wrist, at start and end of a prospective RA study, is safe and well tolerated.

SAT0661 FINGER JOINT CARTILAGE THICKNESS EVALUATED BY ULTRASOUND IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

T. Ogura, A. Hirata, N. Hayashi, H. Ito, S. Takenaka, Y. Fujisawa, K. Mizushima, T. Kagitgir, R. Kuji, M. Imamura, N. Yamashita, H. Kameda. Toho University Ohashi Medical Center, Tokyo, Japan

Background: Joint destruction in RA includes both bone and cartilage lesions. By using the USG-SB method, cartilage thickness is evaluated as a joint space narrowing (JSN). However, joint space narrowing is not a direct evaluation of cartilage.

Objectives: We aimed to examine the finger joint cartilage thickness (CT) by ultrasound (US) imaging and clarify its clinical significance in patients with RA.

Methods: We enrolled 121 RA patients in low disease activity or clinical remission...
EVALUATION OF ANTI-DDOUBLE STRANDED DNA ANTIBODIES IN THE MONITORING OF SYSTEMIC LUPUS ERYTHEMATOSUS

T. Dervieux 1, T. O’Malley 1, J. Conklin 1, C. Ibarra 1, C. Bentow 2, M. A. Aure 2, M. Mahler 2

1 Exagen Diagnostics, Vista, CA; 2 Research and Development, Inova Diagnostics, San Diego, CA, United States

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune rheumatic disease characterized by the production of pathogenic autoantibodies. Amongst these antibodies, those directed to dsDNA are routinely used to monitor disease activity. QUANTA SLEDAI is a scoring index to score severity of SLE disease. Because the predictive value of anti-dsDNA is dependent on the sensitivity and robustness of the assays used, the choice of anti-dsDNA is crucial in the clinical laboratory and clinical research setting.

Objectives: The objective was to compare four anti-dsDNA assays for their performance characteristics of SLE disease activity.

Methods: A cohort of 36 subjects with active SLE presented with classical complement activation were enrolled and followed monthly for 1 year. At each study visit blood was collected, serum isolated and frozen until analysis. A total of 371 specimens were collected. Disease activity was scored on the day of each study visit according to the SELENA-SLEDAI index to score disease activity.

Results: At enrollment the sensitivity of the QUANTA Lite and High Avidity anti-dsDNA both reached 64%; whereas anti-dsDNA positivity was 83% by QUANTA Flash and reached 96% by CLIFT. Study visits with active disease presented with several fold higher anti-dsDNA titers than those with inactive disease status (Table 1). Linear mixed model testing indicated that the decrease in ns-SELENA-SLEDAI scores were associated with significant reduction in titers of all three anti-dsDNA kits (Table 2). QUANTA Flash yielded highest marginal R² in ns-SELENA-SLEDAI scores were associated with significant reduction in titers.

Conclusions: A direct visualization and quantification of finger joint CT, especially MCP joints, by US is valid and useful in RA.

Disclosure of Interest: None declared

with primary SS, 66% with secondary SS). Frequently inhomogeneity was found in all major SG (33%, 22% left and right submandibular, 77%, 44% left and right parotid glands) in primary SS. Both submandibular glands were symmetrically involved (p < 0.02). Duration of disease was negatively correlated to inhomogeneity of right parotid gland (p < 0.02).

Conclusions: Inhomogeneity in major SG in GS US was found in the majority of patients with primary and secondary SS. The symmetrical involvement of submandibular glands was significant. The inhomogeneity appears in the early period of diagnosis. No major differences were found between two groups.

### SAT0665

**DOES PATIENTS’ OPINION OF REMISSION IN RHEUMATOID ARTHRITIS OVERLAP US “TRUE” REMISSION?**

V. Vlad1, F. Berghera2, M. Popescu2, V. Iorgoveanu1, D. Predeteanu1, R. Ionescu2,1

1Rheumatology, Clinical Hospital Sf Maria Bucharest; 2Rheumatology, UMF Carol Davila, Bucharest, Romania

Background: Patients describe RA remission as the absence of any symptoms or return to normality. Ultrasound (US) in RA remission patients did not exactly overlap clinical evaluation of remission in previous studies (residual synovitis frequently described). US tenosynovitis evaluation and scoring seemed to better follow clinical remission scores than synovitis in RA [1].

Objectives: To verify with US/clinical evaluations if patients’ reported remission is “true” remission, and if and which clinical and US scores are lowest possible in that cohort.

Methods: Forty-eight RA patients were enrolled in this pilot study between 2015–2017 according to their positive answer to the question “Are you feeling free of symptoms, like before RA started for you?”; the enrollment was regardless of the treatment they were on. Written informed consent was obtained. Clinical evaluation of tendon and swollen joints was performed the same day with US evaluation of 24 joints and 26 tendon sites and with lab CRP evaluation, blinded from one another. DAS28 and SDAI were calculated after, counting VAS1–5, for both physician and patients.

Results: Mean patients age was 58, 35/48 (72.9%) patients were also in remission per DAS28 criteria. Except for CRP value, no other variables (tendon, swollen joints, RF, CCP, remission duration) were significantly different in the group with overlapping DAS28 remission. Considering 1.00 as the “ideal” situation (absolute overlapping of US remission and remission felt by patients), the closest was PD scoring in tenosynovitis of the ankle and feet (100%) and the furthest (absolute overlapping of US remission and remission felt by patients), the closest group with overlapping DAS28 remission. Considering 1.00 as the “ideal” situation (absolute overlapping of US remission and remission felt by patients), the closest was PD scoring in tenosynovitis of the ankle and feet (100%) and the furthest (absolute overlapping of US remission and remission felt by patients), the closest group with overlapping DAS28 remission.

Conclusions: Patients describe RA remission as the absence of any symptoms or return to normality. Ultrasound (US) in RA remission patients did not exactly overlap clinical evaluation of remission in previous studies (residual synovitis frequently described). US tenosynovitis evaluation and scoring seemed to better follow clinical remission scores than synovitis in RA [1].

**SAMPLE SIZE FOR RA CLINICAL TRIALS USING ULTRASOUND OUTCOME MEASURES MAY BE REDUCED BY NOVEL JOINT SELECTION METHODS: A PILOT STUDY**

J.C. Allen Jr1, J. Thumb2,3,4, W.K. Lye1, P.G. Conaghan5,6, L.C. Chew3,2,4, Y.K. Tan2,3,4,1

1Office of Clinical Sciences, Centre for Quantitative Medicine, Duke-NUS Medical School; 2Yong Loo Lin School of Medicine, National University of Singapore; 3Duke-NUS Medical School; 4Department of Rheumatology and Immunology, Singapore General Hospital, Singapore; 5NHRI Leeds Musculoskeletal Biomedical Research Unit; 6Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

Background: Novel outcome measures selecting a reduced joint count for ultrasonography can be highlyresponsive in demonstrating the improvement in joint inflammation seen in rheumatoid arthritis (RA) patients on treatment [1].

Objectives: To determine whether the use of the novel methods can translate into smaller sample sizes for subject recruitment into RA clinical trials. Results from the existing methods are used for comparison.

Methods: 24 RA patients with treatment starts or escalations had clinical and ultrasonar joint assessment at baseline and 3 months. The novel methods select joints based on (A) ultrasound joint findings (i.e. Individualized Ultrasound (IUS) method) or (B) a composite of ultrasound and clinical joint findings (i.e. Individualized Composite Ultrasound (ICUS) method). In contrast, the existing methods select joint sites for ultrasonography. Scores at the relevant joints per patient are summed up to obtain the total inflammatory score (TIS). The effect size (ES) was measured as the mean change of the TIS divided by the standard deviation of the change in the TIS. Sample sizes were calculated from confidence intervals (CIs) on ES that reflect uncertainty in estimating ES. For a given CI on ES sample sizes are computed as the minimum number of patients required to provide >80% power at α = 0.05 for rejecting the null hypothesis (defined as no difference in the 3-month mean change in TIS comparing novel versus existing methods).

Results: Based on the 95% CI analysis, sample sizes using existing joint assessment methods in conjunction with the 12-joint approach ranged from 10 to 234. The corresponding sample sizes using the ICUS method with the 12-joint approach ranged from 7 to 39, and using the IUS method with the 12-joint approach ranged from 6 to 37. The corresponding sample sizes using the ICUS method with the 7-joint approach ranged from 6 to 24, and using the IUS method with the 7-joint approach ranged from 6 to 35.

Conclusions: Our findings strongly suggest that novel ultrasound joint selection methods result in smaller sample size requirements compared to existing methods, and provide justification for larger studies to confirm these observations.

**PRESEPSIN AND PROCALCITONIN ARE OF DIAGNOSTIC VALUE FOR BACTERIAL INFECTION IN PATIENTS WITH CONNECTIVE TISSUE DISEASES**

Y. Ichimura, Y. Kawaguchi, A. Tochimoto, T. Higuchi, M. Tochihara, Y. Katsumata, H. Yamakawa, Institute of Rheumatology, Tokyo women’s medical university, Tokyo, Japan

Background: Recently, presepsin (soluble CD14-subtype) and procalcitonin are reported as a good diagnostic markers of bacterial infection, especially sepsis. However, their utility in patients with connective tissue diseases (CTDs) has been unknown.

Objectives: To assess the diagnostic value of presepsin and procalcitonin in patients with CTDs.

Methods: We enrolled the consecutive patients with CTDs, who checked the level of procalcitonin and/or presepsin during January to September, 2016, retrospectively. We divided two groups; the infection group and non-infectious group. Infection was diagnosed by symptoms, micro-bacterial methods and the good response to antibiotics. The data analysis were assessed using IBM SPSS statistics 22.

Ct: Confidence Interval; SD: Standard Deviation. 3Forest contains zero which corresponds to the null hypothesis, so upper limit cannot be calculated.
Results: Eighty-four patients with CTDs were enrolled, including 42 patients with rheumatoid arthritis (RA). The level of procalcitonin was evaluated in all patients, and the level of presepsin was in 48 patients. Thirty-six patients were classified in infection group; 38 patients in the CRP-positive non-infection group; and 10 patients in CRP-negative non-infection group. The level of procalcitonin was significant higher in infection group than CRP-positive non-infection group (693 +/- 577 pg/mL vs. 250 +/- 101 pg/mL, p < 0.01) (Fig. 1). Among the patients with RA, the level of procalcitonin was significant higher in infection group than non-infection group (809 +/- 637 pg/mL vs. 233 +/- 135 pg/mL, p < 0.01). AUCs of procalcitonin (0.823) and presepsin (0.821) showed similar diagnostic value. The cut-off value of presepsin and procalcitonin were 265 pg/mL and 0.16 ng/mL, respectively (sensitivity: 78.3% and 82.6%, specificity: 76.0% and 76.0%).

Conclusions: Procalcitonin and presepsin may be of diagnostic value for bacterial infection in patients with CTDs, especially may distinguish bacterial infection from active phase in patients with CTDs.

SAT0668 ASSESSMENT OF INTRACRANIAL VESSELS AND VASCULAR LESION IN RHEUMATOID ARTHRITIS. A DETAILED TRANSCRANIAL DOPPLER, CAROTID ULTRASOUND AND BRAIN MRI STUDY

1Department of Neurosurgery, Borsod County Teaching Hospital; 2Department of Radiology, Semmelweis Teaching Hospital; 3Department of Radiology, University of Debrecen, Medical School, Debrecen; 4Department of Neurology, Semmelweis University, Budapest, Hungary.

Background: Stroke has been associated with rheumatoid arthritis (RA). Vascular physiology should be assessed in the preclinical vascular state.

Objectives: We assessed RA patients and healthy controls by transcranial Doppler (TCD), carotid ultrasonography and brain MRI. We wished to determine preclinical pathophysiological changes in the cerebral vasculature.

Methods: Altogether 63 female RA patients and 60 age-matched controls underwent TCD assessment of the medium cerebral (MCA), basilar and vertebral arteries. Pulsatility (PI), resistance (RI) indices and circulatory reserve capacity (CRC) were determined. The presence of carotid plaques and intima-media thickness (cIMT) were also determined. Intracerebral vascular lesions were investigated by brain MRI. RA subsets include MTX- and biologic-treated patients.

Results: MCA PI and RI values at rest and after aperine are significantly increased in the total RA population vs controls. MCA PI (r) and RI (r) is also lower in biologic-treated patients. MCA CRC was also impaired and basilar artery PI was decreased (CRC) were determined. The presence of carotid plaques and intima-media thickness (cIMT) were also determined. Intracerebral vascular lesions were investigated by brain MRI. RA subsets include MTX- and biologic-treated patients.

Conclusion: Correlation analysis suggested multiple associations between right and left TCD parameters. There may be an association of TCD and carotid features with cerebral atrophy and age. Disease duration, disease activity and anti-CCP may influence left MCA PI and RI, as well as CRC. Lp(a) may also influence the development of carotid plaques.

Conclusions: This may be the first study to show increased distal MCA and basilar artery occlusion in RA as determined by TCD. RA patients also exert CRC defect. We also confirmed increased carotid plaque formation, increased cIMT. Biologics may beneficially influence some parameters in the intracranial vessels.

SAT0669 HOW DO WE USE BIOLOGICS IN PATIENTS WITH A HISTORY OF MALIGNANCY? AN ASSESSMENT OF TREATMENT PATTERNS USING SCANDINAVIAN REGISTERS

1Department of Rheumatology, Karolinska Institute, Stockholm, Sweden; 2Department of Medicine, Helsinki University Central Hospital, Helsinki, Finland; 3Department of Rheumatology, University Hospital Reykjavik; 4Department of Rheumatology, University Hospital of Iceland, Iceland.

Background: Immune competence is of importance for the occurrence and outcome of malignancies. Robust data on risk of relapse of previous cancer following treatment with biological immune-modulators are scarce. Most treatment guidelines caution about their use in patients with a history of cancer, leaving rheumatologists with the decision whether a potential treatment benefit may offset any potential risk of cancer relapse.

Objectives: To assess the overall use of biologics and the relative use of different biological drugs in RA patients with a history of cancer.

Methods: As part of a Nordic collaboration, and using data from the ARTIS (Sweden), ROB-FIN (Finland), and ICEBIO (Iceland) biologics registers, we identified all patients with RA who initiated a first ever biological treatment 2010 through 2014. Through linkage to the national cancer registers, we identified those patients who had a history of any invasive malignancy (including squamous cell skin cancer) either within the years preceding start of biological treatment (‘recent history of malignancy’) or more than five years before start of biological treatment (‘non-recent history malignancy’).

Results: The age- and gender distributions were similar across countries and drugs. Initiators of non-TNFα biologics were older than TNFI-initiators; the median age at treatment start was the highest for rituximab. Out of a total of 8065 bio-initiations, 6% occurred in individuals with a history of cancer (2% with a cancer within 5 years, and 4% with a cancer more than 5 years before treatment start). Whereas there was little variation (around 5%) across TNFI initiators, the proportion of patients with a history of cancer at treatment start was higher among rituximab initiators, in part explained by age (Table). There were only small variations across country (not shown).

Conclusions: In Sweden, Finland and Iceland, one out of 20 biologics-initiators (and almost one out of five rituximab initiators) have a history of an invasive cancer, underscoring the need for more data on benefit/risk in this treatment context. The higher proportion in rituximab initiators is partly explained by differences in age at treatment start and reflects the preference for rituximab by clinicians for treatment of patients with history of cancer.

SAT0670 | THE PREVALENCE OF NEUROPATHIC PAIN-LIKE SYMPTOMS AND ASSOCIATED RISK FACTORS IN THE NOTTINGHAM COMMUNITY: A CROSS-SECTIONAL STUDY

G.S. Fernandes1,2,3, A. Sarmanova1,2, S. Warner1, H. Harvey1, H. Richardson1, N. Frowd1,3, L. Marshall1,3, J. Stocks1,3, M. Hall1,3, A. Valdes1,3, D. Walsh1,2,3, W. Zhang1,2,3, M. Doherty1,2,3, 1Division of Rheumatology, Orthopaedics and Dermatology; 2Arthritis Research UK Centre for Osteoarthritis, Exercise and Rehabilitation; 3Arthritis Research UK Pain Centre, University of Nottingham, Nottingham, United Kingdom

Background: Knee pain (KP) affects 1 in 4 adults over the age of 50. Aside from structural joint changes, person-specific factors influence the KP experience. Increased central sensitisation of neural pathways due to localised joint pain or ineffective descending inhibitory mechanisms can cause an enhanced pain response and neuropathic pain-like (NP) symptoms. Understanding these person-specific factors and how they modulate the pain experience might help profile different KP and NP phenotypes.

Objectives: a) To determine the prevalence of NP in a KP community population b) To identify significant risk factors associated with NP and those with both NP and non-NP KP.

Methods: 9,513 men and women, aged 40+ years, were recruited from the East Midlands region (United Kingdom) via postal questionnaire. The questionnaire included sections on KP severity (numerical rating scale) and type (NP versus nociceptive) using the modified PainDETECT Questionnaire (mPDQ); quality of KP using the intervention Rats constant osteoarthritis pain (IOAP) tool as well as other risk factors including age, body mass index (BMI), injury, pain catastrophizing scale (PCS) and mental wellness (Hospital Anxiety and Depression Scale). KP participants were those who reported “knee pain for most days of the past month” while likely NP was mPDQ scores of ≥13 and NP ≥19. Differences between groups were assessed using t-tests for continuous data and χ² for categorical data. We used multinomial regression analysis to determine the odds ratios (ORs) of risk factors with 95% confidence intervals (CI) and significance set at p<0.05.

Results: The prevalence of definite NP in the Nottingham Community was 366 (13.62%). There were more women (p=0.04) and higher BMI (p<0.001) in KP vs. non-KP responders but no age difference (p=0.05). When comparing the neuropathic-like KP to non-neuropathic KP responders, significant risk factors associated with adjustment for age, BMI, gender and pain severity included: anxiety (OR 3.17 (95% CI 2.38,4.23)); depression (OR 2.99 (95% CI 2.14,4.19)); PCS in highest tertile (OR 5.39 (95% CI 2.94,9.88)); fibromyalgia (OR 4.06 (95% CI 2.48,6.66)) and previous knee injury (OR 1.5 (95% CI 1.12,2.00)). When comparing non-KP responders to non-KP responders, anxiety (OR 1.74 (95% CI 1.31,2.30)), depression (2.05 (95% CI 1.40,3.01)), PCS 3.78 (95% CI 2.57,5.56), fibromyalgia (OR 1.94 (95% CI 1.10,3.40)) and previous injury (OR 1.35 (95% CI 1.05; 1.73)) were significant risk factors after adjustment.

Conclusions: This is the first population based cross-sectional study in the UK to determine prevalence of NP in people with KP. The results suggest that both psychological factors (depression, anxiety, high catastrophising) and peripheral risk factors (injury) associate with NP reporting. These factors can augment pain sensitivity and produce an amplified response via central and peripheral pathways. Phenotypes based on these risk factor profiles may warrant specific management in KP populations.

SAT0671 | THE IMPACT OF OBESITY ON TARGET GOALS AND FUNCTIONAL ABILITY IN THE ERAS/ERAN UK PROSPECTIVE COHORTS

E. Nikiforou1, S. Norton1, P. Kiely1, A. Young1 on behalf of ERAS/ERAN.

Background: The links between adipose tissue and inflammation on the one hand and obesity and joint dysfunction on the other, are well established. However, how these translate into clinical disease activity and functional disability in rheumatoid arthritis (RA), remains to be clearly defined.

Objectives: To investigate the association between BMI and 1. The achievement of disease remission or low disease activity and 2. Functional ability. In RA.

Methods: Data from two consecutive UK multi-centre RA inception cohorts with similar design were used: the Early RA Study (ERAS) and Early RA Network (ERAN). Recruitment figures/median follow up for ERAS and ERAN were 1465/10 years (maximum) and 1236/6 years (maximum age 81 yrs), respectively. Standard demographic and clinical variables were recorded at baseline and then annually until loss to follow-up or the end of study follow-up. Multilevel logistic regression analysis was used with either remission (R-DAS) or low disease activity status (L-DAS) and health assessment questionnaire (HAQ, <1 vs ≥1) as the outcome. Independent variables of interest in models adjusting for patient disease-related clinical variables and recruitment year. BMI was examined in separate models as both a continuous and categorical predictor variable according to WHO definitions: underweight (BMI less than 18.5), normal (BMI between 18.5 and 25), overweight (BMI between 25 and 30) and obese (BMI greater than 30).

BMI was included in the models relating to the same time point as the outcome assessed.

Results: Baseline BMI data from 2420 patients (90%) indicated that 40.0% had BMI scores in the normal range, 1.8% were overweight, 37.2% were overweight and 21.3% were obese. Mean BMI increased slightly over time from 26.5 at baseline to 26.8 at 2 years and then 27.1 at 5 years. In multilevel logistic models adjusting for age, sex, smoking status, antibody status, haemoglobin, erosions and year of recruitment, higher BMI was associated with reduced odds of achieving R-DAS (OR 0.97;95% CI 0.95, 0.99) (table) and L-DAS, although the latter did not reach statistical significance (OR 0.98;95% CI 0.90, 1.06). Obesity was related to a significantly lower chance of R-DAS by 29% (OR 0.71;95% CI 0.55, 0.93) and L-DAS by 31% (OR 0.69;95% CI 0.55,0.87). Higher BMI was predictive of higher disability (OR 1.04;95% CI 1.01,1.06). More specifically, obesity increased the odds of higher disability by 63% (OR 1.63;95% CI 1.20,2.23) and in the same models, higher BMI was also strongly predictive of higher disability (OR 3.67;95% CI 3.41,3.95).

Table. Impact of BMI category on disease activity and functional ability in models adjusting for patient demographic, clinical & disease variables.

Conclusions: The findings support a link between high BMI and worse clinical outcomes, namely lower disease activity and functional ability. Obesity was associated with lower levels of both remission and low disease activity states, and of higher disability. The findings highlight the importance of monitoring the patients’ weight, screening and targeting obesity as part of routine clinical practice, in order to improve disease outcomes. This work provides clinical insights into the role of BMI on disease outcomes in RA.

SAT0672 | RISK OF FRACTURE FragILE FrACTURE AMong PATIENTS WITH PSORIASIS: A POPULATION BASED MATCHED COHORT STUDY FROM THE UNITED KINGDOM

Z. Paskins1,2, R. Whittle1, A. Abdul Sultan1, S. Muller1, M. Blagojevic-Bucknall1, T. Helliwell1, S. Hider1,2, E. Roddy1,2, M. Callen1.

1Research Institute for Primary Care and Health Sciences, Keele University, Keele; 2Haywood Rheumatology Centre, Haywood Hospital, Burslem, Stoke-on-Trent, United Kingdom

Background: Psoriasis is a common inflammatory skin disease affecting 2–4% of the population and of these a subset will develop an associated inflammatory arthritis (psoriatic arthritis - PsA). An increased risk of osteoporosis has previously been reported in psoriasis patients but the risk of fracture in patients with both psoriasis and PsA has not been established.

Objectives: To estimate the effect of psoriasis, and PsA, on the risk of fracture using a large electronic primary care health database.

Methods: A matched cohort study was conducted utilizing data from the Clinical Practice Research Datalink, a large UK database of primary care medical records. The exposed population was defined as psoriasis patients aged over 40 years with an incident diagnosis between 1990–2004, who were followed up until 2015. Four unmatched patients were matched to each exposed based on age, sex and general practice. The incidence rate of fracture were calculated as the number of incident diagnoses per 10,000 person-years, stratified by sex. Hazard ratio (HR) and 95% confidence intervals were estimated using a Cox proportional hazards model to compare the hazard rate between the exposed and unexposed, adjusting for BMI, alcohol consumption, smoking status, Charlson comorbidity index and steroid use. Fracture risk was estimated for patients with both psoriasis and PsA, identified as patients with an incident diagnosis of psoriasis between 1990–2004.

Results: 24,219 patients with psoriasis and 94,820 controls were included in the study. The mean age was 59 years at study entry and just over half (51%) of the patients were female. The incidence rate of fracture was 4.8 (95% CI 4.55–6.13) and 53.1 (51.7–54.5) per 10,000 person-years for the exposed and unexposed, respectively. After adjusting for confounding factors, patients with psoriasis had 12% increased risk of fracture (HR: 1.12; 95% CI 1.06–1.19) compared to the matched unexposed group. The risk was slightly higher in males (1.22 (1.09–
1.36) than females (1.09 (1.03–1.17)). Among those with psoriasis, 4.1% were also diagnosed with PsA. An increased risk of 45% was found in those exposed to both psoriasis and PsA compared to the unexposed group (1.45 (1.09–1.94)).

**Conclusions:** This study reports for the first time, an increase in fracture risk in patients with psoriasis. A higher risk was found in males than females and the risk was further increased if the patient also had PsA. These findings suggest that fracture risk assessment needs to be considered for individuals with psoriasis and PsA.

**SAT0673** **RISK AGE AND RELATIVE RISK OF CVD IN INFLAMMATORY JOINT DISEASES**

G. Wibetoo1, E. Ikdahl1, S. Rollefstad1, I. Olsen1, K. Bergsmark1, T. Kvien1, S. Rollefstad 1, I. Olsen 1, K. Bergsmark 1, T. Kvien1, 2Lillehammer Hospital for Rheumatic Diseases, Lillehammer; 3Hospital of Southern Norway, Kristiansand; 4University Hospital of Northern Norway, H.C. Gulseth7, G. Haugeberg 8, A.G. Semb 1.

**Background:** Individuals with inflammatory joint diseases (IJD) [rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA)] have increased risk of cardiovascular disease (CVD). In the European guidelines for CVD prevention, calculation of relative risk and risk age is advised in patients with low absolute risk of fatal CVD events the next 10 years estimated by the systematic coronary risk evaluation [SCORe] algorithm; the rational being that low absolute risk may conceal high relative risk and risk ages far beyond chronological age. Thus, more patients needing intensive CVD prevention may be identified. Relative risk is a ratio comparing absolute CVD risk in a specific patient to the risk given optimal CVD risk factor levels (CVDRFs). Risk age denotes the age with similar CVD risk and optimal CVDRFs. At this date, no studies have evaluated relative risk and risk age across IJD entities, neither has the agreement between different risk age models been investigated.

**Objectives:** 1) Estimate relative risk and risk age across IJD entities. 2) Investigate agreement between different risk age models.

**Methods:** RA/axSpA/PsA patients aged ≤65 years with moderate 10-year risk of fatal CVD were included from a nationwide quality assurance project implementing CVD risk assessment. Relative risk and cardiovascular risk age was calculated in accordance with risk charts published by the European Society of Cardiology (2016) and Cooney et al (2012). Vascular age was calculated by matching SCORE to estimated risk ages in accordance with Cuyedi et al (2010). Four different vascular age estimations were calculated, depending on whether the EULAR 1.5 multiplicative factor in RA was applied (mSCORE) and if SCORE version with HDL-c (SCORE-HDL-c) was used: SCORE, SCORE-HDL-c, mSCORE and mSCORE-HDL-c. Risk years beyond chronological age, were calculated. Linear regression models were used to investigate agreement between risk age estimations.

**Results:** Relative risk was increased in 53% of all patients and 20% had three times the risk or higher compared to individuals with optimal CVDRF levels. In total, 42% and 20% had a risk age ≥5 years higher than their chronological age, according to the cardiovascular risk age model and the vascular age model derived from SCORE, respectively. There were minor differences between RA, axSpA and PsA patients in terms of relative risk and risk age. Agreement between cardiovascular risk age and various vascular age models varied (Figure). Discrepancies ≥5 years in estimated risk age were observed in 14–43% of estimations. The largest observed difference in calculated risk age was 24 years. Similarly, linear regression models yielded a R² of 0.81–0.96. Across all models, median difference between risk age and risk age increased with advancing relative risk. Moreover, several patients had high relative risk despite a risk age close to their chronological age.

**Conclusions:** Relative risk and risk age may identify several patients at high need of intensive CVD preventive efforts despite low estimated absolute risk. However, there are considerable discrepancies between risk age models.

**SAT0674** **EARLY TREATMENT RESPONSE TO CONVENTIONAL DMARD THERAPY IN RHEUMATOID ARTHRITIS IS A BETTER PREDICTOR OF LOW DISEASE ACTIVITY OR TREATMENT ESCALATION AT 12 AND 24 MONTHS THAN AUTOANTIBODIES OR EROSIONS**

A. Richter1, A. Strangefeld2, P. Herzer3, J. Kaufmann4, T. Klopfach6, S. Zinke5, J. Listing1, A. Zink1,2,4 German Rheumatism Research Centre, Berlin; 2Scientific Advisory Board, Munich; 3Rheumatologist, Ludwigsheldorf, 4Rheumatologist, Neubrandenburg; 5Rheumatologist; 6Charité University Medicine, Berlin, Germany

**Background:** The EULAR guidelines recommend using the presence of seropositivity or erosions to support treatment decisions. The prognostic value of these factors regarding the primary treatment target in rheumatoid arthritis, remission or low disease activity (LDA), is unclear.

**Objectives:** To investigate biomarkers, csDMARD treatments and response to treatment regarding their usefulness to predict LDA or the need to escalate treatment within 24 month.

**Methods:** The control group in RABBIT (Rheumatoid Arthritis: Observation of biologic therapy) comprises N=2,228 patients who were enrolled at treatment start with conventional-synthetic (cs)DMARDs after failure of at least one csDMARD therapy, mostly methotrexate (MTX) monotherapy. We excluded patients with a DAS28-ESR≤3.2 at enrollment and those with ≥2 csDMARD failures (n=618). 102 patients were excluded due to enrollment less than 12 month prior to closure of the data base (April 30th, 2016). The DAS28-ESR, physical function, age, seropositivity (RF+ACPA+), comorbidities (≥3 vs. <3) and the presence of erosions at baseline were evaluated as prognostic factors. Concomitant treatment with glucocorticoids (mgt/d) and csDMARDs, response to treatment (3–6 month after enrollment) were additionally examined. We applied a multinomial generalized-estimating-equation (GEE) model to investigate: 1) achievement of LDA at month 12/24 or (2) treatment escalation (biologic therapy) in year one and thereafter.

**Results:** More than one third of patients (34.2%) were treated with a combination of MTX and leflunomide (LEF), 23.6% with LEF mono, 20.8% with MTX + hydroxychloroquine (HCQ) or sulfasalazine (SSZ), 16.5% with MTX mono, and 4.9% with SSZ mono. We found no major differences across treatment regimens except for patients treated with MTX+HCQ who had a lower DAS28, better physical function and shorter disease duration at treatment start. Significant predictors for achieving LDA were low DAS28 at baseline, improvement in DAS28 within 3–6 month, better physical function and less than 3 comorbidities (table). Escalation to bDMARD therapy was significantly more frequent in younger patients, those with no improvement in DAS28 or concomitant glucocorticoid treatment, and in patients with less than 3 comorbidities. There were no differences between treatments regarding achievement of LDA. However, switching to bDMARDs was
most frequent in patients treated with LEF mono or with LEF+MTX. The presence of erosions or seropositivity were not associated with any of the outcomes (table).

Conclusions: The highest impact on achieving LDA was found in disease activity at baseline and response to treatment within 3–6 month. The relevance of erosions, and/or seropositivity regarding the prediction of a poorer outcome is disputable.

SAT0675 | THE ROLE OF EROSIONS TYPICAL OF RHEUMATOID ARTHRITIS IN THE 2010 ACR/EULAR RHEUMATOID CLASSIFICATION CRITERIA: RESULTS FROM A VERY EARLY ARTHRITIS COHORT

G.H. Brinkmann 1, 2, E.S. Norli 2, 3, P. Bøyesen 2, D. van der Heijde 4, L. Grøvle 1, (SERONEGATIVE) MALES SHOW BETTER EULAR G.H. Brinkmann 2, E. Lie 2.

Background: A EULAR task force has proposed that in addition to the 2010 ACR/EULAR rheumatoid arthritis (RA) classification criteria (2010 RA criteria), patients can still be classified as having RA with less than 6 criteria points on the ACR/EULAR rheumatoid arthritis (RA) classification criteria (2010 RA criteria), i.e. ≥3 erosive joints (1). We calculated the additional number of patients being classified as RA based on the erosion criterion at baseline and during follow-up. Other cut-offs and the distribution of erosive joints was also examined.

Methods: Patients with arthritis of ≥16 weeks duration and a clinical diagnosis of RA or undifferentiated arthritis (UA) with available hand and feet radiographs were included from the Norwegian Very Early Arthritis Clinic (NOR-VEAC) study. Erosive disease was defined according to the EULAR definition accompanying the 2010 RA criteria. The current study included 289 patients (mean (SD) age 48 (14.7) years, 54.3% females, median (25, 75 perc) duration of joint swelling 46 (19.5, 79.0) days). At baseline, 120 patients (41.5%) fulfilled the 2010 RA criteria. Of the remaining 169 not fulfilling the 2010 RA criteria, 55 patients had ≥1 erosive joint (40 with hand erosions, 28 with feet erosions and 13 with hand and feet erosions) and 15 (5.2%) patients fulfilled the erosion criterion (Figure 1). The distribution of erosive joints in the 169 patients not fulfilling the 2010 RA criteria at baseline is shown in the table.

Results: The current study included 289 patients (mean (SD) age 48 (14.7) years, 54.3% females, median (25, 75 perc) duration of joint swelling 46 (19.5, 79.0) days). At baseline, 120 patients (41.5%) fulfilled the 2010 RA criteria. Of the remaining 169 not fulfilling the 2010 RA criteria, 55 patients had ≥1 erosive joint (40 with hand erosions, 28 with feet erosions and 13 with hand and feet erosions) and 15 (5.2%) patients fulfilled the erosion criterion (Figure 1). The distribution of erosive joints in the 169 patients not fulfilling the 2010 RA criteria at baseline is shown in the table.

> 1 erosive joint (n=55) 23 17 12 8 22 12
> 2 erosive joints (n=27) 11 13 10 8 12 8
> 3 erosive joints (n=15) 6 8 9 6 8 7

118 patients had radiographic follow-up at 2 years, of whom only 1 additional patient solely fulfilled the erosion criterion during follow-up (7 additional patients fulfilled both the 2010 criteria and the erosion criterion). Among patients with no erosions at baseline (N=74), 13 (17.6%) developed erosions during follow-up (PIP joints n=3, MCP n=4, wrist n=3, CMC joint n=1, MTP joints n=9 and IP1 joint in 2 fingers). Of the 118 patients with erosions at baseline (N=74), 13 (17.6%) developed erosions during follow-up (PIP MCP Wrist CMC + os trapezium MTP IP1 feet). Other cut-offs and the distribution of erosive joints was also examined.

Erosive joints at baseline

1 erosive joint (n=55) 23 17 12 8 22 12
2 erosive joints (n=27) 11 13 10 8 12 8
3 erosive joints (n=15) 6 8 9 6 8 7

Conclusions: Among this cohort of patients with very early arthritis, 5.2% were classified as RA at baseline based solely on the erosion criterion. Of the 118 patients with 2-year follow-up data, only 1 additional patient was classified based on the erosion criterion alone during follow-up, thus, follow-up radiographs in patients with early RA do not seem to provide additional information in classifying patients with RA.

Background: Gender has been reported to play a role in attainment of RA remission (1), but the data are inconsistent. The impact of gender in early RA therefore warrants further investigation.

Methods: An audit, designed as a national prospective longitudinal observational study, was conducted to assess early RA care. All NHS providers in England were required to participate. Follow up data were captured over 3 months for subjects with a diagnosis of RA. Logistic regression was used to estimate associations between gender and DAS-28 response. Smoking status, baseline disease activity, age, antibody status, symptom duration, referral times, and treatment were considered in multivariate models.

Results: Of 146 eligible trusts submitted data. 11,752 subjects consented, 5,622 were diagnosed with RA. DAS-28 response was available for 2234/5622 (39.7%). Male patients had a similar 3 month improvement in their DAS-28 to females, despite having a lower mean baseline score. Male gender associated with a higher rate of good EULAR response (DAS improvement ≥1.2, follow up DAS <3.3), with an adjusted odds ratio of 1.42 (CI 1.17–1.72). There were no differences between the genders in their treatment use or in other aspects of care including speed of referral (Table 1).

* t-test ** Chi-squared. Social deprivation decile from deprivation rank calculated via super output area.
The male excess in good EULAR response was more pronounced in seronegative RA (1.98 (CI 1.4–2.8) compared to 1.21 (0.96–1.53)).

Conclusions: The association of male gender with improved outcomes in early RA has not been shown before in a national cohort of this scope. Previous work suggests seronegative individuals achieve greater clinical response (2), here we present this effect amplified in men. To the authors’ knowledge this is a new finding. This is likely multifactorial, with biological effect of gender, greater diagnostic uncertainty and higher reporting of global scores in women all potentially playing a role.

SAT0677 [**THE IMPACT OF DISEASE ACTIVITY DURING PREGNANCY IN WOMEN WITH SLE ON THE OCCURRENCE OF PREECLAMPSIA AND PREMATURE BIRTH**]

A.C.G. Skorpen, M. Wallenius 1,2, N. Gundersen 3, C. Overas 1,4, H. Gjertsen 1,5, K. A. Salvesen 5, M. Wallenius 1,2, 3. National advisory unit on Pregnancy and Rheumatic Diseases, Department of Neurology, University Hospital; 2Department of Neuroimmunology and Movement Science; 3Regional Center for Child and Youth Mental Health and Child Welfare, Norwegian University of Science and Technology, Trondheim; 4Department of Rheumatology, Oslo University Hospital Rikshospitalet, Oslo; 5Department of Laboratory Medicine, Children’s and Women’s Health, Norwegian University of Science and Technology, Trondheim, Norway.

Background: Pregnancy in women with systemic lupus erythematosus (SLE) is associated with an increased risk of complications such as preeclampsia and premature birth. Active disease is considered one of the risk factors.

Objectives: The aim of this study was to explore the impact of disease activity in pregnant women with SLE on preeclampsia and premature birth, and compare the occurrence with pregnancies from the general obstetric population.

Methods: We linked data from RevNatus with data from the Medical Birth Registry of Norway (MBRN). RevNatus is a Norwegian nationwide prospective observational register including women with an inflammatory rheumatic disease when planning pregnancy or after conception. The register was established in 2006 and is administered by the National advisory unit on pregnancy and rheumatic diseases. Women 18 years or older are recruited and followed-up in each trimester of pregnancy and at 6 weeks, 6 months and 12 months after birth. MBRN is a national birth registry. The population constituted all singleton live births recorded in MBRN in the period 2006 – 2014. The births in women diagnosed with SLE in MBRN and included in RevNatus formed the patient group (n=180). The references were all other births (n=498849). We performed logistic regression, and calculated OR for preeclampsia and premature birth in the patient population compared to the references from the general obstetric population. The target population was then split in two groups according to disease activity, assessed in the 2nd trimester, and compared to references.

Results: Women with SLE had a significantly higher risk of preeclampsia and premature birth than references from the general obstetric population. Women with active disease in pregnancy are most prone to these complications.

SAT0678 [**SIGNIFICANTLY INCREASED SEROPOSITIVITY, RHEUMATOID FACTOR TITRES AND RHEUMATOID NODULES IN CORNISH KAOLIN WORKERS**]

D. Murphy 1,2, E. Fleeing 2, K. Bellis 1, D. Hutchinson 1,2. 1Rheumatology, Royal Cornwall Hospital; 2University of Exeter Medical School, Cornwall Campus, Truro, United Kingdom.

Background: Kaolin has been mined in Cornwall, UK for over 250 years. With half of the world’s production originating from the area at the turn of the 20th century. Mineral kaolinite does not react as free silica, and is used in heavy metal contamination containment due to its adsorption capabilities.

Objectives: To investigate the prevalence of occupational kaolin dust exposure in male rheumatoid arthritis (RA) patients in Cornwall, UK.

Methods: All males diagnosed with RA under follow up at the Royal Cornwall Hospital, UK, during the study period April 2015-January 2017, were invited to complete an occupational questionnaire, detailing current occupation, last occupation (if retired) and other occupations for >1 year.

Results: 39/720 (5%) cases were included and 329/720 (45%) had a history of kaolin exposure. 1720 (9%) cases died during the study period (22 months), 54/640 (8%) remaining cases had occupational kaolin exposure, approximately 12 times higher than expected based on current census employment rates. 30/54 had long term kaolin dust exposure, living in the post code region PL22-PL26 (total male population 33693). These were matched for age ±2 years, sex and index of multiple deprivation (IMD) ±1 decile, to RA patients with no occupational dust or fume exposure. 40/110 potential controls were successfully matched. Significant more RA kaolin workers were seropositive for RF and ACPR than non-dust exposed RA controls (Table 1). Of RF seropositive patients, mean RF titres were significantly higher in kaolin workers than unexposed controls (p<0.01). No significant differences were seen in ACPR titre. Smoking prevalence rates were not significantly different between kaolin workers and controls. Amongst ever smokers, median pack years smoked showed no difference between cases and controls.

Conclusion: Kaolin exposed never smokers demonstrated significantly higher RF titres than unexposed never smokers (kaolin median RF 109 (IQR 32–193.5), control median RF 24 (IQR 7–61), p<0.04), as did kaolin exposed smokers (kaolin median RF 146.7 (IQR 56–231.5), control median RF 61 (IQR 18.5–70), p<0.03, figure 1). Interestingly, 7/30 (23%) kaolin workers demonstrated nodular disease, compared to 3/40 (7.5%) matched controls, p=0.06, significantly higher than the background nodular rate 79/720 (11%) of male RA patients throughout Cornwall, p<0.04.

**SAT0679** | ARE ADULT TRAJECTORIES OF WEIGHT OVER A LIFETIME LINKED TO FOOT PROBLEMS YEARS LATER?

A.B. Dufour 1, E. Losina 2, H.B. Menz 3, M.P. LaValley 4, M.T. Hannan 1, 1 Institute for Aging Research, Hebrew SeniorLife; 2 Brigham and Women’s Hospital, Boston, United States; 3 School of Allied Health, La Trobe University, Bundoora, Australia; 4 Biostatistics, Boston University, School of Public Health, Boston, United States

**Background:** Obesity and foot problems are common in older adults and associated with many negative health outcomes. Better understanding of the consequences of patterns of weight change may lead to better prediction and dealing with foot pain and foot disorders.

**Objectives:** This study identified longitudinal trajectories of weight in a population-based study and examined the association of these groups with current foot problems.

**Methods:** We used 28 measures of weight over 57 years to identify trajectories of weight in 2445 members of the Framingham Foot Study using k-means longitudinal cluster analysis. Foot examinations (2002-2008) recorded presence of foot pain, hallux valgus, claw toes, hammer toes and overlapping toes on each foot. Associations between weight group membership and foot problems at time of foot exam, adjusted for age and sex, were examined using logistic regression with generalized estimating equation correction for two feet per subject. The reference group used for analysis was the group with the lowest weight trajectory (“E”).

**Results:** We found 5 trajectories of weight, representing relatively constant patterns over time, with weight increasing from groups E to A. Those in group E were more likely to be older, while the youngest were in group “A.” E had the lowest prevalence of foot pain (14%) while group “A” had the highest (22%). Similarly, group “A” had the lowest prevalence of hallux valgus, while group E had the highest (36%) (Table 1).

Compared to group “E,” other groups were more likely to have foot pain (ORs 1.57–3.50, Table 2) and less likely to have hallux valgus (ORs 0.73–0.99). For claw toes, all but one group were more likely to have claw toes compared to group “E.” Groups “A” and “D” were more likely to have hammer toes (ORs 2.40 and 1.35, respectively) compared to group “E.” We found no associations between overlapping toes and group membership.

**Conclusions:** Trajectories with higher weight over a lifetime had increased odds of foot pain and claw toes, and decreased odds of hallux valgus later in life. These results provide evidence that having lower weight over one’s lifetime can reduce the likelihood of foot problems later in life.

**SAT0680** | THE IMPACT OF DISEASE ACTIVITY DURING PREGNANCY IN WOMEN WITH SLE ON THE BIRTH WEIGHT OF THE CHILD

A.C.G. Skorpen 1, E. Losina 2, S. Lydersen 3, I.-M. Gilboe 4, K.Å. Salvesen 5, 1 Norwegian University of Science and Technology, Trondheim; 2Department of Neuromedicine and Movement Science; 3Regional Center for Child and Youth Mental health and Child Welfare, Oslo; 4Biostatistics, Boston University, School of Public Health, Boston, United States

**Background:** Mean birthweight is lower in children of SLE-mothers than in reference. Active disease in pregnancy is considered one of the risk factors.

**Objectives:** The aim of this study was to explore the association of disease activity in women with SLE in pregnancy and the birth weight of the child expressed as mean birth weight and mean z-score for birth weight.

**Methods:** We linked data from RevNatus with data from the Medical Birth Registry of Norway (MBRN). RevNatus is a Norwegian nationwide prospective observational register including women with an inflammatory rheumatic disease when planning pregnancy or after conception. The register is administered by the National advisory unit on pregnancy and rheumatic diseases. Women 18 years or older are recruited and followed-up in each trimester of pregnancy and at 6 weeks, 6 months, and 12 months after birth. MBRN includes all singleton live births recorded in MBRN in the period 2006–2014. The women in both groups with diagnosed with SLE in MBRN and included in RevNatus formed the patient group (n=180). The references were all other births (n=498649). Mean birth weight in the patient group was compared to mean birth weight in the general obstetric population. We calculated z-score for birth weight adjusted for gestational age and sex. The target population was then split in two groups according to disease activity assessed in the 2nd trimester, and compared to references. One-way ANOVA was performed to compare SLE-women without active disease, SLE-women with active disease and references from the general obstetric population.

**Results:** The mean birth weight and mean z-score were both significantly lower in women with SLE compared to references.

**SAT0681** | RISK OF ACTIVE TUBERCULOSIS IN PATIENTS WITH INFILTRATORY ARTHRITIS RECEIVING TNF-INHIBITORS

A.M. Gheorghi 1,2, A. Garaian 2, A. Radu 1,2, A. Soare 1,2, V. Aramă 2,2, D. Bumbăcea 1,2, D. Roburta 2,2, R. Onetea 1,2, S. Pintilie 1,2, M. Milicescu 1,2, I. Ancuta 1,2, A. Martin 1,2, M. Sasu 1, C. Ciofu 1,2, L. Macovei 1,2, V. Stoica 1,2, M. Bojinca 1,2, M. Boinca 1,2, Internal Medicine and Rheumatology, Cantacuzino Hospital; 2 Carol Davila University of Medicine and Pharmacy; 3 Infectious Diseases 1, Matei Bals National Institute for Infectious Diseases; 4 Dept. of Pneumology, Elias Emergency University Hospital, Bucharest, Romania

**Background:** Tuberculosis (TB) is a major concern in patients receiving TNF inhibitors (TNFi).

**Objectives:** To assess the incidence of active TB and the efficacy of TB prevention measures in a large, single-center cohort of patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and anklylosing spondylitis (AS) receiving TNFi.

**Methods:** Data of all patients in whom treatment with TNFi was initiated in our rheumatology clinic from January 1st 2002 until December 31st 2015 have been retrospectively analysed. The cohort was divided into 2 groups per the mandatory latent TB infection (LTBI) screening method at baseline: tuberculin skin test (group TST), and QuantiFERON®-TB Gold test (group QFT). The incidence of active TB was analysed for each group and compared to TB incidence data in general population.

**Results:** 653 patients were included (344 RA, 52 PsA, 257 AS); 324 patients belonged to the TST and 329 to the QFT group. The number of active TB cases/ time of exposure to TNFi (person-years, PY) was 17/2002.6 and 7/1041.2 respectively. The incidence of active TB was 0.001 and 0.001 respectively. There were no significant differences in disease in women with active as opposed to quiescent disease.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.3038
had pulmonary TB, whereas the rest were disseminated TB (8 cases), TB pleurisy and/or pericarditis (4 cases), one mediastinal lymph node TB and one isolated hepatic TB. Using Pearson chi-square test, we found no significant differences between LTBI group and active TB (Table B).

Conclusions: In our cohort, new infection TB exceeds reactivation TB, suggesting the necessity of periodical LTBI re-screening.

SAT0684 | PREVALENCE OF SARCOPENIA IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES

A. Tournade 1,2, P. Jaffeux 3, T. Fraysse 1, A. Fan 1, M. Couderc 1, J.J. Dubost 1, A. Elmerri 1,2, P. Arnaud 1,2, C. Mihai 1, A. Sato 1,2, P. Arnaud 1,2.

Background: Evaluation of sarcopenia is of major relevance because of these chronic repercussions on morbidity and mortality. Although the definition should include both low muscle mass and function, a combination of the 2 criteria was not reported in inflammatory rheumatic diseases (IRDs).

Objectives: To determine in a cohort of IRDs the prevalence of sarcopenia using an accepted cut-off and evaluate its associations with clinical characteristics.

Methods: 324 patients with chronic inflammatory arthritis (RA, ankylosing spondylitis (SpA), and psoriatic arthritis (PsA)) without known history of cancer, chronic steroid treatment, or severe comorbidities were enrolled. Lean body mass was measured by dual energy X-ray absorptiometry (DXA) and muscle strength by handgrip strength. The prevalence of sarcopenia was defined based on these cut-off values.

Results: The prevalence of sarcopenia was 28% in RA, compared to 20.5% in SpA and 18% in PsA. The prevalence of sarcopenia was associated with age, duration of disease, smoking, low education level, and morning stiffness.

Conclusions: Sarcopenia is frequently observed in patients with chronic inflammatory rheumatic diseases. Its prevalence is lower in SpA and PsA than in RA. Further studies are needed to determine predictive factors and to assess the impact of sarcopenia on outcomes in these patients.

Disclosure of Interest: None declared.

SAT0685 | PREVALENCE OF OSTEOPEOROSIS IN ALBANIAN POSTMENOPAUSAL WOMEN AND THE ROLE OF RISK FACTORS IN OSTEOPOROSIS

A. Kollcaku, J. Kollcaku, V. Duraj, Rheumatology, University Hospital Center "Nene Tereza", Tirana, Albania

Background: Menopause is the time in woman’s life when production of sex hormones ceases. Sex hormone deficiency leads to increasing bone fragility and, thus, fracture risk. Bone turnover and bone mass could be affected by too many other risk factors. Osteoporosis threatens the health and quality of life of women aged over 70 years-old (2). Reduced muscle mass only was not highly prevalent and lower than that reported in elderly supporting important cofactors such as functional limitations or muscle quality in sarcopenia associated with rheumatic diseases.

Objectives: The aims of this study were to assess the prevalence of osteoporosis in Albanian postmenopausal women and the role of risk factors in osteoporosis.

Methods: A cross-sectional study was conducted in Tirana city in a period 2009–2013, including a population-based sample of 4,789 women. All subjects enrolled in the study were asked for risk factors for osteoporosis by completing a specific questionnaire. Low bone mineral density (osteoporosis defined as a bone mineral density T-score less than -1 and osteoporosis for T-score less than -2.5) was assessed with a bone ultrasound device which is simple and easy to use for screening of bone mineral density in population-based studies. Binary logistic regression was used to determine the relationship of osteoporosis and independent factors in this study population.

Results: The prevalence of osteoporosis in this study population was 6.2% (N=286) and prevalence of osteoporosis was 16.6%; 77.1% of osteoporosis women were in postmenopause. In logistic regression models was seen that menopausal women had 69% more chances than no menopausal women to have osteoporosis (OR=1.69, 95% CI=1.45–1.77, P<0.001). Osteoporosis was positively associated with multiparity (P<0.001) and long treatment with glucocorticoids (OR: 1.52; CI95% 1.46–1.64; p=0.020). In multivariable analysis osteoporosis was positively associated with the rheumatoid arthritis component (OR: 1.83; CI95% 1.62–2.06; P<0.001). In Kendall’s correlation coefficient, osteoporosis was negatively associated with level of education (r=0.101, p<0.001) and body mass index (r<0.003, p<0.009) and positively associated with white color of skin (r<0.003, p<0.027) and treatment with diuretics (r=0.007, p<0.001).

Conclusions: This study offers useful evidence about the osteoporosis and osteopenia prevalence among postmenopausal Albanian women. Caucasian females with early menopause, multiparous, lower body-weight, suffering from rheumatoid arthritis, long treated with glucocorticoids and diuretics and lower education should be followed-up more carefully for development of osteoporosis.

Conclusions: Non-persistent patients were more likely female, with multiple comorbid conditions, and more line of biotherapies. Hospital admission for IRMD, and rheumatologist with treatment (COMPARED TO CZP ETA) decreased the risk of non-persistence. Further analyses are needed to better understand behaviours of patients and to assess the impact of non-persistence on clinical and economical outcomes.

DOI: 10.1136/annrheumdis-2017-eular.5081
(CV) risk factors. Tofacitinib is an oral JAK inhibitor for the treatment of RA. Treatment with tofacitinib may increase total cholesterol (TC), low-density lipoprotein-cholesterol (LDL-c) and high-density lipoprotein-cholesterol (HDL-c), without affecting TC/HDL-c ratio.

Objectives: To evaluate major adverse CV event (MACE) risk factors in tofacitinib-treated patients with RA in a clinical development programme.

Methods: Data were pooled from pts with moderately to severely active RA receiving ≥1 tofacitinib dose in 6 Phase 3 and 2 long-term extension (LTE) studies (1 LITE study ongoing, data cut-off: April 2015). MACE was any MI, stroke or CV death (coronary, cerebrovascular, cardiac). Cox model regression evaluated associations between baseline (BL) values and time (BL to first tofacitinib dose) to first MACE. Changes (BL to Week [wk] 24) in MACE predictors and time to future MACE (first occurrence after 24 wks) were evaluated after adjusting for age, BL values and time varying tofacitinib dose. Hazard ratios (HR) and 95% confidence intervals (CI) were calculated.

Results: 52 MACE cases occurred over 12,873 pt-years (py) of exposure in 4076 pts (incidence rate: 0.4 pts with events/100 py). At BL, compared with pts without MACE, pts with MACE were older (mean age 60.2 vs 52.7 years) with a higher mean BMI (29.2 vs 27.0 kg/m²) and longer mean RA disease duration (10.1 vs 7.7 years), and were more likely to have a history of diabetes (15.4% vs 7.8%) and hypertension (57.7% vs 33.7%). Pts with MACE had higher mean TC (208.2 vs 198.3 mg/dL), LDL-c (123.3 vs 114.0 mg/dL), TC/HDL-c ratio (4.0 vs 3.5) and triglycerides (152.1 vs 125.3 mg/dL) at BL, and lower HDL-c (53.5 vs 59.4 mg/dL) pts without MACE. In univariate analyses, traditional CV risk factors and use of corticosteroids or statins at BL were associated with MACE risk (Table). BL disease activity and inflammation measures were not associated with MACE risk (Table). In multivariate analysis, BL age, hypertension and the TC/HDL-c ratio were significantly associated with MACE risk. Increases in LDL-c (p<0.001) and decreases increases in TC/HDL-c ratio (p<0.05) after 24 wks of tofacitinib therapy were significantly associated with decreased risk of future MACE (Figure). Increases in erythrocyte sedimentation rate (ESR; p<0.09) may be associated with increased future MACE risk. Changes in TC, LDL-c or other disease activity measures were not associated with future MACE risk.

Conclusions: In pooled analyses of tofacitinib-treated pts (age and BL value adjusted), increases in LDL-c and TC after 24 wks of tofacitinib therapy were not associated with future MACE risk. Increases in HDL-c and decreases in the TC/HDL-c ratio after 24 wks of tofacitinib therapy were associated with reduced future MACE risk. Increases in ESR after 24 wks may be associated with increased future MACE risk. Changes in TC, LDL-c or other disease activity measures were not associated with future MACE risk.

SAT0687

ADHERENCE OF RHEUMATIC PATIENTS TO INH PROPHYLAXIS PRESCRIBED BEFORE BIOLOGICAL TREATMENT: HUR-BIO SINGLE CENTER REAL LIFE RESULTS

E. Seyho˘glu1, O.A. Uyaro˘glu1, A. Erden2, L. Kılıç2, B. Armaga2, A. Sarı2, M. Baykal2, S. Ak3, Ö. Karada˘g2, A. Akdo˘gan2, S. Apra¸s Bilgen2, S. Kiraz2, I. Ertendi2, U. Kalyoncu2

1Department of Internal Medicine, 2Division of Rheumatology, Department of Internal Medicine, Hacettepe University School of Medicine, Ankara, Turkey

Background: Isoniazid (INH) prophylaxis is strongly recommended for the patients who have latent tuberculosis (TB) and who are going to be under anti-TNF treatment. INH is usually prescribed for 9 months and patient adherence to INH affects the risk of active TB development.

Objectives: In this study we aimed to assess the levels of patient adherence to INH prophylaxis.

Methods: Patients, who are under biological treatment and who have a quantiferon (QFT) test result, were evaluated with a questionnaire between August 2015-August 2016. Questionnaire included the demographic and clinical characteristics. Besides, patients were asked whether they had been prescribed INH. Patients, who were given INH prophylaxis, were asked to answer those questions: i) Did you take INH daily and regularly for 9 months? ii) If not what was the reason? The reasons are classified into three categories: 1) The patient discontinued INH of his/her own volition before 9 months. 2) Continued INH for 9 months but did not take regularly due to forgetfulness. 3) Treatment stopped by physician due to an adverse effect (elevation of liver enzymes, neuropathy, etc.).

Results: 1. 710 patients were recruited. INH was prescribed to 169 (23.8%) of 710. Demographic characteristics of INH-prescribed patients: 88 (52.1%) of 169 were female, mean age was 46.2 (SD:11.4), 82 (48.5%) of 169 at least graduated from a high school. Diagnosis were followed: RA 65 (38.4%), SpA 85 (50.3%), PsA 13 (7.7%), others 6 (3.6%). Totally 34 (20.1%) of 169 took INH irregularly, 19 (11.2%) of 169 patients discontinued INH of his/her own volition before 9 months. During follow-up of 5 were prescribed INH again after the physician and they completed the 9-months duration. 9 (5.3%) of 169 patients did not take INH regularly due to forgetting. INH was stopped by a physician due to liver enzyme elevation in 6 (3.5%) of 169 patients. There was not a statistically difference in demographical and clinical characteristics between regular and irregular INH takers.

Conclusions: There is an inadherence to INH treatment approximately in one of five patients. Only 35% of INH-recommended patients had a medical reason of inadherence. Among other patients, causes of inadherence were discontinuance of own volition and forgetfulness or perfunctoriness. Physicians should be aware that reminding of INH is one of the question in every outpatient clinic visits. Other reminding methods such as regular calling should be considered in those of high risk population. Further studies were needed for reminding process.

SAT0688

JOINT INVOLVEMENT IN PATIENTS WITH KNEE AND HIP OA SCHEDULED FOR SURGERY: MULTI-JOINT OA, THE RULE NOT THE EXCEPTION?

E. M. Badley1, C. Yip1, J. D. Power2, R. Gandhi1, N. Mahomed2, J. R. Davey2, K. Syed3, T. R. Rampersaud2, C. Veillette2, A. V. Perruccio1,2

1Division of Health Care and Outcomes Research, Krembil Research Institute, 2The Arthritis Program, Toronto Western Hospital, Toronto, Canada

Background: Multijoint involvement in osteoarthritis (OA) has long been documented clinically and in the literature. Even so, the vast majority of OA research is conducted on single joint OA, and the implicit assumption is often that OA is OA, irrespective of whether a single joint or several joints are involved. The implicit assumption is often that OA is OA, irrespective of whether a single joint or several joints are involved.

Objectives: To examine the joint sites involved and investigate whether the extent of joint involvement changes with the presence of knee and hip OA.

Methods: A health questionnaire completed prior to surgery captured demographic and clinical characteristics. Baseline joint involvement was measured using 68 joints (28 joints in each of the left and right knee and hip). Patients were given INH prophylaxis, were asked to answer those questions: i) Did you take INH daily and regularly for 9 months? ii) If not what was the reason? The reasons are classified into three categories: 1) The patient discontinued INH of his/her own volition before 9 months. 2) Continued INH for 9 months but did not take regularly due to forgetfulness. 3) Treatment stopped by physician due to an adverse effect (elevation of liver enzymes, neuropathy, etc.).

Results: 1. 710 patients were recruited. INH was prescribed to 169 (23.8%) of 710. Demographic characteristics of INH-prescribed patients: 88 (52.1%) of 169 were female, mean age was 46.2 (SD:11.4), 82 (48.5%) of 169 at least graduated from a high school. Diagnosis were followed: RA 65 (38.4%), SpA 85 (50.3%), PsA 13 (7.7%), others 6 (3.6%). Totally 34 (20.1%) of 169 took INH irregularly, 19 (11.2%) of 169 patients discontinued INH of his/her own volition before 9 months. During follow-up of 5 were prescribed INH again after the physician and they completed the 9-months duration. 9 (5.3%) of 169 patients did not take INH regularly due to forgetting. INH was stopped by a physician due to liver enzyme elevation in 6 (3.5%) of 169 patients. There was not a statistically difference in demographical and clinical characteristics between regular and irregular INH takers.

Conclusions: There is an inadherence to INH treatment approximately in one of five patients. Only 35% of INH-recommended patients had a medical reason of inadherence. Among other patients, causes of inadherence were discontinuance of own volition and forgetfulness or perfunctoriness. Physicians should be aware that reminding of INH is one of the question in every outpatient clinic visits. Other reminding methods such as regular calling should be considered in those of high risk population. Further studies were needed for reminding process.

characteristics (age, sex), symptomatic joints other than the surgical joint (right and left shoulders, elbows, wrists, hands, hips, knees, feet, ankle, neck and back), body mass index (BMI), comorbidities (hypertension, depression, diabetes, migraine headaches, cancer, respiratory disease, heart disease, stomach/bowel disease, stroke) and WOMAC hip- and knee-specific pain and function.

Results: Study questionnaires were completed by 366 hip and 407 knee patients. The mean age of the sample was 65 years (SD=9.2; range 38–89 years), 57% were female. The most frequently reported symptomatic joints among knee patients were the contralateral knee (53.2%), one or both hands (32.1%), and the upper-, mid- or lower-back (31.0%), and among hip patients were one or both knees (49.4%), the back (36.6%), and the contralateral hip (21.3%). The overall mean number of symptomatic joints other than the surgical joint was 3.0 (SD=3.2; range 0–17). Only 19.0% reported the surgical joint as the only symptomatic joint; 23.0% reported 5 or more additional symptomatic joints. Mean hip/knee-specific pain and function scores were significantly worse with increasing symptomatic joint count (p<0.01). Additional symptomatic joints were significantly more frequent in women than men; mean count 3.6 vs. 2.3 (p<0.01). No significant difference in mean joint count (p=0.64) was observed by age. Similarly, no difference was found by BMI (i.e. overweight/obese vs. normal); p=0.24 for mean count. However, the number of co-occurring conditions increased with increasing joint count: 27.2% reported 2+ co-occurring conditions among those with 1–4 symptomatic joints, and 42.8% among those with 5+ symptomatic joints (p<0.01).

Conclusions: In this clinical OA sample, the “average” patient reported multiple symptomatic joints. Increasing age was not associated with increasing frequency of symptomatic joints. Irrespective of age and obesity, multiple symptomatic joints were the rule, not the exception. It was notable that the frequency of co-occurring conditions increased with increasing symptomatic joint count. This may suggest a need to re-examine how OA is characterized and perhaps its underlying etiology as it relates to single vs. multi-joint involvement.

SAT0689 | PREVALENCE OF AND TEMPORAL TRENDS IN HYPERURICAEMIA AMONG ADULT PATIENTS WITH CHRONIC KIDNEY DISEASE IN IRELAND

F. Adeel1,2, A.A. Udayakumar2,3, D. Ryan2, X. Li2, A.D. Fraser1,2, A.G. Stack2,3

on behalf of Health Research Institute, University of Limerick. 1Department of Rheumatology, University Hospital Limerick; 2Graduate Entry Medical School, University of Limerick; 3Department of Nephrology, University Hospital Limerick, Limerick, Ireland

Background: An increasing body of evidence links hyperuricaemia with the development of several metabolic disorders and major cardiovascular outcomes. A better understanding of the burden and variation of hyperuricaemia within the health system is important in order to identify high-risk groups and facilitate early intervention with effective management strategies.

Objectives: The aim of this study was to describe the prevalence of hyperuricaemia, and period trends within the Irish Health System among patients with chronic kidney disease.

Methods: 136,325 adult CKD patients aged 18 and above with valid measurements of serum uric acid and creatinine levels were identified between 2006 and 2014 from the laboratory systems within the Irish health system. Hyperuricaemia was defined as serum uric acid ≥420μmol/L in men and ≥360μmol/L in women. Estimated glomerular filtration rates were determined using the Chronic Kidney Disease-Epidemiology Collaboration (CKD-EPI) equation and patients were classified by CKD stage according to the Kidney Disease Improving Global Outcomes (KDIGO) staging system. Age- and sex-specific prevalence of hyperuricaemia estimates with 95% confidence intervals were determined for each group and across calendar years. Comparisons among groups and across years were conducted using chi-square and multivariate logistic regression was used to explore associations using adjusted odds ratios (AOR) and 95% Confidence Intervals (CI).

Results: Patients with hyperuricaemia were noted to be older [58.2 (18.5) vs. 50.4 (15.8) years]. The prevalence of hyperuricaemia increased progressively between 2006 and 2014 from 20.3% (19.5, 21.0) to 26.5% (25.8, 27.2%) in men and from 17.9% (17.2, 18.6) to 20.4% (19.8, 21.0) in women, p<0.001. Age-specific prevalence increased significantly over time for all age groups (18–39, 40–59, 60–79, and ≥80 years) for men and women, p<0.001. Prevalence was significantly higher with increasing CKD stage: 18.1% (14.5, 15.6) in Stage 1 CKD compared to 43.0% (34.8, 51.1) in Stage 5 CKD, p<0.001. However, rates fell significantly for those Stage 4 and 5 CKD respectively (Figure 1). In multi-variable models, the adjusted likelihood of hyperuricaemia increased with each successive year (Figure 2).

Conclusions: The prevalence of hyperuricaemia is substantial in the Irish health system and has increased in frequency over the past decade. Although the burden was highest among patients with more advanced CKD, an encouraging decline in prevalence was observed in recent years. Greater management of gout and hyperuricaemia from increasing utilization of urate-lowering therapies may be responsible for this trend.

SAT0690 | RISK OF HOSPITALIZED INFECTION IN CANCER PATIENTS WITH AUTOIMMUNE DISEASES: A SINGLE-CENTER COHORT STUDY

H.-H. Chen 1, D.-Y. Chen 1, 2, Department of Medical Research; 2Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China

Background: Whether the risk of hospitalized infection is associated with autoimmune diseases compared with those without autoimmune diseases.

Objectives: To examine the risk of hospitalized infection in incident cancer patients with autoimmune diseases compared with those without autoimmune diseases.

Methods: During 2000–2016, we identified 37,027 incident cancer patients from the Cancer Registry database of Taichung Veterans General Hospital. Autoimmune diseases included rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), ankylosing spondylitis (AS), psoriasis (PSO)/psoriatic arthritis (PSA), antiphospholipid syndrome, polymyositis, dermatomyositis, systemic sclerosis, Sjögren’s syndrome, mixed connective tissue disease, multiple sclerosis, neuromyelitis optica, palindromic rheumatism, myasthenia gravis, Hashimoto’s thyroids, immune thrombocytopenic purpura, autoimmune hemolytic anemia, juvenile idiopathic arthritis, adult onset Still’s disease, Crohn’s disease, ulcerative colitis, Wegner’s granulomatosis, and uveitis. Of all subjects, 1,334 had autoimmune diseases. The association between autoimmune diseases and hospitalized infection risk was studied using hazard ratios (HRs) with 95% confidence intervals (CIs) using Cox proportional regression analyses after adjusting for baseline age, sex, cancer stage, hemoglobin (Hgb), creatinine (Cr), log(ALT), log(WBC), and use of biologic agents or tofacitinib.

Results: Among all cancer subjects, the mean ± SD age was 60.2±14.7 years, and the proportion of male gender was 55.7%. Of the 1,334 patients with autoimmune diseases, 338 (25.3%) patients had RA, 221 (16.6%) patients had SLE, 61 (4.6%) patients had AS, 151 (11.4%) patients had PSO/PSA, and 563 (46.8%) had other autoimmune diseases. The incidence rates of hospitalized infection were 143.8 per 10,000 years in patients with autoimmune diseases and 118.9 per 10,000 years in patients without autoimmune diseases. The risk of hospitalized infection was higher in patients with RA and SLE, but not in patients with AS, PSO/PSA, or other autoimmune diseases. Prior use of biologic agents or tofacitinib did not increase hospitalized infection risk. HRs for risk factors for hospitalized infection included older age (HR, 1.01; 95% CI, 1.01–1.1), higher cancer stage, CR (HR, 1.04; 95% CI, 1.02–1.06), log(WBC) (HR, 1.21; 95% CI, 1.14–1.28), Female gender (HR, 0.85; 95% CI, 0.62–0.68) and Hgb (HR, 0.89; 95% CI, 0.80–0.90) were associated lower hospitalized infection risk.

Table 1: Univariable and multivariable analyses for the association between autoimmune diseases and hospitalized infection among cancer patients

SAT0691 INFLUENCE OF SMOKING IN THE EXPRESSION OF CHRONIC PERIODONTITIS AND ANTI-CITRULLINATED PROTEINS ANTIBODIES IN RHEUMATOID ARTHRITIS

J. Gonzalez Feble1, J.L. Garnier Rodriguez2, F. Sanchez Alonso3, S. Dadiani4, Y. Barros5, S. Bustabad6, F. Diaz Gonzalez7, M. Sanz Alonso1, B. Rodriguez Lozano8, 1. Periodontology, UCM, Madrid; 2.Odontology/Periodontology, Dental Clinic Dr Garnier, Santa Cruz de Tenerife; 3.Research Unit, Sociedad Española de Reumatología Madrid; 4.Inmunology Section Central Laboratory; 5.Rheumatology, Hospital Universitario de Canarias, Tenerife, Spain

Background: Environmental, genetic and epigenetic factors can induce citrullination of structural peptides by the enzyme PAD, which induce anti-citrullinated protein antibodies (ACPA) preceding RA. Among the environmental factors are cigarette smoke, infections, such as P. gingivalis in periodontitis (PD) and Pre-votella copit, intestinal microflora, and silica dust. Given the implication of these two exogenous factors, tobacco and PD, in citrullination, and tobacco enhancer factor in PD, we studied:

Objectives: 1. The risk of smoking for developing advanced PD in patients with RA. 2. Possible influence of smoking on the expression of severe PD and ACPA in RA patients.

Methods: Observational, descriptive, cross-sectional study in RA patients older than 18 yrs. (ACR/EULAR 2010), with ≥4 teeth, without tooth cleaning nor antibiotic intake 6 months previously. Socio-demographic and anthropometric variables included smoking status, social indicators such as Grafta scale, stress level, annual dental visits, prophylaxis, and co-morbidities such as diabetes mellitus, dyslipidemia, ischemic cardiovascular disease. Serum ACPA detection: semiquantification Ab IgG against citrullinated peptides (ELISA) with Immunocan CCPiustest kit. Eurodiagnostica: positive →25% ACPA title stratification: Low (25–75), moderate (75–90), high (>90%). Periodontal parameters: plaque index (PI), Bleeding on probing (Bop), probing pocket depth, recession, clinical attachment level (CAL). CAL loss was categorized according to European Workshop 2005 (Tonetti): T level 0 (absence), T1 (mild), T2 (severe), Statistical analysis: 1-student, Kruskal Wallis, Chi-cudarado by Stata program 13.1.

Results: We studied 187 patients, F: 74.8±21.4%, mean age 54.4 yrs. Follow-up time 8.8 y.o. RF: 74.2%, ACPA positive in 114/167 patients (67.8%). Smoking habit: current smoker (29.15%), former smoker (26.4%); low socioeconomic status (36.5%) relative poverty (33.7%), PD was observed in 97.3%. T1 52.4%, T2 19.6%. A “risk gradient” was observed for PD relative to smoking habit. Former smoker OR 1.62 (95% CI 0.81–3.27), p=0.174; smokers, OR 2.27 (95% CI 1.05–4.91), p=0.037. When analyzing the influence of smoking on PD development according to ACPA profile, a gradient effect of developing severe PD was observed for former smokers OR 2.37 (95% CI 0.52–7.64) to current smokers OR 6.99 (95% CI 1.53–32.07) (p=0.029) in ACPA (−) patients. This relationship was not observed in ACPA (+) patients (p=0.383).

Conclusions: 1. There is a “risk gradient” to develop PD in RA in relation to past or current exposure to tobacco, so that, although not significant, former smokers are at greater risk than non-smokers, and current smokers have a significant risk 2.3 times higher. 2. This risk gradient is shown in ACPA (−) patients, but not in ACPA (+) patients, which suggests an independent relationship between PD and ACPA (+) RA.

SAT0692 PREDICTORS AND PERSISTENCE OF UNACCEPTABLE PAIN DURING THE FIRST YEAR OF RHEUMATOID ARTHRITIS IN SWEDEN

H. Westerling1, M.E. Schein1, R. Altawi2, L. Klareskog3, L. Alfredsson1, J. Lamp9, 1. Institute of Environmental Medicine, 2.Rheumatology Unit, Department of Medicine, Center for Molecular Medicine (CMM); 3.Rheumatology Unit, Department of Medicine, Center for Molecular Medicine (CMM), Karolinska Institutet, Stockholm, Sweden

Background: Pain is a dominant symptom in rheumatoid arthritis (RA). Objectives: Investigate unacceptable pain (VAS-pain ≥40) during the first year of the disease and whether it can be predicted from baseline disease characteristics. Methods: The cohort included all incident RA cases from the Swedish population-based case-control Epidemiological Investigation of Rheumatoid Arthritis study (EIRA), who also were in the Swedish Rheumatology Register. Unacceptable pain was defined as scoring 40 mm or above on the pain visual analog scale (VAS) (i.e. not reaching the patient acceptable symptom state (PASS)) (1), and the proportion of patients going in and out of PASS was traced over the first year. Association between baseline parameters, divided into quartiles, and unacceptable pain at one year was assessed using modified Poisson regression and expressed as risk ratios with 95% confidence intervals (95% CI), adjusted for sex and age at diagnosis. Results: A total of 2808 patients were included in the study and 33.8% of the patients remained in PASS (i.e VAS pain below 40) at inclusion. If a patient had PASS at any given visit, there was over 70% chance that the patient remained in PASS at the following visit. The most common PASS pattern (25.6%), was to present with unacceptable pain, reach PASS at the 3 month visit, and then remain in PASS. However, one year after diagnosis, only two thirds of the patients had PASS. Higher disability (measured as HAQ) at baseline was significantly and independently associated with an increased risk for unacceptable pain at one year (for the highest quartile of HAQ: RR=1.97 [95% CI:1.60–2.42]). Also high tender joint count at baseline was associated with an increased risk for unacceptable pain; RR=1.40 [95% CI: 1.18–1.65] for the highest quartile, whereas high swollen joint count at baseline was associated with a decreased risk; RR=0.79 [95% CI: 0.66–0.95] for the highest quartile.

Conclusions: The results highlight the need for efficient pain treatment strategies early in the disease.

therapy group were found to be significantly lower (-0.41±0.29 mg/dL, \( p < 0.001 \)). However, the serum uric acid levels in the estrogen monotherapy and tibolone groups did not differ significantly from the control group level.

**Conclusions:** Serum uric acid levels decreased in response to estrogen-progestogen combination therapy in postmenopausal women. We attribute our findings to the effects of progestogen, rather than estrogen.

**SUBLIMING OF EARLY RA-PATIENTS IDENTIFIED CLUSTER OF PATIENTS WITH HIGH LEVELS OF PAIN, FATIGUE AND PSYCHOSOCIAL DISTRESS 3 YEARS AFTER DIAGNOSIS**

J. Lindqvist, H. Westerlind, L. Klareskog, J. Alfredsson, L. Lampä. Unit of Rheumatology, Department of Medicine Solna; 2Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden

**Background:** The wide range of effective treatment alternatives for rheumatoid arthritis (RA) makes treating the disease to inflammatory remission a feasible goal for a majority of patients. However, earlier studies have reported that symptoms other than inflammatory disease activity causes a substantial burden of illness for RA-patients. These unmet needs include persistent pain, fatigue, impaired physical function and mental health status (1).

**Objectives:** To identify clusters of early RA-patients based on pain, fatigue, sleep, physical function, mental health status and perceptions of quality of life, 3 years after diagnosis. Withal investigate associations between clusters and clinical parameters at the time of diagnosis.

**Methods:** Data was compiled from the Swedish case-control cohort Epidemiological Investigation of Rheumatoid Arthritis (EIRA) and linked to the Swedish Rheumatology Quality Register (SRQ). All patients were diagnosed with RA according to the 1987 ACR criteria. Early RA-patients with clinical data from diagnosis and 3 year follow-up questionnaire data were included (N=618; 74% women, median age at diagnosis 58 years). Measurements of pain, fatigue, sleep problems, physical and mental functioning and quality of life was entered into a hierarchical agglomerative clustering procedure using Ward’s method of squared Euclidian distances. Number of clusters was determined by largest changes in hierarchical agglomerative clustering procedure using Ward’s method of squared Euclidian distances. At the time of diagnosis compared to cluster 3.

**Results:** Through cluster analysis, we could identify a subgroup of almost a third of the RA-patients with high levels of pain, fatigue, sleep problems and poor physical and mental health related quality of life 3 years after RA-diagnosis. These symptoms are found to be predictive of a central sensitization syndrome. Cluster 3 was associated with female sex (p=0.0007) and lower education level (p=0.0003) compared to cluster 3. Cluster 1 was also associated to higher HAQ (p<0.0001), higher patient global assessment of health (p<0.0001), higher pain ratings (p<0.0001) and lower swollen/tender joint count ratio (STR) (p=0.0065) at the time of diagnosis compared to cluster 3.

**Conclusions:** Through cluster analysis, we could identify a subgroup of almost a third of the RA-patients with high levels of pain, fatigue, sleep problems and poor physical and mental health related quality of life 3 years after RA-diagnosis. These symptoms are found to be predictive of a central sensitization syndrome. Cluster 3 was associated with female sex and lower education level compared to cluster 3. Cluster 1 was also associated to higher HAQ, higher patient global assessment of health, higher pain ratings and lower swollen/tender joint count ratio at the time of diagnosis compared to cluster 3.

**NO ASSOCIATION BETWEEN VITAMIN D LEVELS AND CARDIOVASCULAR DISEASES IN INFLAMMATORY JOINT DISEASES AND SYSTEMIC AUTOIMMUNE DISEASES – A SYSTEMATIC REVIEW**

1Newcastle University Medicine Malaysia, Johor Bahru, Malaysia; 2Epidemiology and Statistics; 3Amsterdam Rheumatology and Immunology Centre, VU University Medical Centre, Amsterdam, Netherlands

**Background:** In recent years, vitamin D deficiency has been linked to disease activity and pathogenesis of systemic autoimmune diseases (SAD) like systemic lupus erythematosus (SLE) and inflammatory joint diseases (IJD) such as rheumatoid arthritis (RA). In the general population, the association between vitamin D with risk for cardiovascular diseases (CVD) is still debatable. While people with IJD and SAD tend to be vitamin D deficient and suffer from an elevated CVD burden, the effect of vitamin D on their cardiometabolic risk factors is of much interest.

**Objectives:** To provide an overall conclusion on whether vitamin D deficiency contributes to an increased cardiovascular morbidity in these patients, a systematic literature review was done.

**Methods:** A systematic literature search was done in PubMed/MEDLINE and EMBASE to identify all articles that assessed the association of vitamin D with cardiovascular disease and its risk factors in patients with IJD (rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis) and SAD (systemic lupus erythematosus (SLE), Behcet’s disease, vasculitis, Sjogren syndromes, systemic sclerosis). Eligible studies were assessed for quality and risk of bias according to the Cochrane Handbook Chapter 13.5.2.1. (Higgins JPT, GS. Cochrane Handbook for Systematic Review of Interventions The Cochrane Collaboration 2011.)

**Results:** In total 3273 abstracts were identified. After screening, selection and quality assessment, 16 studies were included (6 case-control and 10 cohort studies), which described only RA and SLE except for one study which focused on PsA. Therefore, this study focused on RA and SLE because they are the most frequent IJD and with highest CVD risk respectively. In RA patients (n=812) vitamin D deficiency was associated with presence of (components) of metabolic syndrome (OR =1.8 (95% CI:1.3; 2.5), P<0.001) in RA, especially dyslipidemia (OR 1.7; 95% CI:1.2–2.5; P=0.013) and obesity. No studies with prospective design in RA have assessed CVD risk in relation to vitamin D. In SLE patients (n=1850) the only prospective study observed no association between vitamin D deficiency and CVD, although weak associations with dyslipidemia and obesity were observed in some studies.

**Conclusions:** No clear association between vitamin D deficiency and CVD was found in patients with RA and SLE, probably due to large heterogeneity in terms of sample sizes, designs, analyses and outcome measures. As conclusions were made only on cross-sectional data there is a need for long-term prospective studies to assess if vitamin D levels are associated with cardiovascular outcomes.

**ENDOTHELIAL NITRIC OXIDE SYNTHASE T-786C GENOTYPE PROMOTER POLYMORPHISM IS A POTENTIAL PREDICTOR OF LOW RESPONSE TO THE THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS, UKRAINE POPULATION**

K. Zaichko, M. Stanislavchuk, I. Shapoval. The Internal Medicine, National Pirogov Memorial Medical University, Vinnytsya, Ukraine

**Background:** Recently endothelial nitric oxide synthase (eNOS) T-786C gene promoter polymorphism was considered to be a factor of a high severity of RA [1,2]. It is possible that the eNOS T-786C gene promoter polymorphism can modify the efficacy and safety of treatment in patients with RA, but there is no information on this. The aim of this study is to find findings indicate that other factors than inflammatory disease activity causes a significant burden of illness also at an early stage of RA and that there is a need for additional intervention strategies for these patients.

“Ethical principles of medical research involving human subjects” (2000), the requirements of GCP, the applicable national legislation.

Results: Among patients with RA frequency of the genotypes was as follows: TT – 37.2%, TC – 42.6%, CC – 20.3%. Age, seropositivity and the duration of the disease were not differing in patients with RA, carriers of the different genotypes of eNOS. Though, CC genotype was associated with high disease activity according to DAS28-ESR < 5.2 (OR = 9.60; 95% CI 2.18–42.2), HAQ > 2 (OR = 2.38; 95% CI: 0.94–6.02) and extrarticular manifestations (OR = 3.26; 95% CI 1.40–7.56).

After 12 weeks treatment we estimated, that among patients with TC genotype there were 58.3; 16.7; and 8.3% responders ACR20; ACR50; ACR70, and among patients with CC genotype - 20.0; 10.0; 0.0% (p < 0.05). TC heterozygotes patients had lower (by 22–25%, p < 0.05) clinical response to the treatment by DAS28 and HAQ than the homozygotes TT.

Conclusions: eNOS T-786C gene promoter polymorphism influence on the efficacy of the treatment, and CC genotype can be considered as a possible predictor of a low response to the treatment in patients with rheumatoid arthritis.

SAT0697 PREVALENCE OF HEPATITIS B AND C INFECTION AND REACTIVATION IN PATIENTS RECEIVING BIOLOGIC IV THERAPIES

K. Arévalo Ruales 1, B. Soler Bas 2, J. Ivorra Cortes 3, E. Grau Garcia 4, E. Vicens Bernabeu 1, E. Labrador Sánchez 1, J.J. Frigo Gil 1, R. González Mazario 1, C. Alcañiz Escandell 1, I. Cánovas Olmos 5, I. Chalmeta Verdejo 1, C.M. Feced Olmos 1, L. Gonzalez Puig 6, J. Martinez Cordellat 1, C. Nájera Herranz 1, R. Negueroles Albuixech 1, J.E. Oller Rodriguez 1, F. Ortiz-Sanjuyan 1, J.A. Román Ivorra 1,2, 1Rheumatology Department, HUP la Fe; 2Medical School, UCV, Valencia, Spain

Background: With the use of biological therapy, cases of reactivation of hepatitis B (HBV) and C (HCV) have been described, consequently its use has to be carefully evaluated. In some cases these therapies have to be administered together with antiviral treatment. Despite the fact that before the beginning of the biological therapy the screening of HBV and HCV virus is done, during the course of treatment serologies are no longer used to detect serovonversions.

Objectives: To analyze the prevalence of HBV and HCV in patients with rheumatic disease at the beginning of biological therapies. To identify the cases of hepatitis reactivation.

Methods: Retrospective observational analysis of the biological treatments administered to patients with Rhesumatoid Disease of the rheumatology department of La Fe hospital, during the period 2000–2015 who had HBV and/or HCV serology at the beginning of treatment. Demographic data and diagnosis of the patients, months of treatment and the results of the serologies performed at the beginning and in the follow-up of the treatment are specially evaluated. In some cases these therapies have to be administered together with antiviral treatment. Despite the fact that before the beginning of the biological therapy the screening of HBV and HCV virus is done, during the course of treatment serologies are no longer used to detect serovonversions.

Results: A total of 388 patients were selected of which 62.4% were female; the mean age at diagnosis was 38.96±14.46 years. 46.9% of the patients were diagnosed with rheumatoid arthritis (RA), 25.3% of ankylosing spondylitis (AE), 18.6% of psoriatic arthritis (APSO) and 6.7% with other diagnoses. The mean treatment time with patients' biological therapy is 200±118 months (3–464 months), and the mean time between the two serologies is 172±102 months (2–1032 months). Incidence of 10% of cases with HBV infection (39 patients) is observed. The serological pattern was 8 cases with Ac-core (+)/Ac-surface (-)/Ag-surface (+) HBV and 31 HBV/Ac- surface (-). The incidence of HCV at the start of treatment was 1.1% (4 patients). A case of reactivation (12.5%) was detected among the 8 patients with Ac-core (+)/Ac-surface (-)/Ag-surface (-) HBV. The patient had infliximab and methotrexate, and reactivation was observed after 12 years of treatment. No reactivation of HCV has been detected.

Conclusions: In our series of patients the incidence of HBV and HCV has been 10% and 1.1%, respectively. One of the 8 patients with Ac-core (+)/Ac-surface (-)/Ag-surface (-) HBV had reactivation of the virus.

SAT0698 DISEASE ACTIVITY DURING AND AFTER PREGNANCY IN WOMEN WITH AXIAL SPONDYLOARTHRITIS

K. Ursin 1,2, S. Lydersen 3, J. Skromsoll 1, M. Wallenius 1,2, 1National Advisory Unit on Pregnancy and Rheumatic Diseases, St. Olavs Hospital - Trondheim University Hospital; 2Department of Neuroumedicine and Movement Science; 3Regional Centre for Child and Youth Mental Health, NTNU, Norwegian University of Science and Technology, Trondheim, Norway

Background: Studies on disease activity of ankylosing spondylitis in pregnancy have shown diverging results. A large retrospective study from 1998 without validated disease activity scores found no particular pattern of disease course during pregnancy (1). Later two small studies demonstrated a trend towards lower disease activity in the beginning of pregnancy and deterioration in late pregnancy (2,3). None of these studies included women with non-radiographic axial spondyloarthritis. The only large study was conducted before the widespread use of biological DMARDs.

Objectives: The aim of this project was to prospectively study disease activity in women with axial spondyloarthritis before, during and after pregnancy with BASDAI as disease activity measure.

Methods: RevNatus is a Norwegian nationwide register designed for the follow-up of pregnant women with rheumatic diseases. RevNatus included 181 full term pregnancies in 168 women with axial spondyloarthritis between 2006 and 2016. The women had seven visits at a rheumatology unit; before pregnancy, in each trimester, and six weeks, six months and twelve months postpartum. BASDAI-values from each visit were analyzed in a linear mixed model.

Results: Even though we found a statistically significant relationship between disease activity and time point in the follow-up period, our study demonstrated that women with axial spondyloarthritis had stable, low disease activity during and after pregnancy. Disease activity in second trimester was significantly higher than six weeks after delivery, but the change in estimated mean BASDAI was small (BASDAI 3.97 vs. BASDAI 3.46, p = 0.005). The figure below shows changes in disease activity throughout the study period.

SAT0699 RAPID ASSESSMENT PREDICTS DISEASE ACTIVITY IMPROVEMENT IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS (RA)

M. Yates 1, J. Galloway 2, N. Snowden 2, S. Norton 1, J.M. Ledingham 2, E.M. Dennison 4, A. Rivett 2, A.J. Macgregor 1, 1Academic Rheumatology, King’s College London, London; 2Rheumatology Dept, Pennine MSK Partnership, Oldham; 3Rheumatology Dept, Portsmouth Hospitals NHS Trust, Portsmouth; 4MRC, Southampton University, Southampton; 5BSR, The British Society for Rheumatology, London; 6Rheumatology Dept, Norfolk and Norwich University Hospital, Norwich, United Kingdom

Background: Early intervention in RA is associated with improved outcomes in randomised trials. UK guidelines stipulate that those with suspected RA are assessed by a rheumatologist within 3 weeks of referral. However, there are limited real world data confirming the value of early assessment. Previous work suggests social deprivation predicts severe disease at presentation and a worse
Comprehensive Risk of Respiratory Depression in

Methods: An audit, designed as a prospective longitudinal observational study, was conducted to assess early RA care. All NHS providers in England and Wales were required to participate. Follow up data were captured over 3 months for subjects with a diagnosis of RA. Rheumatologist assessment within 3 weeks of referral was the predictor variable. The primary outcome was good EULAR DAS28 response; the secondary outcome was meaningful improvement in RAID score. Logistic regression was used to estimate for associations. Confounders including age, gender, baseline DAS28 and RAID scores were considered in analyses. The index of multiple deprivation (IMD) rank was calculated for each individual based on super-output geographical areas. The IMD rank was then stratified into quintiles and included as a confounder.

Results: 136 of 146 eligible trusts submitted data. 11,752 subjects consented, 5,622 were diagnosed with RA, 94,562 (1.7%) had incomplete assessment data. DAS28 response was available for 2234/5622 (39.7%), and RAID response for 901/5622 (16%). The table shows baseline characteristics and response for subjects with complete data. Assessment within 3 weeks associated with a significantly greater improvement in DAS28 and RAID scores, with an adjusted odds ratio for a good EULAR response 1.38 (1.15–1.66) and meaningful RAID reduction 1.44 (1.03–2.02).

Conclusions: There are few data on the incidence of RD in opioid users for non-malignant pain and no comparative data between drugs. Fentanyl, oxycodone, morphine monotherapy have a significantly higher risk of RD than codeine, but these are not significantly different from each other. Combination opioids confer the highest risk of RD, compared to both codeine and morphine. The strengths of this study include capture of real time and reported outcomes. Amongst those who were assessed within 3 weeks of referral, an additional 8% achieved a good EULAR response. The association with RA severity was strengthened when social deprivation was included as a confounder. The relationship between IMD and RAID response appears to be non-linear and requires further study.

SAT0701 | COMPARATIVE RISK OF RESPIRATORY DEPRESSION IN PATIENTS TREATED WITH OPIOIDS FOR NON-MALIGNANT PAIN

M. Jan1, K. Kopec-Harding1, L. Munt1, W.G. Dixon1,2,3, Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, 2Rheumatology department, Salford Royal NHS Foundation Trust, Salford; 3Health eResearch Centre, University of Manchester, Manchester, United Kingdom

Background: Opioid use for non-cancer pain has increased considerably over the last 30 years. The U.S. Food and Drug Administration announced several boxed warnings in 2016 to highlight serious opioid-related risks (1) in an effort to reduce fatal overdoses, 80% of which are unintentional (2). The most serious opioid related adverse event, respiratory depression (RD), which can be potentially fatal. There are few data on the incidence of RD in opioids users for non-malignant pain and no comparative data between drugs.

Objectives: To assess the comparative risk of RD in new users of opioids for non-malignant pain using routinely collected electronic patient records (EPR).

Methods: Opioid users from Salford hospital EPR were identified between 2014–2016. Patients with prior malignancy were excluded on the basis of ICD-10 codes and health issues. Those with prior history of opioid use were excluded using codeine as the referent, patients on fentanyl, morphine, oxycodone and combination treatment had the highest crude rates of RD (table). In the age and gender adjusted Cox-model, using codeine as the referent, patients on fentanyl, morphine, oxycodone and combination opioids had the highest risk of RD (table), adjusted HR (95% CI) for combination opioids: 2.22 (1.56, 3.16). Compared to morphine, combination opioids had an adjusted HR of 1.52 (1.09, 2.13).

Conclusions:• Fentanyl, oxycodone, morphine monotherapy have a significantly higher risk of RD than codeine, but these are not significantly different from each other. Combination opioids confer the highest risk of RD, compared to both codeine and morphine. The strengths of this study include capture of real time and reported outcomes. Amongst those who were assessed within 3 weeks of referral, an additional 8% achieved a good EULAR response. The association with RA severity was strengthened when social deprivation was included as a confounder. The relationship between IMD and RAID response appears to be non-linear and requires further study.

SAT0701 | TOWARDS DIAGNOSIS-SPECIFIC LIFETIME RISKS FOR TOTAL HIP ARTHROPLASTY REVISION SURGERY

M. Gademan1, L.N. van Steenbergen2, S.C. Canningeter3, R.G. Nelissen4, P.J. Marang-van de Mheen5, Orthopaedics/ Clinical Epidemiology, LUMC, Leiden; 2Dutch Arthroplasty Register (LR01), ’s Hertogenbosch; 3Clinical Epidemiology; 4Orthopaedics; 5Medical Decision Making, LUMC, Leiden, Netherlands

Background: An important aspect regarding optimal timing of primary hip arthroplasty (THA) is to weigh the benefit associated with the primary surgery at a certain point in time against the risk for revision surgery. Revision surgery should be avoided, as outcomes after revision surgery are less favourable than outcomes after primary surgery. Information on lifetime revision risks is needed to guide decision making for individual patients regarding timing of primary surgery.

Objectives: Our aim was to provide the 7 year cumulative percentages for revision surgery stratified for diagnosis, sex, type of fixation and age at which primary THA was performed.

Methods: Data on arthroplasties was available from the Dutch Arthroplasty Register (LR01), a nationwide population-based registry with information on all joint arthroplasties in the Netherlands from 2007 onwards. For the current study, all patients who received a primary THA in the period 2007 to 2015 were included except patients with a metal on metal prosthesis, patients with a hybrid or reversed hybrid fixation type or patients with revision surgery without primary surgery registered. Revision surgery was defined as any change of one or more components of the prosthesis. For the current study age at primary surgery, diagnosis, sex, type of fixation (uncemented, cemented) and survival (alive/dead) and revision of prosthesis (yes/no) were extracted from the LR01 database.
Diagnosis was dichotomized into osteoarthritis (OA) and other diagnoses. Annual revision rates were calculated for each subsequent year after primary arthroplasty by dividing the number of revisions by the total number of patients at risk during that year. The risks were stratified according to the underlying diagnosis, sex, age at primary arthroplasty and fixation type. In addition cumulative annual revision rates were calculated for the full follow-up period. Furthermore we estimated the percentage of avoided OA revisions by assuming that all OA patients received their primary THA 5 years later (in all age groups <85 yrs) and that the revision risks remained the same in all age categories.

Results: In total 134463 primary THA patients were included of whom 68% were female, 89% had OA as underlying indication and 66% of the THAs were uncemented. The 7th year cumulative risk percentage varied between 2.0 and 11.7% (Table 1). Overall cumulative revision percentages were higher in younger age categories (Table 1), with the exception of a 11.7% revision in the group aged 85–90 yrs (uncemented, male, other diagnosis), but this finding is likely due to chance as this group existed of 67 patients. We estimated that by delaying THA for 5 years, a total of 197 revision surgeries (4.4% of all revision surgeries) could be avoided, 48 (14.0%) in the OA male cemented group, 11 (0.9%) in the OA male uncemented group, 69 (3.3%) in the OA female cemented group and 69 (8.6%) in the female uncemented group. This could result in a yearly cost reduction of approximately 4 million euros.

Table 1. Cumulative revision percentages within 7 years after index surgery.

<table>

Conclusions: Cumulative 7th year risk revision percentages decreased by age in all different categories. By delaying the primary THA surgery, revisions might be avoided thereby resulting in cost reduction.

SAT0702 LOCAL AND SYSTEMIC INFLAMMATION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS WITH CHLAMYDIA TRACHOMATIS INFECTION

M. Natalia, K. Svettana, Belorussian State Medical University, Minsk, Belarus

Objectives: We had to study local and systemic inflammation in rheumatoid arthritis patients with persistence Chlamydia trachomatis (Ch tr) in the joint Methods: 31 patients with early RA; mean age 54.5 (10.6) years, disease duration 21.5 (14.4) weeks with persistent Ch tr in the joint (mRNP Ch tr had been revealed in synovial fluid by NASBA PCR) were enrolled in this study. The comparison group was with RA (n=42) without mRNP in synovial fluid (Ch tr-). Mean age was 51.7 (15.4) years, disease duration 20.8 (13.3) weeks. All the patients had been received only symptomatic treatment (NSAID). Disease activity had been detected by DAS 28. Systemic inflammation was estimated by levels of erythrocyte sedimentation rate (ESR), hsp C-reactive protein (hspCRP), and OR in synovial fluid of research group (Ch tr+) and comparison group (Ch tr-). Level of hsp CPR and OR in synovial fluid of research group (Ch tr+) were significantly higher than comparison group (4,1±0,3 mg/l versus 2,4±0,2 mg/l, tr-. Level of hsp CPR and OR in synovial fluid of research group (Ch tr+) were significantly higher than comparison group (4,1±0,3 mg/l versus 2,4±0,2 mg/l, tr-). Differences in specific questionnaires mean they should be used together to provide more detailed information.

SAT0704 THE IMPACT OF AUTOIMMUNE DISEASE IN THE MANAGEMENT AND PROGNOSIS OF ACUTE CORONARY SYNDROME

N. Lozano 1, F.J. Pastor Perez 2, F.L. Linares Ferrando 1, J. Martinez Ferrín 1, J. Ruiz Sara 1, A. Palos Iniesta 1, P. Castillo Dayer 1, A. Bermudez Torrente 1, F.A. Almeida Fernandez 1, R. Tio Jornet 1, M. Farre 1, A. Garcia-Cardo 4, M. Marti 4, 1Rheumatology, 2Cardiology, 3University Hospital Virgen de la Arrixaca, Murcia, Spain

Background: Patients with autoimmune diseases (AID) have a high burden of cardiovascular disease leading to premature morbidity and mortality. But it is unclear if it is due to a higher prevalence of cardiovascular disease, to a worse case fatality or to a different management after an index event.

Objectives: The primary aim of the study is to assess the prognostic implications of the presence of AID both during the hospitalization and after discharge after an acute coronary syndrome (ACS). The secondary objectives included the assessment of the prevalence of AID in patients with ACS, their clinical profile and the management of this index event.

Methods: The study included consecutive patients admitted after ACS from January 2011 to December 2015 at the University Hospital Virgen de la Arrixaca, Murcia, Spain.

Results: Differences in generic and specific questionnaires mean they should be used together to provide more detailed information.

Aknowledgements: This work was funded by project PI/13/00948, integrated in the Plan Nacional I+D+i and cofounded by ISCIII/Subdirección General de Evaluación and European Regional Development Fund (ERDF).

SAT0703 INFLUENCE OF PHYSICAL ACTIVITY AND SLEEP ON FUNCTIONAL CAPACITY AND PAIN IN PATIENTS WITH KNEE OSTEARTHRITIS

M. Nuñez 1, E. Nuñez 2, J.M. Segur 3, L. Lozano 1, J. Montañana 2, V. Segura 3, M. Marti 4, A. Garcia-Cardo 4, S. Sastre 3, X. Alemany 3, 1Rheumatology and IDIBAPS Area 1, Hospital Clinic 2SAP Support at Diagnostic i al Tractament, Institut Català de la Salut; 3Orthopedic Surgery and IDIBAPS; 4Rheumatology, Hospital Clinic, Barcelona, Spain

Background: Knee osteoarthritis (OA) is a degenerative disease in which pain and functional disability progression trend to increase with reducing the health-related quality of life (HRQOL). Factors related to healthy lifestyles, such as physical activity and sleep, are known to have restorative benefits on function and pain in these patients. A previous study found that patients with reparative sleep achieved better WOMAC and SF-36 HROQL questionnaire dimension scores.

Objectives: To investigate the influence of physical activity and sleep on functional capacity and pain in patients with long-term knee OA.

Methods: Cross-sectional study. Sociodemographic and clinical variables, physical activity (PA) (regular physical exercise ≥ 3 times a week >30 minutes per session (PE) and sitting ≤6 hours/day (S)) and sleep quality (RS) were determined using the question: How do you usually sleep? (1=well [RS], 2=regular, 3=badly, 4 =with medication/treatment [NRS]). Functional capacity and pain were evaluated using the WOMAC (specific) and SF-36 (generic) HROQL questionnaire.

Results: 453 patients (84.3% female), mean age 69.73 (8.64), BMI 35.27 [SD 6.3], comorbidities 2.43 (SD 1.5), 78.6% with obesity (BMI 33.68 [SD 6.7]), depression/anxiety in 36.4%, PE 60.5%, S 72.2% and PA 48.6%, were included. 22.5% reported RS. Bivariate analysis showed patients with PA and those with RS had better functional capacity and less pain intensity (< 0.01–0.001, in both WOMAC and SF-36). The four multiple regression showed that patients with PA and SR had better scores, both in functional capacity (dependent variables, WOMAC and SF-36) and pain (dependent variables, WOMAC and SF-36), < 0.006. Age, gender, number of comorbidities and obesity were included in the models as potential confounders. Obesity was associated with worse function and more pain in the four models (p<0.05). Being female and greater comorbidity were associated with poorer functional capacity and pain assessed by the SF-36.

Conclusions: Physical activity and sleep were associated with less pain and better functional capacity. But it is unclear if these variables should be determined systematically in clinical practice due to their significant relationship with HROQL. Obesity was negatively associated with function and pain. There was also a negative relationship between female gender and comorbidity according to the SF-36. Differences in generic and specific questionnaires mean they should be used together to provide more detailed information.

Aknowledgements: This work was funded by the Plan Nacional I+D+i and cofounded by ISCIII/Subdirección General de Evaluación and European Regional Development Fund (ERDF).

DOI: 10.1136/annrheumdis-2017-eular.6876
higher percentage of atrial fibrillation and chronic obstructive pulmonary disease in AID patients. Compared to non-AID patients, AID patients had similar ACS presentation and no differences were found with respect to revascularization strategies or medical treatment at discharge. With respect to prognosis the two groups had comparable rates of adverse events during hospitalization (10% vs 10%, p=0.920) with no statistically significant differences in any single event studied. However after a follow-up of 397 [375–559] years, AID patients had higher rate of combined adverse events (44% vs 28% p<0.001). After multivariate adjustment the presence of AID was associated with increased total mortality (hazard ratio 2.1, 95% CI 1.2 to 3.7, p=0.008) and it was also a borderline risk factor for higher bleeding complications (hazard ratio 2.2, 95% CI 0.9 to 5.5). The presence of AID was not an independent risk factor for neither stroke or recurrent non-fatal myocardial infarction. 

Conclusions: The presence of AID did not change ACS presentation and clinical management. Although AID is not associated with worse outcomes during hospitalization it is independently linked to higher total mortality and a trend to an increased risk of major bleeding during follow-up.

SAT0705 DO DIET CHARACTERISTICS IMPACT EFFECT OF A 12-MONTH VITAMIN D SUPPLEMENTATION ON 25OH-VITAMIN D SERUM LEVEL AMONG OVERWEIGHT ELDERLY? 

R.M. Baddoura1, N.A. Yaghri2, A. Arab3, G. Halaby4, G. El-Hajj-Fuleihan3

Methods: A randomized clinical trial comparing high (3750 IU/day) versus low (600 IU/day) dose of vitamin D supplementation in ambulatory overweight (BMI exceeding 25) elderly subjects (age ≥65 years), with serum 25OH vitamin D level between 10 and 30 ng/ml at screening. Outcome measure: 25OH-D serum levels at 12 months of follow-up.

Results: One hundred and seventy-five participants out of three centers participated in a randomized clinical trial comparing high (3750 IU/day) versus low (600 IU/day) dose of vitamin D supplementation in ambulatory overweight elderly subjects (age ≥65 years), with serum 25OH vitamin D level between 10 and 30 ng/ml at screening. The high-dose group achieved significantly higher 25OH-vitamin D serum levels (1.21) mcg and 8.53 (1.36) mcg from the 24 h recall, and food frequency baseline BMI, Fok, Bsml and Taq genetic polymorphism, baseline serum vitamin D and dietary intake of vitamin D, calcium, proteins, carbohydrates, fats and total calories assessed by food frequency and 24h recall questionnaires, administered a year after the termination of the trial.

Conclusion: Achieving desirable 25OH vitamin D serum levels with vitamin D supplementation may be influenced by many confounders including lifestyle factors and vitamin D receptor genetic polymorphism.

SAT0707 EFFICACY AND SAFETY OF PROPHYLACTIC TREATMENT ON ACTIVATION OF LATENT TUBERCULOSIS DURING GLUCOCORTICOID THERAPY IN PATIENTS WITH RHEUMATIC DISEASES 

R. Wu, Department of Rheumatology, the First Affiliated Hospital of Nanchang University, Nanchang, China

Background: More than 80% of cases of tuberculosis are the result of reactivated latent infection, and nearly all these cases could be prevented by the administration of a course of antibiotic treatment. Therefore, it is suggested screening and treatment are most beneficial for those patients taking immunosuppressive medications. Although the prevalence of latent tuberculosis infection in China was much higher than the United States on the basis of tuberculin skin testing, In China, so far, no study has been done about prophylactic treatment on prevention of tuberculosis activation during glucocorticoid therapy in patients with rheumatic diseases. It should be recommended that all patients with rheumatic diseases be screened for the presence of active tuberculosis or LTBI before the use of long term glucocorticoid or immunosuppressive medications in China? It is reported only about 5% of immunocompetent persons with a positive test will have progression from latent infection to disease in their lifetime. and decisions about whether to treat latent tuberculosis should take into account the individual patient’s risk for the development of active tuberculosis and the risks of therapy.

Objectives: To evaluate the risk of reactivation of LTBI in patients with rheumatic diseases who were undergoing prednisone use and the efficacy and safety of prophylactic treatment on prevention of tuberculosis reactivation.

Methods: 1000 patients with rheumatic diseases who were treated with prednisone were enrolled since 2012. IGRA test (the T-SPOOT.TB test) were performed for all subjects. 50 patients with a IGRA-positive were administrated with rifampin for 4 months. 2-years follow-up was conducted to evaluate the risk factors of reactivation of LTBI and the efficacy and safety of rifampin treatment on prevention of tuberculosis reactivation.

**SAT0708** | SYMPTOMS INDICATIVE OF INFLAMMATORY ARTHRITIS ARE COMMON IN THE PRIMARY CARE POPULATION: FINDINGS FROM THE SYMPTOMS IN PERSONS AT RISK OF RHEUMATOID ARTHRITIS SURVEY

S.L. Hider1,2, S. Muller1, J. Prior1, T. Hellwell1, D. van Schaardenburg3, A. van den Helm-van Mil4, K. Raza5, C.D. Mallen1.  
1Arthritis Research UK Primary Care Centre, Keele University, Keele; 2Haywood Academic Rheumatology Centre, Haywood Hospital, Staffordshire, United Kingdom; 3Reade, Amsterdam; 4Department Rheumatology, Leiden University Medical Centre, Leiden, Netherlands; 5Rheumatology Research Group, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom

**Background:** Early, accurate diagnosis of RA is critical to improving outcomes. Patients with RA may develop a variety of symptoms including joint pain, swelling and stiffness. The Symptoms in Persons at Risk of Rheumatoid Arthritis (SPARRA) questionnaire was derived to assess the presence, severity and impact of common symptoms in patients at risk of RA (1). However, to date there is little data available on how common these symptoms are in primary care consultants.

**Objectives:** To describe the prevalence of self-reported inflammatory joint symptoms in primary care patients consulting for both musculoskeletal and non-musculoskeletal complaints.

**Methods:** Questionnaires were sent to 10161 individuals, of whom 5050 had consulted primary care for musculoskeletal problems. The remainder were matched to this sample by age, gender and general practice and had consulted for any non-musculoskeletal indication. Respondents provided data on presence of common symptoms such as joint pain, stiffness and swelling. The prevalence of these symptoms, their severity and impact was compared between musculoskeletal and non-musculoskeletal consultation groups.

**Results:** 4549 people responded to the survey (adjusted response 45.8%) of whom 523% were in the musculoskeletal consultation group. The mean (SD) age was 61.6 (14.8) years and 58.9% were female. Symptoms commonly associated to increased risk of mortality in univariable analyses (1).

**Conclusions:** Although symptoms such as joint pain, swelling, and stiffness are predictive of inflammatory arthritis, a large proportion of those consulting primary care for musculoskeletal complaints report these symptoms. The impact of these symptoms is significant and it may be important to consider whether these symptoms are due to inflammatory arthritis or other causes.

**SAT0709** | MORTALITY PREDICTION IN MIXED CONNECTIVE TISSUE DISEASE

S. Reiser1, R. Gunnarsson2, T.M. Aalokken3, M.B. Lund4, J. Corander5, G. Molberg6. 1Institute of Clinical Medicine, University of Oslo, Norway; 2Dept. of Rheumatology; 3Dept. of Radiology and Nuclear Medicine; 4Dept. of Respiratory Medicine, Oslo University Hospital; 5Institute of Basic Medical Sciences; 6Institute of Clinical Medicine, University of Oslo, Oslo, Norway

**Background:** Mixed Connective Tissue Disease (MCTD) is a chronic, immune-mediated disorder defined by the combined presence of serum anti-nuclear antibodies and selected clinical features of Systemic Sclerosis, Systemic Lupus Erythematosus, Rheumatoid Arthritis and Polymyositis. Several clinical manifestations and laboratory findings have been found to be associated with increased risk of mortality in univariable analyses (1).

**Objectives:** Here we present a mortality predicting model in a long-term observational unselected nationwide cohort aiming to enhance the knowledge of long-term prognosis in MCTD.

**Methods:** 135 patients were included from our nationwide MCTD cohort. Abnormal high resolution computed tomography (CT) findings of ground glass attenuation and reticular patterns were defined as Interstitial Lung Disease (ILD) and expressed as percentage of Total Lung Volume (TLV). Pulmonary function tests and laboratory tests were performed within 2 months of the HRCT examination. Pleuritis was defined as typical pleurisy for more than one day, pleural effusions or pleural rub present at or before baseline. Pericarditis was defined as typical pericardial pain for more than one day, pericardial friction, pericardial rub or pericarditis by electrocardiography at or before baseline. Myositis was confirmed by muscle biopsy and/or electromyogram and CK elevation at or before baseline. Cox regression analyses were used to find the predictive factors of mortality. Variables at a significant level of P < 0.05 were considered a candidate in the prediction model by manual backward elimination procedure.

**Results:** 21 patients died after a mean (standard deviation) observation of 9 (2) years. The predictive model is shown in Table 1. According to the Harrell's C index, patient outcomes were accurately predicted by this model 85% of the time.

**SAT0710** | RENAL FUNCTION CONTRIBUTE TO RISK OF CARDIOVASCULAR DISEASE IN RHEUMATOID ARTHRITIS

S. Hannawi1, I. Alsalmi2. 1Rheumatology, Ministry of Health and Prevention of UAE, Dubai, United Arab Emirates; 2Renal, Royal Hospital, Muscat, Oman

**Background:** The excess mortality associated with rheumatoid arthritis (RA) is due largely to cardiovascular disease. This highest risk is not related primarily to traditional cardiovascular/atherosclerotic risk factors. The presence of RA independently, as well as high inflammation associated with RA has been reported as a cardiovascular risk factors. Also, subclinical decreased kidney function has been identified as an independent risk factor for CV events in patients with RA. RA-mediated inflammation of impaired kidney function on atherosclerosis in RA requires more elucidation.

**Objectives:** To assess the role of renal parameters, alongside with inflammation and traditional cardiovascular risk factors in predicting cardiovascular disease; as manifested by carotid intima media thickness (cIMT), among RA population.

**Methods:** cIMT measurement was carried out in 68 RA patients, and correlated with renal function parameters with adjustment for traditional CV risk factors and RA associated inflammation. Glomerular filtration rate (GFR) was estimated with the abbreviated Modification of Diet in Renal Disease formula. Linear regression determined the association between renal parameters and the thickness of cIMT.
Results: Carotid intima media thickness was positively associated with 1-demographic characteristics of the participants such as age of the participants (p<0.001), and age at RA symptoms onset (p=0.001). 2-traditional cardiovascular risk factors such as systolic blood pressure (p<0.001), diastolic blood pressure (p=0.016), triglyceride level (p=0.016), and low density lipoprotein (LDL) (p<0.001). 3-Rituximab used as erythrocyte sedimentation rate (ESR) (p=0.020) and C-reactive protein (CRP) (0.020), and 4-renal function parameters such as uric acid level (p=0.006), uric acid microalbumin level (p=0.030), cMTT negatively associated with high density lipoprotein (HDL) (p=0.037), 24 hours uric creatinine level (p=0.020) and glomerular filtration rate (p=0.008).

Conclusions: Subclinical renal function in conjunction with traditional and non-traditional cardiovascular risk factors work synergistically to accelerate atherosclerosis in RA population.

SA07012 SELF-REPORTED SEDENTARY BEHAVIOUR IS ADVERSELY ASSOCIATED WITH MICROVASCULAR ENDOTHELIAL FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS
S.A.M. Fenton1,2, J.J. Veldhuijzen van Zanten1,2, A. Sandoz3, J.L. Duda1, G.S. Metso5,2, G.D. Kitas2, 1School of Sport Exercise and Rehabilitation Sciences, University of Birmingham, Birmingham; 2Rheumatology, Russells Hall Hospital, Dudley; 3School of Sport, Health and Exercise Sciences, Bangor University, Gwynedd, Wales; 4Faculty of Education Health & Wellbeing, University of Wolverhampton, Wolverhampton, United Kingdom

Background: Patients with Rheumatoid Arthritis (RA) are at increased risk for cardiovascular disease (CVD). Research suggests impaired vascular function contributes to this heightened risk. At present, little is known regarding factors associated with vascular function in RA. Epidemiological evidence demonstrates that sedentary behaviour i.e. sitting (7.5 or more hours whilst sitting or lying), to be adversely linked to CVD risk in the general population. Whilst the biological processes underlying this relationship are not understood, vascular dysfunction may play a role (1, 2). However, research is yet to examine the association between sedentary behaviour and vascular function in healthy adults and/or clinical populations. Studies investigating this relationship in RA, will help to determine the extent to which sedentary behaviour may represent a modifiable risk factor for CVD in these patients.

Objectives: To investigate the cross-sectional associations between sedentary behaviour and microvascular and large vessel endothelial function among patients with RA.

Methods: Fifty-three patients with RA participated in the study (M age=52.9±12.8, 72% female). Laser Doppler imaging with iontophoresis was used to assess microvascular endothelium-dependent (acetylcholine, ACh) and endothelium-independent (sodium nitroprusside, SNP) function. Large vessel microvascular-endependent and endothelium-independent functions were measured via flow-mediated dilatation (FMD) and glycyl trinitrate dilatation (GTN), respectively. Sedentary behaviour was self-reported via the International Physical Activity Questionnaire (hours/week sitting). Data were analysed using multiple linear regression adjusting for traditional CVD risk factors.

Results: FMD was negatively associated with self-reported sedentary behaviour (i.e. sitting ≥7.5 hours whilst sitting or lying) (β=−0.568, p<0.01) after adjustment for traditional CVD risk factors. Sitting time accounted for 8% and 12% of the variance in microvascular endothelium-dependent function (ACh) and endothelium-independent function (SNP), respectively (traditional CVD risk factors, R²=0.3). No significant associations were observed between self-reported sitting time and large vessel endothelium-dependent vasodilation (FMD, β=0.16, p=0.29) or endothelium-independent vasodilation (GTN, β=−0.08, p=0.55).

Conclusions: Sedentary behaviour appears to adversely affect microvascular endothelial function, but not large vessel function in patients with RA. It may therefore represent a modifiable risk factor for CVD in this population. Experimental studies employing objective measures of sedentary behaviour are necessary to confirm these findings, and to determine the utility of sedentary behaviour interventions for improving vascular function and reducing CVD risk in RA.

SA07013 SURVEY ON PREVALENCE OF RHEUMATOC DISORDERS IN BANGLADESHI ADULTS
S. Ahmed1, S.A. Haq1, A.Z. Al-gadri1, M.M. Rahman1, S. Paul1, 1Rheumatology, Bangabandhu Sheikh Mujib Medical University; 2Medicine, Dhaka Medical College, Dhaka; 3Medicine, Chittagong Medical College, Chittagong, Bangladesh

Background: From Community based COPCORD (community oriented program for control of rheumatic diseases) study in Bangladesh about a quarter of people is suffering from musculoskeletal disorders. But the study was conducted over a small number of samples and some specific localities of the country. So further study was required, covering the whole Bangladesh to justify this high prevalence.

Objectives: To determine the prevalence of musculoskeletal symptoms and specific rheumatic disorders in adult population of Bangladesh.

Methods: A cross-sectional survey, a random sample of 1,084 individuals age 15 years or older were selected in twenty clusters (primary sample unit) from the seven divisions of the country. Modified COPCORD (Community Oriented Program for Control of Rheumatic Disorders) questionnaire was used to detect positive responses. Standard criteria were used for diagnosing rheumatic disorders. Clinical judgment was used to solve diagnostic problem.

Results: In total 1,843 individuals were interviewed with a response rate of 92.1%. The point prevalence of musculoskeletal pain was 33.7%. It was higher in women (38.7%) than men (28.4%) and higher in rural (34.5%) than in urban (32.4%) areas. Higher prevalence rates were observed in homemakers (16.0%), labores
Background: The increased risk of opportunistic infections (OIs) in rheumatoid arthritis (RA) patients who start biologic disease modifying anti-rheumatic drugs (DMARDs) has been well known. However, it has not been studied regarding the increased risk of OIs in the early stage of RA.

Objectives: To study the increased risk of incidence rate (IR) of OIs in early RA patients compared with established RA patients, and to evaluate the risk factors for developing the OIs in the early stage of RA.

Methods: Retrospective cohorts of early and established RA patients were conducted independently using the Korean National Healthcare claims database. Established RA patients (n = 226,838) were recruited between 2010 and 2012 with using the ICD10 code of RA and any DMARD use. Follow-up started for 1 year before index date, and receiving continuous treatment for over three years. Established RA patients (n = 226,838) were recruited between 2010 and 2012 with using the ICD10 code of RA and any DMARD use. Follow-up started for 1 year before index date, and receiving continuous treatment for over three years.

Results: The increased risk of opportunistic infections (OIs) in the early stage of RA compared with established RA patients, and to evaluate the risk factors for OIs in the early stage of RA.

RA = rheumatoid arthritis, SIR = standardized incidence ratio, PY = person year, N = number, IR = incidence rate, CI = confidence interval.

Conclusion: The increased risk of OIs in early stage of RA is associated with comorbidities, high corticosteroid use, and disease activity.

Disclosure of Interest: None declared

Results: Hospitalisation rates for comorbidity were 13.9/million/year in SLE patients. SLE patients were similar to controls for age and gender, but more likely to be Indigenous, have renal failure, cardiovascular and thrombotic conditions (Table 1). Independent predictors of mortality risk following hospitalisation for a comorbid condition included: SLE diagnosis (OR 1.6, CI: 1.3–1.9, p < 0.001) (Fig. 1), cerebrovascular events (OR 2.0, CI: 1.2–3.7, p < 0.001), renal disease (OR 1.75, CI: 1.4–2.3, p < 0.001), thrombotic events (OR 1.8 CI: 1.1–2.8, p < 0.001) and reliance on Medicare (OR 1.5, CI: 1.3–1.8, p < 0.001) (Table 2).

Conclusions: SLE patients were more frequently hospitalised than controls for cardiovascular or renal conditions and this increased their mortality risk. These results strengthen the need for close monitoring and interventions to prevent such comorbidity in all SLE patients.

Genomics, genetic basis of disease and HLA/T cell recognition

AB0001 FIRST DESCRIPTION AND FUNCTIONAL PROTEOMIC ANALYSIS OF A PROTECTIVE FOR RHEUMATOID ARTHRITIS GENE POLYMORPHISM

A. Sarantopoulos1, I. Theodorou1, A. Notopoulos2, I. Koulas1, P. Boura. 1Clinical Immunology Unit, 2nd Oot of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece; 2Laboratoire d’ Histocompatibilite et Immunogenetique, Departament d’ Immunolgie., Groupe Hopitalier Pitie Salpetriere Charles Foix, Paris, France; 3Department of Nuclear Medicine, Hippokration General Hospital, Thessaloniki, Greece

Background: Rheumatoid Arthritis (RA) is the most common systemic autoimmune disease, with a respective expanded genetic research. Immunogenetic studies have documented the positive correlation of various gene loci with incidence and/or disease profile. However, the description of gene loci negatively related to the incidence of RA is rarely documented. Apart from an early study involving HLA class II, there has been no reference to any genetic locus associated with a protective role against RA incidence.

Objectives: To identify the sequence of the functional areas of the TRAF1 (TNF receptor associated factor 1 - a protein involved in the intracellular signaling pathway of TNF) gene.

Methods: 172 patients and 95 controls were genetically assessed for the sequence of the seven exons of the gene TRAF1.

Results: On the position 9:120905076 of exon 7, the registered polymorphism G/A (rs143265058) was described in the controls group. The same polymorphism was not confirmed in any of the patients. Further functional proteomic study of the polymorphism with controlling programs (software), revealed that the presence of this polymorphism leads to a differentiation of the quaternary structure of TRAF1 protein, possibly affecting the cohesion of intracellular TNF signaling pathway.

Conclusions: The present reference is one of the extremely rare genetic studies describing a protective gene locus against rheumatoid arthritis, and a pioneer of its kind in the use of Applied Informatics in the depiction of the quaternary structure of the encoded protein. At the same time, it is one of the few immunogenetic studies describing the functional proteomics of the encoded protein, plotting on a molecular level specific interaction modifications affecting the intracellular signaling pathway of TNF.

AB0002 GENETIC STUDY OF THREE-PRIME REPAIR EXONUCLEASE (TREX1) IN THE SUSCEPTIBILITY TO SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AMONG EGYPTIAN PATIENTS

D. El Dessouki1, M.S. Abdel-Hamid2, L. Elfaif3, M. Niazy3, G. Abdel-Moneim4, G.M. Abdel-Salam5, 1Rheumatology; 2Medical Molecular Genetcs, National Research Centre; 3Rheumatology, Faculty of Medicine, Cairo University; 4Immunogenetics; 5Clinical Genetics, National Research Centre, Cairo, Egypt; Affiliation not provided

Background: Interferon-alpha (IFNs) pathway has a crucial role in the pathogenesis of SLE. Many genes have been encoding with this pathway and their impaired expression have been reported in patients with SLE. TREX1 is a DNA exonuclease involved in the metabolism and clearance of single stranded DNA from apoptotic cells, which is impaired in SLE. TREX1 mutations have been reported in SLE2.

Objectives: Our study was aiming to assess the role of TREX1 in the genetic susceptibility to systemic lupus erythematosus (SLE) among Egyptian patients.

Methods: Fifty SLE Egyptian patients and 50 age & sex matched healthy controls were included in this study. Based on the clinical history and immunological investigations, the 50 SLE patients were divided into two groups according to the presence of positive family history of autoimmune disease: Group I: 28 patients with positive family history & Group II: 22 patients with no family history. Further, the single exon of TREX1 and its flanking sequences were amplified by PCR and sequenced in both directions.

Results: Our work showed a recurrent TREX1 polymorphism rs11797 (c.531C>T) among Egyptian patients (56%) in comparison to control group (36%) (p value of 0.070) especially in cases with NPSLE, seizures and chilblains; with minor allele frequency of 0.28 in cases and 0.18 in controls (p value=0.342). TREX1 polymorphism was present in 57.1% patients (16/28) of SLE patients in group I versus 54.5% patients (12/22) of SLE cases in, group II. The polymorphism was positively associated with neuropsychiatric manifestations (OR=7.000, 95% CI=0.791–61.975) and chilblains (OR=10.532, 95% CI=0.550– 201.679). Furthermore, there was a statistically significant difference in cases with oral ulcers (p value=0.004), photosensitivity (p value=0.047) and seizures (p value=0.029).

Conclusions: We confirm that rs11797 (c.531C>T) could be associated with the susceptibility to neurological manifestations among the studied SLE patients. References:

Genetic determinants of Psoriatic Arthritis: genes involved in the Mestizo Population

L.A. Gutierrez-Gonzalez 1, F. Herrera 2, M.T. Fernandez Mestre 2 on behalf of GRUES (Grupo Venezolano para el Estudio de las Espondiloartropatías), 1Centro Nacional de Enfermedades Reumáticas (Cner); 2Laboratorio de Fisiopatología, Instituto Venezolano de Investigaciones Científicas (IVIC), Caracas, Venezuela, Bolivarian Republic of

Background: Psoriatic Arthritis (PsA) is a not a regular systemic autoimmune disease, many expert define it as autoinflammatory disease, resulting in chronic inflammation of the synovium and consequent cartilage and bone erosion in approximately 10% of patients with skin psoriasis. It is important to identify novel genomic biomarkers associated with disease susceptibility but also able to detect early those patients with negative prognostic factors who may benefit from a more aggressive therapeutic approach. This paper reports the expression of tumor necrosis factor (TNF)-α, a central element in the pathogenesis of psoriasis and psoriatic arthritis (2). The levels of TNF-alpha are under genetic control. An “A” at position -308 in the TNFA promoter has been shown to be associated with increased level of TNF-alpha expression and “A” at position -238 with a diminished level of TNF-α expression (3,4). Many authors consider that is a disease only of Europeans descendants or Caucasians, however never be studied in mestizo population.

Objectives: We investigate the potential association between the TNFA-238 G/A, TNFA-308 G/A, IL10 -1082 G/A, IL10 -819 C/T and -592 C/A polymorphisms and the Psoriatic Arthritis (PsA) in patients with a history of ancestors, at least back to the third generation.

Methods: The study included 52 PsA patients diagnosed by CASPAR criteria and 52 controls. The polymorphism of TNFA-308 G/A (rs1800629) and TNFA-238 G/A (rs13163525), IL10 -1082 G/A (rs1800886), -819 C/T (rs1800871) and -592 C/A (rs1800872) were genotyped by single specific primers-polymerase chain reaction (SS-PCR). All subjects were from an unrelated Venezuelan-Mestizo population with a history of ancestors, at least back to the third generation.

Results: When comparing allele and genotype frequencies between the groups studied, no significant differences were observed for the TNFA-308 G/A (rs1800629) and IL10 -1082 G/A (rs1800886), -819 C/T (rs1800871) and -592 C/A (rs1800872). However, our results showed a significant decrease in the frequency of the TNF-238A allele among PsA patients compared to healthy individuals (3.8% vs. 10.57%, respectively; OR: 0.31, 95% CI: 0.92–1.05, p=0.02), suggesting that TNF-238A allele may have a protective effect (Table 1).

Table 1: Genotypes and allele frequencies of the 308 G/A (rs1800629) and 238 G/A (rs13163525) variants of the TNFA gene in patients with psoriatic arthritis and healthy controls

Discussion: These results suggest that upregulation of IL23 and TGFβ1 in addition to downregulated Foxp3 expression may contribute to skewing towards Th17 profile in SLE pathogenesis and this was the most markedly manifested at the highest level of disease activity. Our results support indirectly the idea for restoring Th17/Treg balance as a therapeutic target in SLE.

Disclosure of Interest: None declared

Genotyping Assay in blood samples obtained from 47 patients BD diagnosed according to 1990 international criteria for behcet disease and 50 matched healthy controls. Disease activity was done using BD current activity form (BDCAF).

**Results:** Study of miRNA-499 polymorphism, showed that the genotype frequencies of TT, CT, and CC were 21.3%, 63.8%, and 14.9% in BD patients and 18.0%, 52.0%, and 30.0% in the control group respectively. A significant increase in the relative expression of miRNA-499 was found in BD patients compared to control (P < 0.05). There was no significant relation between relative expression of miRNA-499 and activity of BD patients assessed by BDCAF (P > 0.05). In addition there was association between genotypes of miRNA-499 and posterior uveitis (P < 0.05). There was association of the relative expression of miRNA-499 with vascular manifestations and aneurysm.

**AB0007**  
**SHARED GENETIC PREDISPOSITION IN RHEUMATOID ARTHRITIS–INTERSTITIAL LUNG DISEASE AND FAMILIAL PULMONARY FIBROSIS**

**Background:** Despite its high prevalence and mortality, little is known about the pathogenesis of RA–associated interstitial lung disease (RA-ILD). Given that familial pulmonary fibrosis (FPF) and RA–ILD frequently share the usual interstitial pneumonia pattern and common environmental risk factors, we hypothesized that the two diseases may share additional risk factors including FPF-linked genes.

**Objectives:** Our aim was to identify coding mutations of FPF-risk genes associated with RA-ILD.

**Methods:** We used whole-exome sequencing (WES) followed by restricted analysis of a discrete number of FPF-linked genes and performed a Burden test to assess the excess number of mutations in RA–ILD patients compared to controls.

**Results:** Among the 101 RA–ILD patients included, 12 (11.9%) had 13 WES-identified heterozygous mutations in the TERT, RTET1, PARN or SFTP C regions. The burden test, based on 81 RA–ILD patients and 1010 controls, did not show evidence of an excess of TERT, RTET1, PARN or SFTP mutations for RA–ILD patients (p=9.45·10^-6), odds ratio [OR] 3.17 95% CI 1.53–6.12). Tomelores were shorter for RA–ILD patients with a TERT, RTET1 or PARN mutation than controls (p=2.67·10^-1).

**Conclusions:** Our results support the contribution of FPF-linked genes to RA–ILD susceptibility.

**AB0008**  
**THE ASOCIATION OF THE PTNP22 RS2476610 GENOME POLYMORPHISM WITH JUVENILE IDIOPATHIC ARTHRITIS IN CHILDREN FROM RUSSIA**

L.S. Nazarova1, K.V. Danilko1, V.A. Malievsky1, 2, Bashkir State Medical University; 1Institute of Biochemistry and Genetics, Ufa, Russian Federation

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in children. The exact cause of the disease is still unknown, but seems to be related to both genetic and environmental factors [1]. The protein tyrosine phosphatase non-receptor type 22 (PTPN22) gene single-nucleotide polymorphism (SNP) rs2476610 was shown to be associated with JIA in different populations, but according to recent reports this association is restricted only to females [2,3].

**Objectives:** The aim of the study was to determine whether the PTNP22 rs2476610 SNP is associated with the development of JIA and its subtypes in children from Russia.

**Methods:** The study included 330 patients with JIA and 346 healthy controls from Russia. Genotyping was performed using real-time PCR method and statistical analysis - using two-tailed Fisher’s exact test (p), odds ratio (OR), 95% confidence interval (95% CI).

**Results:** The frequencies of the genotype AG and the allele A were significantly higher in patients with JIA than controls (p<0.016, OR=1.65, 95% CI 1.10–2.48; p=0.028, OR=1.48, 95% CI 1.05–2.08; p=0.016, OR=0.62, 95% CI 0.43–0.91; p=0.028, OR=0.68, 95% CI 0.48–0.95, correspondingly). The same analysis was then performed separately for patients with two most frequent ILAR subtypes: persistent oligoarthritis (n=106) and RF-negative polyarthritis (n=85). Significant associations similar to those in the whole JIA group were found only for persistent oligoarthritis (p=0.018 for the genotype AG; p=0.037 for the allele A; p=0.022 for the genotype GG; p=0.037 for the allele G). No significant differences were found for patients with RF-negative polyarthritis (p=0.6). Sex-stratified analysis showed that the frequency of the allele G is higher in girls with the genotype AG: p=0.024 and p=0.008; with the allele A: p=0.016 and p=0.0061; correspondingly; for boys: p=0.2 for all comparisons.

**Conclusions:** In this study we revealed the association of the PTNP22 rs2476610 SNP with the development of JIA and its persistent oligoarticular subtype in girls from Russia.

**GENOMIC SIGURATURES MAY BE ASSOCIATED WITH VASCULAR PATHOLOGY ASSOCIATED WITH RHEUMATOID ARTHRITIS**

S. Polskia1, E. Végh2, A. Vánca3, S. Szamosi2, M. Csurnita3, G. Zahuczky3, G. Szuő3, S. Szántó4, L. Nagy1, Z. Szekanecz3, 1Clinical Genomics Centre; 2Department of Rheumatology, University of Debrecen, Faculty of Medicine; 3UD-Genomed Ltd, Debrecen, Hungary

**Background:** Accelerated atherosclerosis and cardiovascular (CV) disease have been associated with rheumatoid arthritis (RA). Many genes have been implicated in atherosclerosis, RA or both. However, most of these studies described SNPs in CD40, SMAD3, HLDAR, CTLA4 genes, showing GVR also had good clinical response to biologics. Up-regulation of 99 genes was found in responders and non-responders to biologics, as well as patients that show or do not show improvement of vascular pathology.

**Disclose of Interest:** None declared

**LILRB3 EXPRESSION ON T CELLS CORRELATES WITH DISEASE ACTIVITY IN RA**

A. Holz, T. Witte, R.E. Schmidt. Department of Clinical Immunology and Rheumatology, Hannover Medical School, Hannover, Germany

**Background:** Leukocyte immunoglobulin-like receptors (LILR) participate in the generation of immunological tolerance (1-2). LILRB3 can be expressed on T cells and is an inhibiting receptor (3).

**Objectives:** We wanted to study LILR expression on T cells in RA compared to SLE and controls.

**Methods:** Heparinised human blood from blood donors was obtained from the Institute of Transfusion Medicine, Medical School Hannover (Germany). Blood samples from RA (DAS28 \( \leq 3.2 \) n=11; DAS28 \( \leq 3.2 \) n=8) and SLE patients (n=9) were obtained from Outpatients’ Clinic of the Department of Rheumatology and Immunology after informed consent. PBMCs were stained with LILRA2 (Biolegend, APC), LILRB3 (Biolegend, PE), CD3 (Biolegend, APC-Cy 7), CD4 (BD, PerCP-Cy5.5), CD8 (Biolegend, V500), CD25 (Biolegend, PE/Cy5), CDS8 (Biolegend, Pacific Blue). Results were compared to isotype controls. Statistical analyses and figures were made with GraphPad Prism, ANOVA and t-test (Biolegend, APC), LILRB3 (Biolegend, PE), CD3 (Biolegend, APC-Cy 7), CD4 (BD, PerCP-Cy5.5), CD8 (Biolegend, V500), CD25 (Biolegend, PE/Cy5), CDS8 (Biolegend, Pacific Blue).

**Results:** The percentage of both CD4+ and CD8+ T cells expressing LILRB3 was significantly higher in both inactive as well as active RA compared to controls or SLE (See Fig. 1) (p=0.0397 ANOVA: RA all vs. SLE vs. controls). Within the group of RA patients, the percentage of LILRB3 expressing T cells was highest in active compared to inactive (DAS28 \( \leq 3.2 \) RA (p=0.0297). LILRA2 was not expressed on T cells.

**Conclusions:** Expression of LILRB3 correlates with disease activity of RA and is decreased after successful treatment with DMARDS or biologicals. Since LILRB3 is an inhibiting receptor the increased expression in active RA may be a counterregulation to reduce disease activity.

**KLRG1 AS A MARKER OF CD28 NEGATIVITY IN RHEUMATOID ARTHRITIS, COMPARISON WITH CD57 AND CD45RA**

C. Rawlings, E. Choy, R. Davies, G. Jones, A. Williams. Cardiff University, Cardiff, United Kingdom

**Background:** Our research has shown that patients with RA have higher proportions of peripheral blood CD3+CD8+CD28- Treg cells compared to healthy individuals. CD3+CD8+CD28- Treg cells in patients with RA have lost their ability to suppress lymphocyte proliferation 1. Thus CD28 negativity may mark senescent T cells. CD57+ CD45RA+ and killer-cell lectin like receptor G1 (KLRG1)5 cell surface molecules have been associated with CD8+ T cell activation and senescence. Defining the phenotypic signature of CD8+CD28- Treg cells will help establish their significance in the immunoregulation of RA.

**Objectives:** To use immunofluorescence and flow cytometry to define the phenotype of CD3+CD8+CD28+/- cells in relation to early RA progression.

**Methods:** The effector characteristics of peripheral blood CD8 T cells were evaluated by flow cytometry. RA patients with established (n=21) and early disease (n=20) were recruited, and compared to twenty four healthy controls. The mean age of the subjects was 59 (SD=12.5), 25/38 (66%) were female, 27/38 (71%) were anti-CCP positive and 25/38 (66%) rheumatoid factor positive. The mean age for the controls was 43 (SD=11.6), 14/20 (70%) were female. Among RA patients, the percentage of KLRG1+ T cells was highest in active disease (DAS28 \( \leq 3.2 \)) RA (p=0.0287). LILRA2 was not expressed on T cells.

**Conclusions:** Our research has shown that patients with RA have higher proportions of peripheral blood CD3+CD8+CD28- Treg cells compared to healthy individuals. CD3+CD8+CD28- Treg cells in patients with RA have lost their ability to suppress lymphocyte proliferation 1. Thus CD28 negativity may mark senescent T cells. CD57+ CD45RA+ and killer-cell lectin like receptor G1 (KLRG1)5 cell surface molecules have been associated with CD8+ T cell activation and senescence. Defining the phenotypic signature of CD8+CD28- Treg cells will help establish their significance in the immunoregulation of RA.

**Background:** Rheumatoid arthritis (RA) consists of two syndromes, one autoantibody-positive and one autoantibody-negative. This multi-cohort study
assessed the age of onset in relation to the presence of autoantibodies. The association with characteristics of the anti-citrullinated protein antibodies (ACPA)-response was also explored.

Objectives: 1) determine the association between age of RA-onset and the presence of ACPA, rheumatoid factor (RF) and anti-citrabamyalted protein (anti-CBP) antibodies, 2) study age of onset was associated with characteristics of the ACPA-response, 3) substantiate previously reported associations between age of onset and clinical characteristics.

Methods: 3,321 1987-positive RA-patients included in the Leiden-EAC, BARFOT, EPOIR, Umea and Lund cohorts were studied at presentation on age of onset and the presence of ACPA, RF and anti-Carb antibodies. Logistic regression analyses were performed; effect sizes were summarized in inverse-weighted meta-analyses. Within ACPA-positive RA, ACPA-level was studied in all cohorts; ACPA-isotypes, ACPA-line-specificity and ACPA-avidity index and clinical characteristics were assessed in the Leiden-EAC.

Results: From the age of fifty onwards, the proportion of ACPA-negative RA-patients increased in Dutch, Swedish and French cohorts. Similar observations were done for RF and anti-Carb. The composition of the ACPA-response did not change with increasing age of onset with respect to titer, isotype distribution, line specificity and avidity index. With increasing age of onset RA-patients smoked less often, had higher acute phase reactants and more often a sub(acute) symptom onset.

AB0013 IS THERE IMMUNE DISREGULATION IN NON-SJÖGREN SICCA SYNDROME? A STUDY OF BLOOD LYMPHOCYTE SUBPOPULATIONS

Background: A large number of patients with sicca syndrome not fulfilling Sjögren’s syndrome (SS) classification criteria, present manifestations of autoimmunity, like arthritis, Raynaud’s, rash or hematologic disturbances, and have anti-nuclear antibodies, lacking however more specific antibodies. The designation Undifferentiated Connective Tissue Disease was coined to refer to those patients, and some will eventually progress to a definite disease, of which SS would be a likely candidate. Immune cell disturbances could be progression marker, since diseases like pSS have distinct lymphocyte profiles.

Objectives: We aim to study the circulating lymphocyte subsets in non-Sjögren sicca patients (n-SS), and compare them with pSS and healthy controls.

Methods: Blood samples of n-SS patients, 53 pSS patients (2002 AECG criteria) and 22 healthy controls. Lymphocyte subsets were characterized by flow cytometry and PCR after the treatment (p<0.002), leading to marked decrease of CD4+/CD8+ ratio (p<0.009). Except three patients, overall percentage of neutrophils decreased after the treatment (p<0.01). Although ACPA pulse did not influence the percentage of NK, the percentage of NK cells carrying stimulatory receptor: CD69 increased after ACPA (p<0.037). Similarly, CFA enhanced the percentage of co-stimulatory molecule CD27 on B lymphocytes (p<0.048). Among subsets of monocytes, CFA treatment increased percentage of CD14+CD16+ monocytes (p<0.006) and increased expression (MFI) of Fc fragment CD64 (p<0.04). Moreover, increase of HLA-DR was observed on CD14+CD16+ monocytes (p<0.037). The investigations whether the changes in immune cell subpopulations in treated patients have prognostic potential are ongoing.

Conclusions: Single dose of CFA resulted in increase of percentage of CD6+ T lymphocytes (p=0.002), leading to marked decrease of CD4+/CD8+ ratio (p=0.009). Except three patients, overall percentage of neutrophils decreased after the treatment (p=0.01). Although ACPA pulse did not influence the percentage of NK, the percentage of NK cells carrying stimulatory receptor: CD69 increased after ACPA (p=0.037). Similarly, CFA enhanced the percentage of co-stimulatory molecule CD27 on B lymphocytes (p=0.048). Among subsets of monocytes, CFA treatment increased percentage of CD14+CD16+ monocytes (p=0.006) and increased expression (MFI) of Fc fragment CD64 (p<0.04). Moreover, increase of HLA-DR was observed on CD14+CD16+ monocytes (p<0.037). The investigations whether the changes in immune cell subpopulations in treated patients have prognostic potential are ongoing.

AB0015 CAPTURE OF IGA IMMUNE COMPLEXES AND ENRICHMENT IN IGA IG GENE EXPRESSION BOTH SUGGEST A ROLE FOR FCRL4+ B CELLS IN THE LINK BETWEEN MUCOSAL AND JOINT INFLAMMATION

J. Cameron 1, E. Clay 2, K. Amara 2, N. Sippil 2, A. Filer 1, K. Raza 1, V. Malmström 2, D. Scheel-Toellner 1, 1Rheumatology Research Group, RACE AR UK Centre of Excellence in RA Pathogenesis, Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom; 2Rheumatology Unit, Department of Medicine, Karolinska Universitetssjukhuset, Stockholm, Sweden

Background: Recent evidence points to the autoimmune process of rheumatoid arthritis (RA) originating at mucosal surfaces. Previous work from our group described a subset of B cells in the synovium and synovial fluid (SF) of RA patients which can be distinguished by their expression of the Fc-like receptor 4 (FCRL4) and elevated expression of RANKL, indicating a unique pathogenic function. B cells expressing FCRL4 were originally described as a distinct memory B cell subset in human tonsils where they accumulate in the epithelium. We have recently shown that FCRL4+ B cells are enriched in cells recognizing citrullinated autoantigens (Amara, K. et al. under revision). Recent in vitro work suggested that FCRL4 is a low affinity receptor for aggregated IgA.

Objectives: 1) To investigate the interaction of RA synovial fluid FCRL4+ B cells with IgA

Methods: SF mononuclear cells were isolated, labelled for FCRL4, IgA and CD19 and analysed by flow cytometry. In experiments identifying IgA B cell receptors, SF mononuclear cells were briefly incubated in an acidic buffer to remove surface receptor bound antibodies before staining. Heat-aggregated purified human IgA
was added to assess IgA binding to FcRl4+ B cells. Single B cells were sorted from SF of RA patients and their constant region genes probed for identification of their Ig subclass by PCR.

Results: Ex vivo, FcRl4+ B cells in SF of RA patients have a higher load of IgA bound to their surface compared to their FcRl4- counterparts. After in vitro removal of surface bound IgA, they can bind heat-aggregated IgA (p = 0.0313). We also demonstrate that a significantly higher proportion of FcRl4+ B cells use IgA BCRRs (p = 0.0061) by flow cytometry and further more by probing constant region genes by PCR for enrichment for Ig genes coding for the IgA1 isotype (p = 0.009) was found.

Conclusions: Both their ability to capture IgA immune complexes through binding to FcRl4 and their enrichment in IgA Ig gene expression suggest a potential role for synovial fluid FcRl4+ B cells in the mucosal origin of joint inflammation.

B-CELL SUBSETS DIFFERENCES IN INFLAMMATORY RHEUMATIC DISEASES

J.L. Gomes1,2, D. Ligeiro3, A. Lima3, A. Sepriano2,4, C. Teixeira3, C. Lopes1, T. Costa1, S. Ramiro4, M. Mateus1, M. Costa1, J.C. Branco1,2, F. Pimentel-Santos1,2,1, Rheumatology, Hospital Egas Moniz - CHL; 2,CEDEC, NOVA Medical School-Universidade Nova de Lisboa; 3,Centro de Sangue e Transplantação de Lisboa, IPST-Ip, Lisboa, Portugal; 4,Rheumatology, LUMC, Leiden, Netherlands

Background: Targeting humoral immunity has been proved effective in several inflammatory rheumatic diseases (IRD). Though clinical trials have shown some efficacy of B-cell depletion in ankylosing spondylitis (AS), results are less convincing. Other studies have revealed an association between mutations and expression of immune regulatory genes suggesting B-cell dysfunction in the development and progression of AS. Yet, there is still lack of data describing B-cell subsets in AS compared to other inflammatory B-cell compartment homeostasis in the pathophysiology of this disease.

Objectives: To assess and compare the immature, naïve and antigen differentiated subsets of peripheral B-cell compartment in AS with those in healthy controls (HC) and other IRD

Methods: Patients (pts) with AS, RA and SLE according to respective classification criteria were included in this study. Pts under biologic DMARDS were not included. Sociodemographic and clinical variables were recorded. Blood samples were collected for quantification of inflammatory markers (ESR and CRP), immunoglobulins and serum levels and assessment of B-cell immature transitional stages and mature subsets by flow cytometry (figure). Mann-Whitney and Fisher’s exact test were used for comparison of AS with other groups

Results: Overall, 60 pts and 12 HC were included (Table). All patient groups presented similar and rather low levels of inflammation, as measured by CRP, ESR and immunoglobulins, in addition to a decreased lymphocyte count by comparison with HC. There were no differences in the B-cell counts between AS pts and HC, with both groups having higher B-cell counts than RA and SLE pts. Regarding B-cell subsets, the immature transitional compartment of AS pts was found in normal range, but not in the RA and SLE groups. In fact, the latter presented a significant decrease in all transitional maturity stages (T1-T3). The next step in B-cell differentiation is mature naïve cells, also found in normal levels in AS and decreased in RA and in particular in SLE. AS pts presented slightly higher counts of CD27+ IgD- M2-like and class able to switch memory cells with reference to HC and these cell numbers were found to be lower in and even lower in SLE pts. Switched memory CD27+IgD- B-cells were reduced in all patient groups, however, only SLE pts presented highly decreased cell levels.

Conclusions: We found that while a severe dysfunction is present in the homeostasis of the B-cell compartment in RA and in particular SLE pts, which are lymphopenic in both immature and mature B-cell compartments, it appears that AS pts are not affected in the same way. At this stage, functional studies appear to be necessary in order to identify differences in key mechanisms of B cell development and differentiation that may play a role in the etiology and progression of these inflammatory rheumatic diseases. Our first results, however, establish that pathophysiological mechanisms involving B-cells clearly differentiate AS from RA and SLE.

THERAPEUTIC EFFECT OF UMBILICAL CORD-DERIVED MESENCHYAL STEM CELLS TRANSPLANTATION IN A MOUSE MODEL OF PRIMARY BILIARY CIRRHOSIS

J. Fan, Q. Wang, R. Feng, G. Yao, X. Tang, L. Sun. Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, nanjing, China

Background: Primary biliary cirrhosis (PBC) is a cholestatic liver disease characterized by slow progression of non-suppurative cholangitis with immune mediated destruction of intrahepatic bile ducts. Previous studies have shown beneficial effects of mesenchymal stem cells (MSCs) transplantation in many autoimmune diseases. However, few studies have focused on the effects of MSCs on PBC.

Objectives: In our study, we investigated the therapeutic effect of umbilical cord-derived mesenchymal stem cells (UC-MSCs) transplantation in a well-defined mouse model of PBC and explored the potential mechanism.

Methods: After 2OA-BSA-induced autoimmune cholangitis was created in C57BL/6 mice, cultured human UC-MSCs or a vehicle control was administered. Liver injury severity was assessed by clinical and histologic analysis. The immunity suppression effects and mechanism of UC-MSCs were tested.

Results: UC-MSCs administration alleviated biliary duct damage and intrahepatic inflammatory cell infiltration in C57BL/6 mice that had undergone 2OA-BSA immunization. Serum levels of ALT and ALP were significantly decreased. Also, UC-MSCs reduced the production of anti-mitochondrial autoantibodies (AMA) in PBC mice. UC-MSCs downregulated immunoregulatory cytokine, such as IFN-γ, TNF-α, IL-12 and IL-17A production both in peripheral blood and local liver. Notably, Infusion of UC-MSCs resulted in an increase in regulatory T cells (Tregs) in peripheral blood but a decrease of this kind of cells in liver tissues. Furthermore, UC-MSCs significantly suppressed Th1- and Th17-cell responses and these alternations could be detected in spleen, peripheral blood and liver in PBC mice.

Conclusions: In summary, the current study shows that UC-MSCs based therapy has profound inhibitory effects on inflammatory responses and immunoregulatory effects both in local and systemic abnormalities in PBC. This findings also provide further evidence regarding the role of MSCs in the clinical trials of PBC.

B CELL DISTURBANCE IN RHEUMATOID ARTHRITIS PATIENTS: COMPARATIVE STUDY BETWEEN TREATED AND NON-TREATED PATIENTS

M.H. Nassr1, E. Gomaa2, M.M. Eid3, A.A. Hamdy2, A.A. Wegdan2.
1Rheumatology department; 2Microbiology and Immunology; 3Clinical Pathology Department, Fayoum University, Fayoum, Egypt

Background: B cells have been shown to play a key role in the pathogenesis of rheumatoid arthritis (RA). Alterations of B cell homeostasis as well as B cell activation markers, such as B-cell activating factor (BAFF) and A Proliferation-Inducing Ligand (APRIL) have been described in RA patients. Up to our knowledge, no data is currently available on differences between treatment naïve patients and those receiving disease modifying anti-rheumatic drugs (DMARDs), regarding B-cell surface expression as well as levels of circulating BAFF/APRIL.

Objectives: The aim of this study is to investigate disturbance of B cell as well as B cell activation markers namely BAFF and APRIL in patients with rheumatoid arthritis comparing treatment naïve patients with those receiving disease modifying anti-rheumatic drugs.

Methods: Sixty RA patients and 30 healthy controls were enrolled. Thirty patients receiving non biologic DMARDs and had not received prior biological treatment and 30 treatment naïve patients. Absolute number of blood CD19 B cells was determined by flow cytometry using the CD19-PE Kit (Immunotech, France). BAFF and APRIL blood concentration was measured using commercially available ELISA kits (Bosterbio, USA).

Results: There was statistically significant difference (p-value <0.05) between different study groups as regard B cell count with low mean among treated RA patients (137.2±60.5) and high mean among controls (243.7±22.5). The B cell count was diminished in the two groups of RA patients, however it is more pronounced in treated patients. Circulating BAFF levels were increased in RA compared to HC (p-value <0.05) with more increase in patients on treatment. Circulating APRIL levels were significantly lower (p-value <0.05) in treatment naïve rheumatoid arthritis patients (343.9±21.7) than the control group (371.5±24.3). However, there was no statistical significant difference (p-value >0.05) between each of treated rheumatoid arthritis group and controls or with non treated rheumatoid arthritis group.

Conclusions: More decrease in B cell count and more increase in BAFF level were observed in RA patients receiving non-biologic DMARDs. Conversely, APRIL levels were not affected by treatment.

The contribution of B lymphocyte to RA pathogenesis goes beyond autoantibody production. Disturbances in B cell homeostasis in RA are not only due to disease process itself but also closely related to the use of anti-rheumatic drugs.

HDLC PROMOTES A REGULATORY PHENOTYPE OF THE IMMUNE SYSTEM BY INDUCING THE PROLIFERATION OF HUMAN CD4+ T CELLS WHILE INCREASING THE EXPRESSION OF FOXP3 IN REGULATOR T CELLS

M. Fernandes Das Neves1,2, J.R. Batacas2, E.C. Jury3, J. Delgado Alves1,2.
1Medicine IV, Professor Doutor Fernando Fonseca Hospital, Amadora; 2CEDOC - Chronic Disease Research Center, NOVA Medical School/Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; 3Centre for Rheumatology Research, University College London, London, United Kingdom

Background: High-density lipoproteins (HDL) are the plasma lipoproteins responsible for reverse cholesterol transport. Its protective effect on cardiovascular disease is attributed to the cholesterol efflux capacity as well as to its anti-oxidant and anti-inflammatory properties. HDL low levels are associated with immune disturbance, including systemic lupus erythematosus and rheumatoid arthritis, implying a potential link between HDL and immunity.

There is few evidence on the effects of HDL on human T cells. Animal studies suggested that HDL inhibits lymphocyte proliferation1, but the only study in humans showed that HDL from young and healthy subjects increases the proliferation of lymphocytes2. Previous studies also showed that HDL levels are positively correlated with the prevalence of regulator T cells in peripheral blood3. Furthermore, it has been shown that one of the main actions of HDL in lymphocytes is the disaggregation of lipid rafts provoked by cholesterol efflux from the membrane, but the final consequences of this effect are not known.

Objectives: To determine the in vitro effects of HDL in human T cell proliferation and in the frequency of FoxP3+ regulator T cells.

Methods: Peripheral blood mononuclear cells from six healthy donors were cultured with and without HDL to measure membrane cholesterol and proliferative rates. CD19+ lymphocyte membrane cholesterol was measured by filipin binding, assessed by flow cytometry. T cell proliferation was studied by Ki-67 expression and cell trace staining for multiple generations. T cell phenotyping and FoxP3 fluorescence were analyzed by flow cytometry.

Results: HDL significantly reduced the amount of membrane cholesterol in CD4+ T cells, after 24 hours in culture. When added in the absence of stimulation, HDL did not induce any proliferation in CD4+ T cells. When added in conjunction with CD3/CD28 stimulation, HDL significantly increased the proliferation of CD4+ T cells. T cell phenotyping showed a significant increase in CD4+CD25+FoxP3+ regulatory T cells, after culture.

Conclusions: This study shows that HDL promotes cholesterol efflux from the membrane of CD4+ T cells in vitro and increases CD4+ T cell proliferation. However, the increase in T cell numbers seem to favor the expression of FoxP3 in regulator in T cells, which is associated with suppression of inflammation. With the development of therapies to increase HDL levels, the knowledge of the HDL effects on T cell subsets is very important for the future management of cardiovascular and rheumatic diseases.

EXPRESS LEVELS OF SIGNALING LYMPHOCYTE ACTIVATION MOLECULE FAMILY 6 (SLAMF5) ON CIRCULATING FOLLICULAR HELPER T CELLS ARE ASSOCIATED WITH DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

S.E. Kang1, S.J. Lee1,2, D.J. Go1,2, H.M. Kwon3, E.Y. Ahn3, J.K. Park1,2, E.Y. Lee4, E.B. Lee2, Y.W. Song1,2, 1Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, Seoul National University; 2Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of

Background: T follicular helper cells (Tfh) are necessary for B-cell maturation and differentiation in the germinal centers (GC). The signaling lymphocyte activation molecule family (SLAMF) receptors on the cell surface mediate T cell:B cell interaction for formation and maintenance of GC. But it remains to be elucidated whether SLAMF5 is expressed in circulating T follicular helper cells (cTfh).

Objectives: The aim of this study was to investigate the levels of SLAMF3 and SLAMF5 on cTfh and to analyze their association with disease activity in systemic lupus erythematosus (SLE) patients.

Methods: Blood samples were collected from 50 SLE patients, 24 Sjogren’s syndrome (SS) patients and 25 age- and sex-matched healthy controls (HCs). In this study, CXCR5, programmed death protein 1 (PD-1), and CD4 were used as markers to define cTfh in peripheral blood mononuclear cells (PBMCs). The expression levels of SLAMF3 and SLAMF5 on cTfh were compared to that of circulating B cell subsets by flow cytometry. Clinical features including disease activity and laboratory tests were analyzed according to expression of SLAMF3 and SLAMF5.

Results: Surface expression of SLAMF5 on CD4 T cells was significantly increased in SLE patients compared to SS patients (mean fluorescence intensity [MFI], mean ± SD: 1291±319 vs 1098±147, p=0.015) and HCs (1291±319 vs 1098±147, p=0.011). But there was no difference in expression of SLAMF3 on CD4 T cells between SLE patients and SS patients or HCs. SLAMF6 expressions on cTfh cells, identified as CD4+CXCR5+PD-1+, were significantly increased in SLE patients than in SS patients (1500±270 vs 1296±140, p=0.001) and HCs (1500±270 vs 1295±161, p=0.001). SLAMF6 expressions on cTfh cells had correlation with systemic lupus erythematosus disease activity index (SLEDAI) (Spearman’s rho=0.477, p=0.001), proteinuria (rho=0.321, p=0.030) and double strand DNA (rho=0.340, p=0.026) in SLE patients. Moreover, expression levels of SLAMF6 on cTfh cells were correlated with those of several B cell subsets including total B cells (CD19+), naive B cells (CD19+CD27-), and class-
switched memory B cells (CD19+CD27+IgD-). But SLAMF6 expressions of B cell subsets were not correlated with disease activity.

Conclusions: Surface expression of SLAMF6 was increased in cTfh cells in patients of SLE and had correlation with disease activity.

HUMAN T CELL LEUKEMIA VIRUS TYPE 1 (HTLV-1) ASSOCIATION BETWEEN MEX-SLEDAI AND INFECTIONS WITH HTLV-1 INFECTED CELLS

K. Umekita, S. Miyauchi, K. Kubo, A. Kawano, K. Iwao, M. Komura, M. Matsuda, I. Takajo, H. Nomura, Y. Nagatomo, A. Okayama. Division of Rheumatology, Infectious Diseases and Laboratory Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan

Background: Human T cell leukemia virus type 1 (HTLV-1) positive rheumatoid arthritis (RA) patients show severe inflammatory state and resistance to anti-rheumatic therapy, including biologic agents (1). HTLV-1 infected T cells was increased in the synovial fluid and tissue from an HTLV-1 positive RA patients (2). However, the mechanism of worsening RA by HTLV-1 infection remains unclear. We focused on the role of HTLV-1 infected T cells as a key player in the exacerbation of RA.

Objectives: To clarify the role of HTLV-1 infected T cells in the pathogenesis of RA. We investigate inflammatory mediators derived from HTLV-1 infected cells.

Methods: Peripheral blood mononuclear cells (PBMCs) were collected from asymptomatic HTLV-1 carriers (AC) (n=5) and healthy subjects (HS) (n=5). Rheumatoid arthritis synovial fibroblasts (RASFs) were co-cultured with PBMCs for 5 days. Cytokine profiles of supernatants were analyzed by multiplex. Exosomes were isolated and purified from cultured medium of HTLV-1 infected cell line (MT2). RASF was cultured with MT2 derived exosomes with and without IFN-gamma for 24hours. Total RNA was extracted using TRIZOL method. The expression of RIG-I, IL-6, CXCL10, and CCL5 mRNA in RASF was measured using real-time quantitative PCR. The expression of pattern recognition receptor, RIG-I was determined by immune blotting. Silencing of RIG-I in RASF was performed by transfection of siRNA against RIG-I.

Results: The levels of cytokine, including IFN-gamma, IL-2, IL-9, IL-13, IL-6, and CCL20, were higher in supernatants co-cultured with HTLV-1 positive PBMCs than in those of negative PBMC (p<0.05). The expression of CXCL10 and IL-6 mRNA was increased in RASF co-cultured with HTLV-1 positive PBMCs compared to those of negative PBMCs. IFN-gamma expression was increased in the pathogenesis of HTLV-1 associated inflammatory diseases. IFN-gamma induced the expression of IL-6, CCL5, and CXCL10 mRNA in RASF. HTLV-1 infected cell line, MT2, autonomously released a large amount of exosomes which contain nucleic acids such as RNA and DNA. MT2 derived exosomes significantly enhanced the expression of CXCL10 mRNA, but not IL-6 and CCL5, in RASF activated by IFN-gamma. Therefore, we hypothesized that exosomes play the role of ligand for pattern recognition receptors. IFN-gamma increased the expression of RIG-I protein in RASF in a dose-dependent manner. The expression of RIG-I protein also increased in RASF co-cultured with HTLV-1 positive PBMCs compared to those of negative PBMCs. Finally, the silencing of RIG-I suppressed the expression of CXCL10 in RASF induced by co-stimulation of both exosomes and IFN-gamma.

Conclusions: It is possible that HTLV-1 infected T cells exacerbate the inflammatory responses of RASFs. Exosomes derived from HTLV-1 infected cells enhance the expression of CXCL10 in RASF induced by IFN-gamma via pattern recognition receptor, RIG-I.

CYTOTOXIC PROFILE CHARACTERIZATION OF NK AND NKT CELLS IN PATIENTS WITH BEHÇET DISEASE

M. Bonacini 1, A. Soriano2, E. Caló 1, A. Zerbini 1, L. Cinimo 3, L. Fontana3, M. Parmeggiani 1, C. Salvarran2, S. Croci 1, C. Clinical Immunology, Allergy and Advanced Biotechnologies Unit; 2Rheumatology Unit; 3Ocular Immunology Unit. Arcispedale Santa Maria Nuova – IRCCS, Reggio Emilia, Italy, Reggio Emilia, Italy

Background: Behçet disease (BD) is a rare inflammatory small vessel vasculitis. It is a chronic systemic disorder with multorgan damage and various clinical manifestations such as cutaneous ulcers, genital ulcers, oral ulcers and uveitis. Etiology is still unknown. Some gene polymorphisms have been associated with BD [1]. In addition, a high frequency of circulating Natural Killer T cells (NKT cells) has been found in BD patients compared to patients with other inflammatory uveitis such as Vogt-Koyanagi-Harada disease (VKH) [2].

Objectives: The objective of this study was to characterize the cytotoxic profile of circulating Natural Killer (NK) and NKT cells in BD patients.

Methods: Peripheral Blood Mononuclear Cells (PBMCs) were collected from 23 BD patients (according to 1990 ISG criteria), 7 VKH patients (according to 2001 Revised Diagnostic Criteria) and 9 healthy subjects [3,4]. BD activity was evaluated with BD Current Activity Form 2003. Anti-CD56 and anti-CD3 antibodies were used to identify NK (CD56+CD7+) and NKT (CD56−CD3+) cells by flow-cytometry. Expression of one inhibiting receptor (NKG2A) and five activating receptors (CD16, CD69, NKG2D, Nkp30 and Nkp46) was determined on the surface of NK and NKT cells. Cytotoxic potential of NK and NKT cells was assessed through incubation of PBMCs with K526 cells in presence or absence of IL-15 followed by flow-cytometry detection of the surface marker CD107a on NK and NKT cells [5].

Results: A higher frequency of NKT cells was detected in peripheral blood of BD patients than VKH patients. Compared to healthy subjects, an increased proportion of CD16 positive NKT cells was found in BD patients. Furthermore it was observed a higher percentage of NKG2D positive cells in both NK and NKT lymphocytes. No difference in the inhibitory markers was detected. In BD patients, incubation of PBMCs with K562 cells in absence of IL-15 induced a lower percentage of NKT cells expressing CD107a compared to VKH patients. Frequency of CD107a positive NKT cells was -1% and similar between groups. Finally, no differences were found between BD patients with active and inactive phase of the disease.

Conclusions: Our study confirms previous reports about an increased level of NKT cells in peripheral blood of BD patients, but we additionally identified a cytotoxic profile of NK and NKT cells characteristic of BD patients when compared to healthy subjects and patients with VKH. Our data revealed for the first time a potential involvement of NKG2D in the pathogenesis of BD. We conclude that NK and NKT cells of BD patients are more prone to respond to stress/danger signals when exposed on target cells leading to cyclic auto-inflammation.

ASSOCIATION BETWEEN MEX-SLEDIA AND INFECTIONS WITH MBL STRUCTURAL AND PROMOTER GENOTYPES IN MEXICAN-MESTIZO PATIENTS

Background: The mannose-binding lectin protein (MBL) is a multimeric molecule with a structure that is the analogue to the C1q protein. Deficient and low MBL concentrations in serum are due to the presence of mutations in the structural or promoter region.

Objectives: To investigate the role of alleles and haplotypes of MBL2 gene in the clinical expression of systemic lupus erythematosus (SLE) and its association with infections in Mexican-mestizo patients.

Methods: An observational, cross-sectional, retrospective study. We included 74 SLE patients and 75 matched controls. All > 16-years-old who met at least four 1982 ACR criteria for SLE were included. The association of MBL locus haplotypes with disease activity and past history of infection was studied in those patients. Allele and haplotype determinations in the promoter and structural regions of the MBL2 gene were performed from genomic DNA isolated peripheral blood. Probes were sent to Invitrogen (Carlsbad, California) for synthesis. The disease activity was determined by MEX-SLEDIA. Infections were categorized arbitrarily if patients had >4 events. The associations between the codons, clinical activity, and having >4 infection events were by odds ratio.

Results: There were 13/73 (17.8%) SLE patients with >4 infections. The presence of homozygous C/C codon 57 was observed to be greater risk for SLE activity and

Conclusions: MBL2 gene polymorphisms of the homozygous C/C in codon 57 of the structural region and heterozygous HYLX of the promoter region are associated with increased risk of a higher number of infections. Also, we observed that homozygous C/C in codon 57 was associated to a higher MEX-SLEDAI.

A NOVEL REAL-TIME IMAGING TECHNIQUE TO CHARACTERIZE MECHANISMS OF CELL DEATH IN NEUTROPHILS

S. Gupta1, D.W. Chan1, K.J. Zaai2, E. Raftsi2, M.J. Kaplan1, 1Systemic Autoimmunity Branch, 2Light Imaging Section, NIAMS/NIH, Bethesda, United States

Background: Neutrophils play a key role in the pathogenesis of autoimmune diseases through various mechanisms including the formation of neutrophil extracellular traps (NETs), NETosis, a recently described distinct form of program cell death and quantifies NETosis in a rapid, accurate and reproducible way. This technique may facilitate studies in neutrophil biology.

Objectives: Techniques to assess and quantitate NETosis in an unbiased, reproducible and efficient way are lacking. We developed a new method to automatically quantify the percentage of neutrophils undergoing NETosis using real-time quantitative live-cell analysis with IncuCyte ZOOM™ (Essen BioScience, Inc.) platform and a dual-dye system dependent on membrane integrity to stain DNA, to image neutrophils and characterize their mechanisms of cell death.

Methods: Neutrophils were isolated from healthy controls and differentiated into osteoclasts (OCs). These osteoclast progenitors (OCPs) were differentiated in the cytokine milieu and chemokine mediated trafficking.

CHEMOKINE SIGNALS ARE CRITICAL FOR HOMING AND ENHANCED DIFFERENTIATION OF CIRCULATING OSTEOCLAST PROGENITOR CELLS

A. Sucec1, Z. Jacic2, M. Artukovic3, M. Ilic Matijasevic3, F. Grubisic2, B. Anic4, S. Ivcevic1, D. Flegar1, D. Grcevic1. 1Department of Physiology and Immunology, University of Zagreb School of Medicine; 2Department of Rheumatology, Physical Medicine and Rehabilitation, Clinical Hospital Center "Sestre Milosrdnice", University of Zagreb School of Medicine; 3Department of Clinical Immunology and Pulmonology, Clinical Hospital "Sveti Duh"; 4Department of Clinical Immunology and Rheumatology, Clinical Hospital Center "Zagreb", Zagreb, Croatia

Background: Peripheral blood (PB) monocyte pool contains cells capable of differentiating into osteoclasts (OCLs). These osteoclast progenitors (OCPs) contribute to osteoresorption in inflammatory arthritides under influence of the cytokine milieu and chemokine mediated trafficking.
Objectives: Our study aimed to define chemokine receptor profile of peripheral OCPs in rheumatoid arthritis (RA), with comparison to psoriatic arthritis (PSA), as well as their susceptibility to chemotactic signals.

Methods: 129 RA, 53 PSA and 110 control patients were enrolled after Ethical approval. PB samples and synovial fluid (SF) samples, with clinical data of disease activity, progression and autoantibody levels were collected. Patients starting anti-TNF therapy were followed up 6 months. TNF-α and CTX serum levels were measured by ELISA. Frequency of OCP-rich subpopulation (CD3–CD19–CD56–CD11b+CD14+) with expression of FN, RANKL, and IL-33 was measured by FACS. OCPs, cultured with M-CSF and RANKL, were stained for TRAP enzyme and mature OCPs counted. Levels of CCL2, CCL3, CCL4, CCL5, CCLX9 and CCLX10 were measured using cytometric bead array, and of CXCL12 by ELISA. Osteoclastogenic effects of CCL2, CCL5 and CCLX10 were measured in cell culture and chemotactic effects on OCPs were studied by cell migration assay using Transwell, with count of number of migrated cells and subsequently differentiated mature osteoclasts.

Results: OCP population was moderately enlarged in PB, further expanded in SF and correlated with TNF-α and rheumatoid factor (RF) levels in patients with RA. However, sorted OCPs generated similar number of mature OCPs as control. RA RNK+ subpopulation was enlarged in SF vs PB and correlated with number of tendon joints. In PSA, the OCP population was not enlarged, and had a higher RF expression. OCPs in RA and PSA had higher expression of CCR1, CCR2, CCR4, CXCR4, CCR6, and all except CCR4 showed positive PB-to-SF gradient. RA had higher expression of CCL2, CCL3, CCL4, CCL5, CCLX9 and CCLX10, with a positive PB-to-SF gradient for all except CCL5 and CCLX9. OCP frequency correlated with levels of CCL2 and CCL5. Subset expressing CXCR4 was associated with TNF-α, CTX and RF levels and was lower in patients treated with DMARD, who at the same time had lower osteoclast formation (CTX). Subset expressing CXCR4 showed significant negative trend during anti-TNF treatment. CCL2, CCL5 and CCLX10 showed significant osteoclastogenic effect. CCL5 showed greatest chemotactic effect, attracting the highest number of cells in the migration assay. At the same time, attracted cells possessed greater osteoclastogenic potential.

Conclusions: Our study provides evidence of the specific importance of certain chemokine signals for stimulation of OCP mobilization, subsequent tissue homing, and maturation, explaining local as well as generalized bone loss seen in RA. Novel insights in regards to migratory behavior and functional properties of PB OCPs in response to chemotactic signals could open way to new therapeutic targets in RA.

AB0027 EXPRESSION DENSITY OF RECEPTORS TO TNF-ALPHA IS ASSOCIATED WITH DAS-28 SCORE IN RHEUMATOID ARTHRITIS

A.A. Alshevskaya 1, J. Lopatnikova 1, N. Shkaruba 1, O. Chumasova 1, A. Sizikov 1, V. Lukinov 2, A. Moskalev 2,3, S. Sennikov 1.

1 Federal State Budgetary Scientific Institution “Research Institute of Fundamental and Clinical Immunology”; 2EQL Labs Ltd; 3Biostatistics and Clinical Trials Center, Novosibirsk, Russian Federation

Background: For a number of cytokines and growth factors density of receptors expression has been shown to be important in regulation of action intensity and variation. Although TNF-alpha is actively involved in the development and progression of chronic inflammation in rheumatoid arthritis (RA) role of membrane receptors and their regulatory function in RA remains unclear.

Objectives: To assess associations of membrane-bound receptors expression and cytokine content with disease activity score in patients with rheumatoid arthritis.

Methods: To reveal linear relationships among integrated score DAS-28 and studied parameters of intact T-cells, B-cells and monocytes (evaluated by flow cytometry) and parameters of mediators soluble content (evaluated by ELISA) building of multiple linear regression model (MLRM) with a standard assessment of the regression coefficients by least squares method were used. To determine receptor number on the cells QuantibritePE Beads (BD) were used.

Results: For the group of patients with acute stage of RA MLRMs with best statistical quality characteristics revealed that for lymphocytes both TNFR1 and TNFR2 number had significant associations with DAS-28; for monocytes only number of TNFR2 was significant. Lower DAS-28 index is associated with higher number of TNFR2 per cell and lower number of TNFR1. Comparison of models with different combinations of studied TNFR-parameters revealed that percentages of cells expressing receptors for TNFα validated not more than 20% of DAS-28 variation, while the number of receptors indicators on cells validated 40–50% of DAS-28 variation. Full MLRM with all 15 studied parameters validated about 70% of DAS-28 variation.

Conclusions: Number of receptors to TNF-alpha is more associated with RA activity score as compared with soluble receptors or cytokine. Number of receptors type 1 and type 2 to TNF-alpha per cell have opposite influence on disease activity score. Our findings indicate the involvement of receptors expression density changes in the pathological process in RA.

AB0028 FIBROBLAST-LIKE SYNOVIOCYTOMES MAY NOT BE THE TARGET OF IL-33 IN THE JOINT PHISIOPATHOLOGY

C.R.L. Machada 1, G.G. Resende 2, R.B.V. Macedo 2, V.C. Nascimento 2, T.P. Silva 2, A.M. Kakehashi 2, M.V.M. Andrade 2, 1 Universidade Federal Minas Gerais; 2 Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Background: Rheumatoid arthritis (RA) and osteoarthritis (OA) are chronic joint diseases in which fibroblast-like synoviocytes (FLS) actively participate in the synovitis- damage cycle, trough production of cytokines such as IL-8 and metalloproteinases (MMPs). FLS. It has already been showed that serum IL-33 levels correlated with disease activity in RA. IL-33 is capable to enhance TNF-α effects in FLS. In the collagen-induced arthritis (CIA) model, the injection of IL-33 exacerbated the disease. Since ST2 receptor is expressed in FLS, it is hypothesized that IL-33 could activate FLS and increase downstream production of inflammatory cytokines.

Objectives: To evaluate the production of IL-6, MMP-1, and MMP-3 by FLS stimulated with IL-33, TNF-α, and IL-1β.

Methods: FLS were cultured from synovial fluid and tissue of OA patients (OAFLS n=8), RA patients (RAFLS n=3), and patients without rheumatic disease (health) (HFLS n=4). FLS were stimulated with TNF-α at concentrations of 1; 5; 10 and 50 ng/ml, IL-1β at concentrations of 0.1; 0.2; 0.3; 0.5 and 1 ng/ml and IL-33 at concentrations of 1; 3; 10; 30; 100 ng/ml, soon after, IL-6, MMP-1, and MMP-3 levels were evaluated by ELISA, in the cell supernatant.

Results: MMP-1, MMP-3 and IL-6 were constitutively expressed by FLS at baseline in all groups. Both TNF-α and IL-1β stimulated the production of IL-6 and MMP-1 with statistical significance in a dose-dependent manner in all three groups. Only IL-1β increased the production of MMP-3. TNF-α stimulated the production of MMP-3 only on FLS. There was no difference between the concentration of MMP-1, MMP-3 and IL6 in the supernatant of OAFLS, RAFLS and HFLS when IL-33 stimulated and non-stimulated were compared.

Conclusions: This study demonstrated that IL-33 failed to induce the production of IL-6, MMP-1 and MMP-3 by FLS of different diseases sources, suggesting that must be another cell type that plays the role of target to IL-33 in physiopathology of joint inflammation. The absence MMP-3 in response to TNF-α stimulus in RAFLS and OAFLS could be explain by saturation of this cytokine in synovial cells from these diseases.

Background: Skeletal muscle damage can occur as clinical manifestation of Systemic Sclerosis (SSc) [1], and it is known to be associated to type I IFN pathway activation [2]. The type I IFN-induced chemokine CXCL10 is associated with the severe SSc prognosis and skeletal muscle disease [3,4], and it has been reported to play a role in inflammatory myopathy (IM) and in diabetic cardiomyopathy (DCM) [5,6]. In DCM the phosphorysederase type 5 inhibitor (PDE5i) sildenafil significantly decreased CXCL10 systemic and cellular release [7]. In SSc, sildenafil is used to treat pulmonary artery hypertension (PAH) and digital ulcer diseases.

Objectives: To determine the serum levels of CXCL10 in SSc patients with or without muscle involvement and treated or not with sildenafil. To determine the role of sildenafil on IFNγ+TNFα-induced CXCL10 release in human skeletal muscle (Hfsmc).

Methods: Sera from 109 patients fulfilling ACR/EULAR 2013 classification criteria for SSc and 34 age and gender matched healthy controls (HC) were analysed by multiplexed, bead-based immunoassay. Hfsmc were cultured and analysed as previously described [5].

Results: CXCL10 serum level was significantly higher in SSC vs. HC (602 ±155.1 pg/ml vs. 197.5±14.9 pg/ml, P <0.001) independently of diffuse or limited clinical subset (p <0.05); the presence of sildenafil in therapeutic regimen was associated with lower serum CXCL10 (455.2±211.8 pg/ml vs. 633.±183.02 pg/ml, P <0.05). CXCL10 was significantly higher in patients with increased Creatine Kinase (CK) (r=0.52, p=0.017) and Protein Kinase C (r=0.445, P <0.001) and its concentration strongly correlate with the levels of CK (r=0.986, P <0.001) and with Medsger Muscle severity score (r=0.445, P <0.001). In vitro, sildenafil suppressed IFNγ+TNFα-induced CXCL10 release by Hfsmc in a dose dependent manner, down to 50% secretion at 10 μM (P <0.05). The inhibition of CXCL10 secretion was associated with significant reduction in cytokine-induced STAT1, NFkB and JNK phosphorylation (P <0.01).

Conclusions: High CXCL10 level is associated with SSc independently from local or diffuse clinical subset and is lower in patients assuming sildenafil independently of other therapies. The strong correlation of CXCL10 and severity of muscle damage as assessed by serum CK and Medsger Muscle severity score, strongly indicate/confirm the involvement of IFN-1 pathway activation during myositis in SSc. The direct inhibitory effect of PDE5 inhibitor Sildenafil on proinflammatory induced CXCL10 secretion warrant further research on the potential role of PDE5 inhibitors as disease modifying agents in SSc.

IL37 INHIBITS GAG RELEASE FROM HUMAN OA CARTILAGE EXPLANTS

E. Van Geffen, A. van Caam, H. van Beurningen, E. Vitters, C. Dinarello, E. Blanney Davidson, P. van der Kraan. Radboud University Medical Center, Nijmegen, Netherlands

Background: In healthy cartilage, there is a balance between anabolic and catabolic activities of chondrocytes that maintains the functional integrity of the extracellular matrix. However, during osteoarthritis (OA), chondrocytes become more catabolically active and express increased levels of matrix degrading enzymes, such as MMPs and ADAMTSS. Increased MMP and ADAMTS activity results in a net loss of the extracellular matrix and therefore leads to cartilage damage. Previously, we found that the anti-inflammatory cytokine Interleukin 37 (IL37) is able to counter-regulate the catabolic status of chondrocytes by reducing the IL1α-driven expression of pro-inflammatory cytokines and catabolic enzymes.

Objectives: The goal of this study was to investigate, in human OA cartilage explants, the effect of IL37 on the release of matrix degrading enzymes and on the synthesis of extracellular matrix molecules and cartilage degrading enzymes to investigate its therapeutic potential in OA.

Methods: Human cartilage was obtained from eighteen OA patients undergoing total knee or hip arthroplasty. Bopsy punches of 4 mm in diameter were made to equalize sample size. After culturing overnight, explants were incubated for 48 h with three doses (1, 10 or 100 ng/ml) of recombinant-human IL37 (rIL37). In the supernatant of the explant cultures, GAG release was measured with the DMB assay and levels of the ARGS neoepitope, which is one of the products of aggrecan degradation by ADAMTS5, were detected using Western Blot. Furthermore, gene and protein expression of extracellular matrix molecules and cartilage degrading enzymes were measured. Nitric oxide (NO), an important effector molecule that may suppress cartilage matrix synthesis, levels were measured in the supernatant using Griess reagents.

Results: Adding rIL37 (100 ng/ml) to OA cartilage explants caused a highly significant reduction in GAG release to the supernatant of, on average, 32% in eighteen donors (Figure 1). Gene expression of the matrix molecules aggrecan and collagen type II was not affected, indicating that this effect of rIL37 was not due to a loss of aggrecan synthesis. Another mechanism to prevent GAG release in cartilage is via inhibition of NO synthesis, but NO levels in the supernatant were comparable between rIL37 treated groups and the control group. In contrast, after addition of rIL37, ARGS neopeptide levels, which reflect ADAMTS activity, did not change, therefore indicating that the inhibition of GAG release by rIL37 in cartilage is via inhibition of NO synthesis, but not inhibition of aggrecan degradation. Further, protein analysis of the explants showed that rIL37 reduced ADAMTS 5 levels. These data indicate that IL37 interferes with the matrix active degradation enzymes in the cartilage matrix. However, gene expression of ADAMTS 5 was not affected by rIL37, indicating that the effect of IL37 on ADAMTS 5 is post translational.

Conclusions: rIL37 reduces GAG release by OA cartilage explants. The mechanism behind this protective effect of IL37 probably runs via a reduction in ADAMTS 5 abundance in the cartilage matrix, which is the main aggrecanase involved in OA. This effect of rIL37 on ADAMTS 5 is probably post translational. Our data indicate that IL37 can maintain cartilage matrix integrity.
UPREGULATION OF CD64 EXPRESSION ON MONOCYTES IN PATIENTS WITH ACTIVE ADULT-ONSET STILL’S DISEASE: A POSSIBLE BIOMARKER FOR ASSESSING DISEASE ACTIVITY
E. Ogura1, T. Shimizu1, A. Kikuchi-Taura2, S. Tsuji1, Y. Oki1, M. Shigesaka1, H. Matsuoka1, T. Ni1, S. Teshigawara1, E. Kudo-Tanaka1, Y. Harada1, M. Matsushita1, S. Oshima1, Y. Sasaki1,1. Department of Rheumatology and Allergology, 2Department of Clinical Research, NHO Osaka Minami Medical Center, Osaka, Japan

Background: Adult-onset Still’s disease (AOSD) is a systemic inflammatory disease of unknown etiology. Overproduction of multiple inflammatory cytokines and subsequent hyperactivation of monocytes/macrophages are prominent characteristics of AOSD. However, there are no convenient and precise methods for evaluating monocyte/macrophage activation in AOSD. We previously reported that monocyte CD64 (mCD64) expression could be quantitatively measured by flow cytometry and its expression was tightly correlated with the activity of systemic lupus erythematosus.

Objectives: We examined the association between mCD64 expression and AOSD disease activity.

Methods: This was a prospective, single-center, observational study conducted between January 2013 and December 2016. Eleven active AOSD patients who fulfilled the Yamaguchi criteria for AOSD and had the modified Pouchot score of ≥2 were enrolled. The mCD64 expression levels were quantitatively measured by flow cytometry and individually assessed both before (Pouchot score ≥2) and after treatment (score <2). Other disease-related laboratory data, such as C-reactive protein, ferritin, and white blood cell count, were simultaneously measured. As a control, 16 active systemic lupus erythematosus (SLE) patients (SLE disease activity index ≥6), 22 active rheumatoid arthritis (RA) patients (disease activity score 28 with 28-joint counts >10) and 10 healthy individuals (both Biolegend), NK cells (CD15-CD16+), neutrophils (CD15+CD16+), monocytes (CD33+CD14+CD16+-/+), mast cells (CD117+FcER1α+) and eosinophils (CD15+FcER1α+) were used. Different lymphoid and myeloid cell types were IL-17A positive in PsA blood of first diagnosed PsA patients such as CD3+, TCR αβ+, γδ T cells, NK cells, neutrophils, eosinophils, mast cells, and monocytes in PsA blood and on neutrophils, monocytes, mast cells and eosinophils in PsA SF.

Conclusions: These preliminary data show that not only lymphoid cells but also specific myeloid cell types may be sources of IL-17A in PsA. Furthermore, not lymphoid cells but IL-17A/IL-17RC positive myeloid cells such as monocytes, neutrophils, eosinophils and mast cells may be potential IL-17A producers in PsA.

PARAMETERS OF TOTAL BLOOD COUNT; MIGHT THEY BE INDICATORS OF INFLAMMATION IN RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS?
O.G. Illez, F. Ulu Ozkan, I. Aktas. PMR, University of Saglik Bilimleri, Fatih Sultan Meherim Training and Research Hospital, Istanbul, Turkey

Background: Neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) are launched as recent markers of inflammation in chronic inflammatory diseases. However, it is not clear which cell types in PsA patients are responsible for the production of IL-17A. In addition, the expression of IL-17RA and IL-17RC on different cell types is not well defined.

Objectives: To identify IL-17A, IL-17RA and IL-17RC positive cells in blood of first diagnosed PsA patients with arthritis and in synovial fluid of established PsA patients with active disease.

Methods: Fresh blood was taken from first diagnosed DMARD and steroid naïve PsA patients (n=10), having arthritis in 1 or more joints (PsA blood). The diagnosis was made by a rheumatologist according to the CASPAR-criteria. In addition, fresh synovial fluid was obtained from established PsA patients (PsA SF) with arthritis in 1 or more joints (n=3) or NSAIDs (n=4). Multicolor flow cytometric analysis was performed on PsA blood and PsA SF. For the detection of IL-17A, IL-17RA or IL-17RC the following antibodies were used: IL-17A-PE (eBioscience), IL-17RA or isotype control IgG1k (both Boleigen), IL-17RC or isotype control IgG2b (both R&D systems). The following markers were used to discriminate between different cell populations: T cell subsets (CD3, CD4, CD8, CD45RO, CCR6, TCRγδ), B cells (CD19), NK cells (CD15-CD16+), neutrophils (CD15+CD16+), monocytes (CD33+CD14+CD16-/+), mast cells (CD117+FcER1α+) and eosinophils (CD15+FcER1α+). Different lymphoid and myeloid cell types were IL-17A positive in PsA blood of first diagnosed PsA patients such as CD3+, TCRγδ+, CD4+, CD8+ lymphoid cells, CD14+ monocytes and eosinophils. In PsA SF of established PsA patients TCRγδ+ T cells, neutrophils, NK cells and eosinophils were IL-17A positive.

Conclusions: These preliminary data show that not only lymphoid cells but also specific myeloid cell types may be sources of IL-17A in PsA. Furthermore, not lymphoid cells but IL-17A/IL-17RC positive myeloid cells such as monocytes, neutrophils, eosinophils, mast cells and mast cells may be potential IL-17A producers in PsA.

Background: Interleukin (IL)-17A is a pro-inflammatory cytokine and is involved in the pathogenesis of psoriatic arthritis (PsA) (1,2). Various cells can produce IL-17A. However, it is not clear which cell types in PsA patients are responsible for the production of IL-17A. In addition, the expression of IL-17RA and IL-17RC on different cell types is not well defined.

Objectives: To identify IL-17A, IL-17RA and IL-17RC positive cells in blood of first diagnosed PsA patients with arthritis and in synovial fluid of established PsA patients with active disease.

Methods: Fresh blood was taken from first diagnosed DMARD and steroid naïve PsA patients (n=10), having arthritis in 1 or more joints (PsA blood). The diagnosis was made by a rheumatologist according to the CASPAR-criteria. In addition, fresh synovial fluid was obtained from established PsA patients (PsA SF) with arthritis in 1 or more joints (n=3) or NSAIDs (n=4). Multicolor flow cytometric analysis was performed on PsA blood and PsA SF.

Conclusions: Hemoglobin levels of RA patients were significantly (p<0.05) lower than the levels of control group (p>0.05). ESR, CRP, NLR and PLR values were significantly higher in patients with active AOSD than in those with active SLE [34,648 (IQR, 10-6), 22 active rheumatoid arthritis (RA) patients (disease activity score 28 with 28-joint counts >10) and 10 healthy individuals]. Together, these data suggest a more broad, but specific IL-17A-IL-17RA/RC signaling network between different cell types important in the IL-17A-driven pathogenesis of PsA.

and CRP scores (p=0.005, p=0.003) were significantly lower respectively. No statistical significance was found in terms of NLR and PLR (p>0.05). Significant positive correlation was found in RA patients with high disease activity between ESR, CRP, NLR and PLR. In AS patients with high disease activity significant positive correlation was found between ESR, CRP, NLR and PLR. No correlation was found between indices, NLR and PLR.

Conclusions: With the advantage of cost effectiveness and easy calculation NLR and PLR in RA patients, and NLR in AS patients might be used as indicators of inflammation together with ESR and CRP or instances when they are not applicable. Although NLR and PLR are useful in the discrimination of healthy and diseased subjects, they are not sufficient to determine disease activity because not only laboratory parameters but clinical findings and self assessment of the patient are also included in activity measurement.

AB0035 ANGIOPOIETINS: THE MISSING LINK IN POEMS SYNDROME?

F. Caccarelli1, C. Perricone1, V.A. Pacucci2, C. Scirocco1, C. Alessandri1, G. Valesin2, F. Conti3, F. Ceccarelli1, G. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1

Background: The overproduction of VEGF and angiopoietin-1, which plays an essential role in the stabilization and the maturation of blood vessels, and angiopoietin-2 that facilitates angiogenesis in the presence of VEGF.

Methods: Circulating levels of VEGF, Angiopoietin-1 and angiopoietin-2 were determined by ELISA in the serum of 3 patients with POEMS syndrome, before and after therapy. All patients had polyclonar gammopathy, and monoclonal gammopathy (2 IgG1, 1 IgGk) and osteosclerotic lesions. Two patients had typical skin lesions, oedema and one patient had a Castleman disease.

Results: As expected, the serum of patients before treatment exhibited high levels of VEGF (2901±920 pg/mL). Strikingly, angiopoietin-1 levels were highly abundant before treatment (6728±20395 pg/mL) and successful treatment led to a strong reduction in both VEGF and angiopoietin-1. Angiopoietin-1 levels strongly correlated with levels of VEGF (p=0.83). By contrast, angiopoietin-2 levels did not alter significantly before and after treatment.

Conclusions: Thus, angiopoietin-1 seems to be a crucial proangiogenic cytokine overproduced in patients with POEMS syndrome that might explain some of the features of the pathology. The overproduction of VEGF and angiopoietin-1 is likely to promote manifestations encountered in POEMS syndrome such as organomegalgy, osteosclerotic lesions or glomeruloid hemangioma. Restoring the balance between angiopoietin-1, angiopoietin-2 and VEGF could constitute a very promising therapeutic strategy in this disease.

AB0036 ASSOCIATION BETWEEN SYNOVITIS AND INFLAMMATORY CYTOKINE SERUM LEVELS IN ANKLE KNEE JOINTS: AFFECTED BY PRIMARY KNEE OSTEOARTHRITIS

F. Caccarelli1, C. Perricone1, V.A. Pacucci2, C. Scirocco1, C. Alessandri1, G. Valesin2, F. Conti3, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1, F. Ceccarelli1

Background: Osteoarthritis (OA) is characterized by progressive loss of cartilage, deterioration of subchondral bone and mild synovial inflammation. Classified for a long time as a non-inflammatory arthropathy, a growing number of evidences has suggested that OA course could be driven by systemic and localized inflammation. In particular, serum levels of Interleukin (IL)-6 have been associated with higher prevalence of osteophytes in older adults with knee OA. Furthermore, high levels of other inflammatory cytokines have been identified in serum and synovial fluid of OA patients.

Objectives: In the present cross-sectional study, we aimed at analyzing the correlation between articular inflammatory state, reflected by ultrasonographically-detected synovitis, and the serum levels of 27 cytokines, chemokines and growth factors in a cohort of primary knee OA.

Methods: 50 consecutively enrolled 47 patients (M/F 16/31, mean age ±SD 53.8±7.8 years, mean onset interval ±SD 70.0±78.6 months) affected by knee OA according to clinical and radiographic ACR criteria. Patients were excluded if they had received non-steroidal anti-inflammatory drugs or other analgesics within 7 days before enrollment. Pain was assessed with a 100-mm visual analog scale (VAS), and the Lequesne algo-functional index was used to measure the OA severity. BMI was registered. Each patient underwent ultrasonographic (US) assessment of both knees performed by a single operator. According to OMERACT definitions, we assessed the presence of synovial effusion, synovial hypertrophy and power Doppler. These elementary lesions were scored according to a semi-quantitative scale (0 = absent, 1 = mild, 2 = moderate and 3 = severe), the sum of them allows obtaining a total score of the patient’s inflammatory state (0-18).

Results: Blood samples for laboratory assays were obtained and commercially available multiplex bead based immunoassay kits (Human 27-bios, Bio-Rad laboratories, Hercules, CA) were used. Twenty-five serum cytokines (APRIL/TNFSF13, BAFF/TNFSF13B, sCD30/TNFRSF8, sCD163, Chitinase3-like1, gp130/sIL-6Rb, IL-1α, IL-1β, IL-1RA, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12, IL-13, IL-15, IL-17, IL-17F-Basic, G-CSF, GM-CSF, interferon-γ, IP-10, MCP-1, MIP-1α, MIP-1β, PDGF, RANTES, TNF, VEGF).

Conclusions: The results of the study enactment, OA patients showed a mean±SD US synovitis score of 4.4±2.7, a mean±SD VAS pain rating of 35.3±16.6 mm (range 18–90 mm), a mean±SD Lequesne index of 10.2±4.2 (range 1.5–19), a mean±SD BMI of 26.8±4.2 (range 20–34.7). Positive correlations among US synovitis score and serum levels of IL-6 (r=0.3, p<0.01), IL-8 (r=0.3, p<0.01), IL-12 (r=0.2, p=0.04), VEGF (r=0.3, p=0.01), MCP-1b (r=0.3, p=0.01), VEGF (r=0.3, p=0.04) and BMI (r=0.4, p=0.04).

Conclusions: The results of the present study confirmed that OA may be associated with systemic inflammatory changes, as demonstrated by the positive correlation between US synovitis and several inflammatory cytokines serum levels.

AB0037 SERUM CYTOKINE SIGNATURE IN MUCOCUTANEOUS AND OCULAR BEHÇET’S DISEASE

G. Lopalo1, C.M. Lucherini2, L. Cantarini3, A. Lopalo3, V. Venerito1, M. Fornaro1, D. Natuzzi1, M. Galeazzi3, G. Lapadula1, F. Iannone1, A. Bencini4, F. Ceccarelli5

Background: Behcet’s disease (BD) is a multi-systemic inflammatory disorder characterized by recurrent oral and genital ulcers, ocular involvement, chronic constitutional bilateral uveitis. However, many other organs including the vascular, gastrointestinal, neurological, and musculoskeletal systems can be affected. Pathogenetically, both innate and adaptive immunity have shown to play a pivotal role, and several proinflammatory cytokines derived from Th1 and Th17 lymphocytes seem to be involved in different pathogenic pathways leading to development of the clinical manifestations.

Objectives: The primary aim of our study was to compare a core set of proinflammatory cytokines between patients with BD and healthy control (HC). The secondary aim was to determine correlations between these putative circulating biomarkers, the status of disease activity, and the specific organ involvement at the time of sample collection.

Methods: Fifty-four serum samples were collected from 46 BD patients (17 males, 29 females, mean age 45.5±11.3 years), and 19 HC (10 males, 9 females, mean age 43±8.3 years). Twenty-five serum cytokines (APRIL/TNFSF13, BAFF/TNFSF13B, sCD30/TNFRSF8, sCD163, Chitinase3-like1, gp130/sIL-6Rb, IL-1α, IL-1β, IL-1RA, IL-2, IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12, IL-13, IL-15, IL-17, IL-17F-Basic, G-CSF, GM-CSF, interferon-γ, IP-10, MCP-1, MIP-1a, MIP-1β, PDGF, RANTES, TNF, VEGF).

Results: Levels of Chitinase3-like1, gp130/sIL-6Rb, IL-1α, IL-1β, IL-2, IL-6, IL-17 (p<0.05), IL-10 (p<0.01), IFN-γ (p<0.001), TNF-α (p<0.001), sTNF-R1 (p<0.001) resulted higher in BD patients than in HC. No differences were observed between active- and inactive-BD group. In addition, comparing cytokines levels in patients affected by mucocutaneous manifestations with (MO-BD) or without (M-BD) ocular
increased interferon-alpha production by plasmacytoid dendritic cells stimulated with a TLR-7 agonist in systemic lupus erythematosus

G. Murayama,
\textsuperscript{1,2} F. U. Furusawa\textsuperscript{2}, A. Chiha\textsuperscript{2}, K. Yamaji\textsuperscript{1}, N. Tamura\textsuperscript{1}, S. Miyake\textsuperscript{2}.
\textsuperscript{1}Department of Internal Medicine and Rheumatology, \textsuperscript{2}Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan

Background: Type I interferon (IFN) appears to contribute to the development of systemic lupus erythematosus (SLE). IFN-\(\alpha\) production is known to be increased in peripheral blood mononuclear cells (PBMCs) from SLE patients. Although plasmacytoid dendritic cells (pDCs) is a major source of IFN-\(\alpha\), recent studies reported that IFN-\(\alpha\) production by pDCs stimulated with a TLR-7 agonist was decreased in SLE compared to healthy controls (HC).

Objectives: We set out to investigate an endosomal TLR-signaling pathway in SLE by using TLR-7 agonist stimulation.

Methods: Blood samples were obtained from 55 HC and 73 SLE patients, diagnosed according to the systemic lupus international collaborating clinics classification criteria for systemic lupus erythematosus (2012). PBMC from SLE patients and HC were stimulated with a TLR-7 agonist, CpG-A oligodeoxynucleotides (CpG-A ODN)-2216, and a TLR-9 agonist, imiquimod. The proportion of pDCs producing IFN-\(\alpha\) was investigated by intracellular cytokine staining and flow cytometry. PBMC were pretreated with IFN-\(\alpha\) for 24 hours, and then IFN-\(\alpha\) production by pDCs was assessed after stimulated with CpG-A.

Results: As previously reported, the level of IFN-\(\alpha\) production by pDCs stimulated with CpG-A CDN was reduced in SLE compared with HC. However, the proportion of IFN-\(\alpha\) production by pDCs stimulated with imiquimod was significantly increased in SLE patients. The percentage of IFN-\(\alpha\) producing pDCs stimulated with imiquimod was positively correlated with SLE disease activity index (SLEDAI) score, and that of pDCs stimulated with CpG-A ODN was negatively correlated with SLEDAI.

Conclusions: IFN-\(\alpha\) production by pDCs from SLE patients was increased when stimulated with a TLR-7 agonist, and this was accompanied with upregulated TLR7 expression in these cells. In murine lupus-models, TLR7-deletion has been shown to reduce autoimmune disease. The enhanced TLR7-signaling pathway in pDC may play an important role in lupus pathology.

AB0038 REDUCTION OF TH17+ LYMPHO CYTES IN PART OF SAPHO PATIENTS ON TREATMENT WITH SECUKINUMAB

G. Assmann,\textsuperscript{1} A. Tajali,\textsuperscript{2} S. Bamberger,\textsuperscript{1} M. Pfreundschuh,\textsuperscript{1} C. Schormann,\textsuperscript{1} F. Neumann,\textsuperscript{1} \textsuperscript{1}Rheumatology and Oncology, University Medical School of Saarland, Homburg;\textsuperscript{2}Rheumatology, Püttlingen Hospital, Püttlingen, Germany

Background: The SAPHO syndrome has to be considered as a rare subtype of the disease entity of the seronegative spondylarthropathy. The characteristic defining symptoms are synovitis, acne, pustulosis, hyperostosis, and osteitis with ostetiit.

Objectives: To evaluate the count of Th17+ lymphocytes in patients with SAPHO syndrome and psoriatic arthritis before and under treatment with secukinumab.

Methods: Peripheral blood was derived from 4 patients with SAPHO syndrome and 4 patients with psoriatic arthritis, respectively before and under 12 week treatment with secukinumab 200mg (dosage: 4 times weekly, then monthly). All patients received at least one conventional DMARDs and one TNF blocking agent in their medical history. All patients showed active disease with elevated scores of DAS28 and/or HAQ. The patients activity scores of ostetiit (from 0 to 6) and PPP (0–6) were estimated by physician. The blood specimen were separated in EDTA containing tubes to separate lymphocytes, which were analyzed using FACScan-cytometry.

Results: The Th17+ lymphocytes were detectable in 4 patients with psoriatic arthritis and 2 of 4 SAPHO patients before and under 12 week treatment with secukinumab. In 2 of 4 SAPHO patients the fractions of Th17+ lymphocytes were prominent prior to secukinumab application; after treatment duration of 12 weeks one of both developed a depletion of Th17+ cells (figure), the other SAPHO patient a Th17+ cell reduction. Only the two SAPHO patients with diminishing Th17+ lymphocytes have developed treatment response evaluated by reduction of HAQ score (from 1.75 to 1.25), ostetiit score (4.5 to 3.0), and PPP score (5.0 to 4.0). Three of 4 psoriatic arthritis patients showed reduced diseases activity under treatment with secukinumab (DAS28 score from 4.22 to 3.45, HAQ 2.25 to 1.5).

Conclusions: The measurement of Th17+ lymphocytes in the peripheral blood of SAPHO patients could be suggested for further evaluation as possible predictor of treatment response by secukinumab.

References:
[1] Firini D, et al. (Ref.) has previously published data of higher Th17+ lymphocytes in the peripheral blood in SAPHO patients compared with psoriatic arthritis patients or healthy controls. Activation of the Th17 pathway leads to pro-inflammatory effects mediated by interleukin 17 with stimulation of osteobe last, macrophages, and neutrophils with the consequences of secretion pro-inflammatory cytokines such as interleukin 6 and 1, TNF alpha, and MMPs. The interleukin 17 blocking agent secukinumab has been introduced in the armamentarium of antirheumatic drugs against seronegative spondylarthritids including psoriatic arthritis.

IMMUNE MODULATORY EFFECTS OF MESENCHYMAL STEM CELL TO MONONUCLEAR CELLS FROM PATIENTS WITH ACTIVE ADULT ONSET STILL’S DISEASE

I.W. Sohn\(^1\), H.-J. Jeong\(^2\), G.Y. Ahn\(^1\), M.J. Kim\(^1\), H. Kim\(^1\), S. Kang\(^1\), D.H. Yoo\(^1\).

\(^1\)Rheumatology, Hanyang University Hospital for Rheumatic diseases, Seoul; \(^2\)Rheumatology, Keimyung University Dongsan Medical Center, Daegu, Korea, Republic Of

Background: Adult onset Still’s disease (AOSD) is an inflammatory disorder of unknown etiology, which is accompanied by increased levels of serum pro-inflammatory cytokine. Mesenchymal stem cells (MSCs) have immunomodulatory capacities and might be a promising therapeutic option in the treatment of refractory autoimmune diseases. Both cell-to-cell contact and the release of soluble factors mediate immune modulatory functions of MSCs.

Objectives: We aimed to determine if MSCs could modulate serum cytokine level in patients with active untreated AOSD, either through paracrine secretion or via direct interaction with the MSCs.

Methods: Human peripheral blood mononuclear cells (PBMCs) from 6 patients with active AOSD were co-cultured for 72 hours with human MSCs (hMSCs at a ratio of 1:10) in each culture. We compared the cytokine levels before and after direct or indirect (transwell cultures) exposure to activated mononuclear cells (LPS, 10ng/ml) or T-cell inducing conditions (anti-CD3 [5 μg/ml], anti-CD28 [5 μg/ml]) recombinant human IL-2 (5 ng/ml). Cytokine levels were detected by multiplex cytokine detection kit by flow cytometry, or ELISA with culture supernatant. In vitro platform for studying the effects of MSCs on individual cytokines, the Wilcoxon signed-rank test was employed for comparison of serum cytokine levels.

Results: Treatment of MSCs with hMSCs resulted in a significant reduction of mean TNF-α level (mean 463.4 pg/ml vs 137.8 pg/ml, p < 0.05) and IL-1β (mean 1887.1 pg/ml vs 1127.9 pg/ml, p < 0.05). When the hMSCs were present during the T-cell differentiation, there was a significant decrease in the mean secreted TNF-α (mean 10953.5 pg/ml vs 454.9 pg/ml, p < 0.05) IFN-γ (mean 14301.0 pg/ml vs 5094.9 pg/ml, p < 0.05) and IL-2 receptor (mean 3550.8 pg/ml vs 2506.4 pg/ml, p < 0.05). On the contrary, level of TGF-β was significantly increased (mean 4088.8 pg/ml vs 5104.8 pg/ml, p < 0.05). But, there was a significant increase in the amount of IL-6 (mean 2215.5 pg/ml vs 25130.6 pg/ml, p < 0.05) and IL-17 (mean 1327.0 pg/ml vs 2453.6 pg/ml, p < 0.05). Two chamber experiments also showed similar pattern of cytokine modulation.

Conclusions: This preliminary experiment demonstrated that MSCs can modulate cytokine profiles of AOSD mononuclear cells by decreasing pro-inflammatory cytokines, and increasing anti-inflammatory cytokine such as TGF-β. However, up-regulation of IL-6 and IL-17 might be a hurdle to overcome in the clinical application of MSCs in AOSD patients.

LARGE VESSEL VASCULITIS INDUCED BY CANDIDA ALBICAN WATER-SOLUBLE-FRACTION (CAWS) IN THE C57BL/6J MOUSE MODEL IS ASSOCIATED WITH OVEREXPRESSION OF IL-6, TNF-α, AND IL-10 WITH MODEST CHANGE IN SOCS-1

J.M. Springer\(^1\), M. Zhang\(^2\), D. Smith\(^1\), N. Mira\(^3\), N. Onno\(^3\), O. Tawk\(^4\), M. Maze\(^5\), K. Dileepan\(^1\).

Background: We have previously demonstrated that mast cell degranulation acutely downregulates lipopolysaccharide induced aerobic expression and serum levels of IL-6 in vivo. This is accompanied by aortic upregulation of suppressor of cytokine signaling-1 (SOCS-1) gene expression. This effect is not seen in histamine H1 receptor-knockout mice suggesting that mast cell-derived histamine is a key mediator involved in IL-6 homeostasis. Mice injected with Candida albican water-soluble-fraction (CAWS) have been shown to develop coronary and aortic vasculitis. Our long-term objective is to determine the pathogenic mechanisms of large vessel vasculitis (LVV).

Objectives: The aim of this pilot study was to replicate and develop a working mouse model to determine the regulatory role of mast cells in LVV.

Methods: Eight to ten weeks-old male C57Bl/6J mice were randomly distributed into two groups [CAWS, N=8; and Control, N=8] and were injected i.p. daily for 5 days with either CAWS in normal saline (2 mg/day/mouse) or normal saline alone (controls). All mice were sacrificed 30 days after the 5th injection. We examined serum levels of IL-6 and TNF-α, as well as aortic tissue expressions of IL-6, TNF-α, IL-10 and SOCS-1 mRNA. Heart and aortic sections were evaluated for inflammation and mast cells after staining with H & E and toluidine blue, respectively.

Results: Treatment of mice with CAWS for 5-consecutive days led to overexpression of IL-6, TNF-α and IL-10 genes in the aortic tissue with modest upregulation of SOCS-1. At the root of the aorta, all animals in the CAWS group had intense inflammatory infiltrates composed of mixed acute and chronic inflammatory cells. There is also evidence of vasculitis in the coronary arteries. In contrast, none of the control mice had any evidence of aortic inflammation or vasculitis. Serum IL-6 concentrations were below detectable levels in both controls and CAWS-treated mice whereas TNF-α levels were elevated in 3 out of 8 mice in the CAWS group. There were no signs or increased presence of intact or degranulating mast cells in the area of inflammation.

Conclusions: These results suggest that CAWS-induced LVV involves acute and chronic inflammatory response and vascular tissue expression of both pro- and anti-inflammatory cytokines and SOCS-1. Detailed kinetic studies are warranted to determine the optimum windows of peak inflammatory response and the expression of these genes to understand the pathobiology of CAWS-induced LVV.

AB0042

HIGH EXPRESSION OF S100 CALGRANULIN GENES IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF PATIENTS WITH TAKAYASU ARTERITIS

J. Kabedaross, R. Goel, H. Mohan, D. Danda. Department of Rheumatology, Christian Medical College, Vellore, India

Background: Takayasu arteritis (TA) is inflammatory disorder that affects aorta and its branches. Toll-like receptors (TLR) 1 to 4 are highly expressed in aorta (1). Activation of TLR4 causes transmural arteritis in human temporal artery-SCID chimera model (2). Ligand responsible for TLR4 activation is not known in TA.

Objectives: Aim of the study is to examine the expression of TLR4 and its endogenous ligands in peripheral blood mononuclear cells (PBMCs) of patient with TA.

Methods: RNA from PBMCs of 24 TA patients and 19 sex and age matched healthy controls were extracted. The mRNA expression of various endogenous TLR4 ligands, TLR4, RAGE, interleukin-6 (IL-6) and IL-8 were quantified in real time PCR using specific primers and SYBR Green qPCR master mix. Serum S100A9A8 and S100A12 level were measured using commercial ELISA kits. S100A8A9 and S100A12 were measured in cell culture supernatant of un-stimulated and lipopolysaccharides (LPS) stimulated PBMCs, cultured for 4 hours. t-test was used to compare between the groups. P < 0.05 was considered as statistically significant.

Results: The mRNA of S100A8, S100A9, S100A12 and TLR4 were highly expressed in TA as compared to healthy controls, while RAGE, HSP70 and IL-6 had lower expression in TA. No difference in serum levels of S100A8A9 and S100A12 was noted between TA and healthy controls. LPS induced high secretion of both S100A8A9 and S100A12 levels in both TA and healthy controls (Figure-1). However, the stimulatory response in healthy controls [2.86 (1.7–3.53) fold] was significantly higher as compared to TA [1.345 (1.1–1.82) fold; p < 0.05] as measured by delta S100A12 (LPS/unstimulated control). Numerically delta S100A9A8 was also higher in healthy controls [2.04 (1.7–5.6) fold] as compared to TA [1.38 (1.09–3.6) fold; p<0.129].

DOI: 10.1136/annrheumdis-2017-eular.2610

Scientific Abstracts
Conclusions: mRNA expression of S100A8, S100A9, S100A12 and TLR4 in PBMCs of TA patients were higher as compared to healthy controls. Despite this, S100A12 secretion was lower in TA as compared to healthy controls upon LPS challenge.

Background: Toll-like receptor 4 (TLR4) is a pattern recognition receptor involved in the initiation of inflammatory responses to control pathogen infections, but its role in rheumatic diseases is becoming evident, as well as its potential role as a therapeutic option.

Objectives: The aim of this study was to evaluate the effect, both on articular histophatology and pain behaviour, of a TLR4 antagonist (TLR4-A1) on an experimental model of OA. The effect of the TLR4-A1 on the activating transcription factor-3 (ATF-3) signalling pathway was also assessed.

Methods: OA was induced in adult Wistar rats through an intra-articular injection of 2mg of sodium mono-iodeacetate (MIA) into the left knee. Control animals received a similar injection with saline. TLR4-A1 (10 mg/kg), synthesized by Dr. Quesada from a compound previously described 3. Although the principal TAC action is thought to be the recognition host-derived endogenous molecules called damage-associated molecular patterns (DAMPs). The role of TLR4 in rheumatic diseases is becoming evident, as well as its potential role as a therapeutic option.

Results: TLR4-A1 significantly reduced the nociceptive behavior of OA animals both in the Knee-Bend and Catwalk tests, before and after TLR4-A1 or vehicle administration, at several time-points. Animals were sacrificed 28 days after OA induction. L3-L5 Dorsal Root Ganglia (DRG) were used for immunohistochemistry for TLR4 and ATF-3, signal cords were immunoreacted for TLR4 and knee joints were processed for histopathological evaluation.

Objectives: Methods: A novel TAC structure (SAF2012–40075-C02–02) was intraperitoneally administered, daily, from days 14 to 28 after OA induction. At several time-points, animals were sacrificed 28 days after OA induction. L3-L5 Dorsal Root Ganglia (DRG) were used for immunohistochemistry for TLR4 and ATF-3, signal cords were immunoreacted for TLR4 and knee joints were processed for histopathological evaluation.

Results: Antagonism by TLR4-A1 significantly reduced the nociceptive behavior of OA animals both in the Knee-Bend and Catwalk tests. The effect was immediately observed 1 day after TLR4-A1 administration, but became more evident 4 days later, maintaining thereafter. No improvement in the cartilage histology was observed. The increased ATF-3 expression observed in DRG of OA animals was significantly reduced by TLR4-A1. On the contrary, TLR4 expression slightly increased after antagonist administration both at DRG and superficial dorsal horn levels.

Conclusions: Chronic treatment with TLR4-A1 showed an antinociceptive effect on OA animals, not related to articular histopathological improvement, possibly through an ATF-3 dependent mechanism.

AB0045 IL-17 INDUCED GLUCOCORTICOID INSENSITIVITY MIGHT BE DEPENDENT ON THE REDUCED 11β-HSD1 ENZYME ACTIVITY

M. Vaitkute 1, V. Kunnauthuly 1, O. Orsolini 2, V. Viapiana 1, F. Poli 3, A. Mattà 2, L. Idalise 4, D. Gatti 3, M. Rossini 3, C. Goicoechea 5, J. Castro-Lopes 1,2,3, F. Unidad Asociada UERJ-ICM-CSIC, Alcorcon; 2Instituto de Quimica Médica, Conairo Superior de Investigaciones Científicas. Unidad Asociada UERJ-ICM-CSIC, Madrid, Spain

Background: It has been demonstrated that IL-17A is able to induce GC insensitivity. Although several studies have reported the role of IL-17 in GC insensitivity the mechanism underlying remains still largely unclear.

Objectives: To understand the effects of interleukin-17 (IL-17) on the enzyme 11β-hydroxysteroid dehydrogenases (11β-HSDs) in the two main classes of monocytes, CD14 and CD16.

Methods: Peripheral Blood Mononuclear Cells (PBMCs) were isolated from healthy donors and were sorted into CD14 and CD16 subpopulations using cell sorting. Effect of IL-17 on 11β-HSD1 enzyme activity was measured in terms of conversion of cortisone to cortisol in sorted and unsorted monocytes using Homogeneous Time-Resolved Fluorescence (HTRF). The direct involvement of 11β-HSD1 in the conversion of cortisone to cortisol was confirmed using carbonoxylene, an inhibitor of 11β-HSD1.

Results: Monocytes showed a concentration-dependent decrease in the 11β-HSD1 enzyme activity when incubated with increasing concentrations of IL-17. CD14 and CD16 cells stimulated similarly with IL-17 showed a significant
difference in the enzyme activity between the untreated and stimulated cells in all treatment groups. However, a dose dependent decrease was observed only in case of CD14 cells. Both unsorted monocytes and monocyte sub-populations showed a significant decrease in the concentration of cortisol measured when co-incubated with carbenoxolone, indicative of the direct involvement of 11β-HSD1 enzyme in the conversion of cortisone to cortisol.

Conclusions: The results of this study showed that IL-17 induced GC insensitivity might be dependent on the reduced 11β-HSD1 enzyme activity in inflammatory conditions. We showed that the pro-inflammatory cytokine IL-17 causes a significant decrease in the 11β-HSD1 enzyme activity.

AB0044 METABOLISM AND OSTEOARTHRITIS ARE LINKED BY ADIPOKINES

M.-L. Hölsler1, C. Schreyäck1, Y. Luo2, A. Bozec2, G. Schett2, E. Neumann1, U. Müller-Ladner1, 1 Internal Medicine and Rheumatology, Justus-Liebig-University Giessen, Bad Nauheim; 2 Clinic of Medicine 3 - Immunology and Rheumatology, University of Erlangen-Nuremberg, Erlangen, Germany

Background: Obesity and hyperinsulinemia are of increasing importance in the Western society. Both obesity and insulin resistance lead to changes in expression of adipokines such as adiponectin, visfatin or leptin, which appear to be immunomodulatory factors also in rheumatic diseases.

Objectives: Since osteoarthritis (OA) is often accompanied by hyperinsulinemia and obesity, we combined both mouse models (destabilization of the medial meniscus (DMM) and high-fat diet (HFD)). Here, we evaluated and correlated the systemic and local effects of both models at different stages of OA development with special focus on the local/systemic expression of the adipokines adiponectin, visfatin and leptin over time.

Methods: HFD (mainly consisting of saturated fatty acids) to induce obesity and hyperinsulinemia, and ND (normal diet) as control were fed to C57Bl/6 mice for 3 months followed by surgical OA induction (time point 0). Tissue and sera were collected at different time points after DMM-mediated OA induction (4, 6, 8 weeks).

Adipokytine (leptin, visfatin, adiponectin and IL-6) serum levels were measured by ELISA. Histological stainings of the joints (H&E, satirin O, pappenheim and Masson-Golden’s trichrome) were evaluated and arthritis progress was scored. Immunohistochemical stainings of the joints were performed to evaluate the local distribution of adipokines, which were correlated to systemic adipokytine levels and the respective arthritis score.

Results: Low systemic IL-6 levels confirmed that no acute inflammation due to surgery or infection was present in all animals. OA induction was visible at all timepoints, which was aggravated in HFD compared to ND mice (OA score: 4 weeks ND 0.87 vs. HFD 0.93, 6 weeks ND 1.44 vs. HFD 3.69, 8 weeks ND 1.78 vs. HFD 2.18). Systemic levels of leptin were significantly induced by HFD confirming the induction of insulin resistance, but DMM decreased leptin levels at all timepoints (significantly for 3 out of 6 groups, e.g. 4 weeks: HFD healthy vs. HFD DMM 18.4 ng/ml vs. 3.7 ng/ml). Interestingly, the systemic increase of adiponectin by DMM was time dependent (only 8 weeks after surgery: HFD healthy vs. HFD DMM 3176 ng/ml vs. 6149 ng/ml). But independently of diet. However, HFD in combination with DMM did not show significant effects on systemic levels of adiponectin, visfatin or IL-6.

Conclusion: HFD deteriorates OA in the DMM model. Systemic leptin levels were elevated by HFD/insulin resistance but reduced by DMM, which could not be observed for the mainly proinflammatory adipokytine visfatin. Of note, systemic inflammation as shown by systemic IL-6 levels was low in all animals. The stage of OA development influences adipokine levels, which were only increased systemically 8 weeks after surgery. In summary, systemic levels of adipokines are altered by DMM and HFD as well as the combination of both models and the analyzed adipokines show differing reactions to these factors.

AB0047 TYPE I INTERFERON IS HIGHLY EXPRESSED IN RA SYNOVIAL FLUID AND JOINT CARTILAGE CORRELATED WITH SERUM RHEUMATOID FACTOR; A PRELIMINARY EXPERIMENTAL STUDY

M. Nakayama1, H. Tobimatsu1, H. Imamura1, Y. Sakuma1, K. Yano1, Y. Niki2, N.A. Bashlakova1. 1 Ultrasound Diagnostics Department; 2 Ultrasound Diagnostics Department, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus

Background: Systemic inflammation has been postulated to be an independent cardiovascular risk factor, particularly in patients with autoimmune rheumatic disorders (ARD), such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), and is associated with accelerated atherosclerosis. There is some evidence to suggest that antiphospholipid antibodies (aPL) may also play a role in the development of atherosclerosis. However, it is few data about the relationship between these autoantibodies and inflammatory mediators in the development of atherosclerosis.

Objectives: To clarify the involvement of inflammatory mediators and aPL in the atherosclerotic process in patients with ARD.

Methods: The study included 87 female patients with ARD (RA n=47), mean age 45.0 (33.0; 51.0) years old, disease duration 9.0 (3.0; 14.0) years, disease activity (DAS28=5.37, 4.69; 5.86 points); SLE (n=40), mean age 33.5 (27.5; 44.5) years old, disease duration 8.0 (5.0; 14.5) years, disease activity SLEDAI-2K 7.0 (4.0; 6.0) points. Sixty healthy women (mean age 40.5 (36.0; 47.0) years old) formed the control group.

Results: A significant increase in the expression of type I interferons was found in RA patients in comparison with SLE patients and healthy controls (Table 1). Serum levels of IFN alpha and beta of RA cartilage were much higher than those of OA whereas tissue IFN gamma was expressed predominantly in both RA and OA. Expression of IFN alpha was not correlated with that of TNF alpha in RA patients. Statistical analysis revealed that IFN was highly expressed in RA synovial fluid, joint cartilage and blood, not in OA. IFN immunotherapy has been reported to induce RA (4–5), therefore abundant IFN might induce RA and inhibit cure of RA. Our results showed that IFN was related with blood and joint IFN. It can be speculated that IFN might be an index of IFN regulation in RA patient, however, more samples must be investigated to prove this speculation.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.4913
We revealed a correlation between IgG aCL, IgG aIgG, IgG aANV and TNF-α, IgG aCL and IL-6 in SLE patients, and only one between IgG aANV and hs-CRP in RA patients. There wasn’t any correlation between aPL and inflammatory mediators in the control group.

Univariate analysis has demonstrated an association of IgG aANV with IMT (r=0.00, p=0.044) and IgG aANV and TNF-α (r=0.362, p=0.028) in RA patients. Furthermore, we found an association between IL-6 and IgG aPT (r=0.426, p=0.038), TNF-α and IgG aCL (r=0.419, p=0.042) in SLE patients with carotid atherosclerosis. There wasn’t any association between investigated parameters in the control group.

Conclusions: The association between inflammatory mediators and disease activity has been confirmed in ARD patients. Increased autoimmune immune has been verified both in patients with SLE and RA. It has been determined that IgG aANV had more significance for IMT in patients with SLE, TNF-α - in RA patients. Our data also suggest that inflammatory mediators and antiphospholipid antibodies are involved in the atherosclerotic process in patients with ARD.

NF-κB-INDUCING KINASE REGULATES LTβR-DRIVEN NF-κB SIGNALING AND INFLAMMATORY ACTIVATION OF ENDOTHELIUM

P. Kucharzewka1, C. X. Maracle2, J.P. van Hamburg2, K.C. Jeucken2, H. Olsson2, S.W. Tas1, 1. Imed Ria, AstraZeneca, Mölndal, Sweden; 2. Department of Clinical Immunology & Rheumatology and Laboratory for Experimental Immunology, AMC, University of Amsterdam, Amsterdam, Netherlands

Background: Sites of chronic inflammation, such as rheumatoid arthritis synovial tissue, are characterized by neovascularization and often contain tertiary lymphoid structures with characteristic features of lymphoid organs such as endothelial venules (HEV), and sometimes even true germinal centers. Ligation of the lymphotixin (LT)-β receptor (LTβR) results in activation of both canonical and NF-κB-dependent pathways. This study aimed to determine whether LTβR can promote inflammation-induced angiogenesis and triggers the development of the cuboidal HEV appearance. However, the relative contribution of the individual pathways to the acquisition of leukocyte traffic-regulating properties by ECs is less well understood.

Objectives: To identify the molecular pathways by which LTβR drives inflammatory activation of ECs to promote interactions with leukocytes.

Methods: Primary human ECs were treated with LTβR or LIGHT to activate LTβR. Induction of downstream signaling pathways was assessed by western blot analysis and NF-κB transcription factor ELISA. The expression of adhesion molecules, inflammatory cytokines and chemokines, such as CXCL1, CXCL5, CXCL8 and GM-CSF in ECs was measured by RT-qPCR and cytokine antibody arrays. EC interactions with leukocytes were determined by an adhesion assay, and EC barrier integrity was assessed by a permeability assay. To repress canonical NF-κB signaling pathway, a small molecule inhibitor of IKKβ was used, and inactivation of non-canonical NF-κB signaling was achieved with siRNAs targeting NFκB.E.

Results: LTβR triggering in ECs resulted in activation of both canonical and non-canonical NF-κB signaling pathways and induced the expression of inflammatory cytokines and chemokines (CXCL1, CXCL5, CXCL8, GM-CSF, CCL5). Consistent with inflammatory activation of ECs, LTβR ligation also induced adhesion of immune cells to activated endothelium and increased permeability across EC monolayers. IKKβ inhibition completely repressed LTβR-induced inflammatory activation of ECs, indicating that this process was mediated through canonical NF-κB signaling. Interestingly, inactivation of IKK with small molecule inhibitors and siRNAs significantly decreased LTβR-induced expression of inflammatory cytokines and adhesion of immune cells to endothelium, whereas silencing of NFκB had no effect. This suggests that the non-canonical pathway is not involved in LTβR-dependent activation of endothelial cells through the canonical NFκB pathway. Further analyses, including silencing of NIK and NFκB overexpression, demonstrated a role for NIK in activation of the canonical NFκB pathway by amplifying IKK complex activity.

Conclusions: These findings suggest that in addition to its pivotal role in the non-canonical pathway, NIK can serve as an amplifier of the canonical NFκB pathway and associated inflammatory responses in ECs mediated by LTβR ligation, which may play a role in development and maintenance of chronic inflammation.

INTERLEUKIN-6 BLOCKADE WITH TOCILIZUMAB DECREASES METALLOPROTEINASE-9 ACTIVITY IN SYNOVIAL FIBROBLASTS STIMULATED WITH SYNOVIAL FLUIDS OF PATIENTS WITH RHEUMATOID ARTHRITIS OR SPONDYLOARTHRITIS

Background: Fibroblast-like synoviocytes (FLS) exhibit a transformed aggressive phenotype characterized by increased secretion of pro-inflammatory cytokines and matrix metalloproteinases (MMPs). Early pathological mechanisms that explain the change to an altered phenotype in FLS of chronic inflammatory arthropathies remain largely unknown. The composition of synovial fluids (SF) is very complex and strongly influences the microenvironment of joints including FLS thus representing an inseparable element of the disease. The MMP-9 is a
INCREASED PERIPHERAL CD8+ T CELL RESPONSES IN SLE
MANGIFERIN MODULATES TNF-ALPHA AND MMP-9

Methods: Primary FLS were obtained from SF of the RA patients. Furthermore, the SW928 human synovial cell line was used. The SF of patients with OA (n=11), RA (n=11) or SpA (n=9) patients were pooled. The FLS were stimulated with OA SF or SpA SF pools and supernatants (SN) were collected after 24, 48 and 72 h. The IL-6 levels were assessed in the SN by ELISA. The gelatinase activity of the SN was determined by zymography. The IL-6 function was blocked with the anti-IL-6 receptor antagonist tocilizumab (TCZ) (200μg/ml).

Results: Earlier induction of IL-6 in SW928 cell line was observed by RA and SpA SF stimulation since significant levels were detected at 24 h (p<0.001 and p<0.01 compared with non-stimulated cells, respectively), whilst OA SF induced significant IL-6 secretion at 72 h (p<0.01). Similar results were observed in primary FLS. In contrast to SF of OA patients, SF of patients with RA or SpA induced increased and sustained secretion of active MMP-9. Moreover, the molecular weight band corresponding with NGAL-MMP-9 complex, considered a protease inhibitor, was detected with higher intensity in the SN of FLS stimulated with RA or SpA SF compared with OA SF (p<0.001 compared with FLS stimulated with OA SF). In the presence of TCZ, significant inhibition in the gelatinase activity of all MMP-9 forms was observed at 48h of stimulation with RA or SpA SF (p<0.001 for MMP-9 dimer and NGAL-MMP-9 complex; p<0.01 for MMP-9 monomer, compared with FLS stimulated with RA or SpA SF).

Conclusions: We conclude that SF of patients with inflammatory arthritis reiterate a differential microenvironment for FLS that impacts on early phenotypic changes of these cells. The IL-6 provokes augmented and persistent MMP-9 activity in FLS stimulated with RA or SpA SF. This work identifies TCZ as an inhibitor of all forms of MMP-9.

AB0052 INCREASED PERIPHERAL CD8+ T CELL RESPONSES IN SLE BY LOW-DOSE IL-2 TREATMENT
R. Zhang, J. He, X. Sun, Y. Zou, Y. Gan, Z. Li. Peking University People’s Hospital, Beijing, China

Background: CD8+ T cell responses to viral pathogens is crucial for the prompt resolution of acute infections. SLE patients are more likely to have infections due to suppression of immune system by long-term glucocorticoid and immunosuppressive agent intake. Our previous study showed that low-dose IL-2 is effective in SLE.

Objectives: The present study is to evaluate the potential anti-infection effect of low-dose IL-2 in refractory SLE patients.

Methods: Nine refractory SLE patients and 9 health controls (HCs) were recruited. Low-dose IL-2 in refractory SLE patients.

Results: Low-dose IL-2 treatment was effective and safe in refractory SLE patients.

Conclusions: Low-dose IL-2 treatment was effective and safe in refractory SLE patients. We investigated the therapeutic potential of Mangiferin; in a clinical relevant chronic model of SLE induced colitis in mice.

Methods: Female BALB/c mice (8 to 12 wks) were randomized into four groups. Colitis was induced by cyclical administration of 5% DSS to mice i.e. 3 cycles of DSS with 1-week cycle comprised of 5% DSS following by 7 days of autoclaved drinking water (7D DSS + 7D water). Group I (Normal control): free access to autoclaved drinking water. Group II (DSS control): free access to 5% DSS. Group III (DSS + Mangiferin_30mg/kg): free access to 5% DSS + oral Mangiferin at 30mg/kg. Group IV (DSS + Mangiferin_60mg/kg): free access to 5% DSS + oral Mangiferin at 60mg/kg. Mangiferin treatment was initiated following second cycle of DSS (i.e. Day 21); after assuring that colitis relapsed in mice. One fragment of the colon was fixed in 10% neutral buffered formalin for microscopic examination while the remaining tissue was divided into parts and stored at -70°C for assessment of biochemical markers of oxidative stress and inflammatory cytokines such as TNF-α, IL-1β, MMP-9.

Results: Mangiferin treatment ameliorated the clinical parameters (body weight loss, stool consistency, occult blood), reduced mucosal damage (re-established mucosal architecture, abridged neutrophil infiltration), restored epithelial barrier integrity (diminished goblet cell loss), attenuated biochemical markers of oxidative stress (GSH, CAT, SOD, MDA, MPO), crucial inflammatory cytokines TNF-α, IL-1β and attenuates MMP-9 levels implicated in the pathogenesis of arthritis and IBD.

Conclusions: Considering the beneficial effects of Mangiferin in arthritis and IBD, we suggest that it would be valuable to use Mangiferin in IBD patients with arthritis as its extra-intestinal manifestation.

AB0054 CXCL4 POTENTIATES TLR-DRIVEN POLARIZATION OF HUMAN DENDRITIC CELLS TOWARDS CYTOKINE PRODUCTION, ANTIGEN CROSS-PRESENTATION AND INCREASES STIMULATION OF CD8+ T-CELLS
S.C. Silva-Cardoso 1,2, A.J. Affandi 1,2, L. Spoel 1,2, M. Cossu 1,2, M. Boes 2,3, T.R. Radstake 1,2, 1Department of Rheumatology & Clinical Immunology; 2Laboratory of Translational Immunology; 3Department of Pediatrics, University Medical Center, Utrecht, Netherlands

Background: CXCL4 is a chemokine produced by activated platelets and immune cells. Several studies have reported that CXCL4 plays a critical role on physiological processes since it affects the proliferation and maturation of megakaryocyte and hematopoietic progenitor cells, regulates coagulation and wound healing, displays anti-tumoral and angiostatic activity and induces immune cell modulation. Dysregulation of these processes causes the disturbance of the immune system and homeostasis, and might lead to pathological conditions. Indeed, a strong correlation was previously found between elevated CXCL4 levels in the circulation and the clinical features of patients with systemic sclerosis (SSc) (1). Dendritic cells are essential players in innate defence and bridging towards adaptive immune responses, thereby contributing to both immune activation and maintenance of homeostasis.

Objectives: Considering previous observations on the association of dendritic cells and T-cell dysfunction in SSc, we here investigated the effect of CXCL4 on monocyte-derived DC (moDC) differentiation, on Toll-like receptor (TLR)-mediated responses and on activation of polyclonal and antigen-specific CD8+ T-cells.
Methods: To this end, we compared the phenotype, TLR-mediated responses and CD8+ T-cell activation by moDCs and CXCL4-exposed moDCs.

Results: Already prior to TLR stimulation, CXCL4-exposed moDCs displayed a more mature phenotype. We found that CXCL4 exposure can sensitize moDCs for TLR-ligand responsiveness, as illustrated by a dramatic upregulation of CD83, CD86 and MHC class I, and markedly increased secretion of IL-12 and TNF-α in response to TLR3 and TLR7/8-agonists. Next, we analyzed the effect of CXCL4 in modulating DC-mediated CD8+ T-cell activation. CXCL4-exposed moDCs strongly potentiated proliferation of polyclonal CD8+ T-cells and production of interferon (IFN)-γ and IL-4 in an antigen-independent manner. While the internalization of antigen was comparable to moDCs, antigen processing by CXCL4-exposed moDCs was impaired. Yet, these cells were more potent at stimulating antigen-specific CD8+ T-cell responses.

Conclusions: Together our data supports that increased levels of circulating CXCL4 may contribute to immune dysregulation through the modulation of innate and adaptive responses by dendritic cells.

LEVEL OF VASCULAR ENDOTHELIAL GROWTH FACTOR A AND INTIMA-MEDIA THICKNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS

Background: Early development of atherosclerosis (AS) with higher mortality risk is observed in patients with rheumatoid arthritis (RA). Actually, this problem hasn’t been solved. That’s why researches devoted to finding of relationships between RA and AS is still of current interest. In RA pannus formation accompanied by the development of new blood vessels forms main clinical manifestation. Vascular endothelial growth factor A (VEGF-A) is a heparin-binding glycoprotein, that induces the growth of blood vessels and plays a role in differentiation of endothelial cells. The expression of VEGF-A increases when plaque develops. Objective: To determine particular qualities of VEGF-A production in patients with RA and various atherosclerotic damage of vessels.

Methods: 67 Caucasian patients with RA (age - 52 yr., [38;59], DAS28 5,25 [5,5;6,4]) were included in our study. Patients had American Rheumatism (ACR)-defined RA (1987 classification criteria). 45 European patients with OA (56 yr., [50;63]) were in control group. All patients gave written informed consent before enrollment. VEGF-A was determined by ELISA for quantitative detection of human VEGF-A (Bender MedSystem GmbH, Austria). Range of atherosclerotic damage was assessed by ultrasonography with measurement of carotid intima-media thickness (IMT). IMT measured was compared with normal values according to the age and sex classes: younger 40 yr - 0.7 mm, 40–50 yr - 0.8 mm, elder 50 yr - 0.9 mm for men; younger 45 yr - 0.7 mm, 45–60 yr - 0.8 mm, elder 60 yr - 0.9 mm for women. Results is presented as median and 25th/75th percentiles (Me [25th percentile; 75th percentile]). Descriptive statistics, non-parametric Mann-Whitney U-test, Kruskal-Wallis test were used for analysis of the results.

Results: No significant differences of IMT were found between groups with RA and OA. Abnormal IMT were observed in about half of patients (Table 1).

Table 1. IMT in patients with RA and OA

The highest level of VEGF-A was in OA-group with stenosing plaque (p<0.01). No significant differences were found between other OA-subgroup. In patients with RA the highest level of VEGF-A was observed in subgroup with abnormal IMT (p<0.05), but not with plagues. Generally, VEGF-A production in patients with normal IMT was higher in RA-patients, but not significantly.

Conclusions: Pro-inflammatory cytokine secretion induced by MSU crystals in synovioocytes triggers chondrocyte activation, intensifying the articular inflammatory state in gouty attacks. Furthermore, the increase in reactive species (particularly NO, which inhibits proteoglycan synthesis) compromises the homeostasis of the extracellular matrix of the cartilage. Finally, overproduction of NGF and H2O2 by the chondrocytes functions a pain modulator during gout attacks.

MODELLING DELAYED BONE HEALING IN A MOUSE-OSTEOTOMY MODEL TO EVALUATE THERAPEUTIC STRATEGIES FOR AFFECTED PATIENTS WITH RA

A. Lang1,2,3, S. Fügener1, P. Hoff1, K. Schmidt-Bleek4, T. Gaber1,3, F. Buttgereit1,3.
1Department of Rheumatology and Clinical Immunology; 2Department of Medical Genetics, Charité University Hospital; 3German Arthritis Research Center; 4Julius Wolff Institute and Center for Musculoskeletal Surgery, Charité University Hospital, Berlin, Germany.

Background: Anti-inflammatory treatment of rheumatoid arthritis (RA) using non-steroidal anti-inflammatory drugs (NSAID) or glucocorticoids (GC) as well as the disease itself, are supposed to negatively influence bone metabolism and healing. However, in vivo models allowing to evaluate therapeutic strategies for patients suffering from delayed bone healing are scarce and mainly created by critical size defects that are not representative for comorbidity-induced disorders. In addition, there are no adequate rodent models allowing the analyses of the influence on the bone metabolism by the complete dysregulation of the immune system in RA as well as long-term medications with NSAID or GC. Previously, we have shown that immunologically restricted patients lack an adequate adaptation to hypoxia in the fracture hematoma thus facilitating healing disorders (1). The hypoxic microenvironment during the initial fracture-healing phase is known to be stimulative for activating the immunological reactions, which induce the regeneration. Furthermore, we performed a single-center retrospective study on fracture healing disorders showing a significant high prevalence for RA patients to be affected by delayed bone healing.

Objectives: In order to evaluate therapeutic strategies for affected patients with RA, we developed a model for delayed bone healing in a mouse-osteotomy model.

Methods: Female C57BL aged 12 weeks underwent osteotomy of the femur (fracture gap 0.7 mm) that was fixated with an external fixator (RIS-System). Lysostaphin (based on bovine-Col I; mimicking extracellular matrix) was applied in the fracture gap and analysis was performed 2 and 3 weeks after surgery. The ratio of bone volume (BV) per total volume (TV) in the fracture gap was evaluated using in vitro µCT. In addition, Movat’s pentachrome staining was performed to analyze the cellular and tissue composition within the fracture gap. To investigate the number of cells as well as the vessel formation, we used immunofluorescence to stain for Endomucin, CIBER-BBN, A Coruña, Spain.

Background: Osteoarthritis is the most prevalent inflammatory arthritis in young men, in which clinical manifestations are triggered by the deposits of monosodium urate (MSU) crystals in and around joints. From a clinical perspective, gouty attacks and tophaceous deposits have been associated to nodal osteoarthritis [1,2].

Objectives: To determine the molecular mechanisms associating MSU crystals deposit with chondrocyte activation and changes in articular cartilage.

Methods: Primary cultures of synoviocytes were activated with MSU crystals for 24 h, the resulting supernatant was used as a supplementary conditioning basal medium (CBM) for 24 h chondrocyte growth. The expression level profile of cytokines (IL-6, IL-8) and nerve growth factor (NGF) in the supernatant was measured. Production of reactive oxygen and nitrogen species, such as O2, H2O2, and NO*, was also measured intraincellularly.

Conclusions: Secretion of these soluble mediators in synoviocytes inactivated NGF by the chondrocytes directly stimulated with MSU crystals.

SYNOVIAL SECRETION OF PRO-INFLAMMATORY AND PRO-OXIDANT MOLECULES TRIGGERED BY MONOSODIUM URATE CRYSTALS INDUCES NGF AND H2O2 PAIN MEDIATORS IN THE CHONDROCYTE

Background: Gout is the most prevalent inflammatory arthropathy in young men, in which clinical manifestations are triggered by the deposits of monosodium urate (MSU) crystals in and around joints. From a clinical perspective, gouty attacks and tophaceous deposits have been associated to nodal osteoarthritis [1,2].

Objectives: To determine the molecular mechanisms associating MSU crystals deposit with chondrocyte activation and changes in articular cartilage.

Methods: Primary cultures of synoviocytes were activated with MSU crystals.
ratio was significantly higher in the controls (empty gap = normal healing; n=8 per timepoint) as compared to the Lysostaphin group (n=8 per timepoint) 2 weeks after osteotomy and slightly higher after 3 weeks. Histological investigation showed the clear presence of the scaffold on both timepoints without bridging cartilaginous tissue. The cell number as well as the vessel formation was significantly reduced within the fracture gap.

**Conclusions:** The results obtained so far support the hypothesis that we were able to develop a delayed healing or even non-union osteotomy model in mice by avoiding to create a critical size defect. Therefore, this approach represents a promising alternative animal model to evaluate therapeutic strategies to overcome bone healing complications in RA patients and perhaps other immunologically restricted patients.

**35SULPHATE INCORPORATION ASSAY AS A NEW TOOL FOR MEASURING EARLY CARTILAGE DEGRADATION FOLLOWING BLOOD EXPOSURE IN VITRO AND IN VIVO IN F8 KO RATS**

_**A.E. Pulles**_ 1-2, _**K.R. Christensen**_ 3-4, _**C. Kjelgaard-Hansen**_ 4,

1. _Department of Rheumatology & Clinical Immunology; 2Van CreveldKliniek, University Medical Center Utrecht, Utrecht, Netherlands; 3Veterinary Disease Biology, University of Copenhagen, Copenhagen; 4Global research, Novo Nordisk A/S, Maaloev, Denmark

**Background:** Joint damage upon bleeding causes significant morbidity in patients in cartilage, by incorporation of radioactive $^{35}$Sulphate, is a sensitive method often used. However, histological changes take time to develop. To study the pathophysiology, rodent models with histology as primary outcome are often applied. Therefore, histological changes take time to develop and are subject to interpretation. Determining proteoglycan synthesis rate (PSR) in vitro through incorporation of radioactive $^{35}$Sulphate, is a sensitive method previously applied in human tissue and larger animal models to detect early cartilage changes. Isolating cartilage of small animals can be challenging, so a technique to shave off rat cartilage was developed.

**Objective:** To study cartilage degradation following blood exposure, applying the $^{35}$Sulphate incorporation assay on rat tibial cartilage.

**Methods:** A total of 13 factor VIII knock out (F8KO) rats were bred and housed at Novo Nordisk A/S, Maaloev, Denmark. After euthanasia, the legs were removed and transported to UMC Utrecht, The Netherlands.

In vivo: When 24 hours after euthanasia the cartilage of 6 healthy F8KO rats was obtained by shaving off cartilage pieces of the tibia plateau by use of a scalpel. All cartilage explants were cultured for four days; in addition to culture medium, half of the cartilage samples were cultured with 50% v/v whole blood. After four days PSR was determined by adding 4μCi Na$_2$SO$_4$ to the cultures for four hours. $^{35}$SO$_4$ is incorporated into newly synthesized proteoglycans. After digesting the cartilage pieces and precipitating the proteoglycans with cetylpyridinium chloride, the amount of radioactivity was measured by liquid scintillation analysis and normalized to the specific activity of the pulse medium, labeling time and wet cartilage weight.

In vivo: In 7 F8KO rats a unilateral joint bleed was induced by needle puncture and in the following four days until euthanasia, the animals received analgesia. At UMCU, the tibial cartilage was removed and PSR determined as described above.

All animal experiments were performed in accordance with and approved by the Danish Animal Experiments Council, Ministry of Food, Agriculture and Fisheries, Denmark.

**Results:** On average, a total of 1.6mg (0.8–3.1mg) cartilage per tibia could be obtained. The PSR of healthy cartilage determined after four days of culturing in vitro was on average 49.5 nmol/h.g. In vitro blood exposure resulted in a diminished synthesis: 7.7 nmol/h.g (p<0.0191), corresponding to an 84% decrease comparable to previously published experiments using human tissue [1]. In vivo, an induced joint bleed led to a 44% decrease in PSR (13.5 vs. 7.5 nmol/h.g, p=0.0151).

**Conclusions:** This study demonstrates for the first time that PSR, by use of the $^{35}$Sulphate incorporation assay, can be determined in rat tibial cartilage and is affected by blood exposure in vitro and in vivo. As such, this assay can be a valuable tool to detect cartilage changes using joint degenerative rat models.

**EX VIVO BACK-TRANSLATION OF FOSTAMATINIB’S EFFECT ON JOINT ECM TURNOVER SHOWS SIGNIFICANT EFFECT ON BONE BUT NO EFFECT ON THE SYNOVIM**

1Biomarkers and Research, Rheumatology, Nordic Bioscience, Herlev; 2Bioengineering, Technical University of Denmark, Lyngby; 3Orthopaedic surgery Unit, Gentotto University Hospital, Gentotto; 4Biomarkers and Research, Rheumatology, Nordic Bioscience, Herlev, Denmark

**Background:** It is important to establish translational methods that aid in pre-clinical go/no-go decision points to increase the success rate of approved DMARDs. The Spleen tyrosine kinase (Syk) inhibitor Fostamatinib (Fosta) was terminated for development for RA, due to insufficient effect on joint structure in phase III.

**Objectives:** The objective was to use a translational system of ex vivo cultures to back-translate the insufficient effect on joint structure described in clinical studies.

**Methods:** Human mature osteoclasts (HOC) seeded on bone, bovine cartilage explants (BEX) and human synovial explants (SME) were treated with R406 (API of Fosta) at 5μM-0.05μM. Osteoclasts were co-stimulated with 25 ng/ml M-CSF and RANKL, while BEX and SME were co-stimulated with TNFα 2 ng/ml and OSM 10 ng/ml (O=O) or TNFa 10 ng/ml respectively. CTX-1 and CaM were measured in conditioned medium (CM) from HOC. Metabolic activity of HOC was assessed with Alamar Blue. C2M and AGN1x were measured in CM from BEX, while acMMP3, C1M, and C3M were measured in CM from SME. The biomarkers in BEX and SME CM were measured at 4 time points and the total release were quantified by area under the curve (AUC). CTX-1, C2M, AGN1x, acMMP3, C1M, CSM and C3M were measured with ELISA. CaM was measured down to 5μM (P=0.034) and measured down to 0.5μM (P=0.012). In SME R406 only decreased the release of C1M and C3M (Fig 1e) significantly at 5 μM (C1M: P=0.03, C3M: P=0.046), and tended to decrease release of acMMP3 (Fig 1f) at 5μM. The later was however not significant.

**Results:** R406 decreased the release of CTX-1 (Fig 1A) and C2M in a dose-dependent manner, with a significant decrease at 1μM (P<0.01). This might be due to a toxic effect of R406 on HOC (Fig 1B) (P<0.05). R406 decreased the total release of C2M and AGN1x in a dose-dependent manner in BEX. C2M was inhibited a concentrations down to 1.25μM (P<0.034), and AGN1x down to 5μM (P<0.012). In SME R406 only decreased the release of C1M and C3M (Fig 1e) significantly at 5 μM (C1M: P=0.03, C3M: P=0.046), and tended to decrease release of acMMP3 (Fig 1f) at 5μM. The later was however not significant.

**Conclusions:** Serum-based biomarkers of the joint ECM turnover were measured in CM from HOC, cartilage and synovial explant cultures. R406 decreased bone resorption and HOC metabolic activity in a dose–dependent manner, together with the MMP-mediated degradation of type II (C2M) collagen and aggrecanase degradation of aggrecan (AGN1x) in cartilage. However, R406 had limited effect on the inflammation driven MMP-mediated degradation of type I (C1M) and III (C3M) collagen and activation of MMP-3. CTX-1, C2M, and C3M have previously been measured in OSKIRA-1, with a profile identical to the ex vivo measurements here [1].

ADISO763 THE PROTECTIVE EFFECT OF PFTα ON ALCOHOL-INDUCED OSTEONECROSIS OF THE FEMORAL HEAD

C. Yixuan, Orthopedics, Shanghai Jiao Tong University Affiliated Sixth People’s Hospital, Shanghai, China

Background: Epidemiological studies have shown that alcohol plays a pivotal role in the development of osteonecrosis of the femoral head (ONFH). However, few studies have investigated the pathogenesis or interventions for alcohol-induced ONFH.

Objectives: The aim of this study was to explore the underlying mechanism of alcohol-induced ONFH and the protective effect ofpitthrin-α (PFTα).

Results: Through a series of in vitro assessments, we found that ethanol treatment significantly activated p38, suppressed Wnt/β-catenin signaling and inhibited osteogenic-related proteins, including runt-related transcription factor 2 (RUNX2), osteocalcin (OCN), osteopontin (OPN) and collagen I (COL1). Furthermore, by separating the cytoplasmic and nuclear proteins, we found that ethanol inhibited osteogenesis by impairing the accumulation of β-catenin both in the cytoplasm and nucleus in human bone mesenchymal stem cells (hBMSCs), which resulted from activating glycogen synthase kinase-3β (GSK-3β) in this in vivo study, we established alcohol-induced ONFH in rats and investigated the protective effect of PFTα. Micro-C, hematoyxlin & eosin (H&E) staining, immunohistochemical analyses, immunofluorescence staining, TUNEL staining, and immunohistochemical staining were performed to reveal the PFTα-induced therapeutic effects. H&E findings combined with TUNEL, caspase-3/4-cleaved immunohistochemical staining, and micro-CT images revealed obvious ONFH in the alcohol-administered rats, whereas significantly less osteonecrosis developed in the rats injected with PFTα. As the inhibitor of osteogenesis, RUNX2 and its downstream targets OCN, OPN, and COL1 were immunostained in the femoral heads. These results indicated that these osteogenic-related proteins were significantly decreased in the alcohol-administered rats, whereas these results were reversed in the PFTα-injected rats. Fluorochrome labeling showed a similar result in that alcohol significantly decreased the osteogenic activity in the rat femoral head, which was blocked by the injection of PFTα.

Conclusions: Pitthrin-α, a p38 inhibitor, was able to block the ethanol-triggered activation of p38 in hBMSCs and alcohol-induced ONFH in a rat model. Its antagonistic effect against ethanol’s effect on hBMSCs could be a clinical strategy to prevent the development of alcohol-induced ONFH.

ADISO764 ADIPOSE STROMAL CELLS EXERT SPECIFIC EFFECTS ON OSTEOARTHRITIC SYNOVIAL MACROPHAGES

C. Manferti1, F. Paolella1, E. Gabusi1, L. Gambari2, A. Piacentini1, S. Fleury-Cappellessa3, A. Barbero4, M. Murphy1, G. Lisignoli1, 1Laboratory of Immunoochonoqueology and tissue regeneration, 2RAMSES Laboratory, Rizzoli Orthopaedic Institute, Bologna, Italy, 3FES-Pyrénées-Méditerranée, Toulouse, France, 4Department of Biomedicine, University Hospital Basel, Basel, Switzerland, 2Regenerative Medicine Institute, Galway, Ireland

Background: Osteoarthritis (OA) is the most common joint disease and the major cause of pain and disability in the aging population [1]. Adipose stromal cells (ASC) are promising candidate for cell therapy in OA, because they have immunomodulatory, trophic and differentiation capacities [2,3]. Synovial inflammation is accepted as important OA feature for the symptoms and disease progression [4]. Synovial tissue is mainly composed of synovial fibroblasts (SF) macrophages (SM) and a low percentage of other cell types [5].

Objectives: Aim of the study was to analyze the effects of adipose stromal cells in co-culture with SF and SM. Methods: GMP clinical grade ASC were isolated from subcutaneous adipose tissue. Synoviocytes were isolated from synovial tissue of OA patients undergoing total joint replacement. Synoviocyte cultures at passage 1 and 5 were analyzed for: 1. different phenotypical markers by flow cytometric analysis, 2. inflammatory factors by multiplex immunoassay, 3. anabolic and degradative factors by qRT-PCR. Both p.1 (mix of SF and SM) and p.5 (only SF) synoviocyte cultures, as different cell models, were co-cultured with adipose stem cells (ASC) to define their effects. Furthermore macrophages type 1 (M1) were isolated and co-cultured with ASC.

Results: Synoviocytes at passage 1 were positive to typical markers of SM (CD14,CD16,CD68, CD80,CD105,CD106) and SF (CD55,CD73,CD90,CD105,CD106), whereas at passage 5 were only positive to SF markers and showed a higher percentage of CD55 and CD106. P1 synoviocytes cells released a significantly higher amount of all inflammatory (IL6,CXCL8,CCL2,CLL3,CLL5) and anabolic (IL10) factors than those at p.5. Moreover, p.1 synoviocytes cells expressed higher amount of some degradative factors (MMP13, MMP1,S100A9) than p.5 synoviocyte cells. Co-culture experiments showed that the amount of SM in p.1 synoviocytes cells specifically orchestrate the up or down-modulation of some inflammatory (IL6,CXCL8,CCL2,CCL3,CCL5) and degradative factors (ADAMTS5,MMP13,S100A9,S100A8) analyzed. Interestingly, p.5 synoviocytes cells induced all factors analyzed, except COL5. Finally, we demonstrated that ASC effects were strictly dependent by M1, that decreased the release of typical macrophages cytokines (IL1,IL, TNFs and CCL3/MIP1α) and that ASC effects are responsible for the switching by M1 like inflammatory macrophages to M2 like phenotype mainly due to IFNγ only made of the information set out.

Conclusions: These data demonstrate that the GMP-ASC effects on OA synovial inflammation are strictly dependent by macrophages, that the switching activated-M1 inflammatory macrophages to a M2-like phenotype, mainly through PG2E.

ADISO765 2-CARBA-CYCLO PHOSPHATIC ACIDIC ACID SUPPRESSES EXPRESSION OF CARTILAGE DEGRADING ENZYMES SUCH AS MMP-13 IN INFLAMMATORY SYNOVIAL FIBROBLASTS AND ARTICULAR CHONDROCYTES INDUCED BY IL-1 Beta AND/OR TNF ALF.

I. Masuda1,2, K. Okada3, H. Yamanaka1, S. Momohara1,2,4, 1Laboratory of Rheumatology, Tokyo Women’s Medical University, Tokyo; 2Rheumatology, Inst. for Rheumatic diseases, Jyujyo-Takeda Rehabilitation Hospital, Kyoto; 3SANOHO, CO, Ltd; 4Keio University, Tokyo, Japan

Background: Cyclic phosphathic acid (cPA) is one of bioactive lipid, has been implicated as a mediator of various biological effects including inhibitory effects of proliferation, invasion and metastasis of cancer cells. cPA is naturally occurring mediator even in normal human serum, 2-carba-cPA (2ccPA) is structurally modified formula of cPA and has shown improved bioactivity. We have previously confirmed that 2ccPA stimulated HAS-2 production on human osteoarthritic chondrocytes and synovial fibroblasts (SFs) in vitro. Furthermore, intra-articular administration of 2ccPA has shown its suppressing effect of pain, swelling, and articular cartilage destruction in rabbit experimental osteoarthritis (OA). We have established experimental osteoarthritis in rabbits and demonstrated that 2ccPA might had direct inhibitory effect of cartilage degrading enzymes on rheumatoid synovial fibroblasts (SFs) in vitro. Inflammatory arthrits such as rheumatoid arthritis (RA) and early stage of OA involves synovial inflammation and subsequent production of cartilage degrading enzymes also from chondrocytes. 2ccPA may be possible another therapeutic option for degenerative arthrits.

Objectives: The aim of this study was to evaluate the direct effects of 2ccPA on cartilage matrix degrading enzymes using SFs and articular chondrocytes under influence of inflammatory cytokines.

Methods: In vitro studies were performed using SFs and chondrocytes obtained from arthritic patients (RA and OA) at joint replacement surgery. First, 2ccPA 0–25 μM was added to cell cultures and effects of 2ccPA on ADAMTS-4, -5, MMP-3, 9, -13 expression was assessed by real time PCR using specific primers for human transcript. Basic fibroblast growth factor was used as endogenous expression control for PCR. As we confirmed that 2ccPA had dose-dependent inhibitory effects on expression of above enzymes, the second experiment was performed. SFs or chondrocytes were pre-cultured with IL-1β (1 ng/ml) and/or TNF-α (10 ng/ml) for 24 hours, then added 10 μM 2ccPA to study attenuated effect of 2ccPA on synthesis of above cartilage degrading enzymes. Newly synthesized MMP-3, -13 from SFs or chondrocytes in cultured media after 24 hours of 2ccPA addition were measured by sandwich ELISA.

Results: 2ccPA itself repressed cartilage degrading enzymes, ADAMTS-4, -5, MMP-3, -9 and MMP-13 expression in both SFs and chondrocytes. 2ccPA was all repressed by low dose of 2ccPA. Even after cells had been stimulated by cytokines, 10 μM 2ccPA repressed expression of cartilage degrading enzymes in SFs or chondrocytes. Expression of MMP-13 was repressed more in chondrocytes by 2ccPA. ELISA results also confirmed the inhibitory effect of 2ccPA on expression of MMP-3 SFs (n=5) by SD±3 or in RA c3, S100A9 3%–43%. In OA, MMP-13 production was reduced by 31% in OA SFs (n=6) and 34% in OA chondrocytes (n=4). However, not significant reduction of MMP-3 in both SFs or chondrocytes. MMP-9 expression by ELISA was under the detectable limit.
Conclusions: The in vitro results confirmed that 2ccPA had suppressing effect of cartilage degrading enzymes expression on SFs and chondrocytes, supports the hypothesis that 2ccPA might have played direct role to suppress inflammation and also protect articular cartilage in arthritic condition.

AB0066 HUMAN MULTIPOTENTIAL STROMAL CELLS EXPRESS LOW SURFACE LEVELS OF PRO-INFLAMMATORY CYTOKINE RECEPTORS IN BONE HEALING DEFECTS

J.J. El-Jawahri 1, G. Kleitouris 1, Y.M. El-sherbiny 1, R. West 2, E. Jones 1, P.V. Giannoudis 1
1 Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRM); 2 Leeds Institute of Health Sciences, University of Leeds, Leeds, United Kingdom

Background: Osteoimmunology is an evolving field where the multipotential stromal cells (MSCs) can be considered as an important player linking immune response with bone generation. A group of pro-inflammatory cytokines including IFN-γ, TNF-α, IL-17, IL-1β and IL-1α has been proven to have a licensing effect on MSCs promoting the immunomodulatory activities of MSCs (1). Importantly, these cytokines can regulate the osteogenic differentiation capability of MSCs and in particular, IL-1β and IL-1α can enhance the MSC osteogenesis as shown in previous in vitro studies (2,3). However, little is known about the role of these cytokine-MSC interactions in the bone-related diseases in humans.

Objectives: The main focus of this study was to assess if the immune-dependent licensing process of MSCs could be involved in defective bone regeneration.

Methods: We used samples of bone marrow aspirates (n=15) from two groups of traumatic bone fracture patients; normal union and non-union. Bone marrow MSCs were analyzed for the surface expression of the receptors of the pro-inflammatory licensing cytokines using flowcytometry-optimized panels. Additionally, a comparison of the cytokine effect on the proliferation of cultured MSCs was compared between normal union and non-union groups using the cell proliferation XTT test.

Results: Interestingly, there were significant lower expression levels of IL-1 receptors 1 and 3 (IL-1R1 and IL-1R3) on non-union MSCs compared to normal-union MSCs (p=0.0478 and p=0.0113 respectively). Furthermore, the surface levels of TNF-α-R1 (CD120a) were significantly lesser on non-union MSCs (p=0.0119). There was a clear trend of reduced expression of IL-17 receptors (CD217) on the surface of non-union MSCs but it was not statistically significant (p=0.0119). The XTT data showed a significant less proliferation index for IL-1-treated non-union MSCs compared to normal-union (p=0.0726). The XTT data showed a significant less proliferation index for IL-1-treated non-union MSCs compared to normal-union MSCs (p=0.0446). Also, a consistent trend of lower proliferation index of non-union MSCs was detected when these cells were treated by IFN-γ, TNF-α or IL-17.

Conclusions: Together, the lower levels of the pro-inflammatory cytokine receptors indicated a possible mechanism for a defective response of non-union MSCs to the inflammatory signals (particularly IL-1). Further understanding of the impact of immune-MSC interactions on human bone healing and regeneration will help to develop new therapies for musculoskeletal diseases involving osteolytic lesions.

AB0067 INFLUENCE OF ADIPOKINES ON DIFFERENTIATION OF CULTURED SPONGIOSA-DERIVED MESENCHYMAL STEM CELLS FROM OSTEOPOROTIC AND OSTEARTHRITIS PATIENTS

L. Tsiklauri 1, E. Neumann 1, J. Werner 2, K. Frommer 1, R. Engel 1, S. Rehart 3, S. Wenisch 2, U. Müller-Ladner 1
1 Department of Internal Medicine and Rheumatology, Justus-Liebig-University Giessen, Kerckhoff-Klinik, Bad Nauheim; 2 Institute of Veterinary-Anatomy, -Histology and –Embryology, Clinic of Small Animals, Justus-Liebig-University, Giessen; 3 Department of Orthopedics and Trauma Surgery, Apollenius Krankenhaus Hospital, Frankfurt, Germany

Background: Osteoporosis (OP) and osteoarthritis (OA) are two common age-related disorders leading to chronic pain and disability in elderly people. Age-related bone loss and articular cartilage damage are associated with increased bone marrow adiposity due to a possible shift of osteogenic differentiation towards adipogenic differentiation of bone marrow mesenchymal stem cells (MSC). The differentiation of MSC into adipocytes or osteoblasts is an important determinant of bone structural integrity. Adipose tissue is an metabolically active tissue. Therefore adipocyte-derived factors -adipokines- might influence differentiation of bone marrow-derived MSC.

Objectives: The role of adipocyte interactions in the pathogenesis of OP is poorly understood. Therefore, we analyzed the presence of distinct adipokines (visfatin, resistin and leptin) in the bone marrow cavity and their effects on MSC differentiation.

Methods: Spongosia from femoral heads was collected (hip replacement surgery or revision surgery) from patients with a history of osteoarthritis (OA) (n=7, mean age 62±7 years) or non-osteoporotic bone (n=14). In contrast to leptin and resistin, visfatin induced the secretion of proinflammatory cytokines (IL-6, IL-8, MCP-1) during both, osteogenic and adipogenic differentiation. Visfatin significantly increased the matrix mineralization and downregulated collagen type I expression (e.g. fold 4.6) in osteogenic differentiated cells. Visfatin also reduced the expression of MMP2, MMP13, Runx2, Timp1 and Timp2 (e.g. fold 2-4, 3.18-5.85, fold 3.2-4 fold respectively) during osteogenic differentiation, but not leptin and resistin. In contrast to osteogenesis, visfatin significantly induced MMP13 expression (e.g. fold 104.4) during adipogenic differentiation under standard cell culture conditions. However, visfatin-induced MMP13-expression was markedly reduced during differentiation on purified autologous cancellous bone.

Conclusions: Visfatin and leptin levels were increased in OP bone vs. non-osteoporotic bone (n=14). In contrast to leptin and resistin, visfatin induced the secretion of proinflammatory cytokines (IL-6, IL-8, MCP-1) during both, osteogenic and adipogenic differentiation. Visfatin significantly increased the matrix mineralization and downregulated collagen type I expression (e.g. fold 4.6) in osteogenic differentiated cells. Visfatin also reduced the expression of MMP2, MMP13, Runx2, Timp1 and Timp2 (e.g. fold 2-4, 3.18-5.85, fold 3.2-4 fold respectively) during osteogenic differentiation, but not leptin and resistin. In contrast to osteogenesis, visfatin significantly induced MMP13 expression (e.g. fold 104.4) during adipogenic differentiation under standard cell culture conditions. However, visfatin-induced MMP13-expression was markedly reduced during differentiation on purified autologous cancellous bone.

AB0068 HYPOXIA AND RHEUMATOID PHENOTYPE DECREASE THE CAPACITY OF ADIPOCYTES TO SUPPRESS HELPER CELL PROLIFERATION THROUGH IDO1-MEDIATED TRYPTOPHAN CATABILISM

L.-O. Tykocinski 1, N.-C. Kaul 1, I. Adam 2, S.R. Mohapatra 3, S. Krienke 1, G.A. Opitz 1, H.-M. Lorenz 1
1 Department of Medicine V, Division of Rheumatology, University of Heidelberg; 2 Brain Cancer Metabolism, German Cancer Research Center (DKFZ), Heidelberg, Germany

Background: The pathogenesis of rheumatoid arthritis (RA) is linked to functional changes in synovial fibroblasts (SF) and local infiltration of T lymphocytes. Increased synovial inflammation is also associated with a hypoxic joint microenvironment. Oxygen levels in the joints of RA patients are significantly decreased compared to those of osteoarthritis (OA) patients with values of about 22.5mMhg corresponding to ambient oxygen tensions of 3.2%. So far, little is known about the effects of hypoxia on the interaction between fibroblasts and T lymphocytes and its implications on the pathophysiology of RA.

Objectives: The aim of this study was to compare the influence of SF from RA versus OA patients on T helper (Th) cell responses both under normoxic and hypoxic conditions.

Methods: SF were isolated from synovectomy tissues of OA or RA patients, Th cells were isolated from peripheral blood of RA patients or healthy donors. Cell cultures were performed under normoxic or hypoxic (3% O2) conditions. Th cell proliferation was determined by PKH26 labelling and flow cytometry. Cytokine secretion was quantified by ELISA. Indoleamine 2,3-dioxygenase 1

AB0069 SCIENTIFIC ABSTRACTS
(IDO1) expression was analysed by Western Blot and expression of enzymes of the kynurenine pathway by real-time PCR. Tryptophan's kynurenine levels in culture supernatants were quantified by HPLC.

Results: SF strongly inhibited the proliferation of co-cultured TH cells. Tryptophan was completely depleted within a few days in co-cultures of SF and TH cells, resulting in erythrocyte-initiation factor (eIF2α) phosphorylation, TCR:chain down-regulation and proliferation arrest. Blocking of IDO1 completely restored TH cell proliferation, indicating that SF suppressed the proliferation of TH cells through IDO1-mediated tryptophan catabolism. Interestingly, RASF showed a significantly lower IDO1 expression, tryptophan metabolism and a weaker TH cell suppressive capacity compared to OASF. Under hypoxic conditions, the secretion of IFNγ, the expression of IDO1, the tryptophan metabolism and the TH cell suppressive capacity of both OASF and RASF were significantly reduced.

Conclusions: SF suppressed TH cell growth through IDO1-mediated tryptophan catabolism, playing an important role in preventing addipogenic differentiation. TH cell responses under normal conditions. The reduced tryptophan metabolism under hypoxia together with the inferior efficiency of RASF to restrict T cell proliferation likely supports the development of synovitis in RA.

AB0069 STRONG AGE-DEPENDENT EFFECTS OF DOPAMINE ON JOINT INVASION IN ARTHRITIS

L. Van Nie1, S. Rehert2, E. Neumann1, U. Müller-Lachere1, S. Capellino2,

1Department of Internal Medicine and Justus-Liebig-University Gießen, Kerckhoff-Klinik, Bad Nauheim, Bad Nauheim; 2Department of Orthopedics and Trauma Surgery, Apagelus Markus Hospital, Frankfurt am Main, Frankfurt am Main; 3Dept. of Immunology, Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany

Background: Preventing synovial fibroblasts (SF) from migrating into the adjacent cartilage is a desirable therapeutic target in rheumatoid arthritis (RA) in order to avoid joint destruction and disability. In our previous studies we could show that RASF as well as SF from osteoarthritis (OA) patients express all dopamine receptor (DR) subtypes and dopamine stimulation alters pro-inflammatory cytokines (Capellino S et al, AAR 2014).

Objectives: Therefore, we aimed to elucidate a potential dopamine-mediated impact on joint invasion and destruction in arthritis.

Methods: SF from RA and OA patients were obtained from patients undergoing knee joint replacement surgery (mean age: 74.3±11.3yrs at OA and 73.7±10.3yrs at RA patients) to investigate dopamine receptor (DR)-distribution within the RA synovium and in the invasion zone. Immunohistochemistry was performed for all five DR-subtypes. Migration and motility assays were performed under D1-like (D1DR and D5DR) and D2-like (D2DR, D3DR and D4DR) receptor stimulation. Dopamine effects on MMP3 and proMMP1 were evaluated using ELISA. Migration of SF from RA and OA and the invasion zone were studied under hypoxia together with the inferior efficiency of RASF to restrict T cell proliferation. There was no difference between RA and OA patients and between all dopamine receptor (DR) subtypes and dopamine stimulation alters pro-inflammatory cytokines.

Conclusions: SF strongly inhibited the proliferation of co-cultured TH cells. Tryptophan was completely depleted within a few days in co-cultures of SF and TH cells, resulting in erythrocyte-initiation factor (eIF2α) phosphorylation, TCR:chain down-regulation and proliferation arrest. Blocking of IDO1 completely restored TH cell proliferation, indicating that SF suppressed the proliferation of TH cells through IDO1-mediated tryptophan catabolism. Interestingly, RASF showed a significantly lower IDO1 expression, tryptophan metabolism and a weaker TH cell suppressive capacity compared to OASF. Under hypoxic conditions, the secretion of IFNγ, the expression of IDO1, the tryptophan metabolism and the TH cell suppressive capacity of both OASF and RASF were significantly reduced.

Background: Human bone marrow mesenchymal stem cells (hMSCs) exhibit an age-dependent reduction in osteogenesis and an increased propensity toward adipocyte differentiation. This switch has been associated with different bone disorders characterized by reduced bone formation and increased bone marrow fat accumulation. Connexin43 (Cx43) is an integral membrane protein that forms gap junction channels (GJs) and is implicated in multiple cellular functions including cellular differentiation and control of bone remodelling and cartilage structure and function.

Objectives: In this study we investigated the effect of oleuropein and other molecules isolated from the Olea europaea in cellular differentiation to test if these molecules act as adiogenic suppressors in order to promote bone ad cartilage regeneration through a Cx43-dependent mechanism.

Methods: hMSCs were obtained from bone marrow donors. Human chondrocytes were isolated from cartilage of healthy donors and patients with osteoarthritis (OA). Differentiation assays were carried out in the presence of different concentrations of oleuropein and olive extract (OE). Cellular differentiation was evaluated using histological stains. Scrape loading assays, western-blot, real-time qPCR and Western-blot analysis of hMSCs supplemented with oleuropein/OE showed increased levels of Cx43. On the other hand, OA chondrocytes showed higher levels of Cx43 in comparison with normal chondrocytes; oleuropein and OE treatments significantly decreased Cx43 levels and dye transference through GJ channels. The treatment of OA chondrocytes micromass culture with oleuropein and OE increased the expression of proteoglycans and Col2 in the extracellular matrix. These changes in the micromasses were accompanied by a decrease in Cx43 levels improving protein subcellular localization.

Conclusions: Together, our results suggest that the molecules used in this assays, via Cx43 and GJ intercellular communication increase the propensity towards osteogenesis and chondrogenesis, reducing adipocyte differentiation. Our assays indicate that these molecules may represent a potential therapeutic approach for cartilage and bone age-related disorders such as OA in order to avoid joint destruction. We thus conclude that hMSCs treated with olive-derived molecules could be used for cartilage regeneration through a Cx43-dependent mechanism.

AB0071 ANALYSIS OF SYNOVIAL EXPRESSION OF PARVOVIRUS B19 ASSESSED IMMUNOHISTOCHEMICALY AND CORRELATED TO SYNOVITIS SCORE

M. Tarasovs1, A. Kadisa2, A. Mihailova2, S. Skujā3, M. Murovska3, V. Gromaa1, 1Riga Stradins University; 2Department of Internal Diseases, Riga East Hospital Clinic “Gaižieris”; 3Institute of Anatomy and Anthropology; 1A. Kirchenstein Institute of Microbiology and Virology, Riga Stradins University, Riga, Latvia

Background: Apart from systemic symptoms of viral infection parvovirus B19 (B19) could lead to acute and chronic arthropathy. It has been found in synovial tissue of rheumatoid arthritis (RA) patients, sometimes, being associated with some forms of undifferentiated arthritis. Possibly, it could promote inflammation in various forms of arthritis.

Objectives: To determine the expression of B19 antigens in different compartments of synovial membrane; correlate these findings to the estimated synovitis score.

Methods: 7 RA and 54 osteoarthritis (OA) patients were enrolled in this study. nPCR was used to detect the presence of B19 genomic sequence in 61 samples of synovial tissue. PCR B19 positive tissue samples were immunohistochemically treated with the anti-B19 antibodies detecting B19 capsid proteins’ VP1/VP2 expression estimated thereafter semiquantiitatively. The intimal and subintimal layers of synovium as well as vasculature were estimated. Synovial inflammation was evaluated using synovitis score.

Results: 3 RA and 3 OA patients were PCR B19 tissue positive. B19 antigens’ expression was observed in synovial lining, immune infiltrates and vascular endothelium. Correlation between B19 expression observed in synovial cells and inflammatory infiltrates’ lymphocytes and macrophages was r=0.555 (p<0.0001) and r=0.793 (p<0.0001), respectively. Likewise, correlation between vascular endothelial B19 expression and synovial lymphocytic infiltration was demonstrated r=0.616 (p<0.0001). Determined synovitis score varied from low up to intermediate revealing median value 2. Simultaneously, there was no correlation found between the synovitis score and B19 antigens’ expression.

Conclusions: B19 capsid proteins’ VP1/VP2 expression is detectable in different structural constituents of synovial membrane. Under conditions studied, the tissue expression of B19 antigens does not correlate with the inflammatory indices scored.

RATIONAL DESIGNED GOLD NANOPIRATE SUPPRESSES RANKL-INDUCED OSTEOSTALOGENESIS IN RAW264.7 CELLS VIA NF-KAPPA B PATHWAY AND MAPK PATHWAYS

Q. Yuan 1,2, X. Gao 1,2, 1 Key Laboratory for Biological Effects of Nanomaterial and Nanosafety, Institute of High Energy Physics, CAS; 2 Department of Chemistry and Chemical Engineering, Beijing University of Technology, Beijing, China

Background: Bone erosion in joint is the most deleterious effect induced by rheumatoid arthritis (RA) and is the major cause of disability. New therapies are urgently required to prevent RA-associated bone destruction. The excessive bone resorption in RA was proved to be mediated by osteoclasts which are derived from the monocyte/macrophage lineage and induced by RANKL. Therefore, RANKL could be a potential target for the preservation of bone mass in RA.

Objectives: Chrysotherapy showed potential effects in reducing of joint destruction but with serious side-effects in RA therapy. A rational designed gold nanoparticle named GN was prepared to provide a choice for suppressing bone loss in RA therapy with more safety.

Methods: Mouse macrophage cell line RAW264.7 was activated by RANKL to evaluate the potential osteoclastogenesis suppressing effects of GN. The differentiation, fusion and function of osteoclast were assessed by tartrate-resistant acid (TRAP) staining, actin ring formation assay and osteologic discs detection respectively. Relative expressions of osteoclast-specific genes were evaluated by RT-PCR and the activity of NF-κB pathway as well as MAPK pathways were analyzed by immunoblotting.

Results: Osteoclast differentiation, fusion and bone resorption were activated by RANKL in RAW264.7 cell, while GN significantly attenuates this process in a dose-dependent manner. The expressions of osteoclast-specific genes including TRAP and OSCAR were increased by RANKL stimulation but were effectively suppressed by GN. The activation of NF-κB pathway and MAPK pathways induced by RANKL was also suppressed by GN treatment.

Conclusions: Our findings revealed that treatment with GN could prevent RANKL-induced osteoclastogenesis and reduce increased expression of osteoclast-specific genes which may through the suppression of NF-κB and MAPK activation in macrophage. GN may provide a basis for the design of chrysotherapy drugs that effect in progression of RA-associated articular erosions.

ACCUMULATION OF ADVANCED GLYCAATION END PRODUCTS (AGEs) IN OSTEARTHRITIC CARTILAGE IS RELATED TO AN IMPAIRMENT OF THE ADAPTIVE MECHANISM OF GLYXALASE-1

S. Trelu 1, A. Courtess 1, S. Jaisson 2, B. Friguet 1, X. Houdard 1, F. P-E. Fichot 1, C. Jacques 1, F. Berenbaum 1, J. Sellam 1, 1 UPMC Univ Paris 06, Inserm UMR_S 938, Rheumatology department, AP-HP, Saint-Antoine Hospital, Paris; 2 University of Reims Champagne-Ardenne, UMR CNRS 7369, Laboratory of Biomechanics, Biology and Immunobiology, Reims, France 02 8256, Biological Adaptation and Ageing-IBPS; 1 UPMC Univ Paris 06, Inserm UMR_S 938, Saint-Antoine Hospital; 2 Groupe Mauquis, Clinique des Mauquis-Ramsay, General de Sante, Paris, France

Background: Advanced glycation end-products (AGEs) that result from a non-enzymatic reaction between a sugar and a protein, are generated during tissular ageing. Accumulation of AGEs could also be part of the osteoarthritis (OA) process by modifying the biomechanical properties of cartilage and by inducing chondrocyte activation. Glyxalase-1 (Glo-1) is the main enzyme involved in the removal of AGEs precursors, especially the AGE carboxymethyllysine (CML).

Objectives: We aimed to quantify CML in human osteoarthritic cartilage, to investigate Glo-1 expression in chondrocytes and to study chondrocytic Glo-1 regulation in an inflammatory context.

Methods: 1) Ex vivo: Osteoarthritic cartilages from patients undergoing knee replacement were collected, dissected and incubated for 24h with or without IL-1β (5 ng/mL). Osteoarthritic CML in these cartilage explants was measured using liquid chromatography and mass spectrometry. Glo-1 protein expression (Western Blot and immunohistochemistry) and Glo-1 enzymatic activity by measuring the kinetic release of particles or ions from arthroplasty may exert local effects in the peri-prosthetic tissue. Cobalt and chromium ions are released through corrosion from metal-on-metal arthroplasty and modulate the gene expression level of several cytokines, chemokines and other mediators in bone cells.

Objectives: It was the aim of the study to analyse the effect of Co2+ and Cr3+ ions on the expression of TGF-β isoforms in bone forming cells and their impact on mineralization.

Methods: The study investigated the effect of Co2+ and Cr3+ ions on the expression of TGF-β1-3 in the human osteosarcoma cell lines (MG63 and SaOs2) and primary human osteoblasts. Cells (3x105) were seeded in 2 ml DMEM (10%FCS) into 12 well plates and stimulated with CoCl2 and CrCl3 in concentrations between 50–250 μM for 24 hours. Total RNA was extracted and changes of expression levels of TGF-β1-3 were analysed by real-time PCR using sequence-specific primers and probes. For mineralization cells were cultivated for up to 4 weeks in DMEM (10% FCS) supplemented with 0.2mM ascorbic acid, 10nm dexamethasone and 10mM gliceroxide and Co2+ and Cr2+. Calcium deposits were detected by 1% Alizarin Red S (pH 4.1) staining.

Results: The osteoarthritic cells as well as primary human osteoblasts isolated from bone explants expressed all three TGF-β isoforms, with TGF-β1 as most abundantly expressed isoform. A dose dependent reduction of all TGF-β isoforms by Co2+ ions was observed, the strongest effect was found for TGF-β2. In MG63 cells and primary osteoblasts the mRNA levels of TGF-β2 decreased to 15±4% and 17±15% compared to the unstimulated control. The effect was lesser in SaOs2 cells with a reduction to 61±7% compared to control. In contrast to bivalent Co ions, the trivalent Cr ions had no significant effect on the expression of all TGF-β isoforms.

Conclusions: The results of our study show that bivalent cobalt ions and trivalent chromium ions have different effects on bone forming cells. While Co2+ affects the expression of the different TGF-β isoforms in osteoblast-like cells and primary osteoblasts, no inhibitory effect on mineralization in the tested concentrations was seen. Cr3+ however, did not influence the expression of TGF-β but strongly inhibited the mineralization in vitro.

Our data imply that the inhibitory effect of metal ions such as Co and Cr ions on the transcription of the bone regulating cytokines TGF-β1-3 and on bone forming activity may influence bone homeostasis.

TARGETING IMMUNE AND NON-IMMUNO SYNOVITIS BY 1,3,5-TRIZINE-THIAZOLE VIA DUAL INHIBITION OF NF-KB AND EGFR-TK IN POSSIBLE BENEFIT IN RHEUMATOID ARTHRITIS

U.P. Singh 1, J.K. Shrivastava 1, A. Verma 1, H.R. Bhat 1, 1 Department of Pharmaceutical Sciences, Sam Higginbottom University of Agriculture, Technology & Sciences, Allahabad; 2 Department of Pharmaceutical Sciences, Dibrugarh University, Dibrugarh, India

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease which is easily recognised by unrelenting inflammation, joint erosion, joint immobility and severe debilitation. The cause of the disease suggests that, T cells, B cells, macrophages, and dendritic cells gain access to the inflamed synovium causing progression of disease via generation of cytokines and autoantibodies.

Methods: The study investigated the effect of Co2+ and Cr3+ ions on the expression of TGF-β isoforms in bone forming cells and their impact on mineralization.

Results: The osteoarthritic cells as well as primary human osteoblasts isolated from bone explants expressed all three TGF-β isoforms, with TGF-β1 as most abundantly expressed isoform. A dose dependent reduction of all TGF-β isoforms by Co2+ ions was observed, the strongest effect was found for TGF-β2. In MG63 cells and primary osteoblasts the mRNA levels of TGF-β2 decreased to 15±4% and 17±15% compared to the unstimulated control. The effect was lesser in SaOs2 cells with a reduction to 61±7% compared to control. In contrast to bivalent Co ions, the trivalent Cr ions had no significant effect on the expression of all TGF-β isoforms.

Conclusions: The results of our study show that bivalent cobalt ions and trivalent chromium ions have different effects on bone forming cells. Rheumatoid arthritis - etiology, pathogenesis and animal models

AB0076 PERIODONTAL MICROBIA IN EGYPTIAN RA PATIENTS AND THEIR RELATION TO SERUM AND GINGIVAL ANTIBODIES AND OTHER DISEASE PARAMETERS

A.A. Abdelati. Internal Medicine, Rheumatology Unit, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Background: A possible infectious trigger for RA is suspected at the gingival site. Emerging data implicates the microbiome in RA pathogenesis. Mucosal sites representative of the initial site of autoimmune generation. If validated, these findings could lead to the discovery of potential biomarkers and therapeutic approaches in the pre-clinical and clinical phases of RA.

Objectives: To determine the causes causing periodontitis in Egyptian RA patients and their relation to serum and gingival ACPA level and other disease parameters.

Methods: This study was carried out on 100 Egyptian RA patients fulfilling the 2010 ACR/EULAR classification criteria for RA and of less than 5 years disease duration, recruited from Rheumatology Unit, outpatient clinic and Dental clinic at Alexandria Main University Hospital. RA disease activity was assessed by applying DAS28 and functional state of the patients was assessed by applying HAQ score. Dental examination, serum RF, and ACPA in serum and GCF were done for all patients. X-ray of both hands to detect erosions and severity of the disease.

Results: Of the 100 patient, 66 patient had periodontitis, for them, GCF culture was performed and Porphyromonas gingivalis, Aggregatibacter actinomycetemcomitans, and Prevotella intermedia were found in 60.8%, 15.2%, and 30.3% of RA patients with periodontitis respectively. Gingival ACPA was detected in the 3 studied organisms, being of significant higher level with P. gingivalis than P. intermedia (p=0.047).

Conclusions: P. gingivalis is the most prevalent periodontal microbiota in Egyptian RA patients with periodontitis, that associated with significant higher level of gingival ACPA. None of the detected organisms correlated with the degree of RA activity or other disease parameters, apart from significantly higher CRP level with A. actinomycetemcomitans.

TRANSDERMAL DELIVERY OF METHOTREXATE IN RHEUMATOID ARTHRITIS: ARE WE DEEP ENOUGH?

1Pharmacology, Bombay College of Pharmacy, Mumbai; 2Radiopharmaceuticals Program, Board of Radiation and Isotope Technology (BRIT); 3Small Animal Imaging Facility, Advanced Center for Treatment, Research and Education in Cancer (ACTREC), Navi Mumbai, India

Background: Methotrexate (MTX), at low doses, is the first choice in the management of rheumatoid arthritis (RA). Despite its effectiveness, the probability of its discontinuation remains high due to adverse effects such as gastrointestinal intolerance, bone marrow toxicity as well as hepatotoxicity with conventional oral and parenteral therapy. Transdermal delivery epitomizes an attractive alternative for drugs with systemic toxicities. The physicochemical characteristics of MTX such as high polarity and ionisation at physiologic pH make the development of its topical route of delivery challenging. A new class of liposomes termed deformable or flexible liposomes have been reported to possess the virtue of stratum corneum and increase the depth of skin penetration.3

Methods: MTX entrapped in deformable liposomes were prepared and characterised for particle size (PS) and entrapment efficiency (EE). They were incorporated into a hydroxyethyl cellulose gel base and evaluated for ex vivo skin permeation. Optimized liposomal gel was applied on the back of rats (3x4 cm area) and evaluated for its acute dermal toxicity and pharmacokinetics. Biodistribution was studied by topical application of 125I labelled MTX incorporated liposomal gel in rats. Furthermore the efficacy of optimized gel was determined in collagen induced arthritis (CIA) in rats.

Results: The optimized deformable liposomes exhibited a small PS of 110±20 nm and EE 35–50% while the liposomal gel showed a transdermal flux of 17.37±1.5 μg/cm²/hr in ex vivo skin permeation study. Topical application of liposomal gel demonstrated no clinical abnormalities or pathological changes at the site of application in rats. Pharmacokinetic data indicated sustained systemic delivery of MTX from its liposomal gel up to 48 hours. The gel resulted in lower accumulation of MTX in liver, kidneys and gut in contrast to intravenous administration of plain125I labelled MTX solution. In the CIA model, topical MTX gel administration demonstrated significant reduction in hind paw swelling and arthritic score, also validated by histological and radiographic examination of ankle joints and lowering of serum levels of cytokines like TNF-α and IL-6 in comparison to disease control group.

Conclusions: The liposomal gel delivered dermal safety, sustained systemic delivery of MTX at its lower distribution to the organs of toxicity which may enable alleviating systemic side effects. Moreover, topical gel of MTX holds appreciable therapeutic efficacy in the CIA model.

AB0080 MODULATION OF IMMUNOGLOBULIN G2B BINDING IN COMBINATION OF METHOTREXATE AND ACONITE IN A COLLAGEN-INDUCED ARTHRITIS SETTING

D.S. Oh, G. Park, S.H. Lee. The K-herb Research Centre, Korea Institute of Oriental Medicine, Daejeon, Korea, Republic Of

Background: Our previous study showed synergistic responses in TNF-alpha (TNF-α) and interleukin-6 with the combination of methotrexate (MTX) and aconite. Modulation of those cytokines has not been applied to rheumatoid arthritis (RA)-mimicked in vivo models.

Objectives: To translate in vitro effects of MTX, aconite, and MTX/aconite combination towards anti-arthritic responses in vivo, we investigated arthritis index (AI), histopathologic changes, and levels of TNF-α, immunoglobulin G (IgG) 2a and 2b in a collagen-induced arthritis (CIA) setting.

Methods: CIA was induced in male DBA/Claitlnd mouse group by intradermal injection of bovine collagen type II and Complete Freund’s Adjuvant. In Day21, a bovine collagen type II and Incomplete Freund’s Adjuvant were given for booster infection. The mice of arthritis onset were treated daily throughout Day49 with per oral administration of pre-investigated ratios of three to one; MTX (3 mg/kg), aconite (Aconibal®, 1 mg/kg), and MTX/aconite (3 and 1 mg/kg) combination. The AIs were evaluated every week. Histological changes, levels of TNF-α as well as IgG2a and IgG2b in blood using ELISA kit were evaluated at finals. Repeat measure and one-way ANOVA were analysed using SPSS (ver. 18.00.0, Windows; SPSS Inc., Chicago, IL, USA) to evaluate inter-period and inter-group differences with Tukey’s post-hoc tests.

Results: The CIA phenotypes adequately presented through three groups’ AI reductions (CIA vs. MTX, aconite, or MTX/aconite; p<0.001, for three). There were differences of AI scores in aconite group from MTX one in week 4, 5, and 6 (MTX vs. aconite; p=0.038, p=0.001, p=0.042, respectively). Synergistic responses of AI were not shown any of three groups. The recoveries of synovial tissues were observed in MTX and MTX/aconite groups. The levels of TNF-α were not changed (aconite vs. MTX/aconite; p=0.200 and MTX vs. MTX/aconite; p=0.700). MTX group showed IgG2a reduction (CIA vs. MTX; p<0.001). Interestingly, MTX/aconite combination and aconite group slightly downregulated IgG2b levels as 89.845.6% and 90.5±7.4%, respectively (CIA vs. MTX/aconite; p=0.001 and CIA vs. aconite; p=0.010).

Conclusions: Synergistic in vitro effects of MTX and aconite combination brought...
the partial in vivo phenotypic responses: Acomite showed more Al changes than MTX did in 4, 5, and 6 weeks. However, we found the presence of partial FcγRIIB affinity of binding modulation that MTX/Acomite could enhance preventing monocye/macrophage activation via immune complex in RA pathogenesis, as was other benefits of the combination except direct synergies.

D. Damgaard1,2, M.E. Bjønn1, C.H. Nielsen1,2,1 Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Institute for Inflammation Research; 2Department of Odontology, Faculty of Health and Medical Sciences, University of Copenhagen, Section for Periodontology, Microbiology and Community Dentistry, Department of Odontology, Faculty of Health and Medical Sciences, University, Copenhagen, Denmark

Background: Protein citrullination is catalysed by peptidylarginine deiminase (PAD) and plays an important pathogenic role in anti-citrullinated protein antibody (ACPA)-positive rheumatoid arthritis (RA), and possibly in other inflammatory diseases. PAD activity is dependent on calcium and reducing conditions.

Objectives: To determine the ability of H2O2 and reactive oxygen species (ROS) induced by the nitricamide adenine dinucleotide phosphate (NADPH) oxidase to regulate PAD activity.

Methods: Activity of recombinant human (rh) PAD2, rhPAD4 and PAD4 released from phorbol 12-myristate 13-acetate (PMA)-stimulated leucocytes was measured using an in-house PAD activity assay detecting citrullination of fibrinogen. PAD2 released from cells was measured using a luminex-based assay. The NADPH oxidase inhibitor diphenyleneiodonium (DPI) was used to inhibit ROS production in cells.

Results: At concentrations above 40 μM, H2O2 inhibited the catalytic activity of reduced rhPAD2 and rhPAD4. The inhibitory effect increased with increasing H2O2 concentration, reaching complete abrogation at 600 μM. PMA-stimulated leucocytes showed markedly higher PAD activity following inhibition of ROS formation with DPI. At a concentration of 10,000 μM, exogenously added H2O2 inhibited the catalytic activity of PAD released from PMA-stimulated leucocytes.

Conclusions: The ROS H2O2 directly inhibits enzymatic activity of PAD, and generation of ROS by NADPH oxidase down-regulates the activity of PAD released from stimulated leucocytes. This mechanism may play an important role in preventing hypercitrullination of proteins and thereby generation of self-antigens in RA.

D.M.S.H. Chandrupatla1, C.F.M. Molthoff2, E. Elshof2, W. Ritsema2,3, W. Ritsema2,3 Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Institute for Inflammation Research; 2Department of Odontology, Faculty of Health and Medical Sciences, University of Copenhagen, Section for Periodontology, Microbiology and Community Dentistry, Department of Odontology, Faculty of Health and Medical Sciences, University, Copenhagen, Denmark

Background: Alkaline phosphatase (AP) functions as a gate-keeper of the innate immune system [1] by detoxifying inflammation triggering moieties (ITMs). As an eptophosphatase, AP thus acts extracellurally by dephosphorylating ITMs that originate and are released from endogenous sources, e.g. by converting ADP and ATP nucleotides into adenosine to establish a key signalling anti-inflammatory effect. Consequently, AP activity prevents the production of pro-inflammatory cytokines by activated leucocytes and their downstream effects. Due to its broad mechanism of action, AP may potentially serve as an attractive therapeutic moiety in chronic inflammation disorders, including rheumatoid arthritis (RA).

Objectives: To examine the anti-arthritic effects of prophylactic and therapeutic AP interventions in arthritic rats.

Methods: Wistar rats were immunized twice with methylated bovine serum albumin (mBSA), followed by local arthritis induction (intra-articular i.a.) mBSA injection with 3 repeated injections) in the right knee (arthritic knee) with the contralateral left knee serving as internal control [2]. Interventions were performed using 200 μg human recombinant placental AP, administered subcutaneously, either before i.a. mBSA injections (2x, every 3 days, 2 rats/group; prophylactic setting) or after arthritis induction (4x, every 3 days, 4 rats/group; therapeutic setting). AP treatment, ex vivo tissue sections, knees were dissected, cryo-processed, embedded in paraffin and paraffin-embedded. Knee sections were examined for synovial macrophage infiltration by immunohistochemistry with ED1 (CD68) and ED2 (CD163) macrophage specific antibodies. Results were compared with untreated arthritic rats and arthritic rats receiving MTX therapy (1 mg/kg, intraperitoneally, 4x, every 3 days, 4 rats/group).

Results: Prophylactic and therapeutic schedules of AP treatment were well tolerated and reduced knee swelling comparable with MTX treatment. Following AP prophylactic intervention, synovial macrophage infiltration in the arthritic setting was reduced 4-fold (ED1) and 6-fold (ED2) when compared with affected knees of untreated arthritic rats, approaching macrophage counts in contralateral (non-arthritic) knees of AP treated rats. Therapeutic AP interventions resulted in 3.5-fold lower synovial infiltration of both ED1 and ED2 macrophages in arthritic knees, comparable with effects of MTX treatment.

Conclusions: AP, both as prophylactic and as therapeutic intervention, demonstrated favourable anti-arthritic efficacy in a rat model of arthritis. These studies warrant further preclinical and clinical evaluation as a putative novel therapeutic entity for arthritis.

Menchaca”, Guadalajara, Mexico

Background: The role of adipose tissue in RA pathogenesis has been acknowledged since the high frequency of dyslipidemia and insulin resistance in these patients. Leptin, a pleiotropic adipokine, has been associated with inflammation markers and articular damage in RA and the anti-citrullinated protein antibodies. Notwithstanding, these findings have not been consistent across different populations. These points towards that single nucleotide polymorphism (SNP) in leptin and its receptor might influence the participation of this adipokine in RA pathogenesis.

Objectives: To determine the association of the SNPs LEP -2548 G>A and LEPR +668 A>G with adiposity, metabolic and inflammation markers in RA patients.

Methods: We enrolled 116 patients with RA (ACR 1987) matched with 133 control subjects by age, gender, body mass index (BMI) and overweight/obesity. There was no difference in genotypes distribution of LEP -2548 G>A and LEPR +668 A>G were determined by PCR-RFLP using Hhal and MspI restriction enzymes. Results: There was no difference in genotypes distribution of LEP -2548 G>A and LEPR 668 A>G between RA and control. LEPR 668 A=G was associated with higher anti-CCP titers and disease activity score compared to LEPR 668A/A homozygotes, 4.2±1.7 vs. 3.46±1.2 P=0.012. LEPR -2548A allele was associated with younger age of RA diagnosis vs. G/G homozygotes, 35.8±11.5 vs. 41.8±13.9 years old (P =0.045). OR for diagnosis before 40 years old was 2.7 (95%CI 1.04 – 7.45).

Conclusions: LEP -2548 G:A is related with a younger age at diagnosis of RA and LEPR 668 A=G was associated with increased anti-CCP titers and disease activity. This suggests that there is an additive effect between chronic inflammation of RA and obesity were leptin may favor humoral immune response against citrullinated proteins and influence the severity of RA.

AB0084 BREADTH OF BASELINE AUTOANTIBODY PROFILE AND TREATMENT RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS

V.F.A.M. Derksen1, E.C. de Moel1, L.A. Trouw1, R.J. Geekoop2, I. Speyer3, T.W.J. Huizinga1, G.F. Ailait1, R.E.M. Toes1, D. van der Woude1.

1Rheumatology, Leiden University Medical Center, Leiden; 2Rheumatology, Haga Hospital; 3Rheumatology, Haaglanden Medical Center, The Hague, Netherlands

Background: Seropositive and seronegative rheumatoid arthritis (RA) are distinct disease entities with regard to pathophysiological mechanisms and disease outcomes. However, over the past years it has become clear that the autoantibody profile of seropositive RA is very diverse, involving multiple post-translational modifications and isotypes, and it seems unlikely that a single autoantibody will be informative for identifying groups at risk of poor treatment response. Instead of individual autoantibodies, we hypothesized that the breadth of seropositive patients’ profile may be the best reflection of the underlying immunopathology, and would be able to identify homogenous treatment response and inform treatment decisions.

Objectives: To investigate whether baseline autoantibody profile is associated with treatment response and the ability to taper off medication in RA patients.

Methods: All RA patients fulfilling the 2010 ACR/EULAR Criteria included in the IMPROVED study1 that were seropositive for routine clinical testing for anti-cyclic citrullinated peptide-2 (anti-CCP2 IgG), rheumatoid factor (RF IgM), or our in-house assay for anti-carbamylated protein antibodies (anti-CaP IgG) were selected (n=381). In baseline sera of these patients, we measured IgG, IgM, and IgA isotypes for each family (except IgG for RF) and reactivity against 4 citrullinated peptides (cit-vimentin 59–74, cit-fibronogen 36–52 and α–27–43, and cit-elosine 5–20). We investigated associations between autoantibody profile and 1) change in disease activity score (DAS)-44 over time and 2) sustained drug-free remission, defined as the ability to taper off medication and remain in remission for ≥1 year after achieving DAS44<1.6.

Results: The initial treatment response (mean ∆DAS 0–4 months) in seropositive patients with a broad autoantibody profile (7–8 isotypes present) was better than in those with fewer isotypes present (∆DAS 0–4 months of 7–8 isotypes vs 1–2, 3–4, and 5–6 isotypes, respectively: -2.2 vs -1.5 [p<0.001], -1.7 [p<0.04], and -1.8 [p<0.04]). In contrast, the presence of multiple autoantibodies was unfavorable regarding the long-term outcome of sustained drug-free remission.

Within seropositive disease, patients with more isotypes and more reactivities to citrullinated peptides significantly less often achieved sustained drug-free remission (SDFR) (Figure).

AB0085 INTERACTION OF HLA-SHARED EPITOPE (SE) AND SMOKING ON THE DEVELOPMENT OF ANTI-CCP POSITIVE RHEUMATOID ARTHRITIS IN GREEK POPULATION

E.N. Mole1, K. Tarassi2, V. Kitsiou2, T. Athanassiades3, D. Kouniaki2, K. Soufleros2, C. Korkou1, A. Tsirogianni2, C. Sfontouris1.

1Rheumatology, Leiden University Medical Center, Leiden; 2Rheumatology, Haga Hospital; 3Rheumatology, Haaglanden Medical Center, The Hague, Netherlands

Background: Rheumatoid Arthritis (RA) is a complex, multifactorial autoimmune disease, whose etiopathogenesis involves genetic and environmental factors.

Objectives: The aim of the study was the assessment of the association of HLA-DRB1*SE in the presence/absence of anti-CCP autoimmunity in Greek patients with RA (smokers and non-smokers).

Methods: Eighty-three (83) RA patients (41 smokers, 42 have never smoked) were typed for HLA-DRB1* alleles by molecular techniques (PCR-SSOP and -SSP). In 62 out of 83 (74.7%) anti-ccp abs were detected by ELISA.

Results: In RA pts and in comparison to the controls, increased frequency of HLA-DRB1*01:01 (28.9% vs 6.8%, OR=4.4), 10.01 (16.9% vs 2.4%, OR=8.4), 04.04 (7.2% vs 2%, OR=1.8), 04.03 (7.2% vs 1%, OR=7.6) and 04.05 (15.7% vs 3.7%, OR=4.8), as well as decreased frequency of 04.02 (1.2% vs 2%, OR=0.6) and 04.03 (4.8% vs 6.8%, OR=0.7) were found. Among the RA patients, 77.1% possess 1SE vs 18.9% of controls (OR=14.4), whereas 10.8% possess 2SE vs 1% of controls (OR=11.8). In CCP (+) RA patients and in comparison to CCP (-) patients, we assessed the association of HLA-DRB1*01:01 (27.4% vs 14.3%, OR=2.3) and 10.01 (21% vs 4.8%, OR=5.3) was observed. Furthermore, 88.7% of CCP (+) carry 1SE vs 42.9% of CCP (-) patients (OR=10.5). CCP (+) smokers patients in comparison to CCP (+) non-smokers are presented with an increased frequency of DRB1*01:01 (41.9% vs 12.9%, OR=4.9). Among the CCP (+) smokers, 96.8% possess 1SE vs 80.6% of CCP (+) non-smokers (OR=7.2), whereas 12.9% possess 2SE vs 12.9% of CCP (+) non-smokers (OR=1).

Conclusions: a) An increased frequency of HLA-DRB1*01:01, 10.01, 04.05 alleles, as well as the protective role of 04.02, 04.03 alleles in Greek patients with RA were confirmed b) The presence of any SE, particularly *01:01 allele, strongly influences the production of anti-CCP abs and c) Interaction between smoking and any SE, particularly *01:01 allele, is associated with anti-CCP positive RA in Greek patients.

AB0086 PREVENTIVE EFFECTS OF ANGIOTENSIN 1-7 ON NEOANGIOGENESIS AND LEUKOCYTE TRAFFICKING INCREASE IN THE EARLY PHASES OF AN EXPERIMENTAL MODEL OF ANTIGEN INDUCED ARTHRITIS

F. Fischetti, P. Durigutto, D. De Nardo, R. Carretta. University of Trieste Italy, Trieste, Italy

Background: Renin Angiotensin System (RAS) might be supposed to be involved in the early and late phases of development of synovitis, since data exist showing that Angiotensin (AT)-II contributes to the development of vascular damage under early inflammatory conditions (1, 2). Little is known about AT 1–7 functions, which is supposed to play counteracting actions vs AT II, under these conditions (2, 3).

Objectives: to evaluate if, in the early phases of an experimental model of arthritis, namely the antigen-induced arthritis (AIA), treatment with AT 1–7 could interfere with the synovial development of capillary vascular growth, and prevent leukocyte trafficking activation, in vivo, either at synovial and at mesenteric post-capillary venules.

Methods: in compliance with European (86/609/EEC) and the Italian (D.L.116/92) ethics committees, 2 groups each of 8 male (240–270 gr) Wistar rats were randomly chosen and treated respectively with sterile saline, or with AT 1–7 (576 μg/kg/day), during the time of immunization with methylated serum bovine albumin (mBSA). Arthritis was induced by intracutaneous administration of mBSA (0.1mg in 100ml sterile saline) into the right knee of each animal, after previous immunization to mBSA emulsified in complete Freund’s adjuvant. The left knee, injected with the same volume of sterile saline, served as a control. Then, aortic arch, artheritic joint, the count of capillary branches, and the number of fluorescently-labelled leukocytes, showing transient or stable adhesion to the endothelial microvascular layer (EL), were assessed by using an in vivo videomicroscopy technique.

Results: synovial branchung vessels with diameter >20μm were not modified after AIA induction, while microvessels having diameter less than 20 μm were significantly increased. After 2 and 5 days, AT 1–7 reduced the number of neo expressed <20μm diameter vessels (Day2: 3.7±3.4 vs 7.7±5.05, p=ns; Day5: 12.7±6.9 vs 21.0±7.3, p<0.05; both significantly greater than control joints). Transient and stable adhesion to EL showed to be partially reduced 2 days after AIA induction and significantly reduced after 5 days (Day5, transient=12.5±6.2 vs 26.0±9.0, p<0.05; stable=27.0±8.3 vs 41.7±10.6, p<0.05; both significantly greater than control joints). Comparable results were found when analysing the number of leukocytes adhering to mesenteric EL.

Conclusions: we suggest that AT 1–7 could play an immune modulating role in the early phase of synovitis with possible prevention of further inflammatory and secondary structural tissue alterations. These data further support the hypothesis that mechanisms leading to synovial AT-II activation have a detrimental role in the development of arthritis.
SONIC HEDGEHOG PROMOTES FIBROBLAST-LIKE SYNCOYOCITES PROLIFERATION VIA MODULATING THE MAPK/ERK SIGNALING PATHWAY IN RHEUMATOID ARTHRITIS

F. Liu1, S.-L. Zhu2, Y.-F. Pan1, J.-L. Huang1, 2Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University; 2Rheumatology, The Sixth Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: The Sonic hedgehog (Shh) signaling pathway has been reported to be activated in synovium of RA patients and RA-FLS in vitro [1]. Further, Shh signaling plays an important role in RA-FLS proliferation [2]. As for the extracellular signal-regulated kinase (ERK), is a member of mitogen-activated protein kinase (MAPK) [3], which has been reported to be involved in proliferation of RA-FLS [4]. However, the role of MAPK/ERK signaling pathway in the proliferation of RA-FLS modulating by Shh is unclear.

Objectives: To study the effect of MAPK/ERK signaling pathway on cell proliferation modulated by Sonic hedgehog (Shh) signaling in fibroblast-like synoviocytes isolated from patients with active rheumatoid arthritis (RA-FLS).

Methods: The RA-FLS were primarily cultured by the explant culture, and then were treated with Shh agonist Purmorphamine, inhibitor Cyclopamine or MAPK/ERK signaling pathway inhibitor U0126, respectively. Western blots was used to examine the phosphorylation level of ERK 1/2 (p-ERK1/2), which was the critical protein of MAPK/ERK signaling. The cell proliferation activity was detected using cell proliferation and cytotoxicity kit-8 (CCK8), and the cell proliferation rate was detected using a flow cytometry.

Results: Compared with the control group, Purmorphamine transiently increased p-ERK1/2 protein at the concentration of 1 μM, and the peak activations of p-ERK1/2 took place at 15min (P < 0.01). Cyclopamine and U0126 decreased the expression of p-ERK1/2 protein (P < 0.01). After the RA-FLS treated with Purmorphamine (1 μM) for 48 hours, the cell proliferation activity was 114±54% and the percentage of S phase cells was 8.39±0.60%, significantly higher than those of the control group 100±5% (P < 0.01) and 3.29±0.69% (P < 0.01). After treated with Cyclopamine (10 μM) for 48 hours, the cell proliferation activity of RA-FLS was 89±1% (P < 0.05) and the percentage of S phase cells was 1.53±0.22% (P < 0.05). When co-treated with purmorphamine (1 μM) and U0126 (10 μM), the cells proliferative activity was 89% (P < 0.05) and the percentage of S phase cells was 1.70±0.25% (P < 0.05).

Conclusions: Shh might promote proliferation of RA-FLS via modulating MAPK/ERK signaling, subsequently contributing to hyperlasia of synovium and ultimately leading to RA disease.

AB0089 ELECTROKINETIC CHARACTERISTICS OF SYNCOYOCITES (SC) AND THE LEVEL OF ANTIOXIDANT PROTECTION IN RHEUMATOID ARTHRITIS (RA)

G. Kudryavtseva, VI. Shishkin, V.V. Shishkin, YA. Malenkov. Saint Petersburg State University, Saint Petersburg, Russian Federation

Background: Known role of SC in the pathogenesis of RA. It is impossible, however, at this level of knowledge to ascertain all the mechanisms for their involvement in the pathological process. Reduced tissue antioxidant protection can affect cellular metabolism, and as might be expected, through the mechanism of autophagy inducing mitochondrial and lysosomal degradation, facilitating cell membrane depolarization.

Objectives: The aim of this work was to study the electrophoretic mobility (EM) of SC of RA patients and its relationship with the activity of antioxidant enzymes: Cu-Zn superoxide dismutase (Cu-Zn SOD), Se-glutathione peroxidase (Se-GPO) and catalase (CAT).

Methods: SC has been obtained from the knee of 7 patients with RA and 5 donors. SC isolated by standard methods. EM of SC determined by the automatic microscope. Se level in SC determined by atomic absorption spectrometry. The activity of the antioxidant enzymes was determined by classical methods of enzymology.

Results: A significant depolarization of the RA SC, resulting in a reduction of their EM as compared to the normal level of the average in 4 times. Activity of antioxidant enzymes is dramatically reduced by a significant decrease of Se concentrations in SF (150 μg/l normally up to 80 μg/l in RA), which is particularly reflected in the activity of Se GPO (note that SC can be up to 100 Se-containing proteins).

Table 1

<table>
<thead>
<tr>
<th>EM of SC (nV/sec)</th>
<th>Cu-Zn SOD (Units/mg of protein)</th>
<th>Se-GPO (Units/mg of protein)</th>
<th>CAT (μmol/min/mg of protein)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal SF</td>
<td>1.62±10^9</td>
<td>23.4±0.8</td>
<td>1.3±0.3</td>
</tr>
<tr>
<td>RA SF</td>
<td>3.73±10^9</td>
<td>11.7±0.4</td>
<td>0.2±0.0</td>
</tr>
</tbody>
</table>

Conclusions: We can assume that aggravated by RA catabolic processes that caused the dysfunction of the lysosomal and mitochondrial structures (autophagy), consistently shoot antioxidant protection of SC and cause depolarization and the decrease in electrophoretic mobility of these cells.

N-ACETYL-L-CYSTEINE (NAC) CONTROLS OSTEOCLASTOGENESIS THROUGH REGULATING TH17 DIFFERENTIATION AND RANKL PRODUCTION IN RHEUMATOID ARTHRITIS
H.-R. Kim, K.-A. Lee, S.-H. Lee. Rheumatology, Konkuk University School of Medicine, Seoul, Korea, Republic Of

Background: NAC is a thiol antioxidant produced by the body and serves as a precursor of glutathione synthesis. In rheumatoid arthritis (RA), oxidative stress is an important mechanism causing destructive proliferative synovitis. NAC is a thiolic antioxidant produced by the body and serves as a precursor of glutathione synthesis. In rheumatoid arthritis (RA), oxidative stress is an important mechanism causing destructive proliferative synovitis.

Objectives: This study aimed to determine the regulatory role of N-Acetyl-L-cysteine (NAC), an antioxidant, in IL-17-induced osteoclast differentiation in RA.

Methods: After RA synovial fibroblasts were stimulated by IL-17, the expression and production of RANKL were determined by real-time PCR and ELISA. Human peripheral blood monocytes were cultured with M-CSF, IL-17, RANKL, and/or various concentrations of NAC, followed by counting of the cells for trarrrate-resistant acid phosphatase activity to determine osteoclast formation. Osteoclastogenesis was also determined after cocultures of IL-17-stimulated RA synovial fibroblasts, Th17 cells and various concentrations of NAC with monocytes. After human peripheral CD4⁺ T cells were cultured with NAC under Th17 condition, IL-17, IFN-γ, IL-4, Foxp3, RANKL and IL-2 expression and production was determined by flow cytometry or ELISA.

Results: When RA synovial fibroblasts were stimulated by IL-17, IL-17 stimulated the production of RANKL, and NAC reduced the IL-17-induced RANKL production in a dose-dependent manner. NAC decreased IL-17-activated phosphorylation of mTOR, JNK and IkB. When human peripheral blood CD14⁺ monocytes were cultured with M-CSF and IL-17 or RANKL, osteoclasts were differentiated, and NAC reduced the osteoclastogenesis. After human peripheral CD4⁺ T cells were co-cultured with IL-17-pretreated RA synovial fibroblasts or Th17 cells, NAC reduced their osteoclastogenesis. Under Th17 polarization condition, NAC decreased Th17 cell differentiation and IL-17 and RANKL production.

Conclusions: NAC inhibits the IL-17-induced RANKL production in RA synovial fibroblasts and reduces osteoclast differentiation. NAC also reduced Th17 polarization. NAC could be a supplementary therapeutic option for inflammatory and bony destructive processes in RA.

AB0001
SURFACE PHENOTYPE OF CIRCULATING PLATELETS IS ALTERED IN PATIENTS WITH RHEUMATOID ARTHRITIS
H. Yasukawa, K. Yoshimoto, K. Yamaoka, T. Takeuchi. Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

Background: Rheumatoid arthritis (RA) is a connective tissue disease and characterized with multiple synovitis. However, pathogenesis of RA and systemic characteristic of RA is still under the investigation (1). Platelets distribute systemically through blood circulation and classically contribute to hemostasis physiologically (2). On the other hand, platelets can contribute to disease process by producing humoral factors such as cytokines or growth factors (3). Also, platelets have surface molecules not only associated with hemostasis but with other functional properties. Thus, these molecules can trigger the activation of other cells by cell-to-cell contact (4).

Objectives: To examine the association between characteristics of phenotype of circulating platelets based on the expression of surface molecules and clinical characteristics of RA and to seek the possibility as novel biomarkers.

Methods: Eighty patients with RA were involved and 9 with scleroderma and 13 healthy controls were used as controls in this study. Surface expression of CD62P (P-selectin), membrane-bound TGF (transforming growth factor)-beta, CD147 (emmprin), CD142 (tissue factor) component, CD31 (platelet endothelial cell adhesion antigen) on CD62P+CD45+CD142+ platelets was examined using flow cytometry. Comparison between two groups was by non-parametric Mann-Whitney U-test. Clinical parameters at blood drawing were retrospectively obtained from clinical records, and correlation between proportion of platelet subsets and clinical parameters were examined.

Results: Proportion of CD62P+ activated platelets were higher in both RA and SSc compared to HC (P < 0.0005, P < 0.0002, respectively). Interestingly, CD147+ platelets were significantly higher in RA (P < 0.0004), whereas not only proportion of CD147+ platelets but that of TGF-beta+ platelets were higher in SSc compared to healthy controls (P < 0.0001, respectively). In patients with RA, proportion of CD147+ activated platelets was correlated with inflammatory markers such as CRP and ESR and markers for disease activity such as SDAI (P < 0.05, respectively) and these proportion were decreased after treatment (P < 0.03).

Conclusions: In patients with RA, proportion of CD62P⁺ and CD147⁺ platelets were increased compared to healthy controls. Furthermore, phenotype of platelets of RA was altered compared to SSc. Interestingly, proportion of CD62P⁺ platelet is associated with the inflammatory markers and disease activity of RA. These results suggest that platelets reflect disease process of RA and could be utilized as novel biomarkers.

AB0002
EFFECT OF METHOTREXATE, LEFLUNOMIDE AND HYDROXYCHLOROQUINE ON THE INSULIN RESISTANCE AND OBESITY ASSOCIATED WITH RHEUMATOID ARTHRITIS: OBESE MOUSE MODELS OF RHEUMATOID ARTHRITIS

Background: Numerous studies have demonstrated the closely association between rheumatoid arthritis (RA) and metabolic complications such as obesity and insulin resistance. Thus, there is an urgent need for the use of therapies targeting both the activity of the disease and such metabolic disorders. Nowadays, the conventional treatment of RA consists of disease-modifying antirheumatic drugs (DMARDs) in monotherapy or combined. Yet, its negative/beneficial effect on the metabolic complications associated with cardiovascular disease prominent in RA patients is still unravelled.

Objectives: To analyze and compare the effects of methotrexate, leflunomide and hydroxychloroquine on the obesity and insulin resistance in an obese collagen-induced arthritis (CIA) mouse model.

Methods: CIA was developed in obese and lean mice. 55 C57Bl/6 mice (4–5 weeks) were used. Forty-one mice were fed with high fat diet (60%) until reaching 30g (obese) (OB). Groups of study: 5 non-diseased lean mice, 9 CIA lean mice, 5 non-diseased OB mice, 9 OB-CIA mice treated with leflunomide (10 mg/kg daily), 9 OB-CIA mice treated with methotrexate (3mg/kg three times/week) and 9 OB-CIA mice treated with hydroxychloroquine (60 mg/kg daily) for 15 days. Mice were weighted and the number of total inflamed digits was recorded daily. After treatment, before 72 hours of termination, glucose tolerance test (GTT) was performed. Buffy coat, plasma and metabolic tissues (gonadal and inguinal adipose tissue, skeletal muscle and liver) were collected.

Results: CIA obese mice developed the arthritis earlier and more severe (increased number of inflamed digits) compared with CIA lean mice. Regarding the progression of the disease, the three drugs significantly reduced the number of affected joints from the second day of treatment. However, after 15 days of treatment, the therapies more effectively reducing the generation of inflamed digits were hydroxychloroquine and methotrexate. The development of RA in both obese and lean mice did not have effect on the body weight. Among the therapies used, only the hydroxychloroquine significantly reduced the body weight after 11 days of treatment. Glucose tolerance test revealed that the area under the curve was markedly smaller in OB-CIA mice after treatment with hydroxychloroquine compared to other treatments and OB-CIA mice untreated, suggesting an improvement of insulin sensitivity. Analysis on the metabolic tissues of these mice is currently ongoing in order to completely elucidate the effect of these therapies in the metabolic state.

Conclusions: 1) Obesity accelerates the development and aggravates the outcome of the arthritis in CIA mice. 2) Among the three DMARDS administered, hydroxychloroquine promoted a beneficial effect on the metabolism of CIA obese mice, reducing body weight and improving the insulin sensitivity. These results suggest that hydroxychloroquine could be used as a valuable therapeutic strategy in RA patients to reduce the disease activity and ameliorate the metabolic complications associated.

BLYS AND APRIL OVEREXPRESSION IN EARLY RHEUMATOID ARTHRITIS: ASSOCIATION WITH B CELLS AND MYELOID SUBSETS

J. Rodriguez-Carrio 1, M. Alperi-López 2, P. López 1, F.J. Ballina-García 2, A. Suárez 1, 2 1. Area of Immunology, University of Oviedo; 2 Department of Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain

Background: studies on B cell-mediated autoimmune diseases highlight the relevance of the B Lymphocyte Stimulator (BLyS) and A Proliferation-Inducing Ligand (APRIL), but emerging evidence points to an interaction with cell lineages other than B subsets. Although disturbances in the B cell compartment underlie the early stages of rheumatoid arthritis (RA), this phenomenon is poorly understood.

Objectives: to investigate the cellular populations responsible of BLyS expression and their association with the soluble forms of BLyS, APRIL and its receptor TACI (Transmembrane Activator and CALM Interactor) in early RA and to evaluate the changes in these parameters upon TNFα-blockade.

Methods: membrane BLyS (mBLyS) expression was assessed on B cells, monocytes (MØ), myeloid (mDC) and plasmacytoid (pDC) dendritic cells and neutrophils (NØ) by flow cytometry in fresh blood samples from 37 RA patients ([DAS28 score (mean±SD): 4.84±1.44, disease duration (mean range): 1.26 (0–11) years, 23 (62.1%) RF+, 19 (51.3%) ACPA+, 19 untreated] and 31 healthy controls (HC). A subgroup of 13 biologic-naïve RA patients was prospectively followed for three months upon TNFα-blockade. Serum levels of soluble BLyS (sBLyS), APRIL (sAPRIL) and TACI (sTACI) were quantified by immunoassays.

Results: mBLyS expression was increased on B cells (p=0.002), MØ (p<0.001), pDC (p<0.001) and NØ (p=0.014) in RA patients. Higher sBLyS (p=0.018) and sAPRIL (p=0.001) serum levels were found in RA, whereas those of sTACI were not different compared to HC (p=0.460). Serum sAPRIL levels paralleled those of sTACI (r=0.325, p=0.040), and mBLyS expression on B cells (r=0.463, p=0.009), MØ (r=0.521, p=0.003), mDC (r=0.438, p=0.014) and NØ (r=0.509, p=0.009) in HC but not in RA patients. Serum levels of sTACI were negatively associated with DAS28 score (r=-0.272, p=0.006) in RA. However, sAPRIL was associated with mBLyS expression on MØ in patients with longer disease duration (>3 months) (r=0.779, p<0.001), but not with mBLyS expression on B cells (r=0.245, p=0.361). In the whole RA group, TNFα serum levels were found to be correlated with sAPRIL (r=0.499, p<0.001) and sBLyS (r=0.362, p=0.013). Similarly, IFNα and sAPRIL were positively associated (r=0.423, p<0.001). TNFα-blockade was associated with decreasing mBLyS expression on B cells, MØ, mDC and NØ (all p<0.050), and a slight increase in sTACI (p=0.044). Higher levels of mBLyS on MØ and mDC at baseline were associated with a poor clinical response upon TNFα-blockade (n=8; p=0.006 and p=0.010 compared to HC, respectively).

Conclusions: a role for B cell-activating factors in the pathogenesis of early RA is supported. B cells and myeloid populations (MØ, mDC and NØ) can account for the BLyS overexpression in RA, although important differences arise in their involvement. TNFα and IFNα are related to sBLyS and sAPRIL levels. An increased production of the soluble forms of BLyS and APRIL in addition to a less efficient feedback from their decay receptors may delineate its detrimental effect.

BY INTRAVENOUS INFUSION MARKED BY GREEN FLUORESCENT PROTEIN TO REVEAL BONE MARROW MESENCHYMAL STEM CELLS' DISTRIBUTION AND DIFFERENTIATION OF COLLAGEN INDUCED ARTHRITIS RATS

J. Gao, L. Zhang. Rheumatology Department, Shanxi Dayi Hospital, Taiyuan, China

Background: Rheumatoid arthritis (RA) is a autoimmune disease, which is characterized by the osteoclasta or the high deformity rate of cartilage and bone. According to some materials, Mesenchymal stem cells (MSCs) were defined as the cell full of proliferation, differentiation capacity, and potential immune regulation. MSCs transplantation could be a appropriate-design pattern to the joint damaging from rheumatoid arthritis (RA). However, the repairing mechanism against osteoclasta of cartilage and bone is still unclear.

Objectives: This study used collagen induced arthritis (CIA) rats as animal model to explore MSCs’ tissue repairing mechanism.

Methods: We observed the ability of BMSCs differentiating into cartilage cells by toluidine blue staining in vitro; Then, BMSCs were labeled by the green fluorescent protein (GFP), infused into CIA through rats’ tail vein infusion. In different point time, the rat’s joints were made paraffin section, we observed the differentiation of GFP positive cells and the distribution of GFP-positive cells differentiated chondrocytes by immunohistochemically method.

Results: First, we found BMSCs in vitro can differentiate into cartilage cells under a certain-culture condition. Then, BMSCs were labeled by the green fluorescent protein (GFP), infused into CIA through rats’ tail vein infusion. In different point time, the rat’s joints were made paraffin section, which the GFP positive cells were observed in synovium and bone marrow tissues after transplantation on the 3th day, and in cartilage tissues on the 11th day, then increased in cartilage tissues on the 30th day, 42th day by laser scanning confocal microscope. Anti-type II collagen, GFP double positive cells were found in articular cartilages (especially damaged part) by Anti-II collagen immunofluorescence technology.
Conclusions: BMSCs were restricted to the joint injury or inflammatory site, differentiated into chondrocytes, and then participated in the cartilage repair.

**AB0096 EFFICACY AND SAFETY OF ORAL ADMINISTRATION OF PURE CELASTROL IN AIA RATS**

R. Casasco 1, T. Carvalho 1, J. Goncalves 2, L.F. Moita 3, J.E. Fonseca 4, 1Instituto de Medicina Molecular; 2iMed – Research Institute of Medicines, Faculdade de Farmácia, Universidade de Lisboa, Lisbon; 3Instituto Gulbenkian de Ciência, Oeiras; 4Instituto de Medicina Molecular and Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisbon, Portugal.

**Background:** Celastrol, a pentacyclic-triterpene isolated from Tripteris willordii roots, has shown great therapeutic potential for the treatment of several inflammatory diseases, including rheumatoid arthritis (RA). We have previously demonstrated that celastrol has significant anti-inflammatory and bone protective effects in the adjuvant-induced rat model of arthritis (AIA), when administered via intraperitoneal route. For further preclinical evaluation of celastrol as a candidate compound for RA treatment, an effective and safe oral administration is crucial.

**Objectives:** In this work we aimed to study the dose range for both therapeutic and toxic effects for oral administration of pure celastrol using the AIA rat model.

**Methods:** Celastrol (1, 2.5, 5, 7.5, 12.5 and 25 μg/g/day, N=5/group) was administrated orally in female AIA rats after 8 days of disease induction (therapeutic model) for a period of 14-days. A group of healthy (N=8) and non-treated (N=20) and 10 animals under tofacitinib treatment. Rats were monitored during 22 days after disease induction for the inflammatory score, ankle perimeter and body weight. Healthy non-arthritic rats were used as controls.

**Results:** Oral administration of pure celastrol at 2.5, 5 and 7.5 μg/g/day reduced the inflammatory score and ankle swelling, preserved articular joint structure with a reduction in synovial inflammatory infiltrates and proliferation, halted articular bone destruction, and diminished the number of synovial CD68+ macrophages (a biomarker of response to anti-arthritic treatment). This compound also reduced the number of osteoclasts and osteoblasts present in joints. Bone resorption and turnover was also reduced at both 5 and 7.5 μg/g/day, with a significant decrease in bone turnover markers in the levels of TRACP-5b, P1NP and CTX-1. Of note, no significant variation in body weight, evidence of nephro-, hepato- or cardiotoxic effects, nor alterations in bone metabolism, and/or with kinetics of its bone effects that might need longer exposure.

**Conclusions:** Our results clearly show that 2.5 μg/g/day is the lowest and 5 μg/g/day is the highest effective and safe oral doses of celastrol in the setting of AIA rat model. These findings suggest that while celastrol is potentially very effective to treat RA, it has a narrow therapeutic window.

**AB0097 METHOTREXATE AND LOW DOSE PREDNISOLONE DOWNREGULATE OSTEOCLAST FUNCTION IN MONOCYTES FROM EARLY RHEUMATOID ARTHRITIS PATIENTS**

I.P. Perpétuo 1, J. Caetano-Lopes 1, A.M. Rodrigues 1, R. Campanilho-Marques 1, 2, C. Ponte 1, 2, H. Canhão 3, M. Aniola 4, J.E. Fonseca 1, 2, 5, Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa; 2Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria; 3EpiDoC Unit, CEDOC, NOVA Medical School, Universidade Nova de Lisboa, Lisbon, Portugal; 4University of Helsinki, Institute of Clinical Medicine, Helsinki, Finland

**Background:** Rheumatoid arthritis (RA) is a systemic, immune mediated inflammatory disease that is associated with bone erosions and joint destruction. Methotrexate (MTX) slows bone damage but the mechanism by which it acts is still unknown.

**Objectives:** In this study we aimed to assess the effect of MTX and low dose prednisolone (MTX+P) on circulating osteoclast (OC) precursors and OC differentiation in RA patients.

**Results:** RA patients before and at least 6 months after MTX therapy were analyzed and compared with healthy donors. A blood sample was collected to assess receptor activator of NF-κB (RANK) ligand (RANKL) surface expression on circulating leukocytes and frequency and phenotype of monocyte subpopulations. Serum quantification of bone turnover markers and cytokines and in vitro OC differentiating assays were performed.

**Research question:** The number or RANKL+ neutrophils increased in RA patients when compared to healthy donors (p=0.006) and after treatment with MTX+P their count was reduced to healthy control numbers (p=0.0155). Classical activation markers of monocytes such as HLA-DR, CD86, CCR2 and CD11b, and also RANKL were increased in RA patients at baseline, comparing to control healthy donors. After MTX+P exposure, expression decreased to healthy control levels. Serum RANKL levels were increased at baseline comparing to healthy donors (p=0.0164) and normalized after therapy.

**AB0098 EFFECTS OF TOFACITINIB IN EARLY ARTHRITIS BONE LOSS**

B. Vidal 1, R. Casasco 1, M. Finnilä 2, 3, I. Lopes 1, S. Saarakkala 2, 4, 5, Z. Zioupos 6, H. Canhão 3, J. Fonseca 1, 2, 7, 8, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal; 2Research Unit of Medical Imaging, Physics and Technology, Faculty of Medicine, University of Oulu, Oulu; 3Department of Applied Physics, University of Eastern Finland, Kuopio; 4Medical Research Center, University Hospital, Oulu University Hospital, Oulu, Finland; 5Biomechanics Labs, Cranfield Forensic Institute, Cranfield University, Swindon, United Kingdom; 7EpiDoC Unit, CEDOC, NOVA Medical School, NOVA University; 8Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisboa, Portugal.

**Background:** Rheumatoid arthritis (RA) causes immune mediated local and systemic bone damage.

**Objectives:** The main goal of this work was to analyze, how treatment intervention with tofacitinib prevents the early disturbances on bone structure and mechanics in adjuvant induced arthritis rat model. This is the first study to assess the impact of tofacitinib on the systemic bone effects of inflammation.

**Methods:** Fifty Wistar adjuvant-induced arthritis (AIA) rats were randomly housed in experimental groups, as follows: non-arthritis healthy group (N=20), arthritis non-treated (N=20) and 10 animals under tofacitinib treatment. Rats were monitored during 22 days after disease induction for the inflammatory score, ankle perimeter and body weight. Healthy non-arthritis rats were used as controls for comparison. After 22 days of disease progression rats were sacrificed and bone samples were collected for histology, micro-CT, 3-point bending and nonindentation analysis. Blood samples were also collected for bone turnover markers and systemic cytokine quantification.

**Results:** At tissue level, measured by nonindentation, tofacitinib increased bone cortical and trabecular hardness. However, micro-CT and 3-point bending tests revealed that tofacitinib did not revert the effects of arthritis on cortical and trabecular bone structure and on mechanical properties.

**Conclusions:** Possible reasons for these observations might be related with the mechanism of action of tofacitinib, which leads to direct interactions with bone metabolism, and/or with kinetics of its bone effects that might need longer exposure.

AB0009 TAXOL ALLEVIATES COLLAGEN-INDUCED ARTHRITIS IN MICE BY INHIBITING THE FORMATION OF MICROVESSELS

J. Xu1, Z. Fang, J. Zhu2, S. Chen1, X. Chen1, J. Li2, 1Department of Internal Medicine of Traditional Chinese Medicine, College of Traditional Chinese Medicine, Southern Medical University, Guangzhou; 2Department of Traditional Chinese Medicine, Medical College of China Three Gorges University, Yichang; 3Department of Rheumatology, Nanfang Hospital, Southern Medical University; 4Department of Pathogen Biology, School of Public Health, Southern Medical University, Guangzhou, China

Background: Angiogenesis is one of the critical features in rheumatoid arthritis (RA). Uncontrolled neovascularization could help the infiltration of inflammatory cells and lead to synovial hyperplasia and bone destruction further. Precious studies have demonstrated that the medicine taxol (PTX) has anti-angiogenesis effects.

Objectives: To evaluate the inhibitory effects of PTX on angiogenesis in a collagen-induced arthritis (CIA) mouse model.

Methods: A total of 50 mice were used to induce a CIA mouse model with collagen II (CII) and complete Freund’s adjuvant (CFA). Twenty-four with obvious arthritis syndrome were randomly divided into four groups: CIA model group, PTX 1.5 mg/kg group, PTX 1.0 mg/kg group, PTX 0.5 mg/kg group. In addition, 6 normal mice was regarded as the control group. PTX was administered by intraperitoneal injection in the PTX treatment groups 8 times every other day. Arthritis index scores, tissue pathology scores after HE staining and synovium macrophage density analysis after immunohistochemical (IHC) staining were performed. Immunohistochemistry and ELISA were used to detect the expression of vascular endothelial growth factor (VEGF) and hypoxia-inducible factor-α (HIF-1α). Additionally, the correlation between MVD and pathological scores, level of VEGF and HIF-1α in the synovium were also evaluated.

Results: After PTX treatment, the three intervention group arthritis index scores (1.33±0.52, 2.00±0.63, 3.33±1.03) declined when compared with the CIA group (5.67±1.03, p<0.001, p=0.016). The total histological scores in the three PTX treatment groups (2.50±0.6, 3.89±0.86, 3.98±0.66) were lower than those in the CIA group (7.67±0.79, p<0.001, p=0.007). Similarly, PTX significantly alleviated the scores for synovitis, pannus formation and bone destruction. Compared with the CIA group (110.32±6.06/mm²), the MVD of the three intervention groups decreased in dose-dependent manner (53.67±9.77/mm², 34.73±2.36/mm², 57.65±7.22/mm²; p<0.001, p=0.001, p=0.016). In addition, the expression of VEGF and HIF-1α in synovial tissues and serum level also decreased significantly after PTX treatment. Further analysis showed that MVD and pathological scores and levels of VEGF and HIF-1α in the synovium were positively correlated (r=0.921, r=0.944, r=0.889, r=0.969, r=0.933; r=0.001, respectively).

Conclusions: PTX may alleviate CIA by suppressing angiogenesis, providing new insights into the treatment of RA. VEGF and HIF-1α may be the target for PTX suppression of microvessel formation.

AB0100 MTX COMBINED WITH CTX INHIBITED IL-6 INDUCED JAK2-STAT3 ACTIVATION AND THE INDUCTION OF P-GP IN PERIPHERAL BLOOD LYMPHOCYTES OF RHEUMATOID ARTHRITIS PATIENTS

K. Chen1, Y. Mu1, K. Qin1, X. Zhao1, J. Dong1, X. Li1, C. Gao2, C. Wang1, 1Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; 2Pathology, Joint Program in Transfusion Medicine, Brigham and Women’s Hospital/Children’s Hospital Boston, Harvard Medical School, Boston, Massachusetts, United States

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by irreversible joint destruction and disability. At present, the biggest challenge in the field of RA treatment is the emergence of multidrug resistance (MDR) in the application of disease-modifying anti-rheumatic drugs (DMARDs). The Multidrug resistance Related Protein and Multi Drug Resistance protein 1, also called P-glycoprotein can decreases the intracellular concentration of different drugs. Moreover, cytokines play an increasingly important role in the expression regulation mechanisms of P-gp, especially inflammatory cytokines IL-6. Previous research showed that interleukin-6 up-regulates P-gp in peripheral blood lymphocytes via the JAK2-STAT3 pathway in RA patients. Through more than ten-years’ clinical research, we observed that the therapeutic cycle alliance of MTX and CTX overcome MDR in RA patients? This study will give the answer.

Objectives: To Clarify whether the therapeutic alliance of MTX and 4-hydroperoxyxycyclophosphamide (4-HC) suppress expression and mRNA of P-gp in peripheral blood lymphocytes of RA through JAK2-STAT3 pathway.

Methods: RA patients without any DMARDs and biologic therapy (n=15) were enrolled. P-gp expression level was detected by Flow Cytometry. P-gp mRNA of peripheral blood lymphocytes and the intracellular signaling pathway mediating the effects of MTX and 4-HC on IL-6-stimulated JAK2-STAT3 activation was assessed by RT-PCR.

Results: Compared with blank control group, IL-6 induced P-gp, JAK2 and STAT3 expression levels increased significantly (P<0.05). Compared with IL-6 group, P-gp, JAK2 and STAT3 expression levels of 4-HC group and low MTX+4-HC group both decreased (P<0.05). the expression levels of P-gp, JAK2 and STAT3 in low MTX group, middle MTX group and high MTX group were lower than IL-6 group, but there was no statistically significant differences (P>0.05).

Conclusions: Our data indicated that MTX combined with CTX significantly inhibited IL-6 induced JAK2-STAT3 activation, as well as the induction of P-gp. inhibition of IL-6-mediated multidrug resistance signaling pathways by the alliance of MTX and CTX may represents a new reversing drug-resistance therapeutic strategy for RA.

AB0101 NEW MUTATED PEPTIDYLARGININE DEIMINASE FROM PORPHYROMONAS GINGIVALIS A TARGET IN EARLY RA CITRULLINATES MAJOR RA-AUTOANTIGENS

M. Jenning, B. Marklein1, J. Yetterberg2, G. Burmester3, K. Skriner, 1Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin; 2Department of Rheumatology and Clinical Immunology, Karolinska Institutet, Stockholm, Germany

Objectives: Previous reports showed that peptidylarginine deiminase (PPAD) form Porphyromonas gingivalis (Pg) is not able to citrullinate proteins internaly. New mutated PPAD (mPPAD) from Pg. involved in periodontal disease (PD) clonout of Pg. strain was characterized and analyzed for its reactivity in sera from patients with systemic autoimmune diseases

Methods: We cloned a new enzymatically active recombinant mutated PPAD from Pg. mPPAD mutations and citrullination sites were analyzed by DNA sequencing and/or protein mass spectrometry. Autoantibod indiction of enzymatic activity and human autoantigen protein citrullination was investigated by 2D-Elektrophoresis, Mass spectromobol analysis and ELISA. Furthermore we tested anti-mPPAD/ict-mPPAD with human sera (n=83) from early RA before and after onset of RA (n=30), established RA (n=32), SLE (n=16) and healthy blood donors (n=15) in ELISA assays. To study a potential impact on the RA mouse model (CAIA), mPPAD-containing vesicles from Pg. were injected by intraperitoneal injection (IP).

Results: Recombinant mPPAD lacks 43 amino acids at the N-terminus and exhibits so far two new amino acid mutations (amino acid position 73 (F-L) and 447 (E-V)). We were able to demonstrate, mPPAD is enzymatically active over a huge pH-range (3–10) and autoantibodies at amino acid position 63 the arginine to citrulline. Moreover mPPAD citrullinates major autoantigons in RA (Fibrinogen, Vimentin and hNRNP-A/B1) which are detectable by RA patient sera and specific anti-citrulline monoclonal antibodies. mPPAD citrullinates HeLa-protein extracts and these specific citrullinated proteins are recognized by RA patient sera. Anti-citrullinated mPPAD antibodies were detected in 41% (n=32) of patients with RA but not in SLE (n=16) and control sera (n=15). In a RA follow-up study (n=30), we detected nearly similar antibody-sensitivities for citrullinated mPPAD before and after onset of RA (13/20%), Only a minority (7%) of RA patients show higher mPPAD antibody levels after RA diagnosis. In the Collagen antibody-induced arthritis (CAIA) RA mouse model mPPAD containing Pg vesicles when injected IP showed a TL2-dependent protective anti-inflammatory effect like Pg. LPS and Lipomannan.

Conclusions: Pg. infection and RA disease diagnosis occurs on different time points and Pg. infection induces a TL2-dependent protective anti-inflammatory effect. We show the first time that mPPAD can citrullinate major human autoantigens internally and their immunologically and diagnostic relevance.

IMPAIRMENT OF GRANZYME B-PRODUCING REGULATORY B CELLS EXACERBATED RHEUMATOID ARTHRITIS

L. Xu, F. Hu, X. Liu, L. Zhu, L. Ren, H. Liu, H. Zhu, Y. Su. Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China

Background: Rheumatoid arthritis (RA) is a common and complex autoimmune disease characterized by chronic inflammation and cartilage/bone damage involving numerous cells, such as T cells, B cells, chondrocytes, fibroblasts [1]. B cells had long been well-demonstrated to participate in the development of RA [2]. B cells producing specific antibody and inducing T cell activation, impaired immunosuppressive function of B cells further emphasized their roles in RA recently [2].

Objectives: To investigate whether B cells could produce granzyme B and the potential role in the pathogenesis of Rheumatoid arthritis (RA).

Methods: To reveal the expression of granzyme B in B cells, flow cytometry, PCR and Eilispot were performed. The role of IL-21 and anti-BCR stimulation on granzyme B expression was assessed by in vitro stimulation assay. CD4+ T cell-B cell co-culture in the presence of granzyme B neutralizing antibody was performed to demonstrate the function of these cells. Then the levels of granzyme B in B cells between RA patients, OA patients as well as HCs were compared. Next, the correlation analysis between granzyme B-producing B cells and clinical features in RA patients was performed. Finally, the frequencies of granzyme B-producing B cells in RA patients before and after therapy were also evaluated using flow cytometry.

Results: B cells could spontaneously produce granzyme B, which could be perpetuated by IL-21 and anti-BCR stimulation. The frequencies of Th1 and Th17 cells were significantly elevated under the condition of granzyme B blockade when granzyme B was neutralized in CD4+ T cell-B cell co-culture. In RA patients, but not OA patients and HCs, the frequencies of granzyme-B producing Bregs decreased significantly, which was functionally impaired and negatively correlated with disease activity score 28. Moreover, after effective clinical therapy, the frequencies could recover to normal levels.

Conclusions: B cells exert the regulatory functions via granzyme B production. Under RA circumstance, these granzyme B-producing Bregs were impaired and contributed to the disease progression.

ANTI-INFLAMMATORY AND IMMUNOMODULATORY EFFECTS BY HUMAN UMBILICAL CORD MENSECHYMAL STEM CELL DERIVED MICROVESICLES IN RATS WITH COLLAGEN INDUCED COLLAGEN EROSION

M. Tian, K. Xu, L. Zhang, J. Gao. Rheumatology, Shanxi DaYi Hospital, Shanxi Academy of Medical Sciences, Taiyuan, China

Background: Immunologic deranging and persistent inflammation is closely associated with the arising and developing of rheumatoid arthritis (RA). Increasing investigators demonstrated microvesicles (MVs) derived from mesenchymal stem cell (MSC-MVs) might simulate immune regulation and tissue repair of the parental cells. However, the immunotherapeutic potential of MVs in RA remains unknown.

Objectives: We investigated the therapeutic effects of MSC-MVs in RA model collagen induced arthritis (CIA) rats.

Methods: We tested the therapeutic effects of MSC-MVs on CIA rats, levels of T helper 17 (Th17), regulatory T cell, and cytokines related, as well as specific transcriptional regulation factor Foxp3 and ROR-γ T analysis was performed.

Results: Here, we show that MSC-MVs administration effectively improve arthritis symptoms, inhibit synovial hyperplasia, thus delaying the progression to inflammation, bone destruction, as effective as their original cells, exerting arthralprotective effects. MSC-MVs treating inhibited the proliferation of T cell, accelerated the apoptosis. MSC-MVs treating reducing proinflammatory cell Th17, cytokines IL-17, while a decline in the level of an-inflammatory cell Treg, cytokines TGF-β.

In the spleen and ankle joint of CIA rats, MSC-MVs treating increasing the expression level of Foxp3 and coinciding with the ROR-γ T suppressed, which, the enhanced therapeutic effects correlated with the increase of dosage in a certain range.

Conclusions: MSC-MVs showed anti-inflammatory and immunomodulatory activities on CIA rats, suggesting a new and feasible strategy for protection against RA.

ALTERATIONS OF SPLICOSOME COMPONENTS IN LEUKOCYTES FROM PATIENTS WITH RHEUMATOID ARTHRITIS INFLUENCE THEIR AUTOIMMUNE AND INFLAMMATORY PROFILE, AND THE DEVELOPMENT OF CARDIOVASCULAR DISEASE

P. Ruiz-Limon 1, C. Perez-Sanchez 1, R. Ortega-Castro 1, S. Pedrada-Arevalo 2, M. del Rio-Moreno 2, Y. Jimenez-Gomez 1, I. Arias de la Rosa 1, M. Abalos-Aguilera 1, M. Aguirre 1, P. Segui 1, E. Collantes 1, A. Escudero 1, J. Castaño 1, R.M. Luque 2, N. Barbarroja 1, C. Lopez-Pedrera 1, Rheumatology Service, 1Department of Cell Biology, Physiology, and Immunology, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain

Background: A significant percentage of genetic and inflammatory diseases derive from splicing alterations. Therefore, the understanding of what modifications in splicosome determine an alternative splicing and its association with the development of such pathologies is of critical importance.

Objectives: To study the alterations present in the splicosome machinery of patients with rheumatoid arthritis (RA), its influence on the development and activity of the disease and their atherothrombotic profile.

Methods: An array of selected components of the major- (n=12) and minor-splicosome (n=4) and associated splicing factors (n=28) was developed, and their expression levels were measured in splicosome fluidic methodology, in purified leukocytes from 14 RA patients and 14 healthy donors (HD). In parallel, an extensive clinical and serological evaluation was performed. Carotid intima media thickness (CIMT) was used as atherosclerosis marker. Endothelial activity was monitored by laser-doppler flowmetry, and pro-inflammatory and oxidative stress markers were quantified. Association of these splicing components with clinical and analytical features were investigated.

Results: A significant alteration in various components of splicosome and splicing factors was found in all the leukocytes subtypes from RA patients vs HD. Interestingly, we found a specific altered profile of splicing factors and splicosome components when compared monocytes (CA150, PRPS, SRM160, U2AF1, RNU4atc, PTB81, RAVER1, RBM17, SFR54, SFR510), lymphocytes (RNU12, RNU4, RNU6, PRPB, MAGOCH, NOVA1, SRSF3) and neutrophils (SNR111, RNU6, SC5B, RBM3).

Altered levels of various splicosome elements in monocytes were associated with the presence of atheromatous plaques, while in neutrophils were found related to radiological involvement. In lymphocytes, the alteration of these components were linked to the positivity for Rheumatoid Factor and anti-CCP antibodies, indicating that modifications in the splicosome machinery could contribute to the increase in the production and assembly of autoantibodies, inducing autoantibody production.

Correlation studies showed a significant relationship between altered levels of various splicosome components in different leukocyte subtypes and high disease activity (DAS, HAQ), increased expression of proinflammatory mediators (CRF, TF, TNF, IL-8, TLR4) and oxidative stress markers (peroxides, GPX, SOD) as well as with parameters associated with insulin resistance.

Conclusions: These results reveal that there is a significant alteration of splicosome components in RA patients that could be associated with the development and activity of this autoimmune condition, and influence mechanisms that drive the development of cardiovascular disease. Studies in progress will help to clarify the physiological implications of these findings, which could constitute novel diagnostic biomarkers, as well as new therapeutic tools for the treatment of RA.

EFFECT OF SERUM CYTOKINES ON COLLAGEN INDUCED ARTHRITIS RATS AFTER INTRA-ARTICULAR INJECTION OF OZONE

Objectives: To observe the effects of intra-articular ozone injection on the contents of tumor necrosis factor-α (TNF-α), Interleukin-6 (IL-6), IL-17A and vascular endothelial growth factor (VEGF) in the serum of rats with collagen-induced arthritis (CIA) and to explore the therapeutic mechanism of ozone treatment.

Methods: Thirty-two Wistar rats were randomized into 4 groups, including ozone group (O 3 group), Ca blank group (Ca blank group), Doxy group (Doxy group) and DEXA-group (DEXA-group). The rats were divided into 3 equal groups and an additional subcutaneous injection was performed as follows: Doxy-group − doxycycline (50 mg/kg, Saratov, Russia), DEXA-group − dexamethasone (4 mg/kg, KRKA, Slovenia), control group − 0.9% sodium chloride solution (Belarus).

Conclusions: Intra-articular injection of 40 μg/ml ozone can attenuate synovitis in rats with CIA, the mechanism of which may involve the inhibition of TNF-α, IL-6 and VEGF in the serum.

AB0107 THE MODULATION OF MACROPHAGE POLARIZATION BY SIRT1 MAYBE NEW TARGET THERAPY IN RHEUMATOID ARTHRITIS

Background: The polarization of macrophages was the expressed to M1/M2 phenotype by various stimuli or environment signals. The M1 macrophage was the pro-inflammatory phenotype and was key effector cells in the immune response of rheumatoid arthritis (RA). So, M1 macrophage influenced the inflammation of RA synovial membrane and joint destruction in RA, whereas M2 macrophage was anti-inflammatory phenotype and could down-regulate the production of proinflammatory cytokines in RA. The SIRT1 attenuated the RA inflammation via down-regulation of NF-κB signaling. However, the effect of SIRT1 on macrophages polarization remained unclear.

Objectives: We aimed to check out that activated SIRT1 modulated macrophages polarization into M1 phenotype and controlled the inflammation of RA.

Methods: Monocytes from synovial fluid of RA patients, bone marrow-derived monocytes (BMDCs) from mice were studied. monocytes were cultured with M-CSF for 7days to differentiate into M0 macrophages (monocyte-derived mature macrophages M0 phenotype); M0 macrophages were incubated with LPS and IFN-γ to obtain M1 macrophages. M1 macrophages were incubated with M-CSF for 7days to differentiate into M2 macrophages (M2 phenotype). The polarization of macrophages was expressed by M1/M2 ratio.

Conclusions: SIRT1 modifies macrophages polarization and inhibits the inflammation of RA synovial membrane and joint destruction in RA. SIRT1 may be a new target to treat RA.

AB0106 EFFECT OF SERUM CYTOKINES ON COLLAGEN INDUCED ARTHRITIS RATS AFTER INTRA-ARTICULAR INJECTION OF OZONE

R. Guo, G. Zhang, L. Zhang, N. Liu. Department of Rheumatology, Shanxi Dayi Hospital, Taiyuan, taiyuan, China

Background: Ozone is a new treatment method, study confirmed that the ozone intra-articular injection can reduce the level of TNF-α in rat synovial TNF-α, a synovial tissue, the regulation of rat apoptosis inhibiting gene Bcl-2 decreased expression, thereby promoting apoptosis of synovial cells. However, there are few reports on the effects of ozone on the inflammatory cytokines such as serum TNF-α in the pathogenesis of RA.

Objectives: To investigate the effects of intra-articular ozone injection on the contents of tumor necrosis factor-α (TNF-α), Interleukin-6 (IL-6), IL-17A and vascular endothelial growth factor (VEGF) in the serum of rats with collagen-induced arthritis (CIA) and to explore the therapeutic mechanism of ozone treatment.

Methods: Thirty-two Wistar rats were randomized into 4 groups, including ozone group (O 3 group), Ca blank group (Ca blank group), Doxy group (Doxy group) and DEXA-group (DEXA-group). The rats were divided into 3 equal groups and an additional subcutaneous injection was performed as follows: Doxy-group − doxycycline (50 mg/kg, Saratov, Russia), DEXA-group − dexamethasone (4 mg/kg, KRKA, Slovenia), control group − 0.9% sodium chloride solution (Belarus).

Conclusions: Intra-articular injection of 40 μg/ml ozone can attenuate synovitis in rats with CIA, the mechanism of which may involve the inhibition of TNF-α, IL-6 and VEGF in the serum.

PTS Granada, Granada; 5Department of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP); 6School of Medicine, University of Cantabria, Santander, Spain

Background: Mutations in the protein tyrosine phosphatase non-receptor 22 (PTPN22) gene are associated with numerous connective tissue and autoimmune diseases [1]. In particular, PTPN22 has been recognized as the main non-HLA genetic risk factor involved in rheumatoid arthritis (RA) susceptibility [2]. Moreover, it has been suggested that PTPN22 modulation may influence on inflammatory processes associated with RA [3,4].

Objectives: To determine if PTPN22 (rs2476601, rs33996649 and rs2488457) polymorphisms, associated with RA, may influence on PTPN22 expression in RA patients compared to healthy controls. Moreover, the association between PTPN22 expression in patients with RA and their clinical characteristics was studied.

Methods: PTPN22 messenger RNA (mRNA) expression was quantified by quantitative real-time PCR in peripheral blood samples from 42 RA patients and 24 healthy controls. PTPN22 rs2476601 (G→A), PTPN22 rs33996649 (C→T), and PTPN22 rs2488457 (C→G) single-nucleotide polymorphisms (SNP) were genotyped by TaqMan SNP genotyping assays. Differences in PTPN22 expression between patients and controls were analyzed by Student’s t test, according to their genotype. Correlation coefficients were also assessed between PTPN22 expression in RA patients and their clinical characteristics.

Results: A significant down-regulation of PTPN22 expression in RA patients carrying PTPN22 rs2488457 risk allele (G) compared to controls was observed (relative mean values of PTPN22 mRNA levels ± standard deviation: 2.93±0.76 vs 4.33±0.63, p=0.0004). Furthermore, an inverse relationship between PTPN22 expression and disease duration (r=0.38, p=0.03) was found. These results were adjusted by sex, age at time of study and cardiovascular risk factors.

Conclusions: Our study shows for the first time that the risk allele of PTPN22 rs2488457 polymorphism influences on the down-regulation of PTPN22 in patients with RA. This result suggests a transcriptional suppression of PTPN22 gene in RA, which in turn may play an important role in disease diagnosis and progression.

AB0108

AB0109 AUTOPHAGY INHIBITOR REGULATES APOPTOSIS AND PROLIFERATION OF SYNOVIAL FIBROBLASTS THROUGH THE INHIBITION OF PI3K/AKT PATHWAY IN COLLAGEN-INDUCED ARTHRITIS RAT MODEL

S. Li, F. Li, W.J. Chen, C. Deng. Department of Rheumatology and Immunology, the Second Xiang Ya Hospital, Central South University, Changsha, Hunan, China, Changsha, China

Background: Mounting studies have illustrated an important role of autophagy in various diseases, but few studies have reported its contribution to rheumatoid arthritis (RA) and the underlying mechanism is largely unknown.

Objectives: This study aimed to investigate whether autophagy inhibitors could regulate apoptosis and proliferation through PI3K/AKT pathway in RA.

Methods: RA animal model was established by collagen induction. General observations and degree of joint swelling were observed. Inflammatory response, cell survival related factor and apoptosis were also detected in synovial fibroblasts. In addition, cultured rheumatoid arthritis fibroblast-like synoviocytes (RA-FLS) were subjected to TNF-α treatment in vitro, and TNF-α induced cell apoptosis, synovial cell proliferation and apoptosis were detected. Moreover, cell cycle and cytokine secretion protein, along with the above parameters, were analyzed.

Results: Results from the animal model showed that autophagy inhibitors could attenuate inflammatory reaction and synovial hyperplasia, while promoted synovial fibroblasts apoptosis. Meanwhile, inhibition of autophagy promoted cell apoptosis and reversed cell proliferation in vitro, also blocked cell in the G2/M arrest, and reduced the S phase cells. Furthermore, inhibition of PI3K/AKT pathway reversed TNF-α mediated autophagy and cytokine secretion.

Conclusions: Autophagy inhibitors could mitigate inflammation response, inhibiting RA-FLS cell proliferation while promoting cell apoptosis by PI3K/AKT pathway.

AB0109

EVALUATION OF THE EFFECT OF CHUANTENTONGBI DECOCTION ON DBA / 1 MICE CIA MODEL

X.-Q. Wang, X.-D. Shen, X.-Y. Zhang, X. Du. Department of Traditional Chinese Medicine, School of Basic Medical Sciences, Beijing University of Chinese Medicine, Beijing, China

Background: DBA/1 mouse (H2q type) CIA model as a mature model of rheumatoid arthritis is widely used in pharmacology and pharmacodynamics research[1]. Chinese medicine treatment of rheumatoid arthritis has accumulated rich experience. The study of Tripterygium glycosides treatment of rheumatoid arthritis had good effect[2]. ChuanTengTongBi decoction is also the effective prescription commonly used for the treatment of rheumatoid arthritis.

Objectives: To investigate the pathological damage degree of DBA/1 mouse CIA model and the effects of different doses of ChuanTengTongBi decoction on the CIA model mice.

Methods: The mice were divided into normal group, model group, leflunomide group (3.11mg/kg/d), low-dose of ChuanTengTongBi group (0.44g/ml/d), medium-dose group (0.88g/ml/d) and high-dose group (1.76g/ml/d).

Results: The arthritis index (AI) was evaluated every week to determine whether the model was successful. We defined AI score ≤ 4 as successful model (AI score

standard:0. No swelling;1. Slight redness and swelling;2. Moderate redness and swelling of ankle; 3. Severe redness and swelling of the entire paw; 4. Maximally inflamed limb with involvement of multiple joints (p<0.05%). Day 28–42, hind foot redness and swelling of the mouse continued to develop and extended to the forefoot. Compared with the normal group, incidence of CIA model group reached 100%. Day 49, compared with the model group by joint scores, medium-dose group, high-dose group and leflunomide group have significant differences on CIA model (p<0.01). Compared with the Leflunomide group, low-dose group, medium-dose group and high-dose group have no obvious difference (p>0.05). Compared with the low-dose group, medium-dose group and high-dose group have no difference (p>0.05).

AB0111  CADIUM NANOPARTICLES CITRULLINATE INTRACELLULAR CYTOKERATINS: CADMIUM POTENTIALLY LINKS RHEUMATOID ARTHRITIS TO SMOKING AND NUMEROUS WORKING CLASS OCCUPATIONS

D. Hutchinson 1, J. Müller 2, J.E. McCarthy 3, Y. Gun 4, N. Verma 5, X. Bi 6, L. Di Cristo 7, L. Kickham 8, D. Movia 9, A. Prina-Mello 10, V. Volkov 11, Royal Cornwall Hospital Trust, University of Exeter Medical School, Truro, United Kingdom; 2 University of Basel, Switzerland, Basel, Switzerland; 3 Trinity College, Dublin, Ireland; 4 Nan Yang Technological University; 5 Bioprocessing Technology Institute, Singapore, Singapore

Background: Smoking has emerged as a consistent risk factor for ACPA positive RA, although the specific constituents of cigarette smoke that induce citrullination are unknown. It has been hypothesised that cadmium triggers RA as its inhalation risks various well established risk factors for RA such as smoking (the most important environmental source of cadmium) and numerous working class occupations [1].

Objectives: To determine whether the cadmium-derived materials induce intracellular citrullination.

Methods: Human A549 lung epithelial cells were exposed to cadmium in ionic and particulate form represented by cadmium chloride and cadmium oxide, respectively, and their combinations with ultrafine carbon black (uCB) nanoparticles produced following high temperature combustion, imitating cigarette burning. Protein citrullination in cell lysates was analysed by SDS-PAGE electrophoresis with western blotting and verified by immunofluorescence staining and confocal microscopy. Target citrullinated proteins were identified by proteomic analysis.

Results: Cytotoxicity studies demonstrated that cadmium compounds were toxic to the cells. Based on the results of cytotoxicity measurements, all the materials utilised in the experiments were subsequently applied to the cells in sub-toxic concentrations. Cadmium oxide, uCB and its combination with cadmium chloride and cadmium oxide after high temperature combustion induced citrullination of multiple proteins in cultured human lung epithelial cells of A549 cell line, as demonstrated by SDS-SDS-PAGE electrophoresis and western blotting. This phenomenon develops via a peptidylargininedeiminase-dependent mechanism, as demonstrated in our previous studies [2]. The majority of citrullinated proteins were represented by the bands corresponding to the molecular weights between 55 and 72 kDa, and several less abundant bands at the level of ~25 kDa and over 130 kDa. Acidic cytokeratin of type I (9, 10) and basic/neutral cytokeratins type II (1, 2, 5, 6, 6A, 6B and 77) were identified as major intracellular citrullination targets. Immunofluorescent staining demonstrated that the citrullinated proteins were localised both in the cytoplasm and nuclei of cells exposed to cadmium particles, similar to the distribution patterns observed in cells exposed to uCB.

Conclusions: Cadmium nanoparticle exposure facilitates post-translational citrullination of proteins.

Spondyloarthritis - etiology, pathogenesis and animal models

AB0112  INTERFERON-REGULATED GENES (IRG) SIGNATURES DIFFERENTIATE GROUPS OF AS PATIENTS AND ARE ASSOCIATED WITH ANTI-TNF RESPONSE: PILOT DATA

S.R. Harrison, A.N. Burska, P. Emery, H. Marzo-Ortega, F. Ponchel. Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

Background: Ankylosing Spondylitis (AS) is a chronic inflammatory arthritis characterised by sacroiliac/lumbar spinal inflammation and extra-articular manifestations. Currently, TNF inhibitors (TNFi) are licensed for treatment-refractory AS; however, many patients do not respond to treatment and there is no way to predict Response/Non-Response (R/NR). The expression of several Interferon (IFN) signaling related genes (IRG) are associated with inflammatory diseases, including AS. Furthermore, an IRG expression signature has been used to predict treatment response in phase-Ia trials in systemic lupus erythematosus (1), demonstrating the feasibility of the use of IRG signatures as biomarkers in routine clinical practice.

Objectives: To explore whether IRG signatures differentiate groups of AS patients, and can be associated with response to TNFi in AS.

Methods: Twenty-six week-0 peripheral blood mononuclear cell (PBMC) samples...
from AS patients participating in a previously reported in-house clinical trial [infliximab (IFX), n=15 vs. placebo (P), n=11] (2) were selected from our tissue bank. R/NR was defined as a ≥1.1 point reduction in AS Disease Activity Score (ASDAS) at week-30, or a reduction in the number of sacroiliac/vertebral MRI lesions. Expression of 96 IRG was quantified from PBMCs using custom TaqMan assays and analysed using unsupervised hierarchical clustering, Chi-Squared, and Mann-Whitney U tests.

Results: A total of 11 patients were clinical responders [IFX=7; P=4/11]. At week-0, patients clustered into 2 groups (C1/C2) based on expression of 14 IRG. Clinical/demographic characteristics were not significantly different between C1/C2 and groups were not biased for treatment (C1, IFX=8; P=4, C2, IFX=7; P=7, p≤0.735). Improvement in ASDAS was weakly associated with C2 (C2, R=8/14, C1, R=7/12, p=0.098). Looking at IFX treated patients only (n=15), 2 cluster groups were observed (T1/T2) driven by 12 IRG. T2 was associated with a reduction in MRI lesions (T2 R=6/7, T1 R=3/8, p≤0.057). Finally, paired week-0 and week-22 samples from 10 IFX-treated patients were analysed and clustered in 2 groups (H1/H2). Changes in IRG signature following treatment were observed towards segregating pre- and post- IFX treatment samples (H1, 6/8 week-0; H2, 8/12 week-22 p≤0.7).

Conclusions: This pilot study suggests a possible association between IRG and response to IFX treatment in AS. These results now require assessment in a larger cohort in order to determine statistical and possible clinical significance, and to refine the signature further to construct potential predictive algorithms.

AB0114 THE RELATIONSHIP OF POLYMORPHISMS OF ANTXR2 GENE EFFECTS OF ANTI-IL17A BLOCKADE WITH SECUKINUMAB ON SYSTEMIC AND LOCAL IMMUNE RESPONSES: A MECHANISM-OF-ACTION STUDY IN PERIPHERAL SPONDYLOARTHRITIS

L.J.J. Van Mens 1, M.G. van de Sande 1, S. Menegatti 2, I.C.J. Blijdorp 1, I.A. Fluri 1, T.E. Latuhihin 3, A.W.R. van Kuijk 1, N.G. Yeremenko 1, D.L. Baeten 1, 4, AMC, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands; 2Immunology, Institut Pasteur, Paris, France; 3Reade, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands; 4UCB, Brussels, Belgium

Background: IL-17A blockade is an effective therapy for ankylosing spondylitis (AS) and psoriatic arthritis (PsA), the two prototypical forms of spondyloarthritis (SpA). How IL-17A blockade affects the systemic and local immune responses in SpA patients with peripheral disease (pSpA) is unknown.

Methods: 20 active pSpA patients were included in a 12wk open-label trial followed by 2yrs non-investigational extension. All patients received secukinumab 300mg/wk from baseline to wk4 and then every 4wks. Clinical response was measured 4wkly. TruCulture tubes with SEB and zymosan were drawn at baseline, day3, and wk12. Synovial biopsies were obtained by needle arthroscopy at baseline and wk12, analyzed by immunohistochemistry (IHC) and qPCR.

Results: The 20 pSpA patients consisted of 13 PsA, 3 undifferentiated SpA, 2 AS, 1 reactive arthritis, and 1 inflammatory bowel disease associated pSpA. There were no SEAs in the 12wk core study. However, two SEAs occurred in the extension of the study: tosilsitis (suspected to be related to study drug) and myocardial infarction (non related), both fully recovered. Secukinumab induced a rapid and highly significant improvement in SJC (Baseline: 2.5 [IQR1–4] vs wk12: 0.5 [IQR0–1]–p=0.001), TJC (6 [2–8] to 0.5 [0–3]–p=0.001), VASglobal (46 [28–65] to 13 [6–24]–p=0.001). 18/20 patients reached EULAR DAS response at wk12 (10 good and 8 moderate responders). This was paralleled by significant improvements in other activity outcomes such as BASDAI (53 [25–63] to 20 [9–30]–p=0.001) and PASI (5,7 [4,5–7,1] vs 0,6 [0,1–1,8]–p=0.001). Systemic inflammatory response revealed a decrease in CRP (3.85 [1.55–16.6] to 2 [1,15–3.63]–p=0.001) and ESR (16 [6–35] to 6 [2.8–16.3]–p=0.001), which was associated with decreased production of MMP-3, a validated biomarker of inflammation in pSpA, by peripheral blood cells in the TruCulture system (see figure). With exception of a decrease in IL-17A, the TruCulture system did not reveal any impact of secukinumab on the capacity of peripheral blood cells to produce a broad panel of cytokines and chemokines upon stimulation. In contrast with this preserved systemic immune response, IHC confirmed the positive impact of secukinumab on peripheral disease (pSpA).

Conclusions: Secukinumab has a profound beneficial clinical and biological impact on pSpA. Further systemic immune analysis will delineate which inflammatory pathways are blocked by secukinumab in the diseased target tissue.

Background: Psoriatic arthritis (PsA) is a complex inflammatory condition with both genetic and environmental risk factors contributing to disease. A potential environmental risk factor, known to modify the immune system, is the intestinal microbiota. In PsA there is evidence of intestinal inflammation [1,2] and recently dysbiosis of the gut microbiota has been reported in treatment naïve PsA patients [3]. However, there is no information on the temporal stability of the microbiota over time in established PsA on treatment compared to matched PsC controls.

Objectives: To explore the temporal stability of gut microbiota composition and reveal associations with PsA compared to PsC while on stable on treatment with methotrexate.

Methods: Patients with PsA and PsC were recruited to the study if they had been on a stable dose of methotrexate for 6 months. Bacterial DNA was extracted and the V3-V4 hypervariable region of the 16S rRNA was amplified and sequenced on MiSeq. The resultant data was analysed using a bespoke bioinformatics pipeline and taxa were assigned using the Ribosomal Database Project classifier according to the SILVA119 database. The Wilcoxon rank sum test was used to assess alpha diversity indices, while permanova testing using Bray Curtis distance and DESeq2 values corrected for false-discovery rate (FDR) were used to compare beta diversity indices after removing low abundance (<0.5%) Operational Taxonomic Units (OTU). The ALDEx2 analysis package was used to assess effect size.

Results: Stool samples were available from 9 PsA (n=13) and 6 PsC (n=12) individuals. Second stool samples were also obtained from the PsA (n=5) and PsC (n=4) groups. No significant difference in the alpha diversity indices was observed between PsA and PsC. The beta diversity index showed no significant difference between the two conditions using permovana test. However, using the DESeq2-FDR analysis, 8 OTUs were identified which had significantly (p<0.01) different abundances in PsA compared to PsC. The taxa (Lachnospiraceae & Ruminococcaceae) predominately belonged to the Firmicutes phylum, family Lachnospiraceae and Actinobacteria phylum, family Bifidobacteriaceae. The significant OTUs with DESeq2 had an effect size <1 using ALDEx2 but the BH p-value was not significant (p<0.01), which may be due to the small sample size. There were no significant differences in the diversity measures over time.

Conclusions: These results suggest that a gut enterotype with predominant Firmicutes/Actinobacteria composition is associated with stable/well controlled disease and is stable over time. This requires replication in a larger cohort.

Identifying the AS Patient at Risk: Is Aortic Root Dilatation Associated with HLA-B27?

M. Baniaamam 1, S. Heslinga 2, T. Konings 3, O. Kamp 3, L. van der Horst-Bruisma 1, M. Nurmohamed 1, 1Rheumatology; 2Reade/VU medical centre; 3Cardiology, VU Medical Centre, Amsterdam, Netherlands

Background: Cardiac involvement is more common in Ankylosing Spondylitis (AS) patients with HLA-B27 genotype, especially aortic valvular regurgitation (AVR). AVR in AS is caused by aortic root dilatation and fibrotic thickening of the aortic cusps, both linked to inflammation. Inflammation of the aortic root might lead to a weakening in aortic wall strength and dilatation with AVR. Severe AVR can result in heart failure and is an indication for valve replacement or repair. The prevalence of AVR in AS is estimated at 14–18%, which is significantly higher compared to the general population. Therefore, some advocate regular echocardiographic screening of AS patients [1]. However, the cost-benefit of echocardiographic screening in AS is currently unknown and the precise effect of AS specific cardiac pathology on clinically overt cardiovascular morbidity and mortality remains to be elucidated. Hence, we should aim to identify a specific ‘at risk’ AS population that might benefit from routine echocardiographic monitoring.

Objectives: Primary: To assess the association between the aortic root diameter in HLA-B27 positive versus HLA-B27 negative patients.
Secondary: To assess the association between the aortic root diameter with disease duration and inflammation biomarkers.

Methods: We performed a cross-sectional study in AS patients between 50–75 years who were recruited from a large rheumatology outpatient clinic. Patients underwent echocardiography, with 2D, spectral and colour flow Doppler. The aortic root was measured at sinuses of Valsalva during diastole. The aortic root was measured at sinuses of Valsalva during diastole. The aortic root diameter/BSA and disease duration and inflammation biomarkers were assessed.

Results: 132 Consecutive AS patients were included with a mean age of 60.5 years, of whom 110 (83%) were HLA-B27 positive. The median aortic root diameter was corrected for body surface area (BSA). Correlation between aortic root diameter/BSA and disease duration and inflammation biomarkers were assessed.
AB0117 CADHERIN-11 MRNA EXPRESSION IS INCREASED IN THE PERIPHERAL BLOOD OF PATIENTS WITH ACTIVE SPONDYLARTHROPATHY: A PILOT STUDY

Background: Cadherin-11 is a key regulator of synovial architecture and has a central role in the formation of the rheumatoid pannus. Immunohistochemical studies have shown upregulation of cadherin-11 in the synovium of patients with severe psoriatic arthropathies (SpA), comparable to that in rheumatoid arthritis (RA), as well as in the intestinal tissue of patients with inflammatory bowel disease (IBD). Moreover, cadherin-11 mRNA transcripts have been identified in the peripheral blood of patients with RA and independently associated, among various disease characteristics, with the presence of active inflammation in multiple joints [1].

Objectives: To test the hypothesis that cadherin-11 mRNA transcripts are increased in the peripheral blood of patients with active SpA and search for possible associations with clinical features.

Methods: Fifteen patients with active SpA (SpA-FLS), aged between 21 and 71 years, 11 men, and 30 age- and gender-matched healthy controls were examined. Peripheral whole blood samples (3 ml) were subjected to cDNA synthesis and cadherin-11 mRNA expression was quantified by real-time PCR. Available cDNA from 33 IBD patients without axial or peripheral active arthritis served as disease controls and were studied in parallel.

Results: Cadherin-11 mRNA was detected in the peripheral blood of 9/15 (60%) patients with SpA versus 5/30 (17%) healthy controls and 10/33 (30%) patients with IBD (SpA vs healthy controls: p = 0.006, SpA vs IBD: p = 0.06). Notably, cadherin-11 mRNA was not assayed in patients with basal diseases like neoplasia or psoriasis present in 10 patients, but was detected with increased frequency among SpA patients with clinically active peripheral arthritis at the time of sampling (7 out of 10.70%) than the remaining patients (2 out of 5, 40%). Moreover, cadherin-11 positivity associated significantly with increased erythrocyte sedimentation rate in SpA but not in IBD.

Conclusions: Cadherin-11 mRNA is upregulated in the peripheral blood of patients with SpA and may correlate with “spreading” of inflammation in peripheral joints. Since an anti-cadherin-11 mAb is in early clinical development for RA, further studies in patients with inflammatory arthritis are warranted.

AB0110 THE LYMPHATIC SYSTEM: A GATEKEEPER FOR MIGRATION OF T-CELLS TOWARDS SYNOVIAL JOINTS AND ENTESSES IN PSORIASIS

P. Bisogno1, E. Prens1, A. Mus3, P. Asmwadajja3, N. Davealla3, A. Hofman1, J.-B. Jaquet1, J. Hazes3, M. Kok3, E. Lubberts2. 1Department of Rheumatology, Maasstad hospital and Erasmus Medical Center; 2Department of Dermatology; 3Department of Rheumatology, Erasmus University Medical Center; 4Department of Plastic surgery; 5Department of Rheumatology, Maasstad hospital, Rotterdam, Netherlands

Background: The factors underlying the transition of psoriasis (PsO) to psoriatic arthritis (PsA) are poorly understood. The lymphatic system may control the homing of disease-associated T-cells to skin and extra-cutaneous sites like synovial joints and entheses.

Objectives: To study the capacity of lymphatic endothelial cells (LEC) to regulate T-cell homing capabilities in PsA.

Methods: Human dermal LEC (1.0x10⁴), and fibroblast-like synoviocytes of a patient with PsA (PsA-FLS; 1.0x10⁵) were pre-incubated for 3 days with PsA synovial fluid (PsA-SF; 0/100% v/v) and co-cultured with 2.5x10⁴ allogeneic CD4+CD45RO+CD25- T-cells that were sorted from peripheral blood mononuclear cells of 3 donors (with or without stimulation with αCD3/αCD28). After 72 h, T-cell viability was analyzed by the Cytotoxicity. The CCR4+ (Th2) and Th17 (CCR4-/CXCR3-) T-cells were identified. We also looked at lymphocyte-associated antigen (CLA) expression (CLA-). CD11b-IL-22, and TNF protein levels were determined by ELISA. Statistical analysis included unpaired t-test (two-sided) for two-group comparison or one-way ANOVA with the Tukey-Kramer post hoc test for multi-group comparisons.

Results: Stimulation of CD4+CD45RO+ T-cells in co-culture with PsA-FLS skewed towards the CCR6+ subset Th17/Th22, which were predominantly Th17 cells. Th17 differentiation upon stimulation was suppressed in co-culture with LEC, even when LEC were pre-incubated with PsA-SF. T-cell stimulation in co-culture with PsA-FLS, as compared to PsA-SF, promoted the generation of the Th17 secreting receptor CD11b that was co-cultured with PsA-FLS. The proportional reduction in CLA expression on T-cells in the co-cultures with LEC pre-incubated with PsA-SF 20% was comparable to PsA-SF, however LEC conserved CLA expression on CD4+CD45RO T-cells at a higher level than PsA-FLS. The expression of Th22 phenotypic markers was affected by the LEC, with a trend towards lower IL-17A and higher IL-22 levels were observed in the co-cultures with LEC that were pretreated with PsA-SF 20%, as compared to the co-culture with PsA-FLS. No differences were seen for TNF protein levels.

Conclusions: LECs are directly involved in T-cell differentiation and homing capabilities, as well as suppression of Th17 differentiation upon stimulation, as compared to PsA-FLS. LEC, promoted Th22 generation, and conserved CLA expression in CCR6+ T-cells, even when LEC were preincubated with PsA-SF. Studies are underway to confirm that LECs from relevant biological tissues (e.g. synovium and lymph nodes) are critical for tissue-restricted T-cell migration to skin and synovial membranes in PsA.

DOI: 10.1136/annrheumdis-2017-eular.3560
protein 1 (CHD1L1, also known as YKL-40) were validated with ELISA. Further, pirfenidone decreased the secretion of both DKK1 (p=0.006) and OPG (p=0.02) by SpA FLs stimulated with TGFβ1, TNFα, and INFγ, while the concentration of RANKL was below the detection limit of the ELISA assay in all cultures. Finally, pirfenidone inhibited the deposition of hydroxyapatite by osteoblasts in a dose-dependent manner (p=0.0001). This inhibition was partly reversible when removing pirfenidone after the first week of the mineralization assay.

Conclusions: Taken together, pirfenidone inhibited SpA myofibroblast formation and activity and osteoblast mineralization. This encourages further research in anti-fibrotics as treatment of new bone formation in SpA.

AB0120 ACCELERATED OSTEOGENIC DIFFERENTIATION OF HUMAN BONE-DERIVED CELLS IN ANKYLOSING SPONDYLITIS
Y.-S. Park1, S. Jo2, I.-H. Sung3, T.-H. Kim2, 1Orthopaedic Surgery, Hanyang University Hospital, Guri; 2Rheumatology, Hanyang University Hospital for Rheumatic Disease; 3Orthopaedic Surgery, Hanyang University Hospital, Seoul, Korea, Republic Of

Background: Ankylosing spondylitis (AS) is characterized by excessive bone formation with syndesmophytes, leading to bony ankylosis. The contribution of osteoblasts to the pathogenesis of ankylosis is poorly understood.

Objectives: The aim of this study was to determine molecular differences between disease controls (Ct) and AS bone-derived cells (BdCs) during osteogenic differentiation.

Methods: We confirmed osteoblastic differentiation of Ct and AS BdCs under osteogenic medium by observing morphological changes and measuring osteoblastic differentiation markers. Osteoblast differentiation was detected by alkaline phosphatase (ALP) staining and activity, and alizarin red S and hydroxyapatite staining. Osteoblast-specific markers were analyzed by qRT-PCR, immunoblotting, and immunostaining.

Results: Results showed that AS BdCs showed significantly increased osteoblast activity and differentiation capacity by regulating osteoblast-specific transcription factors and proteins compared to Ct BdCs. Active inflammation caused by adding AS serum accelerated bony ankylosis. Our study could provide useful basic data for understanding the molecular mechanism of ankylosis in AS.

SLE, Sjögren’s and APS - etiology, pathogenesis and animal models

AB0121 DYSREGULATED CIRCULATING miRNA LEVELS ARE CHARACTERISTIC OF BOTH NON SJÖGREN’S SICCA AND PRIMARY SJÖGREN’S SYNDROME PATIENTS
A.P. Lopes1,2, M.R. Hillen1,2, E. Chouri1,2, S.L. Blokland1,2, A.A. Kruize1, M. Rossato1,2, T.R. Radstake1,2, J.A. van Roon1,2, 1Department of Rheumatology & Clinical Immunology; 2Laboratory of Translational Immunology, University Medical Centre Utrecht, Utrecht, Netherlands

Background: MicroRNAs are small non-coding RNAs that play important regulatory roles in a variety of biological processes. They can regulate the post-transcriptional expression of target genes and play an important role in gene regulation. Specific microRNAs are stably present in serum and changes in their abundance are potentially disease-specific. Considering their important role in regulation of the immune system, we investigated circulating levels of miRNAs in patients with primary Sjögren’s syndrome (pSS) and those with non-Sjögren’s sicca (nSS) in relation to disease activity.

Objectives: To assess the expression of a large number of miRNAs in the serum of pSS and nSS patients as compared to healthy controls and to investigate their correlation with disease activity.

Methods: Two independent cohorts (discovery and validation) were established, consisting of a total of 37 pSS patients classified according to the 2002 criteria, 20 nSS patients that were not clinically considered to be pSS and did not meet the classification criteria, and 18 healthy controls (HC). Serum miRNAs were isolated and microRNA profiling was performed using the OpenArray platform in the discovery cohort. A selection of 10 miRNAs found to be differentially expressed between the groups was measured in the independent validation cohort using single TaqMan microRNA Assays.

Results: miRNA profiling revealed 10 miRNAs to be differentially expressed between the groups: 2 in pSS vs HC, 7 in nSS vs HC and 1 in both pSS and nSS vs HC. One miRNA was excluded from further analysis after technical validation by single TaqMan microRNA Assay. The other 9 miRNAs were measured in the validation cohort. Surprisingly, 2 miRNAs were validated to be increased in the nSS group as compared to HC (snRNA-U6 and miR-661). Using the discovery cohort of both cohorts of miRNAs, levels of miR-U6 and miR-661 was associated with serum Ig and C4 in the nSS group, but also in the pSS group. This prompted us to investigate miRNA expression in subgroups of pSS patients. snRNA-U6 and miR-661 levels are significantly increased compared to HC in pSS patients negative for autoantibodies. In autoantibody positive pSS patients, levels of miRNA-U6 and miR-661 are comparable to those found in HC and both miRNAs are significantly increased in autoantibody negative patients as compared to autoantibody positive pSS patients. In addition, their expression is strongly associated with leucocyte numbers in the autoantibody positive patients, but not in the negative patients.

Conclusions: Increased circulating levels of snRNA-U6 and miR-661 in patients with nSS and autoantibody negative pSS patients are associated with normal B cell activity and normal numbers of circulating leukocytes. Reduced miRNA levels in autoantibody positive pSS patients are associated with B cell hyperactivity and decreased leucocyte counts, which is possibly the result of immune cell migration to the inflammatory sites. Considering the important role of miRNAs in the control of immune cell activation, this work points to a significant role of miRNAs in pSS and nSS patients.

**T-CELL SURFACE GLYCOSYLATION PATTERN ALTERATIONS IN SLE – A PUTATIVE LINK TO GALECTIN-1-MEDIATED IMMUNOREGULATORY DEFICIENCY**

Á. Horning1, E. Szabó2, Á. Czibula3, É. Monostori2, L. Kovács1. 1Department of Rheumatology and Immunology, University of Szeged; 2Department of Genetics, Hungarian Academy of Sciences, Biological Research Centre, Szeged, Hungary

**Background:** We have previously found that activated T-cells from systemic lupus erythematosus (SLE) patients express lower amount of intracellular galectin-1 (icGal-1) than those of healthy controls and are resistant to the apoptotic effect of extracellular galectin-1 (ecGal-1), an endogenous immunoregulatory lectin. We also demonstrated that the de novo synthesized icGal-1 level affects apoptosis of T-cells induced by ecGal-1, since low icGal-1 expression resulted in reduced sensitivity to ecGal-1 (Deák M et al). We have therefore proposed the defective ecGal-1 production to be an explanation to the insufficient regulatory effects of ecGal-1 in SLE. However, altered binding of ecGal-1 to T-cells due to changes in surface glycosylation may also regulate the apoptotic activity of ecGal-1.

**Objectives:** We have herein hypothesized that the cell-surface glycosylation pattern, and consequently, lectin-binding ability in SLE T-cells is altered, and that an abnormal expression of glycosylation enzymes may account for these changes.

**Methods:** In order to analyse the glycosylation pattern of cell surface glyco-proteins, lectin binding assays were performed using 5 different plant lectins and human recombinant Gal-1 on resting and activated T-cells from patients with active SLE (n=8) with multi-colour flow-cytometry, and were compared with 15 healthy controls. mRNA levels of 13 glycosylation enzymes involved in the development of N-glycan structures on T-cells were measured with qPCR, and were correlated with the specific lectin binding data.

**Results:** As compared with the resting state, the increase in Gal-1 binding during activation was significantly lower in SLE T-cells than in controls, and the level of Gal-1 binding maximum was significantly reduced in SLE activated T-cells than in controls. Binding maximum of plant lectins that recognise high complexity N-glycans was increased less in SLE T-cells than in controls during activation. In addition, mRNA level of sialyltransferase ST3GAL6 was increased and neuraminidase Neu1 was decreased in active SLE patients as compared to controls. The ST6GAL1/NEU1 ratio in SLE patients positively correlated with the SLEDAI activity index.

**Conclusions:** SLE T-cells show decreased complexity of N-glycan structures. Increased ST3GAL6 and decreased Neu1 expression result in an increased density of terminal sialic acids, and this may explain the impaired Gal-1 binding. In addition, to the previously described deficiency in icGal-1 expression upon activation, our present results suggest that an abnormal glycan complexity and a shift toward terminal sialylation provide a further mechanism of pathological T-cell activation and regulation of T-cell viability in SLE.

**SEROLOGICAL MEASURES OF B CELL FUNCTION IN PATIENTS WITH SLE; HOW ROBUST ARE THEY OVER TIME?**

A. Hennessy1, 2, R. Marques2, M. Leandro1, 2, D. Isenberg1, 2, G. Cambridge2. 1Division of Rheumatology, Department of Medicine, University College London Hospitals; 2Centre for Rheumatology and Bloombury Rheumatology Unit, University College London, London, United Kingdom; 3Servicio de Medicina Interna B. Centro Hospitalar Universitario de Coimbra, Coimbra, Portugal

**Background:** In SLE the precise mechanisms whereby parent autoreactive B cells are generated and permitted to escape tolerance checkpoints, proliferate, persist and evade normal regulatory mechanisms remain poorly understood. Hypotheses include defective negative central selection, defective peripheral selection with enhanced germinal center activity as well as positive selection of B cells via autoantigen presentation or T-independent mechanisms. Biomarkers to identify possible breaches in tolerance checkpoints would allow more effective intervention. We have therefore measured relative levels of soluble sCD23 (released during B cell differentiation from naïve to memory B cell status) and the B cell activation factor, BAFF (survival factor and class-switch/differentiation promoter) in SLE sera to determine if relative levels of sCD23 and BAFF were of use as biomarkers to group patients based on B cell kinetics rather than clinical features. BAFF is often raised in SLE patients and can stimulate the aberrant differentiation of transitional B cells and of plasmablasts in vitro. Combining the 2 biomarkers could therefore indicate whether there was an increased expansion of naïve B cells, and whether BAFF was a possible driver/consequence of autoimmune disease in different patients.

**Objectives:** To determine whether relative levels of sCD23 and BAFF reflect disease activity or remain stable over time.

**Methods:** Stored SLE serum from patients who were Rituximab-naïve, had >5 samples available in the biobank over at least 6 months (n=38). Samples were analysed for levels of sCD23 and BAFF via ELISA. Wilcoxon matched-pairs signed rank test were used to compare serial values. Clinical details including BILAG scores were also collected for the available time points. If positive dsDNA at any time during the time period this was deemed positive. The latest BILAG was utilised and reviewed, a patient was deemed not to have system involvement if the final value was an “E” for that system.

**Results:** Sera from 38 SLE patients (32 female, 6 male) with mean age of first sample 42 (range: 25–72). Minimum interval between 1st and last sample was 101 weeks (range: 35–192 weeks). Patients were then sorted into clinical groups according to levels of these serum markers. Normal ranges defined as: sCD23 (1235–5023pg/ml), BAFF (584–1186pg/ml). Group I (n=9): – High (H) sCD23, Normal (N) BAFF; Group II (n=11) – H sCD23, H BAFF; Group III (n=17) – N sCD23, N BAFF; Group IV (n=2) – N sCD23, H BAFF. Figure 1 shows the p values generated from the Wilcoxon matched-pairs signed rank test for each time period demonstrating no significant change over time. Analysis of clinical data showed no differences in terms of organ involvement or anti-dsDNA Ab status.

**Conclusions:** Within a cohort of SLE patients, soluble CD23 and BAFF is stable over time despite variation in disease activity. Grouping patients based on sCD23 and BAFF profile may be useful in identifying distinct B cell maturation pathways reflecting underlying autoimmune pathways which vary between patients.

**BRAIN IMMUNOPATHOLOGY OF LUPUS-PRONE FC′RIIB−/−/YYA MICE - IMPLICATION TO THE INNATE IMMUNE RELATED MECHANISM OF NEUROPSYCHIATRIC SLE**

A. Nomura1, G. Murayama1, 2, A. Chiba1, S. Miyake1. 1Immunology; 2Rheumatology, Juntendo University, Tokyo, Japan

**Background:** Neuropsychiatric SLE (NPSLE) is a common manifestation of SLE and problems such as cognitive impairment or depression are elusive. The importance of innate immune related inflammation in the pathomechanism of neurodegenerative or psychiatric diseases has been recognized recently, and the importance of innate immunity in the pathogenesis of NPSLE has also been suggested. Therefore, we investigated innate immune mechanism of NPSLE by using lupus prone mice.

**Objective:** This study is conducted to understand the brain immune pathology of lupus-prone Fc′RIIB−/−/YYA mice in which innate immune stimulation is potentiated by the finding of Toll-like receptor 7 activation in brains of lupus-prone mice.

**Methods:** Immune cell subsets and histopathology of brains were analyzed by flow cytometry and immunohistochemistry in Fc′RIIB−/−/YYA mice compared with congenic mice at around 16 week-old when glomerulonephritis had developed. For flow cytometric analysis, microglia, myeloid lineage cells and lymphocytes were defined by staining with CD11b and CD45. Subsets of those cells and their activation status were analyzed. For histopathological analysis, microglia, brain macrophages, astrocytes and lymphocytes were immunostained and expression of MHC class I and class II were also analyzed.

**Results:** Flow cytometric analysis revealed increase in the number of microglial cells (CD11b+ CD45+R) and myeloid lineage cells (CD11b+ CD45+R) in the brains of Fc′RIIB−/−/YYA mice compared with congenic Fc′RIIB−/−/YYA mice. Mean fluorescence intensity of MHC class I was increased in microglia and myeloid lineage cells in Fc′RIIB−/−/YYA mice. An increased percentage of CD3 positive cells and CD19 positive cells were observed and their expression of CD69, an activation marker, were increased in Fc′RIIB−/−/YYA mice. In histopathology, number of macrophages and microglia identified by Iba1 (ionized calcium binding adapter molecule 1) positive cells were increased in Fc′RIIB−/−/YYA mice. In areas where MHC class I and II were highly expressed on macrophages, the sensitivity to Fc′RIIB−/−/YYA mice showed no differences in terms of organ involvement or anti-dsDNA Ab status.
reaction of astrocytes and patchy increase of lymphocytes were also observed. Furthermore, MHC class I and class II were also highly expressed in the vascular endothelium in FcγRIIB⁻ Yaa mice.

**Conclusions:** Activation of myeloid lineage cells and reactive changes of glial cells and endothelial cells were observed in the central nervous system of lupus-prone FcγRIIB⁻ Yaa mice. These results imply the role of innate immune mechanisms in the pathology of NPSLE.

**AB0126 AUTOPHAGY AND SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL SIGNIFICANCE OF ATG14⁺, FOXP3⁺, AND CD56⁺ EXPRESSION ON T REGULATORY CELLS AND NK CELLS**

**A. Rodriguez**¹, E.J. Zurita², A.R. Durán², R. Bustamante², A. Sánchez², M.A. Saavedra², C. Arroyo⁴, G. Medina⁴, L.J. Lara³, ¹Immunology Department, Escuela Nacional de Ciencias Biologicas; ²Immunology Department, Escuela Nacional de Ciencias Biologicas; ³Rheumatology Department; ⁴Banco de Sangre, Hospital de Especialidades “Dr. Antonio Fraga Mortex”, Centro Medicó La Raza, IMSS; ⁵Rheumatology Department, Hospital de Especialidades “Dr. Antonio Fraga Mortex”, CENTRO, Mexico City, Mexico

**Background:** Autophagy is a highly conserved protein degradation pathway, essential for removing protein aggregates and misfolded proteins in healthy cells. Autophagy and autophagy-molecules expression have been implicated in autoimmune diseases. Systemic Lupus Erythematosus (SLE) is a prototype of autoimmune illness whose main characteristic is the loss of immune tolerance. Recent evidences suggest that autophagy, and autophagy-related proteins participate in SLE immune regulation. However, little is known about the SLE clinical significance of autophagy-related proteins, T regulatory, and NK cells.

**Objectives:** To evaluate the expression of ATG14⁺ (autophagy-related key regulator protein), FOXP3⁺, CD25⁺ T regulators, CD56⁺NK cells in active and inactive SLE patients.

**Methods:** The expression of ATG14⁺, FOXP3⁺, CD25⁺, and CD56⁺ were measured by flow cytometry, and expressed in percentages in T and NK cells.

**Results:** A total of 40 SLE patients and 20 healthy controls were included. The expression of ATG14⁺, FOXP3⁺, CD25⁺, and CD56⁺ were measured by flow cytometry, and expressed in percentages in T and NK cells.

**Conclusions:** We found that in active patients autophagy is higher than in inactive patients. Inactive patients FOXP3 expression in NK cells is normal. These results can be due to the effect of the different treatments given according to clinical manifestations. Autophagy-related key regulator protein may be a new target of SLE treatment.

**AB0127 ANTI-DS-DNA ANTIBODIES REGULATE ATEROTHROMBOSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS THROUGH THE INDUCTION OF NETOSIS, INFLAMMATION AND ENDOThelial ACTIVATION**

**C. Perez-Sanchez**¹, M.A. Aguirre¹, S. Pedraza-Aravelo¹, M. del Río-Moreno¹, P. Ruiz-Limón¹, N. Barbarroja¹, Y. Jimenez-Gomez¹, I. Arias-de-la Rosa¹, N. Barbarroja¹, Y. Jimenez-Gomez¹, P. Segui¹, E. Collantes-Estevez¹, J.A. Gonzalez-Reyes¹, J.M. Villalba¹, M.J. Cuadrado³, C. Lopez-Pedrera¹, ¹IMIBIC/Reina Sofia Hospital/University of Cordoba; ²Rheumatology Department, Hospital de Especialidades “Dr. Antonio Fraga Mortex”, CENTRO, Mexico City, Mexico.

**Background:** The role of anti-dsDNA in the pathogenesis of the systemic lupus erythematosus (SLE) has been clearly established. However, the influence of these autoantibodies in the atherothrombotic status of SLE patients has not yet been evaluated.

**Objectives:** 1. To analyze in vivo the involvement of anti-dsDNA antibodies in the development of CVD in SLE patients. 2. To evaluate in vitro the mechanisms underlying the effects of anti-dsDNA antibodies in these processes.

**Methods:** The study was conducted in 50 SLE patients and 38 healthy donors. Endothelial function was assessed by measuring the post-occlusive hyperaemia using Laser-Doppler. Various markers of oxidative stress, inflammatory cytokines, prothrombotic mediators and NETosis, were quantified in purified leukocytes and plasma from SLE patients and controls. Activation of intracellular pathways was analyzed in monocytes using intracellular immunocytochemistry. Purified neutrophils, monocytes and lymphocytes from healthy donors and endothelial cells (ECs) were treated separately and in a trans-well co-culture system with anti-dsDNA antibodies isolated from the serum of SLE patients. Then, markers of inflammation, thrombosis, oxidative stress and NETosis were evaluated by flow cytometry (cytometry), RT-PCR (mRNA) and electron microscopy.

**Results:** SLE patients showed impaired micro-vascular endothelial function (reduction of hyperaemia post occlusion area) and altered expression levels of pro-inflammatory proteins (IL6, IL8, MCP-1 and P-CR), prothrombotic molecules (TF), oxidoreductases and prooxidant enzymes, and netosis-related molecules (NE, MPO and cell free-DNA). Monocytes from anti-dsDNA-positive SLE patients showed activation of various pathways related to inflammation, thrombosis and apoptosis (Erk, STAT3, p38, JNK, GSK, Bad and Caspase-3). Association studies demonstrated that molecules related to inflammation and thrombosis, endothelial dysfunction, oxidative stress and netosis were linked to the occurrence of thrombotic events, as well as to the presence of anti-dsDNA antibodies. In vitro treatment of purified leukocytes with anti-dsDNA antibodies promoted an increase in the production of NETosis, level of peroxides and percentage of cells with altered mitochondrial membrane potential, as well as enlarged expression of a number of proinflammatory and prothrombotic molecules. In vitro treatment of HUVEC with anti-dsDNA antibodies promoted an increase in endothelial activation molecules (ICAM-1, VCAM-1 and E-selectin).

**Conclusions:** 1. Positivity for anti-dsDNA antibodies is linked to an increased pro-atherothrombotic status in SLE patients. 2. Anti-dsDNA antibodies, in vitro, promote NETosis on neutrophils, apoptosis on monocytes, modulate the expression of molecules related to inflammation and thrombosis, and induce endothelial activation. Together, that data suggest the involvement of these autoantibodies in atherothrombotic development in SLE.

**AB0128 ALTERATIONS IN THE SPlicing MACHINERY COMPONENTS IN LEUKOCYTES FROM PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS INFLUENCES ITS DEVELOPMENT AND ATEROTHROMBOTIC PROFILE AND DRIVES THE THERAPEUTIC RESPONSE**

**C. Perez-Sanchez**¹, M.A. Aguirre¹, S. Pedraza-Aravelo¹, M. del Río-Moreno¹, P. Ruiz-Limón¹, N. Barbarroja¹, Y. Jimenez-Gomez¹, I. Arias-de-la Rosa¹, M.C. Abalos-Aguilera¹, P. Segui¹, E. Collantes¹, J. Castaño¹, R.M. Luque¹, M.J. Cuadrado³, C. Lopez-Pedrera¹, ¹IMIBIC/Reina Sofia Hospital/University of Cordoba; ²Lupus Research Unit and St. Thomas Hospital, London, United Kingdom

**Background:** Recent studies emphasize the relevance of alternative splicing in the development of genetic and autoimmune diseases and suggest therapeutic possibilities based on the modulation of this process.

**Objectives:** To identify alterations in the leukocyte splicing machinery of patients with systemic lupus erythematosus (SLE) and to evaluate its influence on the development and activity of the disease, its atherothrombotic profile, and the response to specific therapies.

**Methods:** An array of selected components of the major-(n=12) and minor-splicing machinery (n=4) and associated splicing factors (n=28) was developed, and their expression levels were evaluated using a Fluidigm methodology, in purified leukocytes from 36 SLE patients and 29 healthy donors (HD). In parallel, an extensive clinical/serological evaluation was performed. Carotid intima media thickness (CIMT) was used as atherosclerosis marker. Endothelial activity was

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.6883

---
monitored by laser-doppler, and pro-inflammatory and oxidative stress markers were quantified by flow cytometry and RT-PCR. In a parallel cohort of SLE patients (n=12), the effects of in vivo treatment with ubiquinol on spliceosome components was evaluated.

**Results:** As a general feature, a significant reduction in splicing factors and spliceosome components was found in all leukocytes of SLE patients. Interestingly, we found a specific altered profile of splicing factors and spliceosome components when compared monocytes (UZAF1, FBPI11, SRFS9), lymphocytes (RBBM22, PRP8, S1RFSF5) and neutrophils (RN4U, CA150). The reduced levels of some components of spliceosome in both monocytes and neutrophils was linked to the occurrence of thrombotic events, foetal loss and arterial hypertension. In lymphocytes, those reduced levels were strongly related to the positivity for anti-dsDNA antibodies in SLE patients, thus suggesting that reduced spliceosome machinery would contribute to increase in altered autoantigen assembly, inducing immune complexes autoantigen production. Correction studies have demonstrated an inverse relationship among reduced levels of spliceosome components/splicing factors and high activity of the disease (measured as SLEDAI), endothelial dysfunction, and increased expression levels of peroxides and peroxynitrites, as well as of altered mitochondrial membrane potential in monocytes and neutrophils. In vitro treatment of leukocytes from HDs with anti-dsDNA promoted a reduction in spliceosome components associated with the expression of proinflammatory and oxidative mediators. Finally, in vivo treatment with ubiquinol reversed reduced expression in SLE of spliceosome components related to their prothrombotic phenotype.

**Conclusions:** These results reveal the existence of SLE-associated spliceosome alterations -promoted by anti-dsDNA antibodies- which could be related to the development and activity of this autoimmune condition and have influence on the induction of mechanisms that drive atherothrombosis as well as the therapeutic response.

**HMGB1+ MICROPARTICLES IN SYSTEMIC LUPUS ERTHROMYOSITIS PATIENTS WITH LUPUS NEPHRITIS**

C. Burbano, J.A. Gómez-Puerta, M. Rojas, G. Vasquez, J. Orejuela, C.H. Muñoz, A. Vanegas-García, D. Castaño, Universidad de Antioquia, 1Hospital Universitario Vicente Fundación, Medellin, Colombia

**Background:** High mobility group box protein 1 (HMGB1) is a nucleic acid-binding protein that can function as an alarm when is released from activated and dying cells. In association with nucleosomes, HMGB1 may contribute to the pathogenesis of systemic lupus erythematosus (SLE). Some previous reports have associated HMGB1 with the pathogenesis of cutaneous lupus and lupus nephritis (LN). HMGB1 may also be contained in microparticles (MPs). These vesicles have a wide spectrum of biological activities in intercellular communication, and they compete with apoptotic cells to bind mononuclear phagocytes.

**Objectives:** To evaluate the association of MP-HMGB1+ circulating with LN and to correlate them with LN activity.

**Methods:** Blood samples from 60 SLE patients were used to isolated MPs from platelet-poor plasma by centrifugation and their count, cell source and phenotype were characterized by flow cytometry. Renal pathology was reported using the standardized International Society of Nephrology/Renal Pathological Society classification. Inactive lupus nephritis (LN) was defined by the presence of one or more of the following criteria: 24 hrs proteinuria 500 mg/dl or inactive urine sediments (<5 red cells/HPF) and no red leucocytes (<5 white cells/HPF) and stable serum creatinine.

**Results:** Mean age of SLE patients was 31.9±10.8 years, and mean disease duration was 7.8±6.2 years. 73% patients had LN and LN were female. Patients with LN had significantly higher frequency of MP-HMGB1+, no significant differences were found among patients with active versus inactive LN or among patients with complete versus non-renal manifestations. A moderate positive correlation with disease activity (SLEDAI, r=0.367, p=0.020), anti-C1q antibodies titers (r=0.42, p=0.032), and no correlation was found with activity or chronicity indexes on renal biopsies. A ROC curve for MP-HMGB1+ and renal involvement showed a good discriminative ability (AUC 0.705). A cutoff of 15.7% of MP-HMGB1+ showed the best discrimination threshold with a sensitivity of 63.3% and specificity of 83.3%.

**Conclusions:** In our cohort of patients with SLE, MP-HMGB1+ was significantly higher in patients with LN and in patients with active disease. Given the multiple implication of HMGB1 in SLE, including the active kidney recruitment of mononuclear phagocytes, we consider that MP-HMGB1+ could be a potential biomarker for LN in SLE patients.

Antiphospholipid Syndrome Patients show an Altered Profile of Endothelial Progenitor Cells and Endothelial Microparticles

C. Barbatì, F. R. Spinelli, F. Miranda, F. Ceccarelli, M. Vomero, L. Massaro, T. Colasanti, G. Valesini, G. Alessandri, F. Conti. Department of Internal Medicine and Medical Specialties, Lupus Clinic, Sapienza University of Rome, Rome, Italy

Background: Antiphospholipid Syndrome (APS) is an autoimmune disease characterized by recurrent thromboembolic events and pregnancy morbidity associated to the presence of specific serum antibodies directed against membrane phospholipids and proteic co-factors. APS represents the earlier and reversible stage of subclinical atherosclerosis that characterizes these patients. An altered profile of endothelial progenitor cells (EPCs) and endothelial microparticles (EMPs) could promote endothelial damage compared to who did not. Kaplan-Meier survival curve showed no difference compared to healthy subjects.

Objectives: Our aim was to evaluate circulating EPCs and EMPs in primary APS patients (PAPS).

Methods: We studied primary APS patients with previous thromboembolic events and sex and age-matched healthy controls (HC). Circulating EPCs was identified by flow cytometry analysis as CD34+/KDR+ positive cells isolated from peripheral blood mononuclear cells (PBMCs); EMPs was obtained by centrifugation of whole blood and quantified by flow cytometry (CD31+/CD41a+). Data were expressed as mean±standard deviation or median (interquartile range) when appropriate; correlations between EPC and EMP levels with anti-cardiolipin and anticardiolipin like protein I, both IgM and IgG, were scored blindly by a renal pathologist. To identify factors related to the development of LN, Cox proportional hazard regression model and Kaplan-Meier curves were used.

Results: The concentrations of pIGBP1 in SLE patient were higher than those in healthy individual (9.6±8.4 ng/mL vs 4.5±2.4 ng/mL) and positively correlated with SLEDAI score. However, the concentrations were not different between LN and non-nephritis SLE and were not associated with activity index score in renal pathology. During follow-up more than 5 years, nephritis was developed in 20 patients (20.5%) among 39 SLE patients who did not have renal involvement at baseline. Interestingly, levels of pIGBP1 (p=0.002), CRP (p=0.009), or anti-dsDNA antibody (p=0.03) were significantly elevated in 8 patients who developed LN compared to who did not. Kaplan-Meier survival curve showed that initial pIGBP1 (>10.71 ng/mL) as well as anti-dsDNA (>0.7IU/mL) were associated with high probability of LN development in the future.

Conclusions: Based on our results, high concentration of pIGBP1 could be a valuable marker to represent high SLE activity and a predictor for developing nephritis in SLE patients.

**AB0135** BLOOD LYMPHOCYTE SUBSETS ACCORDING TO THE CLINICAL PROFILE IN SJÖGREN'S SYNDROME

**Background:** It has been recently described the occurrence of disturbances in lymphocyte subsets in Sjögren’s syndrome (SS) which may reflect B cell hyper activation and a T cell adjaent role.

**Objectives:** We aim to characterize circulating lymphocyte subsets in SS patients, according to disease activity and antibody profile.

**Methods:** We have included in this study 53 SS patients (2002 AECG criteria) of which 22 with >10 years since diagnosis and 31 with <2 years since diagnosis, and 22 healthy controls. Lymphocyte subsets, including follicular (Thf) and regulatory T (Treg) cells, maturation subsets, plasmablasts (PB) and regulatory B (Breg) cells, were characterized by flow cytometry. Statistical analysis was performed with GraphPad. Significance was considered for p<0.05.

**Results:** Compared to controls, SS patients had lower absolute counts of B (p=0.0337) and T cells (p=0.0012), lower CD4 (p=0.0002) and higher CD8 percentages (p=0.0006), resulting in an increased CD4/CD8 ratio (p=0.0006). Additionally, there was decrease in absolute counts of Tregs (p=0.0008) and Th17 cells (p=0.0005) in SS patients. Moreover, there was a decreased absolute counts (Th1) and Tfh17 cells, identified by CXCR5 expression, though higher levels of IL21+CD4 T cells (p=0.0299) and Th1 cells (p=0.0092). SS patients also presented higher % of naïve B cells (p=0.0412), lower % and absolute counts of memory (% =0.0161; abs p=0.0002) and unswitched memory (% =0.0106; abs p=0.0005) B cells and lower absolute counts (p=0.0001) of switched memory B cells. SS patients had higher naive/memory B cell ratios, compared to healthy subjects (p=0.0219). Accordingly, using the Bm1–5 classification, we have found decreased Bm1 (% =0.0087; Abs p=0.0007), eBm5 (Abs p=0.0005) and Bm5 (Abs p=0.0015) in SS patients. Similar Bm2+Bm3/eBm5+Bm5 ratios were observed in patients and controls. CD24+CD27+ Bregs were also decreased (p=0.0102) in SS patients.

**Conclusions:** SS patients had also an increase in IL21+CD4 T cells, particularly in patients with extra-glandular manifestations (EGM) (n=12), who also presented less Tfh17 cells compared to SSA-. Moreover, there was a decreased absolute count (Bm1) and Bm17 cells, identified by CXCR5 expression, though higher levels of IL21+CD4 T cells (p=0.0299) and Th1 cells (p=0.0092). SS patients also presented higher % of naïve B cells (p=0.0412), lower % and absolute counts of memory (% =0.0161; abs p=0.0002) and unswitched memory (% =0.0106; abs p=0.0005) B cells and lower absolute counts (p=0.0001) of switched memory B cells. SS patients had higher naive/memory B cell ratios, compared to healthy subjects (p=0.0219). Accordingly, using the Bm1–5 classification, we have found decreased Bm1 (% =0.0087; Abs p=0.0007), eBm5 (Abs p=0.0005) and Bm5 (Abs p=0.0015) in SS patients. Similar Bm2+Bm3/eBm5+Bm5 ratios were observed in patients and controls. CD24+CD27+ Bregs were also decreased (p=0.0102) in SS patients.

**AB0136** MICROPARTICLES FROM SLE PATIENTS ARE A SOURCE OF INTERFERON-ALPHA

F. Miranda, C. Barbati, F.R. Spinelli, F. Ceccarelli, S. Truglia, C. Alessandri, G. Valesini, F. Conti. Dipartimento di Medicina Interna e Specialità Mediche, Reumatologia, Sapienza Università di Roma, Rome, Italy

**Background:** Systemic lupus erythematosus (SLE) is the prototype of systemic autoimmune disorders. In the late 1970s, increased serum levels of interferon (IFN) were shown for the first time to be significantly associated with SLE and to correlate with disease activity. IFNα is a pleiotropic cytokine that can affect multiple cell types involved in lupus. Plasmacytoid dendritic cells have a special role in the production of IFN and are the main sources of serum interferon. IFNα has the potential to dramatically influence the development, progression, and pathogenesis of SLE as it can influence the function and activation state of most major immune cell subsets and function as a bridge between innate and adaptive immunity. Lupus-prone mouse models, indicates that the type I interferon system may play a pivotal role in the pathogenesis of several lupus and associated clinical features, such as nephritis, neuropsychiatric and cutaneous lupus. Circulating microparticles (MPs) are ubiquitous in the blood of healthy individuals. These MPs play an active role in coagulation and intercellular communication and assist in activation or suppression of the immune system, depending on their parent cell origin. Changes in the concentration and/or composition of circulating microparticles have been described in various autoimmune diseases, including rheumatoid arthritis (RA) systemic sclerosis (SSc) and systemic lupus erythematosus (SLE). For SLE, the reported microparticle-related changes remain somewhat inconclusive.

**Objectives:** To better understand the role of MPs in SLE patients, we analyzed the presence of interferon alpha on MPs surface.

**Methods:** MPs were isolated from citrate-treated plasma; blood cells were removed by two steps of Ficoll gradients (2500g for 15min at 20 C two time). The resulting platelet-poor-plasma (PPP), was analyzed by flow cytometry with specific antibody against IFN alpha.

**Results:** 20 consecutive SLE patients (10 with active lupus nephritis) and 10 sex- and age-matched healthy control subjects were included in the study. We found that MPs from SLE patients carry on their surface IFN alpha. Moreover, the percentage IFNα+MPs was higher in SLE patients and in lupus nephritis patients than in healthy controls. There was no significant difference between patients with and without renal involvement.

**Conclusions:** The results of the present study show for the first time the presence of IFN alpha on MPs surface. We may assume that INF+MPs derive from dendritic cells. In lupus nephritis patients the increased recruitment of dendritic cells was at tubular interstitial level, with subsequent IFN alpha production. Interestingly, MPs (containing RNA and DNA) could stimulate type I IFN production in plasmacytoid dendritic cells and MPs releasing.

**AB0137** ALTERATIONS IN MICRONA EXPRESSION PROFILES IN PRIMARY SJÖGREN'S SYNDROME AND SYSTEMIC LUPUS ERYTHEMATOSUS

G. Pagg1, J.-Q. Chen1, S. Poliska1, K. Szabó1, T. Tarr1, B.L. Bálint2, P. Szodoray3, M. Zeher1. 1Division of Clinical Immunology; 2Department of Biochemistry and Molecular Biology, University of Debrecen; 3Centre for Immune Regulation, University of Oslo, Debrecen, Hungary

**Background:** MicroRNAs (miRNAs) are single-stranded, endogen non-

- PS) and antibodies against surface markers endothelial cells (CD31+CD41-).

**Mann-Whitney and Spearman correlation tests were used.** A p value ≤0.05 was considered statistically significant.

**Results:** Sixty SLE patients (55F/5M, age 41,7±9.6 Y disease duration 149±12 months) and 29 healthy controls were studied. Twenty-eight patients had renal involvement and the total number of plasmatic MPs was lower in SLE patients than HC (p=0.001). In contrast there was no significant difference in levels of EMPs between the two groups. When the patients were divided according to renal involvement, the patients with active lupus nephritis (A-LN) showed lower plasmatic level of EMPs in comparison to inactive LN (I-LN) (p=0.01), while the patients with LN had higher levels of EMPs than HC (p=0.002). There was no significant difference of total urinary level of MPs between SLE patients and HC. Urinary levels of EMPs were higher in SLE and in lupus nephritis patients than HC.

**Conclusions:** The results of the present study show increased urinary and plasmatic levels of EMPs in patients with lupus nephritis in remission. Circulating EMPs have been considered as a potential biomarker of endothelial activation and damage in several autoimmune disorders, and higher EMP levels have been detected in patients with vasculitis and associated with disease activation. According to our results, plasmatic EMPs levels are higher in inactive LN patients than in healthy donors. These results may suggest a potential role of EMP as a biomarker of lupus nephritis.

**AB0135** PLASMATIC AND URINARY ENDOTHELIAL MICROPARTICLES ARE INCREASED IN PATIENTS WITH LUPUS NEPHRITIS

F. Miranda, C. Barbati, S. Truglia, F.R. Spinelli, F. Ceccarelli, A. Alessandri, G. Valesini, F. Conti. Dipartimento di Medicina Interna e Specialità Mediche, Reumatologia, Sapienza Università di Roma, Rome, Italy

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease presenting with a wide array of clinical manifestations and incompletely understood pathogenesis. It is characterized by alterations in the innate and adaptive immune system ultimately leading to the loss of immunologic tolerance and occurrence of autoantibodies against nuclear material. Lupus nephritis is one of the most severe features of SLE determining an increase in morbidity and mortality rates. Renal biopsy still represent a fundamental diagnostic and prognostic tool for LN. Therefore, non-invasive surrogate biomarkers of active LN are urgently needed. Circulating, heterogeneous submicroparticles (MPs) are released from cells and platelets constitutively and upon cellular activation or apoptosis. Such MPs may reflect the state of their parental cells and tissues and could serve as markers of pathology. Particularly in SLE, MPs are potential biomarkers and triggers of autoimmunity. Recent studies have demonstrated increased levels of plasmatic EMPs in patients with SLE active disease and their reduction after treatment.

**Objectives:** The aim of this study was to investigate plasmatic and urinary levels of microparticles in a cohort of SLE patients with and without renal involvement compared to healthy controls.

**Methods:** Consecutive SLE patients and sex- and age-matched HC were included in the study. MPs were isolated from plasma and urine and characterized by flow cytometry using AnXV (a probe that binds to the exposed phosphatidilserine
cording small RNAs, ranging from 18 to 25 nucleotides in length. miRNAs are essential in regulating gene expression, cell development, differentiation and function. Dysregulation in miRNA expression may contribute to the development of autoimmunity. However, a given miRNA may have hundreds of different mRNA targets and a target might be regulated by multiple miRNAs, thus the conclusion of dysregulated miRNA expression profiles could give a better insight into the development of immunological disturbances in autoimmune diseases.

**Objectives:** The aim of our study was to examine the changes in miRNA expression profiles in patients with primary Sjögren's syndrome (pSS) and systemic lupus erythematosus (SLE).

**Methods:** Eight pSS patients, 8 SLE patients and 7 healthy control subjects were enrolled in the investigation. miRNAs were isolated from peripheral blood mononuclear cells, and expression patterns were determined with Illumina next-generation sequencing technology. Since the immune system, pSS and SLE encompasses pronounced B cell hyperactivity along with specific autoantibody production, we paid a special attention on the association between miRNA expression levels and altered peripheral B cell distribution.

**Results:** In SLE patients 135, while in pSS patients 26 miRNAs showed altered expression. Interestingly, the 25 miRNAs including miR-146a, miR-16 and miR-21, which were over-expressed in pSS patients, were found to be elevated in SLE group, as well. On the contrary, we observed the down-regulation of miR-150-5p, which is a novel and unique finding in pSS. Levels of several miRNAs observed in SLE, were modulated in the pSS group as well, such as miR-148a-3p, miR-152, miR-155, miR-223, miR-224, miR-326 and miR-342. Expression levels of miR-223-5p, miR-150-5p, miR-155-5p and miR-342-3p, which miRNAs are potentially linked to B cell functions, showed associations with the B cell proportions within peripheral blood mononuclear cells.

**Conclusions:** The observed differences in miRNA expression profiles and the better understanding of immune regulatory mechanisms of miRNAs may help to elucidate the pathogenesis of pSS and SLE.

**AB0138**

**INTERFERON-GAMMA CHALLENGE OF PBMC FROM PATIENTS WITH LUPUS NEPHRITIS IN REMISSION DECREASES SUPPRESSOR OF CYTOKINE SIGNALING 1 (SOCS1) AND REGULATORY T CELLS (TREGS) AND PROMOTES IMMUNE ACTIVATION**

G. Gibor1, U. Arad1, J. Walliman1, J. Ablin1, V. Aloush1, I. Kaufman1, S. Jacky2, D. Ospina1, O. Elkind3, D. Paran1, A. Sharabi1,2, Rheumatology, 1 Tel Aviv Medical Center, Tel Aviv, Israel; 3 Harvard BIDMC, Boston MA, United States

**Background:** Interferon-gamma (IFN-γ) plays an important role in the development of lupus nephritis (LN). Regulation of IFN-γ signaling that occurs in disease remission and in active LN is herein addressed.

**Objectives:** To study the impact of IFN-γ on PBMC obtained from patients with LN in remission as compared to active LN.

**Methods:** Sixteen patients fulfilling the ACR classification criteria for systemic lupus erythematosus were recruited. All patients had a history of LN of whom 10 were in remission (as defined by EULAR criteria) and 6 had active LN (as defined by SLEDAI-2K or BILAG). Healthy subjects (n=10) were included as a control group. Sera and PBMC were obtained from each individual. Flow cytometry, western blots and real time RT-PCR were used in processing and detection of cell subtypes, protein and mRNA levels. Recombinant human IFN-γ (rhIFN-γ) and anti-IFN-γ neutralizing antibody were used in vitro. Mann-Whitney and student t-tests were used for statistical analysis.

**Results:** In active LN there was a significant 2-fold increase in CD4+CD69+ activated T cells as compared to healthy subjects and patients in remission. Reactivity to interferon-gamma receptor was determined by the phosphorylation of its predominant transcription factor, signal transducer and activator of transcription 1 (STAT1) in the cells that were incubated with rhIFN-γ. Its predominant transcription factor, signal transducer and activator of transcription 1 (STAT1) in the cells that were incubated with rhIFN-γ all groups had elevated its predominant transcription factor, signal transducer and activator of transcription 1 (STAT1) in the cells that were incubated with rhIFN-γ during 24h and 48h, respectively, and healthy subjects responded likewise. In active LN there was a significant 2-fold increase in CD4+CD69+ activated T cells as compared to healthy subjects and patients in remission.

**Conclusions:** In LN remission a challenge with IFN-γ could lead to immune activation and a risk of flare-up, as it results in a decrease in both SOCS1 and Tregs and a robust STAT1 phosphorylation. In active LN, STAT1 phosphorylation is less diminishing, as both SOCS1 and Tregs are saturated, which could affect their suppressive effectiveness.

**ROLE OF MUCOSAL-ASSOCIATED INVARIANT T (MAIT) CELLS IN A LUPUS MODEL**

G. Murayama1, A. Chiba2, A. Nomura1, H. Amano1, K. Yamaji1, N. Tamura1, S. Miyake1,2, Department of Internal Medicine and Rheumatology, 1Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan; 2Department of Immunology, Tokyo Medical and Dental University, Tokyo, Japan

**Background:** Mucosal associated invariant T (MAIT) cells are innate T cells that are regulated by MHC-related molecule-1 (MR1) and express a semi-invariant TCRγ chain. Vα7.2-Jα33 in humans and Vα19-Jα33 in mice. Previously, we have demonstrated that MAIT cells played a protective role against experimental autoimmune encephalomyelitis, an animal model of multiple sclerosis. We found that MAIT cells are activated in patients with systemic lupus erythematosus (SLE) and that the activation state of MAIT cells correlated with SLE disease activity index (SLEDAI) score, suggesting their association in lupus pathology.

**Objectives:** We set out to clarify functions of MAIT cells in a lupus model by using FcγRIIB+ Yaa mice.

**Results:** Yaa mice were crossed to MR1 deficient mice lacking MAIT cells, and disease progression was compared between MR1+ FcγRIIB+ Yaa and MR1– FcγRIIB+ Yaa mice at 1–4 months of age. Serum anti-dsDNA antibody levels were measured and urinary microalbumin were evaluated. At the time of sacrifice, at 4 months of age, the severity of nephritis and dermatitis were assessed by histologically and IgG deposition in skin and glomeruli was measured.

**Conclusions:** Survival rate was significantly reduced in MR1– FcγRIIB+ Yaa mice compared with MR1+ FcγRIIB+ Yaa mice. Anti-dsDNA antibody levels were remarkably higher in MR1– FcγRIIB+ Yaa mice compared with MR1+ FcγRIIB+ Yaa mice at 4 months of age. Even though Glomeruli were significantly enlarged both in MR1+ and MR1– FcγRIIB+ Yaa mice due to a marked cellular proliferation in glomeruli, the glomerulonephritis score tended to be lower in MR1+ FcγRIIB+ Yaa mice compared with MR1– FcγRIIB+ Yaa mice. A larger amount of IgG deposition was observed in mesangial area and along glomerular capillary walls in MR1+ than MR1– FcγRIIB+ Yaa mice. However, MR1+ FcγRIIB+ Yaa mice showed exacerbated inflammation in the skin lesions. There was a high degree of inflammatory cells infiltration into the skin and a significant worsening of dermatitis score in MR1+ FcγRIIB+ Yaa mice compared with MR1– FcγRIIB+ Yaa mice.

**Conclusions:** These data suggests that MAIT cells exhibit dual roles in lupus pathogenesis. MAIT cells enhance autoantibody production and the disease severity of nephritis, but have a suppressive effect on dermatitis. Further studies are under going to uncover the mechanisms by which MAIT cells are involved in each target tissues.

**LUPUS-PRONE SLAM HAPLOTYPE EXERTS MONOCYTOSIS AND DEVELOPS SPECIFIC PHENOTYPE OF AUTOIMMUNE DISEASE INTRODUCED BY YAA MUTATION**

H. Amano1, K. Nishikawa2, Q. Li3, S. Kawano1, K. Yamaji1, S. Hirose1, N. Tamura1, T. Department of Internal Medicine and Rheumatology; 2Department of Pathology, Juntendo University School of Medicine, Tokyo; 3Department of Biomedical Engineering, Tohoku University School of Medicine and Technology Center, Tohoku University of Yokohama, Yokohama, Japan

**Background:** We previously obtained a 129-derive FcγRIIB-deficient C57BL/6 (B6) congenic strain of mice, which spontaneously developed severe rheumatoid arthritis (RA)1. The introduction of the Yaa (Y-linked autoimmune acceleration) mutation, which is a consequence of a translocation from the telomeric end of the X chromosome containing the Ya gene onto the Y chromosome, to the FcγRIIB-deficient B6 mice (B6.FcγRIIB–/–Yaa) developed lupus-like nephritis but not RA2.

**Objectives:** By extensively backcrossing 129-derived FcγRIIB-deficient mice to B6 mice, we established wildtype FcγRIIB and 129-derive autoimmune-prone SLAM haplopyte (SLAM) strains.2 We examined the phenotypes of SLAM mice, and also Yaa mice by introducing Yaa mutation to these mice.

**Methods:** We analyzed peripheral blood monocyte subset and also serum autoantibodies as well as immunohistopathological findings of kidneys and lungs.

**Results:** SLAM mice showed age-associated monocytosis with marked expan-
sion of Gr-1 negative monocytes, also perivascular inflammatory cell infiltration in lungs. But they did not show any pathogenic autoantibodies. When introducing Ya mouse, Slam129. Ya mice showed significant increase the serum levels of anti-RNP antibodies and anti-Sm antibodies. Although they showed significant increase of serum levels of IgM class anti-dsDNA antibodies, they did not show the elevation of IgG class anti-dsDNA antibodies. Also they developed nephritis but the pathological score was significantly lower than B6.FcRRIIB-/-, Ya mice.

Conclusions: Autoimmune-prone SLAM haplotype plays a role for Gr-1 negative monocytosis and Slam129. Ya mice developed specific lupus phenotype with elevation of anti-RNP and anti-Sm autoantibodies.

LOW DOSE IL-2 CIRCUMVENTED CD3 SIGNAL TRANSMITTING IN T CELLS IN THE TREATMENT OF SLE

J. He 1, X. Sun 1, J. Li 1, R. Zhang 1, D. Yu 2, Z. Li 1.

1 Peking University People’s Hospital. Beijing, China; 2School of Biomedical Sciences, Monash University, Melbourne, Australia

Background: mTOR signaling is proved to be one of the most important pathway in the pathogenesis in SLE. However, in patients with SLE, whether mTOR pathway can be inhibited by low-dose IL-2 remains controversial.

Objectives: To clarify the effects of low-dose IL-2 therapy on mTOR signaling in the treatment of SLE.

Methods: Eight patients with active SLE were treated with 1 million IU IL-2. Phophrylation of S6 ribosomal protein (S6RP), AKT and pSTAT5 were measured before and after the first 2 week of low-dose rhlIL-2 administration. C57BL/6 mice (male, 8–12 weeks old) were intraperitoneally immunized with SRB and followed by administration of different doses (low:10,000 IU and high:300,000 IU) of rhlIL-2 or PBS from day 3 to day 9. The ratio of Th1, Th2, Th17, Treg and Treg as well as the level of S6RP, AKT and pSTAT5 were assayed by flow cytometry.

Results: Low-dose IL-2 was efficient and well tolerated in active SLE, and was associated with expansion of Treg cells (P<0.001) and reductions of Th17 and Th17 cells (P<0.001). No significant change of pS6RP and pAKT was observed. On the other hand, there was a significant induction of the activation of STAT5. In mouse studies, low-dose IL-2 inhibited the differentiation of Th17 cells and T1h cells. Comparing with high dose IL-2 group, there was no significantly increased mTOR activity after low-dose IL-2 administration.

Conclusions: Low-dose IL-2 might circumvent mTOR pathway and play a regulatory role in the treatment of lupus.

**AB0142**

IGM ANTIBODIES AGAINST PHOSPHORYLCHOLINE PROMOTE POLARIZATION OF T REGULATORY CELLS FROM PATIENTS WITH ATHEROSCLEROTIC PLAQUES, SYSTEMIC LUPUS ERYTHEMATOUS AND HEALTHY DONORS: A NOVEL IMMUNOLOGICAL CONCEPT

Background: Igm antibodies against Phosphorycholine (anti-PC) are negatively associated with atherosclerosis, cardiovascular disease (CVD) and systemic lupus erythematous (SLE) where the risk of CVD and atherosclerosis is very high. Here we study effects of Igm anti-PC on Th17 and T regulatory cells (Tregs).

Objectives: Immunomodulation in atherosclerosis and SLE could have a huge impact on disease prevention and treatment.

Methods: Mononuclear leukocytes were isolated from peripheral blood (PBMC) obtained from healthy blood donors, from six SLE patients with age- and sex-matched controls and from symptom-giving human atherosclerotic plaques. The patient and SLE group on Th17 (CD4+CD14+CD25+CD127−) and Treg (CD4+CD25+CD127+CD102−) cells were determined by flow cytometry in CD4+ T cells after 6 days culture with Th17 or Treg-polarizing cytokines, with PMA and Ionomycin stimulation. IgM anti-PC were extracted from total IgM, with flow-through IgM as controls. Dendritic cells (DC) were differentiated from PBMC. Antibody peptide/protein characterization was done by ELISA.

Results: IgM anti-PC increased significantly the proportion of Tregs from healthy donors, SLE patients and from atherosclerotic plaque cells while control antibodies did not. T cells from SLE patients had a significantly lower proportion of Tregs and higher proportion of Th17 cells as compared to matched controls. IgM anti-PC but not control antibodies significantly reduced production of IL-17 and TNF-alpha in cell culture from SLE patients and from atherosclerotic plaque cells. IgM anti-PC interacted with CDA40 and kept DCs in an immature stage potentially being tolerogenic. We identify differences on the IgM peptide expression level in anti-PC compared to control antibodies.

Conclusions: IgM anti-PC increase Tregs and having low levels could contribute to both SLE and atherosclerosis (and CVD) and could thus represent a novel underlying mechanism in these conditions. This finding could also have therapeutic implications.

IMMUNOMODULATION FOLLOWED BY QUANTITATIVE TRANSSCRIPTOMIC PROFILING TO CHARACTERIZE THE FUNCTIONAL ROLE OF THE SJÖGREN’S-ASSOCIATED NCRNA AC092580.4

Arthritis & Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, United States

Background: Despite concerted efforts to characterize dysregulated transcriptional responses observed in Sjögren’s syndrome and related autoimmune disorders, both in whole blood and target tissues), the functional roles of non-coding RNAs (ncRNAs), many of which have been identified as critical players in transcriptional regulation of disease, remain poorly defined.

Objectives: In the present study, we describe ongoing efforts to functionally characterize the upregulated ncRNA identified by RNA-seq and in silico approaches, AC092580.4 (FC=2.54), which we hypothesize plays a role in T and NK cell responses.

Methods: To study the immunomodulation of the ncRNA AC092580.4, we carried out a time-course experiment (0–36 hrs) using either PMA/I (500x dil) or universal Type I Interferon. Relative gene expression changes were determined using the 129 strain-derived Sle16 locus in rheumatoid arthritis and related autoimmune disease, both in whole blood and target tissues), the functional roles of non-coding RNAs (ncRNAs), many of which have been identified as critical players in transcriptional regulation of disease, remain poorly defined.

Objectives: In the present study, we describe ongoing efforts to functionally characterize the upregulated ncRNA identified by RNA-seq and in silico approaches, AC092580.4 (FC=2.54), which we hypothesize plays a role in T and NK cell responses.

Results: Of the transcripts showing DE in our SS RNA-seq study, we identified 98 as having significantly correlated expression with AC092580.4 in the SS with expression matrix (r=0.70 or < −0.65). To understand the possible effects of immunomodulation on relevant cells, we stimulated HS-2 cells with PMA/I at various time points and assessed AC092580.4 expression by. We observed downregulation of AC092580.4 and the co-expressed transcript GLMAM (tough: 12–16hrs; FC=0.09) followed by slow recovery at 36hrs (FC=0.59). To characterize these transcriptional changes further, we performed RNA-seq using healthy PBMCs exposed to various T cell stimulants. We observed marked upregulation of both AC092580.4 and GLMAM 24/36hrs by all stimulants (FC=4.85–5.98). Other transcripts showed variable responses. Cav2 was upregulated by PMA/I, but downregulated by CD3/CD28 and PHA. Stimulation by PHA leads to upregulation of CD3D (FC=1.56) and SNRPD1 (FC=3.28) with little change in RPL3FA (FC=1.09). Stimulation by CD3/CD28 similarly leads to upregulation of SNRPD1 (FC=2.85) and SNRPD1 (FC=10.04), but clear downregulation of RPL3FA (FC=0.64). We assessed AC092580.4 expression in HS-2 cells exposed to I IFN and observed initial upregulation (6hrs, FC=1.46) followed by gradual downregulation (36hrs, FC=0.18).

Conclusions: In the present study, we have initiated stimulation studies with 1Rheumatology; 2Pediatrics; 3Gynecology and Obstetrics, Faculty of Medicine of the University of Porto, Porto, Portugal

PREGNANCY OUTCOMES IN IMMUNE-MEDIATED RHEUMATIC DISEASES: A RETROSPECTIVE LONGITUDINAL STUDY IN A TERTIARY HOSPITAL

J. Bernardo 1, I. Brito 1, H. Guimarães 2, M. Guimarães 3, R. Fonseca 1.

1 Rheumatology; 2Pediatrics; 3Gynecology and Obstetrics, Faculty of Medicine of the University of Porto, Porto, Portugal

Background: Autoimmune rheumatic diseases such as systemic lupus erythematosus (SLE), antiphospholipid antibody syndrome (APS) and Sjögren’s syndrome (SS) are part of a clinical spectrum eligible to affect women in child-bearing ages, increasing pregnancy morbidity and affecting neonatal outcomes. Pregnancy complications include the teratogenic risk from immunosuppressive drugs, pregnancy-related disease flares, recurrent pregnancy loss, premature

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.4175
delivery, intrauterine growth restriction (IUGR) and preeclampsia. Conceiving in periods of low disease activity helps to reduce these complications.

Objectives: This project aims to describe the occurrence of pregnancy complications among women with immune-mediated rheumatic diseases and to study the associated clinical factors.

Methods: A retrospective, longitudinal study was performed including consecutive pregnant women with immune-mediated rheumatic diseases seen in a multidisciplinary group for autoimmune diseases during pregnancy, in a tertiary hospital, between January 2010 and December 2015. Clinical and demographic data, as well as pregnancy outcomes, were collected through consultation of clinical files. They were compared with pregnancy manifestations (premature delivery, flares during pregnancy, recurrent pregnancy loss and foetal growth restriction) were studied using Mann-Whitney, quiz-square and fisher tests (SPSS 24.0).

Significance level was set as <0.05.

Results: We included 384 gestations from a total of 140 women with a mean age of 32.5±4.4 years; 4 gestations were twin pregnancies. Within these 151 gestations, 54 (35.8%) women had SLE, 17 (11.3%) had Sjögren’s syndrome, 17 (11.3%) had rheumatoid arthritis, 41 had APS (27.2%), 11 (7.3%) had Behçet’s disease, 4 (2.6%) had systemic sclerosis, 8 (5.3%) had mixed connective tissue disease and 16 (10.6%) had other immune-mediated diseases. 35 (23.2%) had anti-SSA/La antibodies, 18 (11.9%) had anti-SSB antibodies, 6 (4.0%) had anti-URNP antibodies and 43 (28.5%) had anti-nuclear antibodies. Seven (4.6%) of the women developed gestational diabetes and 4 (2.6%) developed gestational hypertension. Furthermore, 54 (35.8%) women had pre-existing miscarriages. Pregnancy outcomes were frequently affected with increased GFR (58.8% vs 46.1%; p=0.04), and was associated with gestational diabetes (21.4% vs 2.9%; p=0.018). It also occurred more frequently in multiple pregnancies (75% vs 16.4%; p<0.001), mothers taking glucocorticoids (28.6% vs 9.2%; p=0.003) and active rheumatic disease (23% vs 6.8%; p=0.03). No statistically significant differences were observed in the occurrence of different pregnancy complications among different diseases or in presence of different antibodies.

Conclusions: Our study proved a link between immune-mediated rheumatic diseases and specific pregnancy outcomes such as prematurity and IUGR. Outcomes were worse when taking glucocorticoids, when gestational diabetes were developed and when conception occurred in a period of active disease.

AB0145 TLR4 SIGNALING PATHWAY MEDIATES THE SENESCENCE OF BONE MARROW-MESENCHYMAL STEM CELLS FROM SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

J. Ji, Y. Wu, X. Kong, Z. Zhang, Z. Gu. Department of Rheumatology, Affiliated Hospital of Nantong University, Nantong, China

Background: Previous studies of our research group revealed the senescence of bone marrow-mesenchymal stem cells from systemic lupus erythematosus patients, which participated in the development of SLE. "Inflammatory microenvironment" played a very important role in cellular senescence. In the preliminary experiments, we discovered the level of HMGB1 in serum and Peripheral blood mononuclear cells from SLE patients was higher than those of The healthy control group.

Objectives: The aim of this study was to investigate whether HMGB1 can lead to senescence BM-MSCs from SLE patients and its possible mechanism.

Methods: We included 151 gestations from a total of 140 women with a mean age of 32.5±4.4 years; 4 gestations were twin pregnancies. Within these 151 gestations, 54 (35.8%) women had SLE, 17 (11.3%) had Sjögren’s syndrome, 17 (11.3%) had rheumatoid arthritis, 41 had APS (27.2%), 11 (7.3%) had Behçet’s disease, 4 (2.6%) had systemic sclerosis, 8 (5.3%) had mixed connective tissue disease and 16 (10.6%) had other immune-mediated diseases. 35 (23.2%) had anti-SSA/La antibodies, 18 (11.9%) had anti-SSB antibodies, 6 (4.0%) had anti-URNP antibodies and 43 (28.5%) had anti-nuclear antibodies. Seven (4.6%) of the women developed gestational diabetes and 4 (2.6%) developed gestational hypertension. Furthermore, 54 (35.8%) women had pre-existing miscarriages. Pregnancy outcomes were frequently affected with increased GFR (58.8% vs 46.1%; p=0.04), and was associated with gestational diabetes (21.4% vs 2.9%; p=0.018). It also occurred more frequently in multiple pregnancies (75% vs 16.4%; p<0.001), mothers taking glucocorticoids (28.6% vs 9.2%; p=0.003) and active rheumatic disease (23% vs 6.8%; p=0.03). No statistically significant differences were observed in the occurrence of different pregnancy complications among different diseases or in presence of different antibodies.

Conclusions: Our study proved a link between immune-mediated rheumatic diseases and specific pregnancy outcomes such as prematurity and IUGR. Outcomes were worse when taking glucocorticoids, when gestational diabetes were developed and when conception occurred in a period of active disease.

AB0146 INVOLVEMENT OF PERIPHERAL CD8 T CELL SUBSETS IN SYSTEMIC LUPUS ERYTHEMATOSUS

J. Kikuchi1, M. Ushikubo1,2, S. Saito1, K. Yamaoka1, K. Sugahara3, K. Chiba1, T. Takeuchi1, 1Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; 2Department of Connective Tissue Diseases, National Tokyo Medical Center, Tokyo; 3Sohyaku. Innovative Research Division, Mitsubishi Tanabe Pharma Corporation, Kanagawa, Japan

Background: Although the mainstream of pathogenesis of systemic lupus erythematosus (SLE) is thought to be interactions between antigen-presenting cells, CD4 T cells, helper T cells, B cells and cytokines, previous reports suggested CD8 T cells also involve in the pathogenesis of SLE1,2. However the associations between subsets of CD8 T cells and clinical manifestations remains unclear.

Objectives: We conducted standard immunophenotyping analysis with peripheral blood from SLE patients and focused on CD8 T cell subsets to elucidate the association with clinical phenotype and serological markers.

Methods: Peripheral blood was obtained from inactive SLE patients and healthy subjects as controls and also from active SLE before and 3 months after treatment. CD8 T cell subsets were measured by flow cytometry with fresh whole blood samples.

Results: Thirty-four active SLE patients and 38 inactive patients and 22 healthy controls (HCs) whose age and sex were matched with those in SLE patients were enrolled. Mean SLE disease activity index (SLEDAI) was 14.2 and 1.8 in active and inactive patients respectively. Anti-dsDNA antibody (120%, p=0.016, rho =-0.283), and was also higher in patients with nephritis than patients without nephritis (p=0.074), though it did not correlate with SLEDAI. The expression levels of HLA-DR+ cells was significantly higher in SLE patients than HCs and positively correlated with SLEDAI (p=0.016, rho =-0.283), and was also higher in patients with nephritis than patients without nephritis (p=0.074), though it did not correlate with SLEDAI. The expression levels of HLA-DR+ cells was significantly higher in SLE patients than HCs and positively correlated with SLEDAI (p=0.016, rho =-0.283), and was also higher in patients with nephritis than patients without nephritis (p=0.074), though it did not correlate with SLEDAI.

Conclusions: Pathological state of SLE positively correlated with the proportion of naive CD8 T cells negatively correlated with SLEDAI only with those who were treated with cyclophosphamide.

AB0147 THE EFFECTIVE TREATMENT WITH HYDROXYCHLOROQUINE ON SOLUBLE TISSUE FACTOR LEVELS IN PATIENTS WITH ANTIPHOSPHOLIPID ANTIBODIES AND ANTIPHOSPHOLIPID SYNDROME WITH AND WITHOUT UNDERLYING SYSTEMIC LUPUS ERYTHEMATOSUS

K. Schreiber1,2, K. Breen1, K. Parmar1, B. J. Hunt1, 1Centre for Thrombosis and Haemostasis, Guy’s and St Thomas’ NHS Foundation Trust, London, United Kingdom; 2Department of Rheumatology, Copenhagen University Hospital, Copenhagen, Denmark

Background: Antiphospholipid syndrome (APS) is characterized by venous, arterial, or microvascular thrombosis, and/or arterial or venous thrombosis, and/or fetal losses, in the presence of antiphospholipid antibodies (aPL). The mainstay of treatment is based on anticoagulation therapy; however, increasing interest is currently received by the antimalarial hydroxychloroquine (HCQ). The use of HCQ has been associated with a reduced risk of thrombosis but HCQ’s anti-inflammatory mechanism of action is unclear particularly in patients with aPL and APS.

Objectives: The aim of our study was to assess soluble tissue factor (TF) levels in HCQ naïve-patients with persistent aPL or APS at baseline and 12 weeks after commencing HCQ. We hypothesise that HCQ lowers levels of soluble TF.
Methods: Twenty-two individuals with APS with or without other associated autoimmune disease (20 females, two males, median age 55 (range 18–70) years) had blood samples taken before and 12 weeks after starting HCQ 200mg. Plasma was stored at -80°C and thawed to measure TF using Lumibind TF kit (Invittech Ltd, Cambridgeshire, UK). The assay was performed according to the manufacturer's instructions. Patient characteristics are outlined in Table 1. Statistical analysis was performed using SPSS Version 22. For continuous normally distributed data a two-tailed student's paired t-test was performed. A value of p=0.05 was considered as significant. There are no previous data in this area, so we were unable to do a power calculation to work out study size. Our study is therefore a pilot study.

Results: Soluble TF levels were above our normal range (40–300 pg/ml) prior to the commencement of HCQ and were significantly reduced (pre level mean (SD) 401.8 (152.8) pg/ml versus post 300.9 (108) pg/ml (p=0.010).

Conclusions: There was a significant reduction in soluble TF levels in this patient cohort of patients with aPL and APS after commencing HCQ. Our previous work has shown that HCQ has not affected complement turnover, VEGF levels, thromboelastometry findings or CRP levels. Our findings of a reduction of soluble TF levels in aPL positive patients after the commencement of HCQ maybe a key mechanism by which HCQ reduces thrombotic risk. Further studies of a larger patient cohort are required to conform our observation.

INDUCTION OF HO-1 EXPRESSION IN MONOCYTES MIGHT PREVENT KIDNEY DAMAGE IN LUPUS NEPHRITIS (LN)

L. Cutillo1, J. Obreque1, P. Gajardo-Meneses1, N. Crisostomo1, A. Torres1, A.M. Káleges2, C. Llanos1,2 Departamento de Inmunología Clínica y Reumatología, Instituto de Inmunología e Inmunoterapia, Departamento de Endocrinología, Pontificia Universidad Católica de Chile, Santiago, Chile

Background: Systemic lupus erythematosus (SLE), is an autoimmune disease characterized by autoantibody synthesis and inflammation. During disease course, up to 70% of SLE patients will develop LN. Emerging evidence has demonstrated that infiltrating monocytes and macrophages are associated with LN pathogenesis. We have previously demonstrated that HO-1, a haem-degrading enzyme with anti-inflammatory properties is decreased in peripheral monocytes of SLE patients. Therefore, we decided to explore the contribution of HO-1 expression to LN pathogenesis.

Objectives: To explore the role of HO-1 in modulating innate immunity through a cytoprotective effect in monocytes of LN nephritis patients. Accordingly, we examined the expression of HO-1 in circulating monocytes, and the effect of HO-1 induction in reactive oxygen species (ROS) production and the phagocytic activity of monocytes from peripheral blood of LN patients and healthy controls (HC).

Methods: SLE patients with proliferative LN confirmed by renal biopsy (Class III, IV or V ISN/RPS) were recruited at Hospital Clínico de PUC. All individuals signed an informed consent form. Monocytes were purified from peripheral blood mononuclear cells (PBMCs) of LN patients and HC using pan-monocytes MACS kit. Subpopulations of monocytes and HO-1 expression were measured by FACS. ROS was determined using CellRox Kit. The phagocytic ability of monocytes was assessed by FACS and the total phagocytosis was calculated as the percentage of cells with engulfed beads.

Results: We found that monocytes from LN patients show significant differences when compared to HC in all the parameters analyzed. The percentage of CD16+ inflammatory monocytes was higher in LN patients (6.72±0.98%) compared to HC (4.07±0.48%) (p<0.05). HO-1 protein expression is decreased in circulating LN monocytes (4789±911 vs 1572±481, p=0.005). Baseline levels of ROS are elevated in LN monocytes with similar values that the ones found in monocytes from HC treated with a ROS inducer (HC+TBP: 843±199; LN: 8355±1714). Furthermore, phagocytic activity is increased in LN monocytes (77.97±3.31%) compared to HC (39.63±2.75%). Moreover, our preliminary data indicate that HO-1 induction, using cobalt protoporphyrin (CoPP), leads to downregulation of ROS production in LN (~60%) and HC (~40%) leaving both in similar levels of ROS production. In addition, phagocytic activity is also decreased in LN and HC monocytes in the presence of CoPP (~30%).

Conclusions: Decreased HO-1 expression in circulating monocytes of LN patients leads to higher ROS production and phagocytic activity. ROS level and phagocytosis are reduced when we induce HO-1 expression with CoPP. We propose that HO-1 induction might exert a cytoprotective role in LN by regulating innate immunity. Background: Systemic Lupus Erythematosus (SLE) is a prototype of autoimmune diseases with excessive anti-nuclear autoantibodies production. B cells activation with immune complex formation is the main characteristic of SLE with abnormalities in immune cells, dysregulation of apoptosis, and defects in the clearance of apoptotic materials. Autophagy, a highly conserved protein degradation pathway, is essential for removing protein aggregates and misfolded proteins in cells and its defects contributes to SLE pathogenesis. On the other hand, multiple evidences in humans and experimental models suggest that prolactin (PRL) is associated with active SLE and participates in the immune dysregulation, and one of the mechanisms of PRL action is the inhibition of apoptosis.

Objectives: Analyze the relationship between PRL receptors (PRL-R) on B and T regulatory cells and markers of autophagy in SLE patients and the association, if any, with clinical characteristics of SLE.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.4746
Methods: The expression of PRL-R on B cells CD19+ and autophagy-related key regulator protein ATG14+ on T regulatory cells CD25+, were measured by flow cytometry, and expressed in percentages of SLE patients (1997, ACR criteria), and healthy controls. Active SLE was considered by SLEDAI (≥4). The organs affected and treatments were evaluated.

Results: A total of 40 SLE patients and 20 healthy controls were included. Mean age of patients and controls was 30.67±4.16. Mean duration of disease was 6±4.6 years. Twenty patients were active (SLEDAI 8.45±1.9) and of these, lupus glomerulonephritis was observed in 13 patients (65%). The expression of PRL-R on B cells of active SLE was higher than in inactive SLE (50.5% vs 26.5%). In active SLE especially in patients with glomerulonephritis, the mean amount of PRL-R on B cells/ml was 6.645/ml (range 3167–6957). In contrast, patients with inactive SLE, had a low amount of PRL-R, 52.5/ml (range 15–895). In the relation of autophagy, the mean expression of ATG14+ in 20 active SLE patients was 11.19% in comparison with inactive SLE patients, 7.13%, (p=0.04), and in healthy donors, 7.45% (p=0.028).

Conclusions: Our study suggest: In active SLE patients the expression of PRL-R and autophagy-related key regulator protein ATG14+ are very high in B cells and T regulators respectively, in comparison with inactive SLE and healthy donors. These novel findings suggest the interaction between PRL-R and autophagy in order to promote clinical/immune activation with overproduction of autophagosomes. PRL-R and ATG14+ may be a new target of SLE therapy.

AB0150 INCREASED ERYPTOSIS LEVELS IN PRIMARY ANTIPHOSPHOLIPID SYNDROME PATIENTS

M. Vomero1, F. Ceccarelli1, A. Finucci1, C. Pensà1, C. Barbati1, T. Colasanti1, F. Perrone2, L. Massaro1, S. Truglia1, F. Fomoro1, F.R. Mauro2, R. Foà2, F. Conti1, G. Valesini1, C. Alessandri1, 1Department of Internal Medicine and Medical Specialties, Lupus Clinic, Sapienza University of Rome; 2Department of Cellular Biotechnologies and Hematology, Hematology, Sapienza University of Rome, Rome, Italy

Background: Erythrocytes (RBCs) hold a crucial role in hemostasis and their integrity is influenced by different stimuli including circulating inflammatory mediators. Even though RBCs do not have nuclei and mitochondria, they have developed a process allowing them to undergo a rapid self-destruction named eryptosis. The exact mechanism of eryptocytes cell death is not fully clarified yet but it seems to involve Ca2+ and ceramide formation, leading to cell shrinkage and externalization of phosphatidylserine (PS) (1). Interaction between platelets and eryptocytes could participate in an increasing risk of thrombotic episodes typical of several diseases including antiphospholipid syndrome (APS). In fact, not only signals triggering eryptosis are involved in thrombosis activation, but also recent studies have demonstrated how PS-exposing eryptocytes are able to adhere to the vascular wall causing an impairment of circulation (2,3).

Objectives: Enhanced eryptosis is known to contribute to several pathological conditions (1) but the involvement of this process in APS has not been investigated yet. For this reason the aim of the study was to evaluate eryptosis levels in APS healthy subjects positive for antiphospholipid antibodies without clinical manifestations (aPL carriers), autoimmune haemolytic anemia (AIHA) and healthy donors (HD).

Methods: 27 patients with primary APS (M/F 5/22, mean age 51.1±7.6 years), 14 aPL carriers (M/F 3/11, mean age 48.9±8.4 years) were recruited after written informed consent. Moreover 10 AIHA patients and 12 HD were also enrolled as positive and negative control group respectively. RBCs were isolated from whole blood after centrifugation and eryptosis levels were analysed by flow cytometry, and expressed in percentages of SLE patients (1997, ACR criteria), and healthy controls. Moreover, 10 AIHA patients and 12 HD were also enrolled as positive and negative control group respectively. RBCs were isolated from whole blood after centrifugation and eryptosis levels were analysed by flow cytometry, and expressed in percentages of SLE patients (1997, ACR criteria), and healthy controls.

Results: APS patients showed higher levels of eryptosis compared to HD (p<0.01). Interestingly, the percentage of annexin V-positive RBCs was lower in aPL carriers respect to APS patients (p=0.001). Moreover, an inverse correlation between RBCs volume and eryptosis was found in APS patients (r=-0.4, p=0.03).

Conclusions: Our study provides for the first time evidence of eryptosis enhancement in APS patients suggesting a possible contribution of RBCs apoptosis in the pathogenesis of the disease.

References:
expression revealed suppression in the relative fold change of IL-6 by 23%, IL-8 by 30%, TNF-α by 11%, and IFN-γ by 21% with Tai Chi.

Conclusions: These data suggest that moderate exercise and stress management can have potent immunoregulatory effects on the chronic, systemic inflammation associated with SLE and identify Tai Chi exercise as a viable and effective therapy to complement current pharmacological interventions.

AB0152
DISEASE ACTIVITY AND DAMAGE SCORES CORRELATED DIFFERENTLY WITH THE PATIENT REPORTED OUTCOMES IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME COMPARED TO LUPUS ASSOCIATED WITH SECONDARY SJÖGREN’S SYNDROME

Background: Previous studies showed a poor correlation between EULAR Disease Activity Index (ESSDAI) and assessing comparatively patients with primary (pSS) (1). There are no previous studies correlating these scores with the SS Syndrome Disease Activity Index (ESSDAI) in patients with Sjögren’s syndrome (SLE/SS) patient groups.

Objectives: To that end, WT and RAGE−/− animals were injected intra-peritoneally with a single dose of pristane. Disease manifestations were determined after 7 months and included the determination of proteinuria and renal pathology by evaluating the glomerular cellularity and matrix on H&E stained paraffin-embedded kidney sections. Immunofluorescence for glomerular depositions of IgG and IgC. In addition to that we checked for auto-antibody production at several time points during disease development and immune cell distribution, differentiation and phenotype in infected kidneys and spleen.

Results: Apart from a slight decrease in CD71+/Fas+ germinal center B cells and B220−CD21+CD23− follicular B cells in RAGE−/− animals, we did not detect differences in auto-antibody secretion or disease manifestations between RAGE−/− and WT mice.

Conclusions: Our data contrast with recently published data showing that a deletion of RAGE exacerbates lupus nephritis and lymphoproliferation in a different SLE model (B6-MRL Fas lpr/j). Therefore, we are currently looking into the effects of RAGE deletion in additional models of auto-antibody-mediated immune disease.

DELETION OF RECEPTOR FOR ADVANCED GLYCACTION END PRODUCTS (RAGE) DOES NEITHER AFFECT AUTO-ANTIBODY PRODUCTION NOR DEVELOPMENT OF RENAL DISEASE IN PRISTANE-INDUCED LUPUS

N. Chevalier, R. Rzepka, R. Voll. University Freiburg Medical Center, Freiburg, Germany

Background: Systemic lupus erythematosus (SLE) is characterized by autoantibodies to diverse autoantigens, especially to nuclear components such as double-stranded DNA (dsDNA) or nucleosomes. Still, it remains unclear why poorly immunogenic molecules such as dsDNA and nucleosomes become targets of humoral autoimmunity in SLE. Increased signaling via pattern-recognition receptors (PRRs) through pathogen-associated molecular patterns (PAMPs) or endogenous damage-associated molecular patterns (DAMPs) released from damaged or stressed tissues, may contribute to the break of tolerance against such nuclear antigens. One important PRR in this context may be RAGE. Among many others, RAGE recognizes High mobility group box 1 (HMGB1). HMGB1 is a DNA-binding nuclear protein that has been found at elevated levels in patients with SLE and other autoimmune diseases; likewise perpetuation of RAGE signaling sustains inflammation and leads to the establishment of chronic inflammatory disorders.

Objectives: We therefore examined, using the Pristane-induced SLE model, if increased RAGE signaling may be involved in the break of tolerance against autoantigens in chronic inflammation.

Methods: To that end, WT and RAGE−/− animals were injected intra-peritoneally with a single dose of pristane. Disease manifestations were determined after 7 months and included the determination of proteinuria and renal pathology by evaluating the glomerular cellularity and matrix on H&E stained paraffin-embedded kidney sections. Immunofluorescence for glomerular depositions of IgG and IgC. In addition to that we checked for auto-antibody production at several time points during disease development and immune cell distribution, differentiation and phenotype in infected kidneys and spleen.

Results: Apart from a slight decrease in CD71+/Fas+ germinal center B cells and B220−CD21+CD23− follicular B cells in RAGE−/− animals, we did not detect differences in auto-antibody secretion or disease manifestations between RAGE−/− and WT mice.

Conclusions: Our data contrast with recently published data showing that a deletion of RAGE exacerbates lupus nephritis and lymphoproliferation in a different SLE model (B6-MRL Fas lpr/j). Therefore, we are currently looking into the effects of RAGE deletion in additional models of auto-antibody-mediated immune disease.

Unpaired T test performed; **p<0.01, n = total number, % percentage, IQR = interquartile range, ethnicity: C = Caucasian, A = Asian, MN = African Caribbean, O = Chinese, anti-La = anti-Sjögren’s-syndrome-related antigen A, anti-Ro = anti-Sjögren’s-syndrome-related antigen B.

We found significant correlations of SSDDI score with disease duration and maximum ESSDAI score in patients with pSS (r=0.27, p=0.05 and r=0.67, p=0.001, respectively). In SLE/SS patients, ESSPRI scores correlated with both BILAG and maximum ESSDAI score (r=0.55, p=0.03 and r=0.7, p=0.02, respectively). The SSDDI score correlated with the disease duration only in pSS patients (r=0.27, p=0.05).

Conclusions: Our study showed that there was no similar correlation between various disease scores in patients with pSS compared to SLE/SS patients. If the patient reported outcomes correlated with the disease activity (ESSDAI and BILAG) in SLE/SS patients, this correlation was not seen in pSS patients, in which the significant correlations were found only between damage scores, highest disease activity score and disease duration.

AB0154
CIRCULATING CGP DNA PROMOTER FRAGMENTS IN SLE ACTIVATE INTRARENAL TLR9 SIGNALING AND ACCELERATE RENAL INFLAMMATION AND FIBROGENESIS

P. Korsten, B. Tampe. Department of Nephrology and Rheumatology, Universitätsmedizin Göttingen, Göttingen, Germany

Background: In systemic lupus erythematosus (SLE), lupus nephritis (LN) is associated with chronic inflammation and perpetuated fibroblast activation, both determined by epigenetic mechanisms involving aberrant CpG DNA promoter methylation. During SLE progression, global methylation patterns are commonly lost. These CpG DNA promoter methylation patterns are not limited to the kidney, circulating CpG-rich DNA is also detectable in the blood allowing for biomonitoring (‘liquid biopsy’). However, little is known about its specific contribution to determining disease progression. In the kidney, CpG-rich DNA activates TLR9 signaling mechanisms involved in inflammation and fibrogenesis. Based on these observations, we hypothesized that CpG-rich DNA promoter fragments potentially accelerate renal inflammation and fibrogenesis in SLE-associated LN.

Objectives: To analyze the role of circulating CpG-rich DNA on endothelial TLR9 signalling and the effect of experimental modification of oligonucleotides on kidney inflammation in the Pristane-induced murine model of SLE.

Methods: We isolated circulating CpG-rich DNA from blood samples in a cohort of SLE patients. Then, we tested how these DNA promoter fragments influenced the LN phenotype in a TMPD (‘pristane’)-induced mouse model. Further, we investigated how this renal response could be influenced by the administration of either human or synthetic methylated/unmethylated CpG-rich DNA oligonucleotides. Additionally, the effects of the administration of circulating CpG-rich DNA fragments on TLR9-signalling was analyzed in endothelial cell cultures.

Results: We show that circulating CpG-rich DNA promoter fragments are detectable in SLE patients’ blood. Furthermore, SLE-associated LN is associated with accumulation of unmethylated CpG-rich DNA promoter fragments, implicating a mechanistic connection. These observations were further corroborated in a rodent model of TMPD-induced SLE where administration of CpG-rich DNA (iso-lated from LN patients or synthetic unmethylated CpG-rich DNA oligonucleotides) worsened the renal phenotype in terms of inflammation and fibrogenesis. Causal contribution of TLR9 was further confirmed in Thr29−/− knockout mice with protection from renal inflammation and kidney fibrosis after administration of unmethylated CpG-rich DNA promoter oligonucleotides. TLR9-mediated intrarenal...
inflammation can be therapeutically targeted by administration of synthetic methylated CpG-rich DNA oligonucleotides, ultimately associated with suppression of TLR9-mediated signaling responses and renal injury in experimental SLE/LN.

**Conclusions:** Collectively, our results implicate accumulation of unmethylated CpG-rich promoter DNA fragments in SLE-associated LN. Furthermore, these unmethylated CpG-rich promoter DNA fragments causally contribute to TLR9-mediated inflammation and renal fibrogenesis. Administration of methylated CpG-rich oligonucleotides antagonizes intrarenal TLR9-mediated inflammatory signaling responses and fibrogenesis. Therefore, biomonitoring of CpG-rich promoter DNA fragments and modulation of intrarenal TLR9 signaling is a promising therapeutic target in SLE-associated LN.

**AB0155 LEARNING SLE PATHOLOGICAL MECHANISMS FROM MULTI-OMICS PROFILES**

S.S. Pfister1, N. Kelley2, T. Schilt3, A. Fernandez2, M. Sultan3, M. Hasan1, A. Mir1, J.S. Rush1, J. Autoimmunity, Transplantation and Inflammation; 2Analytical Sciences and Imaging; 3BioMarker Development, Novartis Institutes for BioMedical Research, Basel, Switzerland

**Background:** Precision medicine aims at providing intervention based on clinical and molecular stratification of patients, and is an important approach for targeting heterogeneous diseases. Multiple types of omics data may give rise to different biological hypotheses of disease etiology. Therefore, the integrated analysis of multi-omics data provides a rich dataset to explore associations between molecular and clinical readouts.

**Methods:** We have recently developed a method allowing us to graphically visualize the relationships between molecular and clinical readouts. To overcome this problem we present a method based on L1 regularization of parameters of interest. However, variable selection approaches are often employed in this context.

**Results:** The proposed method allows us to graphically visualize the relationships between molecular and clinical readouts. To overcome this problem we present a method based on L1 regularization of parameters of interest. However, variable selection approaches are often employed in this context.

**Conclusions:** Systemic lupus erythematosus is a complex autoimmune disease characterized by a variety of clinical manifestations. While multi-omics profiling in multi-omics profiles provides a rich dataset to explore associations between molecular and clinical readouts, the specific relationship between molecular and clinical phenotypes is often underexplored for datasets that contain fewer samples than the number of variables. To overcome this problem we present a method based on L1 regularization and variable selection to generate networks of predictive markers across multiple data types.

**AB0156 THYMIC STROMAL LYMPHOPOIETIN (TSLP) IN PRIMARY SJÖGREN’S SYNDROME AND RELATED LYPHOMA: THE POSSIBLE CONTRIBUTION OF A NOVEL GROWTH FACTOR**

S. Gandolfo1,2, C. Fabro1,2,3, M. Bultron1,2, S. Russi1, P. Masolini1, L. Quartuccio1,2, D. Cesselli1,2, S. De Vita1,2, R. Rheumatology Clinic, Udine University Hospital S. Maria della Misericordia; 2Department of Medical and Biologic Sciences, University of Udine; 3Institute of Anatomic Pathology, Udine University Hospital S. Maria della Misericordia, Udine, Italy

**Background:** Primary Sjögren’s syndrome (pSS) is an autoimmune lymphoproliferative systemic disease with a higher risk of non-Hodgkin B cell lymphoma (NLH) evolution. In SS, salivary gland (SG) epithelium plays a crucial role in initiating and perpetuating the autoimmune response. Thymic stromal lymphopoietin (TSLP) is an epithelial and lymphoproliferative cytokine involved in the maintenance of immune tolerance at interfaces between body and environment and in the regulation of lymphocytes homeostasis.

**Objectives:** To study TSLP in serum and SG biopsies of pSS patients stratified by the lymphoproliferative histopathologic status, from fully benign lesions (fbSS) to more malignant ones (nSS) and to NLH, in order to evaluate a possible role of TSLP in SS pathogenesis and in lymphoma evolution.

**Methods:** Serum TSLP levels were determined by ELISA in pSS patients (n=30; 12 fbSS, 10 MESA, 8 NLH) and in controls (healthy blood donors - HD n=20; non-autoimmune sicca without SS - nSS n=10). TSLP was also studied by immunohistochemistry in SG biopsies of the same patients and nSS controls. Correlations with clinical and histopathologic parameters were performed. Of note, sequential samples were also included from three patients evolving from fbSS to NLH.

**Results:** TSLP serum levels were significantly higher in pSS compared to nSS (p<0.01) and HD (p<0.01). A progressive significant increase from fbSS to MESA (p<0.004) and finally to NLH (NLH vs fbSS p=0.0001; NLH vs MESA p=0.003), where the increase was dramatic. This was observed also in metastatic samples from the three pSS patients evolving to NLH. A positive significant correlation between TSLP serum levels and disease activity assessed by ESSDAI was found (r=0.7).

**Conclusion:** Of note, in the affected tissue, TSLP showed an opposite pattern of expression than in the serum. Concerning the salivary epithelium, a declining expression of TSLP was shown from fbSS (expression was similar to nSS) to MESA and finally to NLH. Strikingly, however, the three pSS patients evolving to lymphoma were the only ones showing a low TSLP epithelial expression also at baseline. Concerning the glandular lymphoid infiltrate, the TSLP expression again decreased with progression to NLH. Again, the three pSS patients evolving to lymphoma were the only ones showing a low TSLP inflammatory expression also at baseline.

**AB0157 TREX1 MUTATION IN THE MEMBERS OF A FAMILY WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTI-PHOSPHOLIPID SYNDROME**

S. Ugurtul1, I. Karacan2, H. Ozdogan1, A. Tolun3, E. Tahir Turanli4, 1Division of Rheumatology, Department of Internal Medicine, Cerrahpaşa Medical Faculty, University of Istanbul; 2Graduate School of Science, Engineering and Technology, Molecular Biology, Biotechnology and Genetics Program, Dr. Orhan Ocalgiray Molecular Biology-Biotechnology and Genetics Research Centre, Istanbul Technical University; 3Department of Molecular Biology and Genetics, Bogaçlı University; 4Dr. Orhan Ocalgiray Molecular Biology Biotechnology and Genetics (MOBGAM) Research Centre, Istanbul Technical University, Istanbul, Turkey

**Background:** We report a familial SLE and Antiphospholipid Syndrome (aPL) who are positive for TREX1 mutation and complicated with AA amyloidosis.

**Objectives:** Here we report a family with SLE and Anti-phospholipid Syndrome (aPL) who are positive for TREX1 mutation and complicated with AA amyloidosis.

**Methods:** DNA samples were extracted from peripheral blood samples of two affected (mother and daughter) and two unaffected individuals of the same family. Exome sequencing was performed for the four family members and data was processed according to GATK Best Practices recommendations. Exome variants were used to search for a rare candidate variant causing the disease. Identified variant was screened in four family members using Sanger sequencing.

**Results:** The index case (mother) was a 63 year-old woman who had developed polyarthritis and recurrent cerebrovascular accident (CVA) at the age of 44. She was positive for ANA, anti-ds-DNA and IgG anti-cardiolipin antibodies. On anticoagulant therapy she still experiences frequent CVAs. The daughter who is 43 years old had experienced depression, non-erosive arthritis and alopecia at the age of 13. She was positive for ANA, dsDNA and ACA and was treated with hydroxychloroquine, prednisolone, and rituximab. She had attacks of deep vein thrombosis despite anticoagulant therapy. A renal biopsy was performed because of an increase in her creatinine level, with no proteinuria and normal urinary sediment, which revealed AA amyloidosis. She was heterozygous for the p.T300C variant in MEFV gene. Further genetic testing was performed for the mother and the daughter as well as two other non-affected members of the family. Candidate variant search in exome data resulted a novel c. 27T>A (p.M17?) variant in TREX1 gene. Candidate variant search in exome data resulted a novel c. 27T>A (p.M17?) variant in TREX1 gene. Candidate variant search in exome data resulted a novel c. 27T>A (p.M17?) variant in TREX1 gene. Candidate variant search in exome data resulted a novel c. 27T>A (p.M17?) variant in TREX1 gene. Candidate variant search in exome data resulted a novel c. 27T>A (p.M17?) variant in TREX1 gene. Candidate variant search in exome data resulted a novel c. 27T>A (p.M17?) variant in TREX1 gene.

**Conclusions:** Since the variant disrupts translation initiation codon (ATG/AAG) it is predicted to cause loss of complete protein production.

**Disclosure of Interest:** None declared

Background: The salivary glands of Sjögren's syndrome patients show en-doplasmatic reticulum (ER) stress characterized by intracellular accumulation of secretory products such as MUC1, dilated cisternae of proteins in the ER, by decreasing ERAD activity and ER stress induced by the presence of TUDCA suggests that this chemical chaperone promotes folding of proteins.

Objective: The aim of this study was to evaluate if TUDCA decreases EDEM1, SEL1L and MUC1 expression induced by pro-inflammatory cytokines in salivary gland epithelial cells.

Methods: HSG-cells were incubated with 10 nM of IFN-γ or TNF-α for 24h. After 24h, increased expression for both molecules was determined by Western Blot and RT-qPCR, respectively. EDEM1 and SEL1L localization was determined by immunofluorescence.

Results: HSG cells stimulated with IFN-γ or TNF-α showed a significant increase of EDEM1 and SEL1L protein and mRNA levels. Importantly, TUDCA co-incubation caused a significant decreased expression of both molecules.

Conclusions: Decreased expression of MUC1, SEL1L and EDEM1 in the co-incubation caused a significant decreased expression of both molecules. TUDCA might alleviate the ER stress of salivary glands from Sjögren's syndrome of proteins in the ER, by decreasing ERAD activity and ER stress induced by the presence of TUDCA.

INTERFERON-Γ-INDUCIBLE KYNURENINES INFLAMMATION PATHWAY: THE MISSING LINK BETWEEN DISEASE ACTIVITY AND SYMPTOMS IN SJÖGREN’S SYNDROME

V. Valim1, W.M. Sardinelli2, J.G. Brun2, E. Zanella2, C. Espírito Santo3, O.M. Balairini1, L.V. Tanure1, G.V. Ferreira1, E.V. Serrano1, J.F. Tonini1, K.A. Brokstad5, P. Ueland6, R. Jonsson5, P. Mydel1.
1Medicine, Federal University of Espirito Santo, Vitória, Brazil; 2Clinical Science Department, University of Bergen, Bergen, Norway; 3Statistic Department, Federal University of Espirito Santo; 4Locomotor System Department, Federal University of Minas Gerais, Vitória, Brazil; 5Broegelmann Research Laboratory, University of Bergen, Bergen, Norway; 6Bevital Laboratory A/S, University of Bergen, Vitória, Brazil

Background: Tryptophan (TRP) can be converted to kynurenine (KYN) by indoleamine 2,3-dioxygenase (IDO) driven by interferon-γ. Recent studies have suggested that the KYN pathway reflects an important interface between the immune and nervous system modulation.

Objective: The aim was to study KYN pathway and their correlation to clinical and immunological parameters in primary Sjögren’s syndrome (pSS).

Methods: We included 97 pSS (AECG) and 63 healthy controls matched to age, sex, ethnicity, and body mass index (BMI). KYN metabolites and TRYP were analysed by liquid chromatography/tandem mass spectrometry.

Results: Patients aged 50±11 years showed anti-SSA-Ro of 63%, anti-SSB-La 31%, anti-nuclear antibody 81%, rheumatoid factor 24%, and systemic manifestations 67%. Most (88%) showed low disease activity measured by Eular Sjögren's Syndrome Disease Activity Index (ESSDAI). 22% moderate to high, 10% high ESSDAI. The kynurenine:tryptophan ratio (KTR) was (0.031±0.014 vs. 0.024±0.007, p<0.001), KYN (1.890±0.580 vs. 1.652±0.426, p=0.000), quinolinic acid (QA) (477.82±251.55 vs. 382.05±128.06, p=0.018), hydroxyindoleacetic acid (3HK) (53.45±52.05 vs. 39.15±9.67, p=0.056), anilinic acid (AA) (19.86±6.26 vs. 16.94±4.17, p=0.001) were higher while xanthurenic acid (XA) (11.52±8.87 vs. 10.33±6.58, p=0.019), and TRYP (64.90±13.43 vs. 71.02±8.88, p=0.012) were lower in pSS compared to controls. Higher KTR was associated with disease duration (r=0.211, p=0.042), CRP (r=0.254, p=0.029), lower hemoglobin (r=−0.219, p=0.034), creatinine (r=−0.586, p=0.000), hypergammaglobulinemia (r=0.254, p=0.014), hyper IgG (r=0.354, p=0.004), lower C3 (r=0.233, p=0.014), and C4 (r=−0.294, p=0.004). Higher KTR was observed in those with Biological ESSDAI domain involvement (0.033±0.016 vs. 0.029±0.013, p=0.003), glandular manifestation (0.037±0.014 vs. 0.029±0.013, p=0.007), in the other hand lower KTR in those with presence of musculoskeletal pain (0.029±0.011 vs. 0.032±0.015, p=0.003). ESSDAI showed a tendency to correlate with KTR (r=0.177, p=0.091) and ESSPRI inversely correlated with AA (r=−0.233, p=0.071). Either patient with pain showed lower AA (20.66±6.67 vs. 17.22±5.07, p=0.021).

Conclusions: TRYP is decreased and KYN metabolites pathway is increased in pSS. IDO activity expressed like KTR was positively correlated with disease activity and glandular manifestations but negatively with pain. A better understanding of the KYN pathway can clear the dissociation of symptoms and disease activity in pSS.

ANTIPHOSPHOLIPID ANTIBODIES DIFFERENTIALLY REGULATE THE EXPRESSION & ACTIVITY OF THE PROTEINASES WITH EFFECTS UPON MONOCYTE AUTOPHAGY

V.M. Ripoll-Nunez, A. Khawaja, I.P. Giles, A. Rahman. Division of Medicine, University College London, London, United Kingdom

Background: Antiphospholipid antibodies (aPLs) are known to activate monocytes in the pathogenesis of antiphospholipid syndrome (APS), although the precise mechanisms by which this activation occurs are not fully understood. We have recently identified several novel protein targets using a comprehensive proteomic analysis of human monocytes treated with IgG from patients with APS. Amongst these novel targets lysosomal proteases, including cathepsin B and cathepsin D were identified. These proteases are important in protein degradation, clearance of autolysosomes, apoptosis and autophagy. Dysregulation of these homeostatic cellular functions may be important in the importance of autoantigens and pathogenesis of the APS. Therefore, we have now studied the effects of APS IgG upon the expression/activity of different cathepsins and their effects upon autophagy.

Objectives: Determine the effect of pathogenic aPl antibodies on monocyte autophagy and its association with the regulation of lysosomal activity.

Methods: Healthy monocytes were treated with 200 µg/ml IgG purified from (n=9) patients with APS or (n=9) healthy control (HC) IgG for 6 h. The expression of cathepsin B and cathepsin D were measured by western blotting. Activity assays for lysosomal proteases cathepsin D, cathepsin B and cathepsin L were performed using fluorescence based assays (Tryp200™). Intracellular proteolytic activity of monocytes was determined using DQ-BSA (Molecular probes) and flow cytometry analysis. Autophagy was induced by treating monocytes with 50 µg/ml GM-CSF for 14 h.

Results: Consistent with our previous label free quantification mass spectrometry proteomic analysis, western blot analysis confirmed that levels of cathepsin B and cathepsin D were decreased in monocytes treated with APS IgG compared to HC IgG. Similarly, enzymatic assays revealed that cathepsin B and cathepsin D activities were significantly reduced in monocytes treated with IgG from patients with APS compared to HC (p=0.0188, 0.0323). In contrast, levels of enzymatic activity of cathepsin L were increased in monocytes treated with APS IgG compared to HC IgG (p=0.0106). To determine the effect of APS IgG on autophagy, we exposed healthy monocytes to IgG and induced autophagy by treating them with GM-CSF for 14 h. Subsequently we tested the intracellular proteolytic activity with DQ-BSA. Stimulation of monocytes with APS IgG reduced the lysosomal activity of GM-CSF-treated monocytes whereas HC IgG had no effect, indicating that APS IgG disrupts lysosomal degradation during monocyte autophagy.

Conclusions: We found that IgG from patients with APS regulate the expression and activity of lysosomal proteases cathepsin B/D and cathepsin L in opposite directions. Activity of cathepsin B and D was down-regulated by exposure to IgG from patients with APS whereas cathepsin L was up-regulated. Furthermore, we found APS IgG disrupts lysosomal degradation during monocyte autophagy. Animal experiments are now underway to increase our understanding of how modulation of cathepsin activity and autophagy may be important in the pathogenesis of APS and provide new therapeutic targets.

SERUM LEVEL OF PRO-INFLAMMATORY CYTOKINES IS NEGATIVELY ASSOCIATED WITH FATIGUE IN PRIMARY SJÖGREN’S SYNDROME

D. Gardiner1, W.D. Reid2, J.R. Tarn1, D. Lendrem1, N. Howard-Tripp1, S. Bowman3, B. Griffiths4, W.-F. Ng1.

1 Institute of Cellular Medicine & NIHR Newcastle Biomedical Research Centre; 2School of Biology, Newcastle University, Newcastle upon Tyne; 3Rheumatology, University Hospital Birmingham, Birmingham; 4Rheumatology, Freeman Hospital, Newcastle upon Tyne, United Kingdom

Background: We have previously described a model of fatigue in patients with primary Sjögren’s syndrome (PSS) based on the levels of serum cytokines, pain and depression scores. Importantly, removal of cytokines from this model substantially reduced the accuracy suggesting that cytokines may have a key role in the biological basis of fatigue [1]. However, interpreting the model is complicated by the complexity of the immune system and the likely multiple interactions between numerous cytokines and other variables [2]. Structural equation modelling (SEM) is a statistical technique that allows for analysis of one or multiple independent variables with one or multiple dependent variables. SEM consists of two components – the structural model, which represents the relationships between the theoretical variables, and the measurement model, which are the relationships between the latent variables and their measures [3]. Objectives: To use SEM to test our hypothesis that the balance between pro-inflammatory and anti-inflammatory cytokines play an important role in determining severity of fatigue in patients with PSS.

Methods: We used Canonical Correlation Analysis (CCA) to investigate the variation in cytokine expression across our spectrum of fatigue patients to explore interactions and dependencies between cytokines. We then built a conceptual model based on the literature representing the likely relationships between fatigue and various proinflammatory and anti-inflammatory cytokines and other soluble molecules in the serum. This conceptual model was then challenged using serum data and fatigue scores of 161 PSS patients from the UK primary Sjögren’s syndrome registry. Model fit was assessed using the Confirmatory Factor Index, the Root Mean Square Error of Association and the Standardised Root Mean Square Residual. We also analysed changes in fatigue scores over a period between 1–4 years.

Results: CCA revealed the first axis ofordination (CCA1) broadly correlates with fatigue, consists of many pro-inflammatory cytokines including TNFα, IL6, IL12 and IFNy, IL17, which were negatively correlated with fatigue while IL-6 and MCP1, which were positively associated with increased fatigue severity. The second axis (CCA2) reflects a trend in cytokines which appear to relate to patients’ age. Fatigue scores were largely stable over time and therefore data were not included in the SEM analysis. The main pro-inflammatory SEM model showed fatigue was negatively associated with pro-inflammatory cytokine activity (p=0.019); IL-10 drove IP-10 (p<0.001); and IL-10 was driven by IL-6 (p=0.006) (Fig 1).

Conclusions: Chronic fatigue in PSS is negatively associated with many pro-inflammatory cytokines. We hypothesize that it reflects adaptive biological processes, which occurs after chronic exposure to inflammation in conditions such as PSS.

MESENCHYMAL STEM CELLS INDUCE CD1C+ TOLERGENIC DENDRITIC CELLS IN HUMAN SYSTEMIC LUPUS ERYTHEMATOSUS VIA UP-REGULATING FLT-3 LIGAND

X. Yuan, D. Wang, Z. Zhang, Q. Wang, W. Li, X. Tang, W. Chen, G. Yao, L. Sun. Department of Rheumatology and Immunology, The Affiliated Drum Tower hospital of Nanjing University Medical School, Nanjing, China

Background: CD1c+ tolerogenic dendritic cells (DCs) play important roles in the induction of peripheral tolerance and control of adaptive immune response. Umbilical cord (UC)-derived mesenchymal stem cells (MSCs) exhibit immunoregulation effects in systemic lupus erythematosus (SLE). However, the underlying immunosuppression mechanism of MSCs via tolerogenic DCs in SLE remains unclear.

Objectives: The aim of this study was to examine tolerogenic DCs levels in SLE patients, and to further investigate the mechanism of MSCs in the regulation of tolerogenic DCs.

Methods: Tolerogenic DCs were isolated as Lin (CD3/19/56/14)+CD11c+CD1c+ from peripheral blood mononuclear cells (PBMCs). Levels of tolerogenic DCs were determined by flow cytometry, and serum concentration of Flt-3 ligand (FLT3L) were determined by ELISA from 17 healthy controls and 25 SLE patients. Eight SLE patients were given UC MSCs infusions. We compared the levels of tolerogenic DCs and serum FLT3L before and 24 hours after UC
Scleroderma, myositis and related syndromes - etiology, pathogenesis and animal models

**AB0164 AMYLOIDOSIS IN PROGRESSIVE SYSTEMIC SCLEROSIS – A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 12 PATIENTS**

Á. Apáthy1, M. Bély2. 1Department of Rheumatology, St. Margaret Clinic Budapest, 2Department of Pathology, Hospital of the Orders of the Brothers of Saint John of God, Budapest, Hungary

**Background:** Systemic sclerosis (SSc), like all chronic autoimmune disorders, may be complicated by AA amyloidosis (AAa). An associated B-cell lymphoma or cause amyloid nodal involvement and amyloidosis in SSc patients, but not dose-dependently. The supernatant regulated peripheral CD1c+ DCs, but not dose-dependently. The supernatant level significantly increased after co-cultured with MSCs. However, the addition of FLT3L siRNA significantly abrogated the up-regulation of CD1c+ DCs by MSCs.

**Conclusions:** UC MSCs induce CD1c+ tolerogenic DCs through up-regulating FLT3L in lupus patients.

**AB0165 CXCL4 MAY PLAY A KEY ROLE IN SYSTEMIC SCLEROSIS BY DRIVING CD4 T CELLS TO PRODUCE IL-17**

A.J. Attardi1,2, S.C. Silva Cardoso1,2, S. Garcia-Perez1,2, W. Marut1,2, J.A.G. van Roon1,2, T.R.D.J. Radstake1,2. 1Laboratory of Translational Immunology; 2Dept. of Rheumatology & Clinical Immunology, UMC Utrecht, Utrecht, Netherlands

**Background:** CXCL4 regulates multiple facets of immune response and its level is higher in various Th17-associated autoimmune diseases, including systemic sclerosis (SSc)-1. Recently, CXCL4 was shown to induce type I interferon production as well as endothelial activation in SSc patients1. Th17 skewing has been demonstrated in SSc1,2, however, whether CXCL4 plays a role in the induction of IL-17 production is currently unclear.

**Objectives:** To investigate the effect of CXCL4 on human CD4 T cell phenotype in particular IL-17 production in the absence or presence of antigen presenting cells.

**Methods:** Blood was obtained from healthy donors and CD4 T cells, monocytes, dendritic cells, were isolated using magnetic-based sorting (n=20). In addition, CD4 T cells from SSc patients were isolated (n=10). CD4 T cells were activated using anti-CD3/CD28, or in co-cultures with antigen presenting cells, stimulated using superantigen Staphylococcal enterotoxin B. Exogenous recombinant human CXCL4 was added during (co)-culture in different concentrations. Cytokine production and proliferation were analyzed using Luminex immunoassays, intracellular cytokine staining, and flow cytometry.

**Results:** CXCL4 directly induced CD4 T cells secreting both IL-17 and IFN-γ, as well as IL-22, when costimulated with anti-CD3/CD28 (p<0.05). In many SSc patients, similar IL-17 increase upon CXCL4 treatment was observed, although this did not reach statistical significance. This might be due to the fact that CD4 T cells from SSc patients had already significantly higher levels of IL-17 as compared to healthy donors (2182±222.2 vs 1053±263.6 pg/ml, mean±SEM, p<0.05). Furthermore, in co-culture system of CD4 T cells with monocytes or myeloid dendritic cells, CXCL4 treatment induced IL-17 production upon triggering by superantigen (p<0.05). Moreover, when monocyte-derived dendritic cells were differentiated in the presence of CXCL4, they orchestrated significantly increased levels of IL-17, IFN-γ, and proliferation by CD4 T cells (all p<0.05).

**Conclusions:** Altogether, we demonstrate that CXCL4 may potentially activate immune responses in Th17-mediated rheumatic diseases such as systemic sclerosis.

**AB0166 INTERLEUKIN-6-POLARISED MACROPHAGES PROMOTE DERMAL MYOFIBROBLAST DIFFERENTIATION**

**Background:** Macrophages and fibroblasts are key effector cell types present in scleroderma tissue. While the effect of scleroderma fibroblast conditioned medium on macrophages has been previously studied2, less is known about the effect of scleroderma macrophages on fibroblasts. Interleukin-6 (IL-6) is an important mediator of fibrosis and is overexpressed in scleroderma sera and cells of skin fibroblasts, macrophages and endothelial cells3. Given the increase in IL-6 levels in scleroderma and presence of the IL-6 receptor on the cell surface of macrophages, we are now investigating the phenotype of macrophages exposed to IL-6. Here we present our work into the paracrine function of IL-6-treated macrophages in stimulating fibroblasts using a media transfer approach.

AB0167 CALCULUM INFUX KINETICS AND THE CHARACTERISTICS OF POTASSIUM CHANNELS IN PERIPHERAL T LYMPHOCYTES IN SYSTEMIC SCLEROSIS

N. Legény1, G. Toldi7, I. Ocsosváki2, L. Kovács1, A. Balog1, 1Department of Rheumatology and Immunology, Faculty of Medicine, Albert Szent-Györgyi Health Center, University of Szeged, Szeged; 2First Department of Obstetrics and Gynecology, Semmelweis University, Budapest; 3Department of Biochemistry, Faculty of Medicine, Albert Szent-Györgyi Health Center, University of Szeged, Szeged, Hungary

Background: Systemic sclerosis (SSc) is a chronic connective tissue disorder characterized by microvascular injury, fibrosis and autoimmunity that affects the skin and internal organs. The short-term activation of peripheral blood T lymphocytes plays a crucial role in initiating and maintaining the chronic inflammation. The transient increase of the cytoplasmic free calcium level plays a key role in the process of lymphocyte activation. Kv1.3 and IKCa1 potassium channels are important regulators of the maintenance of calcium influx during lymphocyte activation. The influx of calcium is maintained by the function of potassium channels that conserve the electrochemical potential gradient via the efflux of potassium from the cytoplasm. Recent reports raised the notion that the inhibition of lymphocyte potassium channels, especially that of the Kv1.3 channel would be an straightforward solution for specific immunosuppression in autoimmune diseases. Furthermore, our previous studies described an alteration of the short-term activation of peripheral lymphocytes in rheumatoid arthritis and primary Sjögren’s syndrome (pSS), and the overexpression of Kv1.3 channels in pSS.

Objectives: Therefore, in this study we aimed to characterize the effects of lymphocyte potassium channel inhibition on short-term peripheral blood T lymphocyte activation in major lymphocyte subsets in SSc.

Methods: We enrolled 12 healthy individuals and 16 SSc patients. We evaluated calcium influx kinetics following activation in CD4, Th1, Th2 and CD8 cells applying a novel kinetic flow cytometry approach. We assessed the sensitivity of the above subsets to specific inhibition of the Kv1.3 and IKCa1 potassium channels. We also assessed the Kv1.3 expression on lymphocytes.

Results: We observed increased parameters of calcium influx in CD8+ lymphocytes as compared with Th1 cells in SSc. However, the activation of CD8+ cells was lower in SSc compared to healthy controls. Moreover, activation of Th1 lymphocytes was slower in SSc than in healthy controls. The inhibition of IKCa1 potassium channel decreased the activation of CD8+ lymphocytes in healthy controls and the activation of Th1 cells in SSc. The inhibition of Kv1.3 channel modified the dynamics of activation of Th1 and Th2 lymphocytes in SSc.

Conclusions: The altered function of CD8+ cells and the specific inhibition of potassium channels seem to be a consequence of altered calcium influx kinetics in SSc, distinguishing it both from healthy controls and other autoimmune diseases.

AB0168 PROTECTIVE EFFECTS OF EPIGALLOCATECHIN 3 GALLATE ON FIBROSIS IN SCLERODERMA MODEL

A. Kocak1, D. Harmancı1, M. Birlik2, S. Sarioglu3, G. Guner Akdogan4, 1Department of Molecular Medicine, Institute of Health Sciences, Dokuz Eylul University; 2Department of Internal Medicine, Division of Rheumatology & Immunology; 3Department of Medical Pathology, School of Medicine, Dokuz Eylul University; 4Department of Biochemistry, School of Medicine, Izmir University of Economics, Izmir, Turkey

Background: Scleroderma (SSc) is a disease that shows involvement in internal organs or on the skin characterized by fibrosis (1). Dermis thickening and uncontrolled extracellular matrix (ECM) increase are seen in this disease whose pathogenesis is not fully understood. TGF-β/Smad 2/3 pathway is pivotal role in SSc pathogenesis via induction of profibrotic molecules including collagen and by decrease of matrix metalloproteinases (MMPs) synthesis (2,3). The occurrence of the myofibroblast phenotype at fibrosis is thought to be responsible for the contracted regions of the affected tissues (4).

Objectives: The aim of this study is to investigate the potential effects of epigallocatechin-3-gallate (EGCG) against fibrosis.

Methods: 32 Balbc female mice were randomly selected into four groups. For 21 days: (1) Control group (n: 8) was given 100 μL subcutan (sc) saline (SF) once a day, 100 μL intraperitoneal (ip) SF twice a week, (2) BLM group (n: 8) was given 100 μL (100 μg) sc BLM once a day, 100 μL ip SF twice a week, (3) BLM + EGCG group (n:8) was given 100 μL (100 μg) sc BLM once a day, 100 μL (100 μg) ip EGCG twice a week, (4) EGCG group (n: 8) was given 100 μL sc SF once a day, 100 mL (100 μg) ip EGCG twice a week. Hematoxylin&eosin and Masson trichrome staining of dermal areas were performed. Myofibroblast activity was measured using alpha smooth muscle actin antibody (α-SMA) by immunohistochemistry. Expression levels of MMP-1, MMP-8, MMP-13 and p-SMAD protein were examined by western blot. Expression levels of TGF-β1 mRNA were examined by qPCR. All of the statistical analyses were performed using SPSS software and the quantitative data were expressed as the mean±SEM. The quantitative variables were compared using the a ANOVA-Sidak. Statistical significance was defined as p<0.05.

AB0169 EVALUATION OF FREQUENCY AND TYPE OF PHYSICAL THERAPY IN MORE THAN 3400 PATIENTS WITH SYSTEMIC SCLEROSIS

1Dermatology, University Hospital Cologne, Cologne; 2Rheumatology, University Hospital Heidelberg, Heidelberg; 3Rheumatology, Charité Universitätsmedizin Berlin, Berlin; 4Rheumatology, University Hospital Tuebingen, Tuebingen; 5Dermatology, Charité Universitätsmedizin Berlin, Berlin; 6Dermatology, University Hospital Munich, Munich; 7Rheumatology, University Hospital Wuerzburg, Wuerzburg; 8Dermatology, HELIOS St Elisabeth Klinik Oberhausen, Oberhausen; 9Dermatology, University Hospital Carl Gustav Carus, Dresden; 10Dermatology, St. Josef Hospital Bochum, Bochum; 11Rheumatology, Johanniter-Krankenhäuser im Filming, Treuenbieten, Treuenbieten; 12Rheumatology, Asklepios Klinik Altona, Hamburg; 13Rheumatology, Justus Liebig University Giessen, Kerkhof Clinic, Bad Nauheim; 14Immanuel Krankenhaus Berlin-Buch, Berlin; 15Rheumatology, Krankenhaus St. Josef, Wuppertal; 16Rheumatology, University Medical Center UKSH, Luebeck, Germany; 17Dermatology, Medical University of Graz, Graz, Austria; 18Dermatology, HELIOS University Hospital Wuppertal, Wuppertal; 19Rheumatology, University Hospital Erlangen, Erlangen; 20Dermatology, Ludwig Maximilians University Hospital, Munich; 21Dermatology, University Medical Center Ulm, Ulm; 22IMIS, University of Cologne, Cologne, Germany.

Background: Systemic sclerosis (SSc) is a chronic fibrosing autoimmune disease which leads to severe musculoskeletal dysfunction, disability and contractures. Little is known on the type and extent of physical therapy (PT) prescribed to SSc patients in daily practice.

Objectives: To determine the type and frequency of PT received by SSc patients.

Methods: The data of 3430 clinically well defined SSc patients registered in the database of the German Network for Systemic Sclerosis were analyzed using SPSS.

Results: 48.5% (1662/3430) of the patients were treated with PT. The most frequently used form of PT was lymphatic drainage (23.6%/876), followed by physical exercise therapy (18.1%/671) and paraffin wax bath (10.5%/389). About 30% of the patients (46.9%) received two or three different forms of PT simultaneously. The prescription of PT did not correlate with the SSc subtype, as 49.5% (503/1016) of dcSSc patients, 50.3% (850/1689) of lcSSc patients and 45.7% (143/313) of SSc-Overlap patients received PT. PT was significantly more often prescribed to patients with pulmonary fibrosis in 51.1% (617/1208), synovitis in 61.6% (299/485) and CK elevation in 61.1% (174/285) (p=0.001–0.029). PT did not correlate with patients with pulmonary fibrosis in 51.1% (617/1208), synovitis in 61.6% (299/485) and CK elevation in 61.1% (174/285) (p=0.001–0.029). PT did not correlate with patients with pulmonary fibrosis in 51.1% (617/1208), synovitis in 61.6% (299/485) and CK elevation in 61.1% (174/285) (p=0.001–0.029).

Conclusions: Although SSc is characterized by considerable disability and restriction of motion, less than 50% of patients received PT. The significant decrease in PT prescription during recent years may reflect lack of knowledge how to prescribe PT and more restrictive insurance regulations.

AB0171 ANTI-CARBAMYLATED PROTEIN ANTIBODIES IN PATIENTS WITH SYSTEMIC SCLEROSIS: AN INTRIGUING ASSOCIATION WITH SKIN INVOLVEMENT

E. Favoing 1, M. Prete 1, S. Vettori 2, A. Corrado 3, F.P. Cantatore 3, G. Valentini 3, F. Perosa 1.

1Department of Biomedical Sciences and Human Oncology, Systemic Rheumatic and Autoimmune Disease Unit, University of Bari Medical School, Bari; 2Department of Clinical and Experimental Internal Medicine, Rheumatology Section, Second University of Naples, Naples; 3Department of Medical and Surgery Sciences, Rheumatology Unit, University of Foggia, Foggia, Italy.

Background: Systemic sclerosis (SSc), one of the most complex connective tissue disease, is characterized by three pathogenic events namely, vascular damage, autoimmunity and fibroblast activation, leading to a widespread fibrosis of skin and internal organs (1,2). Previous studies showed that 1) carbanhylation mainly affects structural proteins undergoing to a low turn-over rate, namely dermal skin and tendons-associated proteins; and that 2) carbanhylated proteins accumulate in skin in an age-dependent manner, contributing to tissue alteration (3).

Objectives: As dermis is a disease target and anti-carbanhylated protein antibodies (anti-CarP Ab) have been reported in patients with SSc (4), we sought to evaluate any relationship between anti-CarP Ab and clinical parameters reflecting skin involvement in SSc.

Methods: Serum samples and clinical data from 123 patients with SSc were collected. The samples were collected by indirect ELISA, using carbamylated bovine serum albumin as the antigen. Serum Anti-CarP Ab levels were also measured in 41 healthy aged-matched individuals. Clinical data were retrieved as previously reported (5).

Results: The mean serum levels of anti-CarP Ab did not statistically differ
between healthy and SSc group. In SSc, Spearman analysis showed that anti-CarP was inversely correlated with the modified Rodnan skin score (R) (R=-0.325, p<0.001), independently of patients’ age. Receiver operating characteristics (ROC) analysis identified the anti-CarP cut-off that best discriminated dichotomized clinical variables related to skin involvement. This cut-off was employed to study CarP expression in patients with anti-CarP positive and anti-CarP negative patients. Three SSc skin-related clinical parameters were significantly different between groups: RSS (p=0.001), SI skin (p=0.002), and sclerodema (p=0.001). A worse skin involvement was associated with low anti-CarP levels.

Conclusions: The study shows that anti-CarP Ab serum level inversely associates to the severity of skin involvement in SSc patients. One possible mechanism to explain the inverse association is that the disease-dependent accumulation of carboxamidated proteins in the skin may neutralize circulating anti-CarP Ab, thus contributing to their serum levels decrease. However, further investigation is needed to clarify this issue and to assess whether the levels anti-CarP Ab can be useful in the clinical setting of SSc.

PSGL-1 AND ADAM8 ON DENDRITIC CELLS ARE ASSOCIATED WITH SYSTEMIC SCLEROSIS AND COULD ACT AS BIOMARKERS FOR INTERSTITIAL LUNG DISEASE

J. Silván,1 R. González-Taquelo,1 E. Vicente-Rabaneda2, A. Pérez-Frias1, M. Espartero-Santos1, E. García-Lorenzo1, I. González-Alvaro2, S. Castañeda1, A. Urzainqui1,1 Immunology,2 Rheumatology, Hospital Universitario de la Princesa, Madrid, Spain

Background: Systemic Sclerosis (SSc) is a chronic autoimmune disorder with cutaneous, vascular and immune cells abnormalities that lead to extensive cutaneous and visceral fibrosis with high morbidity and mortality. P-Selectin interacts with PSGL-1 and proteolytically processes it, what could be a regulatory mechanism to control the expression of this inflammatory markers in the immune system.

Objectives: To investigate whether PSGL-1 and ADAM8 expression on leukocytes could be implicated in the pathogenesis of SSc.

Methods: PBLS from 47 SSc patients and 35 healthy donors were analyzed by flow cytometry. The percentage of cells expressing PSGL-1, HLA-DR and ADAM8, as well as the membrane (without cell permeabilization) and total (after cell permeabilization) expression were assessed for each leukocyte subset. For ADAM8, as well as the membrane (without cell permeabilization) and total (after cell permeabilization) expression were assessed for each leukocyte subset. For PSGL-1 and ADAM8 expression in CD16+ monocytes. Remarkably, highest PSGL-1 expression on CD16+ monocytes. Remarkably, highest PSGL-1 expression on conventional DC (CDc) and high levels of ADAM8 on plasmacytoid DC (pDC) associate with interstitial lung disease (ILD), one of the most severe SSc clinical manifestations, suggesting that PSGL-1 and ADAM8 could be prognostic markers of ILD.

Conclusions: This study highlights that PSGL-1 and ADAM8 expression on conventional DC, monocytes and lymphocytes could be implicated in SSc pathogenesis and particularly on DC might act as biomarkers for ILD.

AB0173 MYCOBACTERIAL INFECTION IN SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL SIGNIFICANCE AND ASSOCIATED FACTORS. DATA FROM THE REGISTRY OF PATIENTS WITH SLE OF THE SPANISH SOCIETY OF RHEUMATOLOGY (RELESSER)

J. Pego-Reigosa1, V. Campoo1, A. Lois-Iglesias1, C. Mouriño2, F. López-Longo1, M. Galindo1, J. Caibo1, J. Izabale1, A. Olíve2, R. Melero1, A. Fdez-Nebro3, E. Tore2, L. Horcada1, E. Uriarte1, M. Freire3, I. Rua-Figueroa12 on behalf of EASER-RELESSER, 1Hospital e JJSOS; 2H. Vigo; 3H. Coruña; 4H. Gregorion Mariano; 5H. 12October, Madrid; 6H. Araba; 7Povisa; 8H. Germans Trias; 9H. Curetense; 10H. Carlos Haya; 11H. Alicante; 12H. GCanarina; 13H. la Princesa; 14H. Navarra; 15H. Donostia, Spain

Objectives: To study the prevalence of mycobacterial infection (MI), the associated factors and their clinical significance in patients included in a large SLE cohort.

Methods: Retrospective descriptive study of RELESSER patients with a history of MI and analysis of the factors associated with this infection.

Results: In RELESSER, 3,658 patients with ≥ 1 ACR SLE criteria were included. Three SSc skin-related clinical parameters were significantly different between groups: RSS (p=0.001), SI skin (p=0.002), and sclerodema (p=0.001). A worse skin involvement was associated with low anti-CarP levels.

Conclusions: The study highlights that PSGL-1 and ADAM8 expression on CD16+ monocytes and plasmacytoid DC might act as biomarkers for ILD.

Disclosure of Interest: None declared

AB0174 LYMPHOCYTE SUBSETS T, B AND NK CELLS IN SYSTEMIC SCLEROSIS

L. Schneider1, V. Haix1, N. Marcondes2, R.M. Xavier1, R. Chakr1

1Rheumatology, 2HCPA, Porto Alegre, Brazil

Background: Systemic sclerosis (SSc) is a rare multisystem disease with underlying immune mechanisms, whose pathogenesis remains unclear. Few previous reports have evaluated lymphocyte subpopulations in SSc and your results are conflicting.

Objectives: The present study aimed to analyze the lymphocyte subsets in SSc patients in comparison to healthy individuals.

Methods: Peripheral blood (PB) samples to analyze lymphocyte subsets were obtained from 47 SSc patients who were divided into two groups: ACR SLE criteria were included. Three SSc skin-related clinical parameters were significantly different between groups: RSS (p=0.001), SI skin (p=0.002), and sclerodema (p=0.001). A worse skin involvement was associated with low anti-CarP levels.

Conclusions: The study highlights that PSGL-1 and ADAM8 expression on CD16+ monocytes and plasmacytoid DC might act as biomarkers for ILD.

29.6%, p<0.026) (Table 1). No statistically significant differences were found in the percentages or the absolute numbers of T, B or NK cells.

**Conclusions:** Our data support previous reports indicating that depletion of lymphocyte in the PB of SSc patients. However, we found no significant difference in relation to lymphocyte subtypes, which differs from the literature data.

**References:**

**Results:** Sitaxentan and/or ambrisentan significantly blocked the migration of neutrophils and tumor cell lines. In more detail, neutrophil migration in response to N-formylmethionyl-leucyl-phenylalanine (FMLP) or Protease-activated receptor 2 (Par-2) agonist. Because it has been shown before [2], IgGs from HD and SSc patients were used as additional stimulus for the effects of ETAR antagonists on migration of neutrophils and tumour cells remain to be determined.

**Conclusions:** This is the first attempt to validate circulating biomarkers defining disease phases in SSc patients. These results support that patients diagnosed as early SSc have the highest likelihood of disease progression. Moreover, the presence of autoreactive IgGs in SSc sera can be used to identify patients at risk for particular disease outcomes, such as cardiac involvement or pulmonary fibrosis.

**AB0178 PHENOTYPING OF NATURAL KILLER (NK) RECEPTORS ON NK AND NKT-LIKE CELLS DISCLOSES DEFECTIVE IMMUNE-REGULATORY CAPABILITY IN PATIENTS WITH SYSTEMIC SCLEROSIS**

M. Cossu1,2, L. Beretta3, E. Trombetta4, S.T.A. van Bijnen5,6, M. Rossato1,2, L. van Bon1, M. van der Kroef1,2, E.C. Chouri1,2, C.G. Kichers1,2, N. Mispelaere1,2, M. Vaziparian1,2, M.C. Vonk7, L. Porrettet8, F. Freijer9, H. Dolstra5, T.R.D.J. Radstake1,2,1, Rheumatology & Clinical Immunology; 2Laboratory of Translational Immunology (LTI), UMC Utrecht, Utrecht, Netherlands; 3Referral Center for Systemic Immune Diseases; 4Flow Cytometry Service, Clinical Chemistry and Microbiology Laboratory, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; 5Hematology; 6Laboratory Medicine, Laboratory of Hematology; 7Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by dysregulation of the immune system, vasculopathy and fibrosis of the skin and internal organs. Natural Killer (CD56+CD3- NK) and NKT-like (CD56+CD3+) cells display receptors (NKR) whose expression pattern determines their cytotoxic and immune-regulatory activity. The role of NK and NKT-like cells in the dysregulation of the immune system in SSc has not been fully elucidated yet.

Objectives: To improve our knowledge on the contribution of NK, NKT -like and iNKT cells as immune check-points in fibrotic SSc.

Methods: NKR were assessed by flow cytometry using two 13-color panels on whole blood of 84 SSc patients and 20 healthy controls (HC). In particular, 15 patients with early SSc (EsAaSSc) without signs or symptoms of evolutive disease (2001 LeRoy and Medsger criteria). 24 patients with definite SSc without skin or lung fibrosis (defSSc); 26 patients with limited (iSSc) and 19 patients with diffuse cutaneous SSc (dcSSc) 2013 EULAR/ACR classification for SSC were included. NK degranulation in response to K562 target cells was assessed in iSSc and dcSSc patients versus HC.

Results: The number of circulating lymphocytes, NK-like and iNKT cells - but neither CD3+ T nor NK cells - was reduced in dcSSc versus HC. NKp46+ NK cells were decreased in both iSSc and dcSSc versus HC and EsAaSSc. Consistently with these observations, dcSSc exhibited lower degranulation capability (CD56+KIR+) and activating NKR-expressing NK-like cells were diminished in both iSSc and dcSSc versus HC.

Conclusions: dcSSc patients showed a defective NK cytotoxicity potential, possibly due to the decreased NKp46+ fraction. The regulatory, cytotoxic KIR+ NK-like fraction was also reduced with a parallel decrease of activating receptors expression in both iSSc and dcSSc. Overall these results point towards an impairment of NK and NKT-like cells as immune check-points in fibrotic SSc.

**AB0179 DEGRADATION OF TYPE VII COLLAGEN (COL7) IS ASSOCIATED WITH SYSTEMIC SCLEROSIS – DEVELOPMENT OF A NOVEL NEO-EPITOPE SPECIFIC ASSAY**

J. Sand1, P. Juul1, Y. Tanino2, T. Nikaido2, K. Misa2, Y. Sato2, R. Toggle2, X. Wang2, M. Karasal3, A.C. Bay-Jensen1, D. Leeming1, A.S. Siebuhr1, M. Munakata2,1, Nordic Bioscience, Herlev, Denmark; 2Department of Pulmonary Medicine, Fukushima Medical University School of Medicine, Fukushima, Japan

Background: Idiopathic pulmonary fibrosis (IPF) is characterized by an increased rate of extracellular matrix (ECM) turnover resulting in fibrosis. The pathologic remodeling process increases levels of protein synthesis and degradation mediated by proteases such as matrix metalloproteinases (MMPs). Acute exacerbations of IPF (AE-IPF) represent periods of increased disease activity. Pulmonary involvement, especially pulmonary fibrosis, is common in patients suffering from systemic sclerosis (SSc) and ankylosing spondylitis (AS).

Objectives: The objective was to investigate if ECM remodeling was altered during AE-IPF by serological neo-epitope biomarkers.

Methods: Serum samples were collected from patients with IPF at clinically stable disease (S-IPF, n=29) and at AE-IPF (n=68). Of these, 11 and 28 patients, respectively, had idiopathic pulmonary fibrosis (IPF). 28 IPF patients had paired samples. Biomarkers released from MMP-mediated degradation of collagen type I (C1M), III (C3M), IV (C4M), and VI (C6M), elastin (ELM7), versican (VCAN), biglycan (BGM), and C-reactive protein (CRP) were assessed in serum by competitive ELISAs utilizing neo-epitope specific monoclonal antibodies. Data were analysed using Mann-Whitney test, Wilcoxon test, Spearman’s rank correlation, and Kaplan-Meier curves as appropriate.

Results: Mean age of patients was 71 (range 54–88) at AE-IPF and 69 (range 55–83) at S-IPF. Mean forced vital capacity in percentage of predicted value (%FVC) was 55.6% (SD 19.5) at AE-IPF and 79.0% (SD 26.5) at S-IPF. Serum fibilics that connects the basement membrane to the underlying interstitial matrix and has mainly been investigated for its role in blistering skin diseases. It has been investigated for its role in dystrophic epidermolysis bullosa, a severe skin disease. Furthermore, increased levels of type VII collagen in skin has been reported for patients with systemic sclerosis (SSc).

Objectives: The objectives here were to develop and characterize a bio-functional marker assessing col7 degradation in patients with SSc.

Methods: We identified a specific fragment of col7 in serum from COPD patients, which was not found in controls, using mass spectrometry. A monoclonal antibody was raised against the first ten amino acids of the neo-epitope (KLH-CGG-GPPGPPGRLV) and employed in a competitive ELISA (C7M). The C7M assay was validated technically and was subsequently evaluated in 2 cohorts including SSc patients. The first cohort (SSc#1; n=35) consisted of early (≤2 years of SSc symptoms; n=16) and late (>10 years of disease with stable skin for at least 6 months, n=19) diffuse SSc patients, while the second cohort (SSc#2; n=119) consisted of limited (n=78) and diffuse (n=41) SSc patients. Serum C7M levels were likewise measured in healthy subjects and compared to the levels of SSc patients using the Kruskal-Wallis test with Dunn’s multiple comparisons test comparing healthy individuals with the two SSc cohorts.

Results: A technically robust competitive ELISA (C7M), which was highly specific for a col7 fragment was developed. The assay showed acceptable inter- (13%) and intra-assay (9%) variation, linearity (102% dilution recovery), analyte stability (102% recovery after 4 freeze/thaw cycles), and interference. The C7M marker was evaluated by comparing serum levels in healthy donors with patients with SSc (Figure). Serum C7M levels were not associated with age, gender, BMI, or disease duration. The mean geometric serum C7M level in healthy donors was 4.6 ng/mL (95% CI 3.7–5.6 ng/mL). The geometric mean serum C7M levels were significantly elevated in both cohorts of patients with SSc (SSc#1: 13.6 ng/mL [95% CI 11.1–16.5], p<0.0001; SSc#2: 9.2 ng/mL [95% CI 8.3–10.2], p<0.0001). Furthermore, a significant difference were observed between the two cohorts (P<0.05).

Conclusions: The C7M ELISA enabled quantification of type VII collagen degradation in serum. Elevated serum C7M levels indicated that the remodeling of type VII collagen was significantly increased in patients with SSc, suggesting a pathological role.

DOI: 10.1136/annrheumdis-2017-eular.5059
levels of C4M, C6M, and CRP at AE-IIP were positively correlated with %FVC (r=0.37, p=0.008; r=0.36, p=0.011; r=0.33, p=0.020, respectively). Serum levels of C4 (p=0.002) and C6 (p=0.024) were increased while LEM7 (p=0.024) and VCANM (p=0.0001) were decreased at AE-IIP as compared with S-IIP when analyzing all patients. IPP patients had lower levels of VCANM at AE-IIP (p=0.001). IPP patients had significantly elevated serum levels of C4M (p=0.004) and decreased levels of LEM7 and VCANM (p=0.036 and p=0.0001, respectively) at AE-IIP. C1M and C6M levels at AE-IIP were borderline related to mortality outcome for IPP patients (both p=0.059) with levels above median associated with a higher risk of mortality. Analyses of all or paired patients showed no associations with mortality.

Conclusions: Serological levels of neo-epitope biomarkers of ECM degradation were associated with AE-IIP and weakly with mortality outcome. These results indicate that the rate of ECM remodeling in the lungs of patients with IIP is significantly altered during periods of high disease activity such as an acute exacerbation. The difference in degradation profile for the proteins studied is intriguing and indicate activation of different processes contributing to AE-IIP. Neo-epitope biomarkers of the ECM might be useful in identifying patients diagnosed with rheumatic disease as SSC and AS with pulmonary involvement.

Background: Lung involvement, i.e. interstitial lung disease (ILD) and pulmonary hypertension (PH), is commonly in patients with systemic sclerosis (SSc), significantly limiting quality of life and survival. Data on clinical correlations between lung function and clinical subsets of SSc are sparse.

Objectives: To investigate the relationship of DLCO and clinical characteristics in patients SSc patients within the registry of the German Network for Systemic Sclerosis.

Methods: Clinical data of the patient registry, currently including DLA data of 1917 patients were evaluated. In total, these patients were clinically evaluated 5997 times (i.e., at the first visit and during follow-up visits). At the initial visit and during follow-up visits DLCO were correlated with clinical characteristics.

Results: At initial presentation, 64% of the patients had DLCO levels <75% predicted. Impaired DLCO levels were observed in 74% of dcSSc patients, in 64% of SSc-Overlap patients and 57% of lcsSc patients (p=0.0001). Furthermore, male patients (62%), patients with PH (80%), ILD (80%), dyspnea (78%), and those with presence of anti-topoisomerase I antibodies (71%) exhibited significantly more often DLCO levels <75% (p=0.01). Patients suffering from dcSSc had the lowest DLCO levels (mean value, 62%), followed by patients with SSc-Overlap syndrome (mean value, 67%) and lcsSc patients (mean value, 71%). In addition, significant differences between subsets. Long-term follow-up evaluation (mean follow up, 6.0 years) revealed that in comparison to lcsSc patients dcSSc patients (OR 2.1; p=0.0001; 95%-CI 1.7–2.5) and SSc-Overlap patients (OR 1.55; p<0.0001; 95% CI 1.2–2.0) had a significantly increased risk to a decrease in DLCO levels <75%.

Conclusions: Impairment of pulmonary function as determined by diffusing capacity DLCO is more common and more pronounced in patients with dcSSc and SSc-Overlap Syndrome compared to lcsSc. DLCO may be useful for diagnosing and monitoring pulmonary involvement in SSc.

DOI: 10.1136/annrheumdis-2017-eular.5878
subjects (CNTs). PBMCs, isolated from 9 among the SSc patients, were cultured on fibronectin-coated plates [5]. The non-adherent cells were removed and after 8 days (t0) of culture (standardized time), the adherent spindle shaped cells were lifted through incubation in 0.05% EDTA (ice-cold). Fibrocyte identification (at both t0, t8), was performed by FACS, using anti-CD45, anti-COL I, anti-CXCR4 and anti-CD163, indicating pro-fibrotic and endothelial markers.

**Results**: FACS analysis revealed that, at basal time (t0), among the CD45+ cells, the percentage of fibrocytes, identified as triple positive (CD45+, COL I+, CXCR4+) was 1.0±2.1% in SSc patients and 0.4±0.3% in healthy subjects (CNTs). In addition, the HLA-DR expression on fibrocytes in both SSc patients and CNTs showed low values (22.1±11.1 and 7.1±14.1, respectively). After 8 days (t8) of culture, fibrocytes presented adherent and spindle shaped morphology. Interestingly, the FACS analysis at t8 of culture, demonstrated that the percentage of SSc fibrocytes CD45+, COL I+, CXCR4+ increased up to 50.8±27.3%, compared to basal time (t0), as well as strongly increasing the HLA-DR expression (10.0±22.7%).

**Conclusions**: Fibrocytes isolated from CPCS of SSc patients were confirmed to express CD45, COL I and CXCR4 molecules, but in very low percentage at the beginning. Already after 8 days of culture in proper conditions, the percentage of differentiated fibrocytes (CD45+, COL I+ and CXCR4+) increased up to 50.8±27.3%, compared to basal time (t0), as well as strongly increasing the HLA-DR expression (10.0±22.7%). Additional markers of progressive fibrocyte differentiation are now under test to further characterize the fibrocyte phenotype(s) of SSc patients vs healthy controls.

Long-term administration of fenspiride has no negative impact on bone mineral density and selected markers on bone turnover in young growing rats.

Methods: The experiment was carried out on 118 young (8-week-old) male Wistar rats receiving standard diet containing 1.2% of calcium and 0.7% of phosphate. Rats were randomly assigned to two groups (9 in each group): group F—rats receiving fenspiride (15 mg/kg) in saline solution (4ml/kg), and group C (control group)—rats receiving saline solution (4ml/kg). Saline solution and fenspiride were given intragastrically once daily for 90 days (from day 3 to day 93). Blood samples and 93 blood cultures for serum isolation were collected. Markers of bone turnover were assessed with commercial ELISA kits according to producers' instruction. Bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry (DXA) with Hologic DXA equipment (Hologic Discovery W 9600) using a small animal software. The experiment was performed with the approval of the Local Ethics Committee for Experiments on Animals in Wroclaw.

Results: On Day 1 there was no difference in age and body weight between groups. On Day 1, no difference in total body bone mineral density (BMD) (0.160±0.0065 g/cm² vs. 0.1608±0.0056 g/cm²), lower limbs BMD (0.230±0.0267 g/cm² vs. 0.233±0.0315 g/cm²), serum levels of bone turnover markers (osteocalcin: 1000.921±109.0705 pg/ml vs. 952.577±178.5306 pg/ml; BCTX: 280.089±54.4298 pg/ml vs. 292.8979±116.0042 pg/ml; osteoprotegerin: 3.5±0.6338 pg/ml vs. 3.7963±0.6894 pg/ml; RANKL: 0.167±0.4099 pg/ml vs. 0.201±0.2717 pg/ml) was detected. On Day 93 there was no difference in body weight, total body BMD and lower limbs (0.212±0.0104 g/cm² vs. 0.205±0.0242 g/cm²; 0.264±0.0159 g/cm² vs. 0.252±0.0271 g/cm², respectively) between groups. On Day 93 no difference between groups in serum bone turnover markers was detected (OC: 422.756±32.3316 pg/ml vs. 429.2071±83.0520 pg/ml; BCTX: 307.748±77.6753 pg/ml vs. 285.3486±79.1334 pg/ml; OPG: 5.466±7.815 pg/ml vs. 5.3520±1.6458 pg/ml; RANKL: 0.647±0.8457 pg/ml vs. 0.5639±0.8608 pg/ml).

Conclusions: Long-term administration of fenspiride has no negative impact on bone mineral density and bone turnover in young growing rats.

AB0187 LONG-TERM ADMINISTRATION OF FENSPIRIDE HAS NO NEGATIVE IMPACT ON BONE MINERAL DENSITY AND BONE TURNOVER IN YOUNG GROWING RATS

A. Matuszewska 1, B. Nowak 1, D. Jedrzejuk 2, M. Landwotwicki 2, M. Bolanowski 3, W. Dziewiszek 1, E. Szelag 4, K. Zduniak 4, J. Kwiatkowska 1

1 Department of Pharmacology; 2 Department of Endocrinology; 3 Department of Maxillofacial Orthopaedics and Orthodontics; 4 Department of Pathomorphology, Wroclaw Medical University, Wroclaw, Poland

Background: In young organisms intensive bone turnover is observed and it allows the skeleton to achieve proper size, shape and weight of bones. It is extremely important to assess the influence on various drugs on growing bones. Fenspiride is registered for therapy of acute and chronic respiratory tract infections in children and adolescence. It decreases the synthesis of proinflammatory cytokines, blocks H1 receptors and has bronchodilatatory properties.

Objectives: The aim of the study was to assess the influence of long-term administration of fenspiride on bone mineral density and selected markers on bone turnover in young growing rats.

Methods: The experiment was carried out on 118 young (8-week-old) male Wistar rats receiving standard diet containing 1.2% of calcium and 0.7% of phosphate. Rats were randomly assigned to two groups (9 in each group): group F—rats receiving fenspiride (15 mg/kg) in saline solution (4ml/kg), and group C (control group)—rats receiving saline solution (4ml/kg). Saline solution and fenspiride were given intragastrically once daily for 90 days (from day 3 to day 93). Blood samples and 93 blood cultures for serum isolation were collected. Markers of bone turnover were assessed with commercial ELISA kits according to producers' instruction. Bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry (DXA) with Hologic DXA equipment (Hologic Discovery W 9600) using a small animal software. The experiment was performed with the approval of the Local Ethics Committee for Experiments on Animals in Wroclaw.

Results: On Day 1 there was no difference in age and body weight between groups. On Day 1, no difference in total body bone mineral density (BMD) (0.160±0.0065 g/cm² vs. 0.1608±0.0056 g/cm²), lower limbs BMD (0.230±0.0267 g/cm² vs. 0.233±0.0315 g/cm²), serum levels of bone turnover markers (osteocalcin: 1000.921±109.0705 pg/ml vs. 952.577±178.5306 pg/ml; BCTX: 280.089±54.4298 pg/ml vs. 292.8979±116.0042 pg/ml; osteoprotegerin: 3.5±0.6338 pg/ml vs. 3.7963±0.6894 pg/ml; RANKL: 0.167±0.4099 pg/ml vs. 0.201±0.2717 pg/ml) was detected. On Day 93 there was no difference in body weight, total body BMD and lower limbs (0.212±0.0104 g/cm² vs. 0.205±0.0242 g/cm²; 0.264±0.0159 g/cm² vs. 0.252±0.0271 g/cm², respectively) between groups. On Day 93 no difference between groups in serum bone turnover markers was detected (OC: 422.756±32.3316 pg/ml vs. 429.2071±83.0520 pg/ml; BCTX: 307.748±77.6753 pg/ml vs. 285.3486±79.1334 pg/ml; OPG: 5.466±7.815 pg/ml vs. 5.3520±1.6458 pg/ml; RANKL: 0.647±0.8457 pg/ml vs. 0.5639±0.8608 pg/ml).

Conclusions: Long-term administration of fenspiride has no negative impact on bone mineral density and bone turnover in young growing rats.

Rheumatoid arthritis - prognosis, predictors and outcome

**AB0189**

**RAID COMPOSITE INDEX IN THE EVALUATION OF RA PATIENTS RECEIVING BIOLOGICAL TREATMENT: HUR-BIO REAL-LIFE RESULTS**

A. Erden, L. Kilic, B. Armanag, A. Sari, A. Alkdogan, S.A. Bilgen, O. Karadag, I. Ertensli, S. Kiraz, U. Kalyoncu. Department of Rheumatology, Hacettepe University Faculty of Medicine, Ankara, Turkey

**Background:** Rheumatoid Arthritis Impact of Disease (RAID) is a composite index. There are seven domains of this index (pain, function, fatigue, sleep disturbance, physical wellbeing, psychological/emotional well-being and coping). This index is validated and recommended to be used in clinical trials to measure the effect of RA.

**Objectives:** The aim of this study is to examine the relationship between RAID composite index and other indexes.

**Methods:** This study was carried out from the HUR-BIO reserved database since August, 2016. In addition to the demographic characteristics of the patients, DAS-28, HAQ-DI, pain, fatigue, Patient Global Assessment (PGA), Tender joint counts (TJC), Swollen joint counts (SJC), CRP and ESR are recorded. Since August, 2016. In addition to the demographic characteristics of the patients, DAS-28, HAQ-DI, pain, fatigue, Patient Global Assessment (PGA), Tender joint counts (TJC), Swollen joint counts (SJC), CRP and ESR are recorded. Since August, 2016.

**Results:** HUR-BIO database contains 1235 RA patients as of August 2016. A RAID form was filled for 149 of these patients before initiating biological agent.

**Conclusions:** RAID has moderate correlation with pain, fatigue and PGA. RAID also has moderate correlation with pain, fatigue and PGA.

**Disclosure of Interest:** None declared

**AB0190**

**ASSESSMENT OF PLASMA MICRO-RNA 155 IN RHEUMATOID ARTHRITIS**

A.A. Negm 1, S. Al Arably 1, E. Abdulazim 1, E. Alalwany 1, M. Mohamed 1, M. Abeldagh 2, M. Hamed 2, S. Ismail 2

**Background:** Several observations have indicated that Epigenetics now play a role in the pathogenesis of many diseases including Rheumatological and Inflammatory diseases (Rheumatoid Arthritis). Unlike the genetic code, the epigenome is altered by endogenous (e.g. hormonal) and environmental (e.g. diet, exercise) factors and changes with age. There are three main and interrelated mechanisms: DNA methylation, post-translational modification of histone proteins and non-coding RNA which includes Micro RNA (miR).

**Objectives:** 1. To determine the level of miR-155 in plasma of RA patients. 2. To determine the potential value of miR-155 as molecular biomarker for diagnosis, prognosis of disease outcome, and prediction of therapeutic response in RA patients, and to test the relation miR-155 and serum levels of Matrix Metalloproteinase 3 (MMP). 3. To determine the potential value of miR-155 as molecular biomarker for diagnosis, prognosis of disease outcome, and prediction of therapeutic response in RA patients, and to test the relation miR-155 and serum levels of Matrix Metalloproteinase 3 (MMP).

**Methods:** The study group consisted of 50 female RA patients in active disease and 25 controls of matched age and sex. Disease duration of 1 to 10 years and age range from 20 to 45 years old. They underwent detailed history taking including questionnaire for disability and health assessment scoring, clinical examination, radiological assessment by modified Sharp score. Routine laboratory investigations in addition to assessment of Plasma miR-155 expression levels and serum MMP-3 levels were done for all patients. Ten of the cases were resampled for miR-155 and MMP-3 after receiving treatment and entering disease remission (By DAS 28 score).

**Results:** Plasma miR-155 expression levels and serum MMP-3 titers were significantly higher in RA patients than in controls (mean 4.071 and 1, p < 0.001, mean 323.7 and 84.5, p<0.001 respectively). MMP-3 titers in serum were significantly higher in erosive than in non-erosive arthritis (mean 366.9 and 163.4, p<0.001). There was a significant positive difference between serum MMP-3 levels in disease activity and remission (mean 630 and 390, p<0.001). Mean values of the clinical parameters of our study group: STLV score (37.4±15.90), HAQ score (56.8±16.69), ACR disability class (2.224±0.672), DAS 28 score (4.86±1.222), ESR (58.16±29.44), Sharp score (32.63±23.91). There was a significant positive moderate correlation between Plasma miR-155 and serum MMP-3 (r=0.596, p<0.001). Correlation between Plasma miR-155 expression levels and HAQ (p=0.612, r=0.03744), with ESR (p=0.13, r=0.219) with DAS 28 score (p=0.187, r=0.192), with Sharp score (p=0.675, r=0.0179). There was a significant positive moderate correlation between Plasma miR-155 and serum MMP-3 (r=0.596, p<0.001). Correlation between Plasma miR-155 expression levels and HAQ (p=0.612, r=0.03744), with ESR (p=0.13, r=0.219) with DAS 28 score (p=0.187, r=0.192), with Sharp score (p=0.675, r=0.0179).

**Conclusions:** miR-155 is indeed related to the presence of Rheumatoid arthritis, although not directly related to disease activity like MMP-3, miR-155 significantly but moderately correlates with MMP-3 in blood, but whether it plays a role in the pathogenesis of the disease with or without directly influencing MMP-3 in the joint will require more work on both markers inside the synovial fluid, tissue and the synovial fibroblasts. MMP-3 was re-established in our study as a marker of disease activity and predictor of erosive arthritis.

**CLINICAL SIGNIFICANCE OF MULTIPLE AUTOANTIBODY SPECIFICITIES IN RHEUMATOID ARTHRITIS: THE ROLE OF ANTI-CITRULLINATED ALPHA ENOLASE AND ANTI-INTERFERON INDUCIBLE PROTEIN 16**

A. Alunno 1, O. Bistoni 1, F. Pratasi 2, V. Caneparo 3, G.M.C. La Paglia 1, I. Puxeddu 1, M. De Andrea 4, E. Bartoloni 1, S. Landolfo 4, P. Migliorini 2, R. Geri 1, 1Department of Medicine, Rheumatology Unit, University of Perugia, Perugia; 2Department of Clinical and Experimental Medicine, University of Pisa, Pisa; 3Department of Translational Medicine, University of Pisa; 4Istituto Ortopedico Rizzoli, Bologna; 5Department of Public Health and Epidemiology, University of Bologna, Bologna, Italy.

**Background:** Anti-cyclic citrullinated peptide antibody (anti-CCP) auto-antibodies (auto- Abs) represent the current gold standard for the diagnosis of rheumatoid arthritis (RA). However, growing evidence suggests that a variety of other citrullinated or not citrullinated self-proteins may act as autoantigens and lead to the production of auto-Abs. The identification of the diagnostic and/or prognostic value of such novel auto-Abs is under intense investigation. We recently demonstrated that RA patients display a higher prevalence of auto-Abs against the interferon-inducible protein 16 (anti-IF16) but these auto-Abs do not have a good diagnostic value (1). Recently, it was shown that auto-Abs against citrullinated alpha-enolase (anti-CEP1) are associated with erosive RA (2).

**Objectives:** The purpose of this study was to investigate the possible prognostic value of anti-CEP1-1 and anti-IF16 as well as the clinical implication of their association with anti-CCP in a cohort of RA patients.

**Methods:** Two hundred and fifty two RA patients were enrolled and serum samples were collected. Auto-Ab were assessed as follows: anti-CCP EIA second generation ELISA kit (Euroimmun); anti-CEP-1 IgG ELISA kit (Euroimmun). In a subgroup of 113 patients also anti-IFI16 auto-Abs were assessed with an in-house ELISA kit (1). Clinical and serumological records of patients were collected and statistical analysis was performed with SPSS 21.0 software.

**Results:** One hundred and twenty two patients (44%) displayed anti-CEP1-1 auto-Abs and of these 97 patients (87%) also displayed anti-IF16. Logistic regression analysis revealed an association between both anti-Abs and RA-associated pulmonary disease (odds ratio 10.21, 95% CI: 1.98–69.7; p=0.04). We also confirmed that anti-CEP1-1 are associated with erosive RA but of interest to a greater extent compared to anti-CCP (anti-CEP1-1: OR=4.12; p=0.04; anti-CCP: OR=2.1; p=0.03). The analysis that included anti-IF16 auto-Abs revealed that a small proportion of patients display all the three auto-Abs (9%) but
the triple positivity was significantly associated with male gender (OR=3.5; p<0.02), the presence of rheumatoid nodules (OR=5.3; p=0.015) and pulmonary involvement (OR=2.6; p<0.007). Anti-IF16 auto-Abs were associated to male gender independently of the presence of the other two auto-Abs.

Conclusions: Our study demonstrated that anti-CEP-1 auto-Abs may participate to the development of RA-associated pulmonary manifestation together with anti-CCP and that the assessment of multiple auto-Abs in daily practice may help clinician to stratify RA patients at identify those at higher risk to develop extra-articular manifestations.

SERUM MEASURES OF TYPE I COLLAGEN DEGRADATION ARE SURROGATE MARKERS OF JOINT DESTRUCTION AND PROGRESSION; FIRST STEPS TOWARDS A PROGNOSTIC SCORE

A.C. Bay-Jensen 1, C. Bager 2, A.S. Siebuth 3, H. Bay Nielsen 3, M.A. Karsdal 1, 3
1 Rheumatology, Nordic Bioscience Biomarkers and Research; 2 Proscion, Herlev, Denmark

Background: Monitoring of patients with rheumatoid arthritis (RA) requires assessment of biomarkers reflecting disease activity and its progression. There is a need for non-invasive markers for frequent monitoring of disease severity and progression as well as response to therapy.

Objectives: Serological markers together with clinical parameters was tested in a multi-marker model to assess its ability to objectively predict progression of RA.

Methods: Current post-hoc analysis included RA patients from the biomarker substudy of the phase III clinical study LITHE investigating the safety and efficacy of tocilizumab 1–4. Patients had moderate/severe, active RA. In addition, only patients of the placebo arm and with total sharp score (SHP) recorded at baseline (BL), week 24 (W24) and W52 were included. Progressors were defined as the delta from BL to W24 and W24 to W52. Biochemical markers reflecting tissue turnover (table) were assessed at BL and W16. Associations with structural progression (deltaSHP) were investigated by spearman’s r, least squared multivariate and logistic regression. Covariates were CRP, sex, BMI, age, disease duration, DAS-ESR, no. prior DMARDs/antiTNF use and SBL/SHP. The data were divided into a training and confirmation set; 1) association between markers/W16 and deltaSHP/W24 (n=31 prog./42 non-prog.), 2) association reflecting tissue turnover (table) were assessed at BL and W16. Associations with structural progression (deltaSHP) were investigated by spearman’s r, least squared multivariate and logistic regression. Covariates were CRP, sex, BMI, age, disease duration, DAS-ESR, no. prior DMARDs/antiTNF use and SBL/SHP. The data were divided into a training and confirmation set; 1) association between markers/W16 and deltaSHP/W24 (n=31 prog./42 non-prog.), 2) association

Results: The training set. Eight markers were correlated (R=0.2–0.7) with deltaSHP/W52. Of these C1M, PINP, ICTP and MMP3 were predictive for of progression (deltaSHP/W52=0) with ORs of 3.2 [1.3–8.0], 4.0 [1.4–12], 8.5 [2.4–31], and 2.5 [1.3–5.1]; all p<0.01, respectively. A logistic model for prediction of disease progression incorporating C1M, ICTP, disease duration and BMI demonstrated an AUC of 0.77 [0.66–0.86], p<0.01. The model correctly identified 72% of the progressors. The confirmation set: The results were confirmed in the second dataset with an AUC of 0.75 [0.64–0.81], p<0.01. The model correctly identified 65% of the progressors.

DAS: Disease activity score.

Conclusions: Our RA patients who were closely followed had 50% high medication adherence. This rate is quite high compared to other studies using MMAS-8. It should be kept in mind that tight control and adequate communication increase medication adherence but different parameters may also be effective. Assessing cognitive disorders and emotional problems of the patient will be beneficial for improving adherence and controlling disease activity.

AB0194  JOURNEY OF A PATIENT WITH RHEUMATOID ARTHRITIS: DELAY IN DIAGNOSIS AND TREATMENT

Background: It has been shown that there is a window of opportunity for treatment in Rheumatoid Arthritis (RA). Several Argentinian studies showed an average of 8 months to arrive to a rheumatology visit and 12 months to receive DMARDs. There aren’t recent studies.

Objectives: To establish delay time from onset of rheumatoid arthritis (RA) symptoms to the first rheumatology visit, to diagnosis of the disease and to the beginning of treatment with DMARDs; and to assess impact of such delay on structural damage, in a cohort of RA patients.

Methods: A retrospective study was performed including all patients with RA (fulfilling ACR/EULAR 2010 criteria) seen at a Prepaid Medical Health Plan between 2002–2015. Diagnosis delay and its impact on functional capacity measured by HAQ and structural damage by Sharp van der Hejde score (SvDH) were estimated. Descriptive and clinical data, and rates of clinical remission, onset of symptoms and HAQ-A were extracted from electronic medical records. Svdh score was performed by an experienced rheumatologist.

Results: 246 patients (mean age at diagnosis 67.25±14 years, 199 (81%) female) were included. Clinical presentation was poliarthritis in 49% of the cases, oligoarticular in 47% and monarticular in 3%. 79% had high titers of anti-citrulline-cyclic peptide antibodies, 12% low titers, and 9% were negative. Rheumatoid factor was positive in 82.5%. Mean time of follow up was 7 years (SD: 3.8). At the end of the follow-up,median HAQ-A (n=145) was 0.125 (IQR: 0–0.87). Hands and feet of 171 patients, Median Sv Dh score was 15 (IQR: 6–33), 242 patients (98.4%) received DMARDs as initial treatment: methotrexate monotherapy (76%) was the most frequent one. 41 patients (17%) received biological agents at some point of their disease. Table 1 shows different delay times in accessing rheumatology consultation, diagnosis and beginning of treatment.

Conclusions: Delay in diagnosis greater than 12 months was associated with more radiological damage. At the end of follow up, 21 patients (12.8%) had noradiological damage (SvDH score =0). In the ROC curve (AUC 0.57,95% CI: 0.45 - 0.69), 5.6 months of diagnosis delay was the best cut off value to discriminate the presence of erosions (SvDH erosions score>0), with a sensitivity and specificity of 54.17% and 61.90%, respectively. Delay in diagnosis greater than 12 months (n=70) was associated with significantly radiological damage: Svdh mean 30.91 (IC 95% 21.99–39.79) vs 21.32 (IC 95% 16.93–25.72); p=0.0325.

AB0195  IS THERE AN ASSOCIATION BETWEEN PERIODONTITIS AND LEVELS OF ANTI-CITRULLINATED PEPTIDES ANTIBODIES IN RHEUMATOID ARTHRITIS?

B. Rodriguez-Lozano1, J. González Febles2, F. Sánchez Alonso2, J.L. Garner Rodriguez3, S. Daadlani, Y. Barrios1, M. Sanz Alonso1, F. Diaz Gonzalez1, 1Rheumatology, Hospital Universitario de Canarias, Tenerife; 2Periodontology, UCM, Madrid; 3Research Unit, Sociedad Española de Reumatología, Madrid;

Background: There is evidence for chronic periodontitis (PD) in RA autoimmune response by periodontopathogenic bacteria such as P gingivalis, through citrullination of L-arginine.

Objectives: 1. To determine whether there is an association between PD and its severity with ACPA titres and number of periodontal pockets ≥5mm (NPP),2. To assess relationship between PD and ACPA titres.3. To identify association between certain periodontal parameters and ACPA titres and their possible cutoff points.

Methods: Observational, cross-sectional study RA patients ≥18 with ≥4 teeth, no tooth cleaning, antibiotic intake 6 months before.Socio-demographic and anthropometric variables, annual dental prophylaxis and comorbidities.Serum ACPA detection: Ab IgA against CCP2 (ELISA) Eurodiagnostica.positive≥25; ACPA titres stratification: Low (25–75), moderate (76–300) and high (>300). Periodontal parameters: plaque index (PI), bleeding on probing (Bop), probing pocket depth, clinical attachment level (CAL). CAL loss was categorized according to European Workshop 2005 (Tenneti): T0 level (absence), T1 (mild), T2 (severe). Statistical analysis: t-student, Kruskal Wallis, Chi- squared tests by Stata program 13.1.

Results: 187 RA patients included (table 1). ACPA determined in 168 patients: 67.86% (+) with similar titles distribution: low 18%, moderate 26%, high 23%. PD:182 patients (97.3%); T1 52.4%, T2 44.9%. Although prevalence of severe PD (ACPAs+) was higher compared to PD/ACPAs (69.2% vs 30.7%), there was no association between PD and ACPA positivity/titres. Regarding the association with periodontal parameters, there was tendency of association between ACPAs+ and number of periodontal pockets ≥5mm (NPP), OR 1.02 (95% CI 0.9–1.04) assessed. There was a gradient effect, where NPP increased as ACPA titre increased, which was significant for high ACPA titres (p=0.05, OR 1.03 95% CI 1.0–1.05). When ACPAs+ was related to %PI and BoP, a strong association was observed for PI, OR 10.32 (p<0.026), and only a tendency for BoP (p<0.062). With cutoff points of 8% PI and 65% BoP, a risk for ACPAs+ was detected with an OR 2.19 and OR 2.45, respectively.

Conclusion: 1.Despite higher prevalence of severe PD in ACPA(+), patients were not associated between the presence of PD and ACPA positivity nor with serum titres. 2. On analysis of ACPA titres in relation to the severity of the periodontal parameters, there was a “gradient” risk, where NPP increased as ACPA titres increased, which was significant for high ACPA titres.3. Risk cutoff points for ACPA+ were 8% for PI and 65% for BoP.

AB0196  VASCULAR ENDOTHELIAL GROWTH FACTOR IN PATIENTS WITH RHEUMATOID ARTHRITIS

B. Rebroy1, E. Komarova1, A. Blagodarenko1, G. Belkina1, I. Pokryshka3, 1Internal Medicine; 2Medical Chemistry, SI “Lugansk State Medical University”; 3Rheumatology, Lugansk Clinical Regional Hospital, Lugansk, Ukraine

Background: The level of vascular endothelial growth factor (VEGF) may reflect the intensity of angiogenesis, which is an important step in the initiation and development of chronic rheumatic arthritis (RA).

Objectives: To study features of VEGF level changes in the blood of RA patients, depending on the duration of the disease, the degree of activity, the level of antibodies to cyclic citrullinated peptide (anti-CCP)

Methods: 194 patients were examined with a diagnosis of RA (verified according to criteria ACR/EULAR 2010), without concomitant pathology. Among the examined patients with RA women predominated 168 (86.6%), and there were 26 men (13.4%). The age of patients was 22 to 65 years (mean age 47±10.22 years), mean duration of the disease was 3.82±3.43 years. Assessment of RA activity was done by DAS28 index in the form of VEGF measurement for the presence of anti-CCP (≥20 U/ml) (78%) and 42% (22%) - negative. Serum CRP concentrations (Vector-Russia), anti-CCP (Orengect, Germany), VEGF BCM Diagnostic, Canada) were determined by ELISA. Statistical processing of the data was performed using non-parametric methods, univariate (ANOVA) variance analysis on a personal computer using a licensed software packages (“Microsoft-Excel” and “Statistica-Stat-Soft”, USA).

Results: Analysis of VEGF level changes in the blood depending on the duration of RA revealed that the measure was high in patients with small diseases duration (194 patients) and the intensity of angiogenesis, which is an important step in the initiation and development of chronic rheumatic arthritis (RA).

Conclusions: The level of vascular endothelial growth factor (VEGF) may reflect the intensity of angiogenesis, which is an important step in the initiation and development of chronic rheumatic arthritis (RA).

Disclosures of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.2967

DOI: 10.1136/annrheumdis-2017-eular.2387
showed a significant increase in VEGF level (343.35 (190.62; 561.28) pg/ml) in the group of high positive ACCP (>60 U/ml) compared with the group of low positive ACCP (≤60 U/ml) – 470.23 (324.3, 676.65) pg/ml (p=0.005). Using ANOVA variance analysis, it was found that the level of anti-CCP in the blood of studied RA patients influences the VEGF level in high degree in blood (K=7;8; p=0.005).

Objectives: The objective of this study is to assess VEGF levels in the blood of RA patients, to examine the correlation between VEGF levels in the blood and clinical parameters of RA activity, and to determine the role of VEGF in the development of early joint destruction.

Disclosure of Interest: None declared.

**AB0198**

**DIFFERENTIAL CHARACTERISTICS OF PATIENTS DISCONTINUING SEVERAL BIOLOGICAL THERAPIES IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS**

C. Tornero 1, C. Plasencia 1, D. Pascual-Salcedo 2, B. Hernández 1, M. González 1, M.G. Bonilla 1, L. Nuño 1, A. Villalba 1, D. Peiteado 1, P. Bogas 1, E. Moral 1, A. Balsa 1.

1Rheumatology; 2Immunology, la Paz University Hospital, Madrid, Spain

Background: The treatment of Rheumatoid Arthritis (RA) has been transformed in the last decade with the introduction of biologic therapy. Nevertheless, a significant proportion of patients are primary or secondary nonresponders and will receive several biologics during the course of the disease. Evidence is lacking on the characterization of patients failing several agents and those who have adequate clinical response to their first biologic treatment.

Objectives: To compare demographic, clinical and analytical characteristics in a cohort of RA pts who have failed treatment with at least two biological agents (“switchers”) and another cohort of RA patients showing a sustained clinical good response to their first therapy (“maintainers”). As a secondary objective, reasons for therapy discontinuation were also evaluated.

Methods: A total of 186 patients under biological therapy of the RA-PAZ cohort were included in this observational study. In this cohort, 63 pts were switchers and 123, maintainers. Baseline demographic data and clinical disease activity (DAS 28 –ESR), clinical improvement (delta-DAS 28) and serological data (CRP and ESR) were evaluated at baseline and after six months after starting the first biological treatment. Serum anti-drug antibodies (ADA) were measured by bridging ELISA at the last visit available during the follow-up period under the first treatment. Reasons for discontinuation of the first therapy and the number of biologic treatments received during the course of the disease were also evaluated.

Results: Demographic and clinical characteristics of both groups are shown in Table 1. Mean Age (49.96±10.82 vs 53.77±12.91, p=0.046) and disease duration (6.79±6.19 vs 9.97±8.56, p=0.001) prior to biologic therapy initiation were lower in the switchers. Furthermore, a higher proportion of switchers had extrarticular manifestations in comparison to the maintainers (18/63 (28.6%) vs 16/123 (12.8%), p=0.016). Clinical activity at baseline (DAS28: 5.74±1.26 vs 5.01±1.14, p=0.01) and after 6 months of starting the first biological therapy (DAS28: 4.45±1.6 vs 3.22±1.1, p=0.001) were statistically significantly higher in the switchers. At the last visit under the first biologic, there were also more ADA-positive pts in the switchers (6/25 (24%) vs 1/73 (1.4%), p=0.01). Moreover, duration under biologic treatment was higher in this group. In terms of the reason for discontinuation of the first biologic, 22.2% of pts showed primary lack of efficacy, 38.1%, secondary loss of efficacy; 33.3%, adverse effects; 4.8% interrupted because of other reasons and 1.6% because of death.

Table 1: Demographic and clinical characteristics of switchers and maintainers. Mean (SD) or Median (IQR).

Conclusions: We find a high frequent of lung involvement in early RA, in most of cases subclinical. Performing Respiratory function tests may help in early detection of lung involvement. These results should be ratified in larger series.
remission. There was no association between reasons for discontinuation of the first therapy because of primary or secondary failure and adverse effects (3.4±0.9 vs 3.7±5.1, 11 vs 3.86±1.3, p=0.6) with the number of treatments received.

Conclusions: In our biologic therapy RA-PAZ cohort, we found a subgroup of younger pts, with a more systemic phenotype of the disease and a higher disease activity who required a prompter biological therapy initiation. This subgroup of pts is more susceptible to biological treatment failures. The development of ADA after the first biological agent was also associated with the need to use more biologics.

AB0199 METHOTREXATE RESPONSE IN EARLY RHEUMATOID ARTHRITIS ASSESSED USING A SOMAMER PROTEOMIC ASSAY

C. Hitchen, V. Spicer, X. Meng, A. Gao, H.S. El-Gabalawy, J. Williams. University of Manitoba, Winnipeg, Canada

Background: Optimizing treatment in early rheumatoid arthritis (ERA) improves clinical outcomes. Developing approaches that would allow for accurate outcome predictions would be useful. We examined the possibility of employing SOMAscan to identify biomarkers that predict treatment response.

Objectives: To define methotrexate (MTX) 6 month treatment associated response protein changes using SOMAscan.

Methods: Sera from 14 Disease Modifying Antirheumatic Drug (DMARD) naive ERA patients at baseline (PRE) and after six months of MTX (POST) were analyzed using SOMAscan, an aptamer based assay that offers simultaneous relative quantitation of 1310 proteins. RA activity was measured by DAS28ESR3var abbrev DAS3. Data were measured at baseline. SOMAmeter intensity data was log2 transformed and differences (D=POST-PRE) clustered using undirected hierarchical self-organization. Kolmogorov-Smirnov differential analysis determined SOMAmers contributing to these populations at p<0.05. Potential processes associated with these SOMAmers regulation groups were identified using an in-house biological enrichment tool.

The potential for SOMAmers to predict treatment response was also explored: for this we defined a fractional clinical response metric dDAS3= (DAS3_POST- DAS3_PRE)/DAS3_PRE. We then selected a population of proteins (n=3 to avoid over-fitting) with PRE expression levels best correlating to dDAS3. These three PRE expression values formed a weighted average, with weighting coefficients optimized by a simple Monte-Carlo method. We included this weighted average with clinical variables in logistic regression models, where 6 month DAS3 was the dependent variable.

Results: Clustering gave two populations of 6 and 8 patients (POP0, POP1) with mean delta DAS3 values of -1.71 and -0.46 respectively. In POP0 compared to POP1, 113 proteins were upregulated and 121 proteins were downregulated. The upregulated proteins were involved in VEGF signalling and platelet activation. The downregulated proteins were involved in regulation of immune response, cellular response to TNF and cytokine–cytokine receptor interactions. The fractional change dDAS3 correlated well with the treatment response panel (R²=0.8645; p=6.8e-5), with the caution that expression values of the 3 best-correlating proteins exhibited low coefficients of variation (0.1). However, these proteins did reflect RA response. The weighted sum was also independently associated with treatment response in regression models including baseline DAS3 (or components) and RF/ACPA.

Conclusions: This pilot study suggests that high content proteomic approaches such as SOMAscan may be useful for developing prediction tools of patient responses to treatment. Extension of this work to a larger patient population is ongoing.

AB0201 INFUENCE OF SIGA ON CLINICAL ACTIVITY MARKERS IN SPA PATIENTS WITH NON-RADIOGRAPHIC AND PERIPHERAL COMPROMISE

1Department of Rheumatology and Immunology, Hospital Militar Central; 2School of Medicine, Universidad Nacional de Colombia; 3Universidad Javeriana; 4Department of Rheumatology and Immunology, Hospital Militar Central, Bogotá, Colombia; 5UdBO Institute, Universidad El Bosque, Bogotá D.C., Colombia

Background: There are previous evidence about inflammatory signs related with the intestinal mucosa in spondyloarthritis patients with seronegative arthritis and them relation with articular inflammatory activity. It is uncertain the role of these serological markers on the inflammatory/clinical activity in patients with SPA.

Objectives: To establish the relationship among activity variables and indices, and soluble markers associated to mucosal associated lymphoid tissue in a group of SPA patients.

Methods: Patients were selected by rheumatologists with the ESSG criteria. Levels of SigA, IgA, IgA Chlamydia trachomatis, Shigel spp., Verrucomicrobium spp., Campylobacter spp and Salmonella spp, CRP, ESR, HLA-B27, BASDAI, ASAS-CRP and ASDAS-ESR were determined. A principal components analysis (PCA), Poisson Regression and multiple correspondence analysis were performed to find relationships between clinical and laboratory variables and SigA. This study was approved by Ethics Committee.

Results: 46 patients were included (78.2% males with a mean age 34.8±12.3 years). It was reported at least one gastrointestinal sing in 69.2% of patients: abdominal bloating (45%), abdominal pain (43%); all patients showed at least one musculoskeletal symptom, 69.5% enhethesis, 63% inflammatory back pain and 58.6% arthritis, as well as 43.4% previous infection and 47.8% present HLA-B27. The PCA showed three principal factors which cover a contribution of 82.2% to explain the SigA variation. The ASDAS-CRP, ASDAS-ESR, BASDAI variables which provide the 47.12% the regression model shows an inverse association among SigA and BASDAI (prevalence ratio (PR):0.43 95% CI:0.25–0.70 p=0.001), ASDAS-CRP (PR=0.72, 95% CI:0.24–0.95 p=0.021) and ASDAS-ESR (PR=0.69, 95% CI:0.39–0.95 p=0.007); however, a risk was demonstrated among BASDAI and Yersinia IgA (PR:1.68 95% CI:1.03–2.74 p=0.036) and between CRP and ASDAS-ESR with HLA-B27 (PR=1.62 95% CI:1.16–2.19 p=0.002). There was a relationship between the absence of clinical activity (ASDAS-CRP, ASDAS-ESR, and BASDAI), previous infection, Yersinia IgA with SIgA Q1 (27.8–43.0 ug/mL); Chlamydia trachomatis, Shigel spp.

AB0200 MUSCULOSKELETAL ULTRASOUND ADDED TO ROUTINE EVALUATIONS OF RHEUMATOID ARTHRITIS PATIENTS HAS A DIFFERENT IMPACT ON THE TREATMENT PROPOSAL DEPENDING ON PHYSICIAN EXPERIENCE

C. Sifuentes1, I. Contreras-Yáñez1, M. Gutierrez2, V. Pascual1. 1Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán; 2Instituto de Rehabilitación y Ortopedia, Mexico, D.F, Mexico

Background: Disease activity (DA) is the most important factor in the treatment decision/monitoring during rheumatoid arthritis (RA) patient’s follow-up. In routine clinical practice, it is recommended to regularly evaluate DA level from patients with RA. Musculoskeletal ultrasound has been suggested to add value to establish the level of DA; evaluations that assess a reduced number of joints, as the German ultrasound score of 7 joints (GUS-7) are easy to incorporate in clinical practice (1).

Objectives: To explore the real impact of GUS-7 in the treatment recommendation to RA outpatients, currently attending an Early Arthritis Clinic (EAC). The primary objective was to determine the proportion of patients in whom treatment recommendation differed after GUS-7 examination. We additionally tested the variations of GUS-7 impact according to the physician’s experience (senior rheumatologist [SR] vs. trainee in rheumatology [TR]).

Methods: A sample size of 84 evaluations was calculated to achieve the primary objective. Eighty-seven consecutive and randomly selected RA outpatients were invited to participate; 2 patients denied because of administrative reasons and the 85 pts left underwent 170 assessments (85 each by the SR and the TR). At first, both physicians (blinded to each other evaluations) performed a clinical evaluation that included DAS28 scoring and recommended a RA-treatment. Then, patients underwent GUS-7 by a blinded (to clinical evaluations) rheumatologist that additionally determined the sonographic disease activity. In the final step, the TR and the SR integrated the US findings to their previous evaluation and reviewed their prescription; GUS-7 findings, pre- and post-GUS-7 treatments were recorded on standardized forms. Patients received final recommendation only after the SR. All the patients signed informed consent and were instructed about the process. Descriptive statistics was used.

Results: Patients were primarily middle-aged [(mean±SD) 45.1±12.4 years] female (91.4%), with (mean±SD) disease duration of 7.5±3.9 years. Most of the patients (69.2% according to TR and 71.6% to SR) were in DAS28-ESR-remission, although the four levels of DA were represented. Agreement between both physicians was good (Kappa: 0.82; p<0.001). Most frequent GUS-7 findings were grey scale synovitis in at least one joint in 98.8% of the patients, among whom 22.6% had Power Doppler activity (PD); one third of the patients had tenosynovitis although few (12%) had PD; erosions were detected in 38.6% of the population.

In 34 of 170 clinical scenarios (20%), GUS-7 findings modified treatment; treatment changes (after GUS-7 findings were incorporated to clinical findings) consisted of an increase in 24 (70.6%) scenarios, a decrease in 8 (23.5%) and joint injection with corticosteroids in 2 (5.9%). Interestingly, 24 of the 34 clinical scenarios with GUS-7 treatment impact were performed by the TR vs. 10 performed by the SR: 70.5% vs. 29.5%, p=0.01. Treatment changes (increase, decrease and joint injection) were similar among both specialists.

Conclusions: In routine clinical practice of RA patients, GUS-7 assessments impacted treatment decisions in 20% of the patients; the impact was stronger among TR than among SR.

of BASDAI and ASDAS-CRP, absence of previous infection had a strong relation with low levels of S IgA.

Conclusions: S IgA serum level were the only one serologic maker, which had an inverse correlation with all clinical activity variables of disease, previous infection and some specific antibodies associated with intestinal mucosal infection, suggesting a protective role of this molecular shape of IgA that is characteristic of mucosal immune responses.

AB0202

LOW DOSE ACETYLSALICYLIC ACID AS PRIMARY PROPHYLAXIS OF CARdiovascular EVENTS in RHEUMATOID ARTHRITIS: A LONGITUDINAL, RETROSPECTIVE STUDY

D. Iacono, S. Fasano, V. D’Arosca, I. Pantano, R. Chieffo, G. Valentini.
Rheumatology Unit, University of Campania “Luigi Vanvitelli”, Naples, Italy

Background: Cardiovascular events (CV) i.e. acute myocardial infarction and stroke are recognized as a leading cause of mortality in patients with Rheumatoid Arthritis (RA) [1]. Acetylsalicylic acid (ASA) is known to be associated with a significant decrease in the incidence of CV events in patients at high risk for atherothrombotic disease like patients with diabetes [2] and has been recently reported to play a primary prophylactic role of CV events in Systemic Lupus Erythematosus by our team [4].

Objectives: To investigate the so far unexplored role of ASA in reducing CV morbidity in RA.

Methods: We analysed patients admitted to our Outpatient clinic from January to December 2015. Out of 199, 155 patients, who had been followed from January 2000 and had not experienced any CV event at the first visit, were enrolled. The incidence of CV morbidity was recorded at December 2016.

Results: The 115 patients had been followed-up for a median of 8 years (range 1–15 years). Out of them, 111 patients had been treated with ASA, that we currently administer to patients undergoing steroid treatment. During the 15-years of follow up, 5 CV events (2 cerebrovascular, 3 acute myocardial infarction) had occurred (incidence rate 3.33/1000 person/year). Interestingly, only 1 CV event had occurred in ASA treated patients (incidence rate 1.12/1000 person/year) with respect to 4 in the non-ASA group (44 patients) (Incidence rate 10.48/1000 person/year) (p=0.0146).

Conclusion: This study has several limitations including the low number of patients and CV events. Nevertheless, it might suggest a primary prophylactic role of ASA in RA, that awaits to be investigated in large controlled prospective studies.

DISEASE FACTORS ASSOCIATED TO ABNORMAL INTIMA-MEDIA THICKNESS IN MEXICAN MESTIZO RHEUMATOID ARTHRITIS PATIENTS

D.A. Galzarra-Delgado 1, J.R. Azpiri-Lopez 2, I.J. Colunga- Pedraza 3, R.E. Ramos-Cazares 1, F.J. Torres-Quintanilla 4, A. Valdivinos-Bahuelos 5, R.I. Arvizu-Rivera 6, A. Martinez-Moreno 7, J.A. Cardenas-de la Garza 8, R. Vera-Pineda 9, G. Elizondo-Rojas 10, J.I. Garcia-Colunga 1, Rheumatology; 2Internal Medicine; 3Radiology and Imaging, Hospital Universitario Dr. José Eleuterio Gonzalez, Monterrey, Mexico

Background: Atherosclerotic cardiovascular disease (ASCVD) is the main mortality cause in patients with rheumatoid arthritis (RA) [1]. It has been proven that the carotid intima-media thickness (CIMT) measured with carotid duplex ultrasonography is an important ASCVD predictor with a measurement >0.9 mm (2–4).

Objectives: To characterize the disease factors related with abnormal carotid duplex US findings in Mexican mestizo RA patients with RA.

Methods: In a cross-sectional setting, we enrolled consecutive RA patients. Patients with overlap syndromes, personal history of ASCVD, dyslipidemia and previous use of any statin were excluded. A board-certified radiologist performed a bilateral carotid duplex US to all patients. Abnormal CIMT was defined as >0.9 mm (hypertrophy ≤0.9 – 1.2 mm and carotid plaque ≥1.2 mm). A clinical history and blood tests were performed at the time of the patient’s visit. Disease activity was measured with Disease Activity Score using 28 joints-C-reactive protein (DAS28-CRP).

Results: We enrolled 57 patients. Demographic characteristics are shown in table 1. A total of 30 (52.2%) patients had an abnormal CIMT. US findings are shown in table 2. A significant correlation between abnormal CIMT and RA disease duration (p=0.04), as well as between the former and anti-cytokine circulatory peptide antibodies (ACPA) positivity (p=0.033) was found.

Conclusions: There is a strong relationship between CIMT and the chronic inflammatory process of RA, as well as ACPA positivity. These results might be influenced by the high mean disease duration of our patients. Prospective studies that evaluate CIMT among disease duration intervals are necessary to support these findings.
CAROTID INTIMA-MEDIA THICKNESS LINKED TO THE PRESENCE OF CARDIOVASCULAR RISK FACTORS IN MEXICAN MESTIZO PATIENTS WITH RHEUMATOID ARTHRITIS

Objectives: The aim of this study is to relate abnormal carotid intima-media thickness (CIMT) to the presence of cardiovascular risk factors.

Methods: Observational cross-section design. We included patients who fulfilled the 1987 ACR and/or 2010 ACR/EULAR classification criteria for RA, 40 to 75 years old, with no personal history of atherosclerotic CV disease. A board-certified radiologist performed carotid duplex ultrasonograms. Patients were distributed in two groups according to the absence (Group 1) or presence (Group 2) of traditional risk factors for cardiovascular disease (smoking status, dyslipidemia, high blood pressure, and diabetes).

Results: A total of 82 patients were included. Demographic characteristics for each group are shown in Table 1. Ultrasound findings are shown in Table 2. CIMT alterations were more common in Group 2 (66.7%) than in Group 1 (38.7%), with a p-value of 0.013. Presence of carotid plaque was more common in Group 2 (27.5%) than in Group 1 (16.1%), shown clinical relevance, although this effect has not been universally demonstrated [2].

Objectives: The aim of the present study was to investigate if serum IL-17 and CCL20 reflect activity of the disease and whether they could be of prognostic value for predicting therapeutic response to biologic therapy in RA.

Methods: Thirty RA patients qualified to receive biologic treatment were prospectively assessed before and 12 weeks of therapy with either TNF-α blocker (adalimumab, certolizumab, golimumab, and infliximab) or IL-6 blocker (tocilizumab).

Results: The patient baseline characteristics were summarized in Table 1. Serum levels of IL-17 and CCL20 did not change significantly over the course of therapy and they did not correlate with the disease activity, response to therapy, the type of biologic intervention and other medication used.

Conclusions: Serum IL-17 and CCL20 levels showed no correlation with DAS28, and standard inflammatory markers.

**AB0207** CHANGE IN ANTI-CITRULLINATED PROTEIN AUTOANTIBODY LEVELS IN CLINICAL PRACTICE ARE ASSOCIATED WITH RESOURCE USE AND DISEASE ACTIVITY MEASURES

1Bristol-Myers Squibb, Princeton; 2Brigham and Women’s Hospital, Boston, United States

Background: High anti-citrullinated protein antibody (ACPA) concentration, beyond ACPA positivity, is indicative of more aggressive radiographic progression in patients (pts) with RA. However, there is limited information on changes in ACPA levels in clinical practice settings, and the association of changes in ACPA with measures of resource use and/or disease activity.

Objectives: To evaluate the association between change in ACPA levels with hospitalizations/durable medical equipment (DME) use and change in disease activity.

Methods: Pts enrolled in a tertiary care centre RA registry, established in 2003, were analysed. The registry mostly comprises pts with established RA who were evaluated semi-annually for multiple clinical patient-reported outcomes as well as resource utilization parameters, and annually for disease activity measures such as DAS28 (CRP), SDAI and CDAI. The current analysis is based on pts enrolled in the registry with ACPA values at the time of baseline (BL) and follow-up visits.

BL and follow-up ACPA levels were based on well-documented and validated ELISAs from Euro-Diagnostica (distributed by IBL-America, Minneapolis, MN, USA). Annual mean ACPA change from BL over the first year of enrolment in the registry was calculated. Changes (follow-up – BL)/BL x 100) in ACPA levels were categorized as decrease (–>10%), no change (–10% to +10%) or increase (>+10%). Use of DME (canes, wheelchairs, walkers and commodes) and as well as hospitalizations during 12-month follow-up and annual change in disease activity (DAS28 [CRP], SDAI, CDAI, swollen painful joint counts and pain) were assessed. Multivariate logistic regression analyses for binary outcome variables (DME and hospitalizations) and linear regression for change in disease activity measures were conducted, controlling for BL covariates.

Results: A total of 840 (65%) pts in the registry had BL and follow-up ACPA values and were included in the analysis. Overall, 34.6% (n=291) of pts had a decrease, 31.7% (n=266) had no change and 33.7% (n=283) had an increase in ACPA levels. There were no significant differences in BL characteristics between the three groups except for disease duration. Pts with RA with an increase in ACPA levels had significantly longer disease duration at BL. In univariate analyses, DME use was 23.4%, 30.1% and 28.6%, and hospitalization rate was 13.4%, 16.5% and 20.1% in pts with a decrease, no change or an increase in ACPA levels, respectively. Unadjusted mean (SD) change from BL in DAS28 (CRP), SDAI and CDAI in pts with reductions in ACPA levels was −0.7 (1.4), −6.1 (15.7) and −5.9 (15.1), and 0.5 (1.4), −5.0 (15.7) and −4.7 (14.6) in pts with an increase in ACPA levels. After controlling for BL covariates, the odds ratio (OR) for DME (vs no change) across all cohorts. Unadjusted 12M hospitalization rate in ACPA+ vs ACPA− pts was 10.8 vs 16.4%, 13.7 vs 14.3% and 8.5 vs 10.8% in the ABA, cDMARD and non-ABA bDMARD cohorts, respectively. After controlling for baseline covariates, the hazard ratio for hospitalizations in the ACPA+ (vs ACPA−) group was 0.57 (95% CI: 0.34, 0.98; p=0.04), 0.95 (95% CI: 0.84, 1.09; p=0.47) and 0.88 (95% CI: 0.66, 1.17; p=0.38) in the ABA, cDMARD and non-ABA bDMARD cohorts, respectively (Figure).

Disclosures: ACPA+ pts with RA treated with abatacept have a lower rate of hospitalization than ACPA− pts. This pattern was not observed with cDMARDs or non-abatacept bDMARDs. Further efforts including matching and subgroup analysis should be explored for direct comparisons between the cohorts.

**AB0208** HOSPITALIZATION RATES IN PATIENTS WITH RA BY POOR PROGNOSTIC FACTORS: IMPACT OF ABATACEPT AND OTHER DISEASE-MODIFYING ANTI-RHEUMATIC THERAPIES

E. Alemao, L. Burns, Z. Guo. Bristol-Myers Squibb, Princeton, United States

Background: Studies have reported that poor prognostic factors (PPF) in RA, such as high anti-citrullinated protein antibodies (ACPA), are associated with erosions, rapid radiographic progression and/or extra-articular manifestations.1,2 Evidence from clinical trials and clinical practice indicate differences in treatment effects of biologic (b)DMARDs by ACPA status and/or level.3,4 PPF also play an important role in clinical management of patients (pts) with RA, including inpatient admissions.

Objectives: To compare hospitalization rates of ACPA-positive (+) with ACPA-negative (−) pts managed with abatacept (ABA), non-ABA bDMARDs or conventional (c)DMARDs.

Methods: This is a retrospective cohort analysis of Clinformatics Data Mart, a database of administrative health claims including results for outpatient laboratory tests, processed by national laboratory vendors under contract with the managed care organization, for a total of ∼53 million unique lives over 13 years. This analysis was restricted to adult pts (aged ≥18 years) who had at least two ICD-9-CM diagnosis codes for RA between Jan 2007 and Dec 2014 (identification period) and 12 months (M) of membershipdrug benefit. Pts with ankylosing spondylitis, Crohn’s disease, lupus, psoriasis or ulcerative colitis at or before the index date were excluded. ACPA+ was based on >19 or >5 U/mL, depending on the test utilized. Follow-up for pts initiating ABA was from first day of treatment to first hospitalization, end of enrolment or end of 12M follow-up. The primary outcome was all-cause hospitalization at 12M. Descriptive statistics such as Wilcoxon rank-sum test for continuous variables or Pearson’s chi-square test for categorical variables were used. Cox proportional hazard model was used to examine all-cause hospitalization adjusted for age, sex, region and past hospitalization. Additional covariates included co-morbidities that were different between ACPA+/− pts. Similar analyses were performed for pts treated with cDMARDs and non-ABA bDMARDs.

Results: A total of 496 ABA, 7438 cDMARD and 2118 non-ABA bDMARD pts were included, with an overall past hospitalization rate of 35.5, 25.4 and 23.2%, respectively, Overall, 59.5, 51.7 and 51.7% of pts were ACPA+ in the ABA, cDMARD and non-ABA bDMARD cohorts, respectively. ACPA+ pts were older and less likely to have obstructive sleep apnoea, depression and myalgia/myositis across all cohorts. Unadjusted 12M hospitalization rate in ACPA+ vs ACPA− pts was 10.8 vs 16.4%, 13.7 vs 14.3% and 8.5 vs 10.8% in the ABA, cDMARD and non-ABA bDMARD cohorts, respectively. ACPA+ pts were older and less likely to have rheumatoid nodules, depression and myalgia/myositis across all cohorts. Unadjusted 12M hospitalization rate in ACPA+ vs ACPA− pts was 10.8 vs 16.4%, 13.7 vs 14.3% and 8.5 vs 10.8% in the ABA, cDMARD and non-ABA bDMARD cohorts, respectively. After controlling for baseline covariates, the hazard ratio for hospitalizations in the ACPA+ (vs ACPA−) group was 0.57 (95% CI: 0.34, 0.98; p=0.04), 0.95 (95% CI: 0.84, 1.09; p=0.47) and 0.88 (95% CI: 0.66, 1.17; p=0.38) in the ABA, cDMARD and non-ABA bDMARD cohorts, respectively (Figure).

Conclusions: ACPA+ pts with RA treated with abatacept have a lower rate of hospitalization than ACPA− pts. This pattern was not observed with cDMARDs or non-abatacept bDMARDs. Further efforts including matching and subgroup analysis should be explored for direct comparisons between the cohorts.

**THE CHANGES OF SIGNAL PEPTIDE-CUB-EGF DOMAIN-CONTAINING PROTEIN (SCUBE) AND OTHER ANGIogenesis PROTEINS DURING DISEASE ACTIVITY AND RELATIONSHIP WITH THE JOINT ULTRASOUND FINDINGS IN RHEUMATOID ARTHRITIS PATIENTS**

E. Capkin, N. Cilesizoglu, S. Ozer Yaman, M. Garapoglu, D. Altay, Karadeniz Technical University, Trabzon, Turkey

**Background:** Rheumatoid arthritis (RA) is a multifactorial, systemic, progressive, inflammatory disease which is characterized with bone and cartilage destruction. Synovial angiogenesis is important at the etiopathogenesis. SCUBE (Signal peptide-CUB-EGF domain-containing protein) is rather a new surface cell protein. Its secretion increases with inflammation and hypoxic conditions. Its relations with inflammation and angiogenesis are shown in preclinical studies.

**Objectives:** To study serum levels of newly identified plasmaSCUBE 1 and 3 and other angiogenesis markers and analysis of changes after treatment in RA patients. Moreover, to determine whether a correlation with this change in SCUBE proteins after treatment, clinical parameters and with joint ultrasound findings.

**Methods:** This study covers patients diagnosed with RA associated with 2010 American Collage of Rheumatology (ACR) diagnosis criteria matched with healthy controllers who are equivalent of RA patients in terms of age and gender. Detailed background information and examination of the patients were recorded and disease activity scores (DAS28) were figured out and US7 scores were calculated. The levels of SCUBE 1–3, Vascular Endothelial Growth Factor (VEGF), Matrix metaloproteinaz-9 (MM-9), Interlökin-6 (IL-6), CD40L were evaluated with the method of Enzyme-Linked ImmunoSorbent Assay (ELISA). Clinical and laboratory measurements were re-evaluated at the third month after treatment.

**Results:** This study covers 56 individuals; 28 of whom were diagnosed with RA and 28 of them were healthy controllers. Significant differences were observed between RA patients and healthy controller groups in terms of MMP-9 levels and 28 of them were healthy controllers. Significant differences were observed in SCUBE proteins after treatment, clinical parameters and with joint ultrasound findings.

**Conclusions:** This study covers patients diagnosed with 2010 American Collage of Rheumatology (ACR) diagnosis criteria matched with healthy controllers who are equivalent of RA patients in terms of age and gender. Detailed background information and examination of the patients were recorded and disease activity scores (DAS28) were figured out and US7 scores were calculated. The levels of SCUBE 1–3, Vascular Endothelial Growth Factor (VEGF), Matrix metaloproteinaz-9 (MM-9), Interlökin-6 (IL-6), CD40L were evaluated with the method of Enzyme-Linked ImmunoSorbent Assay (ELISA). Clinical and laboratory measurements were re-evaluated at the third month after treatment.

**THE MULTI-BIOMARKER DISEASE ACTIVITY SCORE FOR ASSESSING RESPONSE TO TREATMENT WITH ADALIMUMAB**

D. Pappas1,2, E.H. Sasso3, R.J. Bolce3, X. Liu1, C.J. Etel1,4,5, CORRONA, LLC, Southborough; 6Columbia University Medical Center, New York; 7Crescendo Bioscience Inc., South San Francisco; 8University of Texas MD Anderson Cancer Center, Houston, United States

**Background:** The multi-biomarker disease activity (MBDA) score measures 12 serum biomarkers to assess disease activity in patients with rheumatoid arthritis (RA) on a scale of 1–100. The MBDA score was validated in several different cohorts but has not been evaluated in a cohort consisting only of patients initiating TNF inhibitor therapy in clinical practice. We utilized patients enrolled in the Corrona-CERTAIN study to evaluate MBDA scores for patients initiating adalimumab (ADA) in several clinical practices in the US.

**Objectives:** Evaluate the ability of the MBDA score to assess response to treatment with ADA.

**Methods:** We studied 106 biologic-naïve RA patients who had been treated with ADA for at least 12 months, had initiated ADA in CERTAIN while in moderate or high disease activity by CDAI, and for whom sera were available at baseline (BL) and Months 3 and 6. Changes (Δ) in MBDA score and DAS28-CRP were evaluated from BL to Months 3 and 6 by the one-sample paired t-test. MBDA scores were evaluated for patients grouped by EULAR response categories, using the Cochran-Armitage test for trend. Receiver Operating Characteristic (ROC) analysis with bootstrap sampling (20,000 iterations) was used to evaluate MBDA score to discriminate ΔDAS28-CRP improvement ≥1.2 units at Month 3, and to determine the optimal MBDA threshold by maximizing the sum of sensitivity and specificity (Youden’s index criterion).

**Results:** At BL, median values were age 54.5 years, disease duration 2 years. BMI 28.2, DAS28-CRP 4.7, CDAI 24, SDI 25.4; 74.5%/65.4% were RF+/ACPA+. Median MBDA score was 49 with 17 (16%) patients in low (<42), 3 (22%) patients in moderate (30–44), and 66 (62%) patients in high (>44). MBDA categories. The relative magnitude and the direction of median change from BL to Months 3 and 6 were similar for MBDA score (Δ−8, −9) and DAS28-CRP (Δ−4, −8), with statistically significant changes from BL for each (line graphs in Figure). Similar results were observed for SDAI and CDAI. Pearson’s correlations with ΔMBDA score at Months 3 and 6 were 0.56, 0.59, respectively, for ΔDAS28-CRP, 0.48, 0.47 for ΔSDA1, 0.42 for ΔCDAI (all p<0.0001). Median reductions in MBDA score were significantly greater for patients with concurrent DAS28-CRP improvement >1.2 units (n=67) vs. ≤1.2 units (n=39) at Month 3 (15 vs. 2) and Month 6 (13 vs. 1.5) (both p<0.0001); and for patients with EULAR Good vs. Moderate vs. Non-responses (p=0.0002 at Month 3, p<0.0001 at Month 6) (bar graphs in Figure). Area under the ROC curve (AUCROC) for the ability of ΔMBDA score from BL to Month 3 to discriminate DAS28-CRP improvement >1.2 units at Month 3 was 0.82 (95% CI, 0.74–0.90). The optimal threshold for this discrimination was a reduction in MBDA score ≥9 units, with sensitivity/specificity=0.63/0.82 and PPV/NPV=0.86/0.56.

**Conclusions:** This study expands the previous validation of the MBDA score by demonstrating its ability to assess response to treatment with adalimumab in a US clinical practice cohort. The AUCROC value of 0.82 for discriminating improvements in DAS28-CRP >1.2 units indicates a significant association between change in MBDA score and clinical improvement.

**THE EFFECT OF SMOKING, ALCOHOL AND CAFFEINE ON EARLY RHEUMATOID ARTHRITIS OUTCOMES**

E. Chamizo-Carmona1, C. Carrasco Cubero4, J.J. Aznar Sanchez1, R. Veroz Gonzalez1, P.J. Cosio Jimenez1, S.M. Rojas Herrera1, R. Veroz Mezquida2, J. Perez-Adan1.1 1Rheumatology, H. University Hospital ofJDania, Dania, Spain

**Background:** The aim of early RA treatment is remission. Intensive treatment with MTX achieves remission in 30–50% patients (pts). Modifiable risk factors, as smoking, alcohol, coffee and tea, may affect response to MTX.

**Objectives:** To study the influence of tobacco, alcohol, caffeine on the MTX response in early RA pts.

**Methods:** A case-control study (2010–2015): cases were pts who achieved DSAS28−2.6 (remission) and controls were pts who did not. We collected information from pts 18-years with early RA, treated with MTX, evaluated quantified RA, specialized in early RA. All the pts underwent a structured interview about their smoking history and others habits. A descriptive and comparative study, was performed (SPSS21).

**Results:** 182 pts (age 50,96±13,11y, 67.6% female, 81.3% RF+ and 65.7% ACPA+) was treated with MTX and followed 105,03±7,15 months since 1995. More than 95% pts received MTX in (rapid escalation) in the first 24 months of the onset of symptoms. DSAS28−2.6 was achieved for 67 (36.8%) pts, who required an lower average dose of MTX (15.07mg/w) than those who did not (18,40mg/w) (p=0.000). Age, DAS28 and physical function at baseline, treatment delay, smoking and adverse events by MTX were related to remission.The univariate and multivariate analysis of the baseline pts characteristics and the relationship of their smoking history with age, RF, ACPA and outcome of MTX monotherapy are shown in table 1and 2, respectively. The median survival of MTX monotherapy was 87,39 months (100.27 non-smokers and 47.70 months for current smokers (Log Rank 10.32, p=0.001) (see graphic).

**Conclusions:** The treatment of early RA with MTX alone achieved high rates of remission, especially in non-smokers. Smoking cessation could significantly improve the response to MTX and therefore should be an integral part of the treatment of early RA patients.
**RA-onset and OR as ACAs levels and MTXm duration. MTXm persistence at 5 years was 59% pts and their median survival was 93 months (77.14 to 108.8). We only found significant differences in favor of non-smokers and RF < 100.**

### Conclusions:

The initial treatment of RA with MTX is an effective and safe option, with a high drug survival. MTX response was not associated with antibody positivity (RF or ACPA), but it was significantly better in non-smokers patients and RF < 100. Smoking cessation could significantly improve the response to MTX of RA patients.

**HIGH POWER DOPPLER SIGNALS SEEMS MORE IMPORTANT THAN SYNOVITIS SCORES IN ESTABLISHED RHEUMATOID ARTHRITIS**

E. Keskin1, F.G. Yurdakul1, H. Bodur2, A. Akinc T3, L. Özçakar3, 1. Physical Medicine and Rehabilitation, Kırıkkale University Faculty of Medicine, Kırıkkale; 2. Physical Medicine and Rehabilitation, Ankara Numune Training and Research Hospital; 3. Physical Medicine and Rehabilitation, Hacettepe University Faculty of Medicine, Ankara, Turkey

**Background:** Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease characterized by synovial inflammation, potential cartilage and bone damages. Evaluation with ultrasound (US) has come into prominence due to its usefulness in soft tissue inflammatory changes and early bone erosions (1,2).

**Objectives:** The value of US has been shown in early arthritis, but is not well known for established RA. The aim of this study is to determine the relation between US signal, disease activity, articular damage and disability in established RA patients.

**Methods:** Forty-four RA patients (21 women, 23 men) were enrolled to the study. Age and gender, duration of disease, morning stiffness, disease activity score 28 (DAS28), The Rheumatoid Arthritis Articular Damage (RAAD) score, Hand disability index (HDI), DASH (Disabilities of the Arm, Shoulder and Hand) scale, and grip strength values were recorded. Wrist, I-III metacarpophalangeal and proximal interphalangeal joints of dominant hand were examined by both B mode (BMOD) and Power Doppler US (PDUS).

**Results:** All of the 44 patients were established RA. The median of disease duration was 12 years (IQR 7 to 18). RA patients were divided into two groups according to their Hand disability index (HDI). In HDI < 20 group, the most important parameters were Power Doppler US signal and Hand disability index (HDI), in HDI ≥ 20 group, the most important parameters were Power Doppler US signal and Morning stiffness. When we take the HDI < 20 group, RA patients with Power Doppler US signal ≥ 4 were HDI < 20 (30/34, p < 0.05) and when we take the HDI ≥ 20 group, RA patients with Power Doppler US signal ≥ 4 were HDI ≥ 20 (12/12, p < 0.05).

**Conclusions:** RA patients with Power Doppler US signal ≥ 4 were HDI ≥ 20 (12/12, p < 0.05).
duration was 156 (48–420) months. DAS 28 score was 2.86 (0.68–5.70) and 54.5% of the patients were in remission. BMDQ synovitis, erosion and PDUS synovitis total scores were 20 (6–36); 6 (0–17); 1 (0–14) respectively. Although US findings were not correlated with DAS 28 and grip strength; there was poor correlation between US findings and DASH, RAAD and disease duration (Table 1). Signs of synovitis associated with PDUS score, 63% of the joints assessed. High-grade PDUS signal (grade 3) was found in 10 (22.7%) of the patients. Duration of morning stiffness, HDI and DASH scores were worse in the patients with high-grade PDUS signals (p=0.01, 0.04, 0.01 respectively) Table 1. Correlation coefficients between clinical, ultrasound and functional variables

Conclusions: US scores in established RA patients are usually high because of synovial hyperplasia. It is considered that high grade PDUS signals are more appropriate for evaluation of long-standing RA patients. Furthermore in this study, grade 3 PDUS signals were found to be a good indicator of synovial inflammation, morning stiffness, and disability. References:

AB0214 METHOTREXATE IN EARLY RHEUMATOID ARTHRITIS: A SINGLE-CENTER EVALUATION OF CLINICAL OUTCOME COMPARING TWO STARTING TREATMENT STRATEGIES

F. Benaglio, S. Bugatti, G. Sakellarious, G. Cereatti, G. Zanfirmando, C. Montecucco, R. Caporali. Early Arthritis Clinic, Division of Rheumatology, University of Padova, Padova, PADOVA, Italy

Background: methotrexate (MTX) is the 'anchor drug' in the treatment of rheumatoid arthritis (RA) and it should be part of the first treatment strategy: at 6 months, according with EULAR guidelines. It is considered that high grade PDUS signals are more appropriate for evaluation of long-standing RA patients. Furthermore in this study, grade 3 PDUS signals were found to be a good indicator of synovial inflammation, morning stiffness, and disability.

Objectives: to compare the different starting treatment strategies with MTX in patients with early RA evaluated at our Early Arthritis Clinic (EAC) in order to assess the rate of patients who reaches the target (remission/low disease activity) at 6 months, according with EULAR guidelines.

Methods: patients with RA (disease duration <12 months) evaluated at our EAC between 2005 and 2016 and treated with MTX parenterally and glucocorticoids (GC) were included. Patients followed a treat-to-target strategy to reach low disease activity with bimonthly tight control. Patients included between 2005 and 2009 were initially treated with MTX 10 mg/week + GC (group A) with increase of 10 mg/week in case of failure to reach the target; patients evaluated between 2010 and 2016 were initially treated with MTX 15 mg/week + GC (group B) with possible increase to 20 and 25 mg/week. The DAS28 response was assessed after 6 months.

Results: 260 patients were analyzed: 123 in group A vs 137 in group B. At baseline patients showed differences in DAS28 (5.68±1.15 vs 4.6±1.16, p=0.006) and HAG (1.125 vs 1 IQR IQR 0.75–1.875 0.375–1.85, p=0.006); there were no differences in terms of autoimmunity. After 6 months of therapy there were no differences in clinical response: 32% of patients in the group A reached the DAS28 remission vs 40% in the group B (p=ns), 27% in the group A reached the DAS28 low disease activity vs 24% of the group B (p=ns), 41% of the group A was in moderate disease activity vs 36% in the group B (p=ns). The need to increase the dosage of MTX during the first 6 months was similar: 27.6% of the group A vs 29.9% of the group B (p=ns), conversely, the need to reduce the dosage of MTX due to intolerance and/or adverse event was significantly higher in the group B (group A: 1.6% vs group B: 9.5%, p=0.014).

Conclusions: the use of higher dose of MTX is associated with a higher rate of side effects but does not provide, at short term, a significant improvement in term of clinical outcome. The initial use of MTX 10 mg/week, with a quick dose titration in case of persistent disease activity, seems to be an appropriate option for many patients with early RA, as also recently suggested by the Utrecht Arthritis Cohort Study Group; in spite of this, there is an amount of patients who do not achieve the clinical target at short term regardless of the initial dose of MTX. Our experience suggests that in the early phase of RA treatment, in a context based on early diagnosis, tight control and treat to target, the clinical outcome seems to be linked more to the treatment strategy than to the drug dosage used.

AB0215 A LONGER MEAN SURVIVAL OF BIOLOGIC TREATMENTS IS ASSOCIATED WITH DAS28 REMISSION IN RHEUMATOID ARTHRITIS PATIENTS

F. Omneto, C. Bottisio, B. Raiffeiner, D. Astorri, L. Friso, L. Bernardi, L. Punzi, A. Donà. Rheumatology Unit, Department of Medicine - Dimed, University of Padova, PADOVA, Italy

Objectives: to determine factors associated with remission (DAS28<2.6). We specifically considered the association of biologic treatment duration, number of biologic switches and survival of biologic treatment with remission.

Methods: we conducted a retrospective analysis on a monocentric cohort of rheumatoid arthritis patients. Patients included patients who were on biologic drugs at the time of the analysis (31st December 2016). We considered patients starting the first biologic treatment since January 2000 and with a follow-up >12 months. We considered the following variables: demographics, positive rheumatoid factor (RF) and anti-citrullinated peptides (ACPA), disease duration at the start of the first biologic treatment, number of biologic switches, clinical assessment at the last follow-up, concomitant DMARDs, prednisone dose, current biologic treatment.

We also considered the mean survival of biologic treatments, defined as the duration of the biologic treatment of each patient divided by the number of biologics undergone by the patient.

Mann-Whitney test and chi-square test were used to assess the association of continuous and categorical variables with the outcome. Continuous measures are reported as medians and interquartile range. Multivariate regression analysis included all variables reaching a p value <0.2 in univariate analysis.

Results: we collected data of 330 patients. All patients had complete data. One hundred thirty-five patients (40.9%) were in DAS28 remission. Characteristics of the patients are reported in Table I. We considered 609 biologic treatments (abatacept n=61; anti-TNF alpha n=445; anakinra n=43; tocilizumab n=56; rituximab n=6). Total biologic treatment duration in all patients was 9.62 years (5.68–12.53), in patients in remission 8.95 (4.70–12.53) and in patients not in remission 10.12 (6.28–12.62) (p=0.248). Median number of previous biologic switches was 1.00 (0–1.00) in patients in remission and not in remission (p=0.436). Survival for biologic treatments was 5.33 years (2.89–7.72) in all patients, 4.57 (2.54–7.28) in patients in remission and 5.61 (3.49–7.53) in patients not in remission (p=0.013).

All clinical assessments at the last follow-up were significantly associated with DAS28 remission. Mean prednisone dose was significantly lower in patients in DAS28 remission but was negatively associated with remission as a consequence of remission rather than a predictor (Table I). The type of current biologic treatment was not significantly associated with DAS28 remission.

Variables included in the multivariate regression analysis were: BMI, age, disease duration, positive RF/ACPA mean survival of each biologic treatment. All variables included in the model were independently associated with DAS28 remission. A higher BMI, older age, longer disease duration and positive RF/ACPA were negatively associated with remission. A longer mean survival of biologic treatment was associated with DAS28 remission.

EFFECTS OF ANTI-CITRULLINATED PROTEIN ANTIBODIES ON SYSTEMIC BONE MASS IN RHEUMATOID ARTHRITIS PATIENTS

G. Orsolini, C. Caimini, O. Viapiana, L. Idolazzi, E. Fracassi, D. Gatti, G. Adami, M. Rossini. Rheumatology Unit, University of Verona, Verona, Italy

Background: Bone loss in rheumatoid arthritis (RA) is a key feature both local and systemic. Anti-citrullinated protein antibodies (ACPA) have recently been found to directly induce differentiation and activation of osteoclasts and therefore contribute to periarticular bone loss.

Objectives: The aim of this study was to analyze the effect of ACPA on systemic bone mineral density (BMD) in patients with established RA.

Methods: This is a cross-sectional study with a single-center RA population. BMD was measured with Dual X-ray absorptiometry at lumbar and femoral sites. ACPA were measured with ELISA. Multivariate analysis was performed adjusting for the main confounding variables.

Results: One hundred twenty-seven RA patients were enrolled. In univariate analysis ACPA-positive patients showed lower BMD T-score (SD below the age-and-gendermatched normal value) at femoral sites (p<0.01). A negative correlation between ACPA titers and BMD Z-score at all sites was observed (p<0.01). The multivariate analysis adjusted for the main confounding variables confirmed the negative effect of ACPA at femoral sites (p<0.05); but not at lumbar spine BMD. No significant effect of rheumatoid factor has been observed.

Conclusions: ACPA have a negative titer-dependent effect on BMD at femoral sites, mainly constituted by cortical bone. ACPA-positive patients, especially if at high titer, should undergo bone investigations and be treated with bone protecting agents. Disease-modifying anti-rheumatic drugs lowering ACPA titer might have positive effects on systemic bone mass.

AB0217

THE PROGNOSTIC VALUE OF IgA AUTOANTIBODIES (RHEUMATOID FACTOR AND ACPA) FOR PREDICTION OF THERAPEUTIC RESPONSES TO ANTI-TNF THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Steinr 1, D. Sieghart 1, F. Alast 1, P. Studenic 1, T. Perkmann 2, T. Horn 2, D. Aletaha 1, J.S. Smolen 2. 1Internal Medicine III-Rheumatology, 2Laboratory Medicine, Medical University Vienna, 3Phadia Austria GmbH, Thermo Fisher Scientific, Vienna, Austria

Background: Anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) are important diagnostic markers in rheumatoid arthritis (RA). These antibodies are predominantly of the IgM (RF) or IgG (ACPA) isotype. The added diagnostic and prognostic value of IgA autoantibodies is being debated.

Objectives: To determine the prevalence of IgM-RAF and IgG-ACPA in patients with RA and to investigate their potential predictive value regarding response to treatment with methotrexate (MTX) and TNF inhibitors.

Methods: A total of 255 patients were tested for the presence of IgM-RAF, IgG-ACPA and IgA-ACPA by EIA (Thermo Fisher Scientific). IgM-RAF was measured by nephelometry. Therapeutic responses to MTX and TNF blocking biologicals were calculated in an inception cohort (n=104) who had started their DMARD therapy at our clinic. To define therapeutic responses simplified disease activity index (SDAI) 50 and American College of Rheumatology (ACR) 20 responses were calculated.

Results: Among the 255 patients tested 125 (49%) had at least one type of IgA autoantibody: 114 (44.7%) were found to be IgA-RAF positive and of these 10.5% were negative for IgM-RAF and 5.2% were double negative for both IgM-RAF and IgG-ACPA; thus, in these patients IgA-RAF was the only detectable antibody. IgA-ACPA were detected in 79 (31%) patients and apart from one exception all of them had also IgG-ACPA. Remarkably, the percentage of patients showing a SDAI50 response to TNF inhibitors was significantly lower in patients positive for IgA-RAF and/or IgA-ACPA (p<0.0001) compared to IgA negative patients. Thus, 58% of IgA negative (but IgM-RAF and/or IgG-ACPA positive) patients showed a SDAI50 response whereas only 25% of the IgA-RAF and/or IgG-ACPA positive ones were responders. Interestingly, while the presence of both IgA specificities did not further change the percentage of responders, patients positive for IgA-ACPA but negative for IgA-RAF showed the lowest response rate to anti-TNF treatment. Completely seronegative patients also showed a significantly lower SDAI50 response (p<0.0001) to TNF inhibitors compared with those with the positive ACPA but negative for IgA-RAF. Similar results were obtained when ACR20 was used as response criteria. No differences between the various serological groups were seen with respect to treatment with MTX.

Conclusions: While the added diagnostic value of IgA antibody measurement was moderate, IgA-RAF and particularly IgA-ACPA appear to be associated with poorer therapeutic responses to TNF inhibitory biological drugs and therefore may help in further stratification of RA patients and therapeutic decision making.

CORRELATION OF GRAY SCALE AND POWER DOPPLER ULTRASONOGRAPHY WITH CLINICAL EVALUATION IN RHEUMATOID ARTHRITIS

I.E. Okatan, M. Torgutalp, M.E. Yayla, A.B. Keleşoğlu Dinçer, E. Eulu Yurtleri, A. Ateş, T.M. Turgay, Ş. Kınıklı. Department of Internal Medicine, Division of Rheumatology, Ankara University Faculty of Medicine, Ankara, Turkey

Background: While the added diagnostic value of IgA antibody measurement was moderate, IgA-RAF and particularly IgA-ACPA appear to be associated with poorer therapeutic responses to TNF inhibitory biological drugs and therefore may help in further stratification of RA patients and therapeutic decision making.

Objective: The objective of this study was to compare the tender joint and swollen joint in patients with rheumatoid arthritis (RA) with gray scale (GS) and power doppler (PD) ultrasonography (US).

Methods: Thirty RA patients were included. Median disease duration was 53.7 months. Demographic and clinical data, C reactive protein (CRP) level and erythrocyte sedimentation rate (ESR) were recorded for each patient. Disease activity was evaluated using the Disease Activity Score in 28 joints (DAS28) with a median score 3.8. The joint tenderness and swelling were assessed for 10 joints (wrists, second and third proximal interphalangeal and metacarpophalangeal) in each patient. These joints were evaluated by GS and PD by ultrasonography. US joint effusion, synovitis and PD signals were graded from 1 to 3 for each joints. The 10-joint GS and 10-joint PD scores were then calculated. Correlations were tested using the Spearman coefficient.

Results: GS: effusion, synovitis scores (r =0.565, p<0.001) and PD signals (r=0.883, p<0.001) correlated highly with the corresponding swollen joints. There was a significant correlation between DAS28 and number of tender joints (r=0.745, p<0.001) but no correlation was found between the tender joints and ultrasonographical effusion, synovitis grade (r=0.073, p=0.001) and the PD signal (r=0.089, p<0.001). There was moderate correlation between 10 joint GS, 10 joints PD and DAS28, but it was not statistically significant.

Table 1. Demographic and clinical characteristics of the patients (n=30)

| Age (years) | (mean) | SD | 53±11.9 |
| RA duration (months) | 42 (67) |

INTENSIVE COMBINATION THERAPY WITH MEDICATION AND ARTHROPEDEUTIC SURGICAL INTERVENTION FOR TREATING RHEUMATOID ARTHRITIS PATIENTS WITH DETERIORATED JOINTS

H. Ishikawa 1, A. Abe 1, Y. Nomura 1, S. Ito 1, T. Kojima 2, M. Kojima 2, N. Ishiguro 2, A. Murasawa 1. 1Rheumatology, Nigata Rheumatic Center, Shibata; 2Orthopedic Surgery, Nagoya University Hospital; 2Medical Education, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan

Background: The aim of treatment of rheumatoid arthritis (RA) is achieving and maintaining remission (REM) or low disease activity (LDA) via tight medical control. However, despite remarkable advances in medication, progressive deterioration and/or deformity of the joint sometimes occurs, if adequate medication is not administered in the early stage. Surgical reconstruction is still required in the joints with functional loss caused by structural damage. Recently, patients have expressed a desire to achieve functional REM with a higher quality of life (QOL) and improved mental wellness.

Objectives: The objective of this study was to clarify the effectiveness of intensive combination therapy with medication and orthopedic surgical intervention in patients who have already achieved REM or LDA.

INTENSIVE COMBINATION THERAPY WITH MEDICATION AND ARTHROPEDEUTIC SURGICAL INTERVENTION FOR TREATING RHEUMATOID ARTHRITIS PATIENTS WITH DETERIORATED JOINTS

H. Ishikawa 1, A. Abe 1, Y. Nomura 1, S. Ito 1, T. Kojima 2, M. Kojima 2, N. Ishiguro 2, A. Murasawa 1. 1Rheumatology, Nigata Rheumatic Center, Shibata; 2Orthopedic Surgery, Nagoya University Hospital; 2Medical Education, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan

Background: The treatment aim of rheumatoid arthritis (RA) is achieving and maintaining remission (REM) or low disease activity (LDA) via tight medical control. However, despite remarkable advances in medication, progressive deterioration and/or deformity of the joint sometimes occurs, if adequate medication is not administered in the early stage. Surgical reconstruction is still required in the joints with functional loss caused by structural damage. Recently, patients have expressed a desire to achieve functional REM with a higher quality of life (QOL) and improved mental wellness.

Objectives: The objective of this study was to clarify the effectiveness of intensive combination therapy with medication and orthopedic surgical intervention in patients who have already achieved REM or LDA.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.4859
Methods: A prospective cohort study was performed on 294 sites in 276 patients with functional loss due to RA scheduled to undergo primary elective surgery between October 2012 and September 2014. There were 99 sites in 96 patients (males: 10, females: 86) whose disease activity was REM or LDA just before surgery. In the REM/LDA group, the average age was 63 (29–82) years, and the average disease duration was 7 (2–17) years. The surgical site was the shoulder in 1 patient, elbow in 7, wrist in 21, hand in 24, hip in 5, knee in 10, ankle in 4, and forehead in 27. The procedures performed included 38 arthroplasties, 41 arthroplasties without prosthesis, 19 arthrodesis, and 9 synovectomies. The patient-reported outcome (PRO) was assessed using the Health Assessment Questionnaire (HAQ-DI, EuroQol 5 Dimensions (EQ-5D), Body Mass Index (BMI), Depression Inventory-II (BDI-II), and Patient’s General Health using visual analogue questionnaire (Pt-GH), and Disease Activity Score (DAS28-ESR, DAS28-CRP). All of these items were investigated just before surgery (baseline) and again at 6 and 12 months after surgery.

Results: On the whole, the physical function (HAQ-DI, DASH, TUG), QOL (HAQ-DI, EQ-SD, Pt-GH), mental wellness (BDI-II, Pt-GH), and disease activity (DAS28-ESR, DAS28-CRP) were significantly improved at 6 and 12 months after surgery compared to baseline (p<0.01). In the REM/LDA group, a significant improvement was noted in the physical function (DASH, TUG) and QOL (EQ-SD) at 6 and 12 months after surgery; however, we did not observe any significant changes in any other items (Table 1).

Table 1: Outcome of combination therapy with medication and orthopedic surgical intervention

Conclusions: Achieving REM or LDA is not the only ultimate goal of treatment for patients with functional loss caused by structural damage. Further “wellness” can be achieved by surgical intervention. Intensive combination therapy with medication and orthopedic surgical intervention is effective in improving the QOL and mental health of the patient as well as the physical function. Such intervention can also ameliorate the disease activity.

AB0221 IMPACT OF SMALL TO MEDIUM DOSE OF PREDNISOLONE ON BONE MINERAL DENSITY AMONG EARLY RHEUMATOID ARTHRITIS PATIENTS

H.M. Lam1, M.C. Wan2, L.S. Tam1 on behalf of CRYSTAL study group, The Hong Kong Society of Rheumatology, 1Dept. of Medicine and Therapeutics, The Chinese University of Hong Kong, Shatin, 2Dept. of Medicine, Ruttonjee Hospital, Wan Chai, Hong Kong

Background: Recent randomized trials in rheumatoid arthritis (RA) using low to medium dose of corticosteroids showed that bone mineral density (BMD) loss over 2 years was not significantly different from that with placebo. Another study in early RA and undifferentiated arthritis even showed a positive correlation between cumulative glucocorticoid (GC) dose with an increase in BMD at the ultradistal forearm. Whether the use of prednisolone (pred) can prevent bone loss in early RA patients remained controversial.

Objectives: The aim of this study was to investigate the impact of small dose pred (<10mg/day) on BMD in early RA patients.

Methods: Data from 107 patients recruited from 5 sites: 53±11.92 years; females: 79 (73.8%), median disease duration at entry: 7-month (IQR, 4–12) from the Hong Kong early arthritis registry (Clinical Rheumatology Systematic Treat to Target in Asia Leadership [CRYSTAL] project)were analyzed. In this register, clinical and treatment information were systematically recorded, including cumulative GC dose. Hip, spine and forearm BMDs were measured by dual-energy X-ray absorptiometry (DXA) at baseline and month 12. Patients were categorized into three groups according to pred use (never/<3/≥3 months) during the first year of follow-up. Patients who ever took ≥10mg/day of pred were excluded. The change in BMD was compared between groups and between the two time points.

Results: The baseline characteristics of patients were shown in Table 1. Patients were randomized into three groups according to pred use (never/<3/≥3 months) during the first year of follow-up. Patients who ever took ≥10mg/day of pred were excluded. The change in BMD was compared between groups and between the two time points.

Conclusion: Ultrasound guided synovial tissue biopsies are feasible in the United States. Based on our recent success using minimally invasive ultrasound guided synovial biopsies, we believe that this procedure coupled with cutting-edge technologies will provide the critical information to rheumatologists to establish precision based medicine as a reality for RA patients.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.5488
who required ≥3 months of pred treatment are older, with a shorter disease duration and a higher disease activity. Significant differences in the percentage change of BMD in forearm was found among the groups (Pred never/Pred ≥3 months: -2.99±4.21/1.05±3.10/0.65±3.45, p=0.045). Post-hoc analysis revealed that the percentage reduction of forearm BMD was significantly less in the Pred ≥3 months group compared to the Pred never group (p=0.043). After adjusting for age, gender, disease duration and baseline DAS-CRP, the changes in forearm BMD was still significantly different among the three groups (p<0.015). No significant differences in the changes of hip and spine BMD were observed. Significant changes in forearm BMD were observed between baseline and month 12 only in the Pred never group (0.54±0.08/0.53±0.0 p<0.001, graph1).

Conclusions: Small to medium dose of prednisolone might protect bone loss in forearm among early RA patients. These results need to be further validated.

AB0224 SIMULATION FOR CHOICE OF BDMAARDS AND TSDMARDS IN ORDER TO SUCCESS FOR THREE-YEAR SURVIVAL IN RHEUMATOID ARTHRITIS TREATMENT

I. Yoshii, Rheumatology, Yoshii Hospital, Shimanto City, Japan

Background: In rheumatoid arthritis (RA) treatment, bDMARDs and tsDMARDs (BiO) perform tremendous disease activity control, however, its effectiveness is uncertain and unstable, because their survival ratio is not good enough to tolerate. If more right choice is done in guided by some simulation.

Objectives: This study aims more than 80% of three-year survival ratio (SR100 of BiO) in simulating risk of BiO by using statistical clinical data and post marketing surveillance (PMS) data with Bayes estimation.

Methods: Infection risk and survival risk were harvested from Japanese PMS data, and our clinical data. All our cases were calculated with last observation carried forward method (LOCF). If BiO was continued for more than three years or discontinued by attaining clinical remission, it was evaluated as success, while other cases were evaluated as failure. Patient’s clinical data and general status was calculated for each case, and SR100 for success was statistically evaluated with Binary Logistic Analysis for success. Evaluation methods for parameters were divided according to general risk and drug specific possibility. If calculated general risk went above 0.2, selection of BiO was discarded. In other case which had gone below, choice of BiO is done in according to point that had been cumulated by drug specific possibility in choosing what took maximum calculated expectation value.

If chosen drug have matched used BiO, it was evaluated as true, if not, it was evaluated as false, while if true case was in success, it was evaluated as true success, and if in failure, it was evaluated as true failure, while false case was in success, it was evaluated as false success, and if in failure, it was evaluated as true failure. Sensitivity in success cases and specificity in failure cases was calculated for each case, and SR100 for success was statistically evaluated with chi-square test.

Results: 188 cases have had enough data for simulating. In these, 108 were success and 80 were failure. In success cases, simulated TNF inhibitor (TNF-i) counted 37, Tocilizumab (TCZ) counted 11, Abatacept (ABT) counted 12, and...
Tofacitinib (TOF) counted 2 while real chosen cases were TNF-α counted 65, TCZ counted 11, ABT counted 21, and TOF counted 11. Overall success ratio was 57.4%. In these cases, true choice had been done in 97 cases of 108. In failure cases, simulated TNF-α counted 44, TCZ counted 16, ABT counted 2, and TOF counted 1, while real chosen cases were TNF-α counted 49, TCZ counted 17, ABT counted 10, and TOF counted 4. True success counted 97, and false success counted 11, while false success counted 37 and true failure counted 54. Then, sensitivity was 89.8% and specificity was 67.5% (0.01).

**Conclusions:** Drug choice of BIO supported with simulation was superior to real choice. If risk management was adequately performed, SR/37Y is expected more than 85%.

### AB0225 CHARACTERISTICS OF MHAQ FOR UPPER AND LOWER EXTREMITY FUNCTION, AND RELATIONSHIP WITH AGE AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENT

**I Yoshih1, T. Chijiwa2, 1Rheumatology, Yoshii Hospital, Shimanto City; 2Rheumatology, Kochi Memorial Hospital, Kochi, Japan**

**Background:** Activity in daily living (ADL) is one of main target to maintain patient's quality of life in rheumatoid arthritis (RA) treatment. Modified Health Assessment Questionnaire (mHAQ) is a most popular index for ADL in routine practice. mHAQ is divided into five function of extremity; namely the first four categories are reflections of upper extremities (mHAQ-UE), while the latter are of lower extremities (mHAQ-LE). If function of each extremity is separately disabled, it should be reflected on each part of mHAQ.

**Objectives:** mHAQ was separately investigated in order to evaluate characteristics of each part of mHAQ.

**Methods:** 964 RA patients since January 2010 had been treated. In these, patients who have been treated consecutively for more than five years at December 2016 were recruited in this study. Patient who had been operated musculoskeletal surgery was excluded. mHAQ-UE and mHAQ-LE, and 28-joint disease activity index with C-reactive protein (DAS28-CRP) were measured every time since first visit. Average value of these parameters including Sharp/van der Heijde Score (SvdHS) were calculated annually. Relationship between each of mHAQ and parameters for each year were evaluated used with multiple linear regression analysis.

**Results:** Predominant extremity in mHAQ was evaluated as in which upper extremity predominant (G-UE), lower extremity predominant (G-LE), same weight (G-EV), and both of them were zero (G-Z). Changes of the evaluation from first to the last was evaluated by interrupted time series analysis.

**Results:** One hundred and two male and three hundred and thirty-three female, totally four hundred and thirty five patients were picked up. Their average value of age, SvdHS, DAS28-2CRP, mHAQ, mHAQ-UE, and mHAQ-LE were 64.65, 52.1, 2.96, 0.439, 0.286 and 0.491 at first consult, and 71.05, 52.1, 1.72, 0.425, 0.344, and 0.505 at last time follow up, respectively. Both of mHAQ-UE and mHAQ-LE have demonstrated significant regression with both age and SvdHS throughout treatment, while not significant with DAS28-CRP however, mHAQ-UE correlated with tender joints joint except of knee, and mHAQ-LE have correlated with swelling of the knee joint significantly.

G-UE had counted for 85 patients, G-LE for 136, G-EV for 49, and G-Z for 165 at first consult. Once evaluation had changed, there have continued to the last in all patients. G-UE resulted in G-UE for 83, while G-LE for 2 at last. G-LE resulted in G-UE for 133, G-Z for 2, and G-EV for 1, G-EV resulted in G-LE for 24, G-UE for 7, and G-EV for 18. G-Z resulted in G-Z for 137, G-EV for 19, G-UE for 4, and G-EV for 5. G-UE to G-EV demonstrated significant higher DAS28-CRP improvement from first to the last than to G-LE, and to G-UE, and G-EV to G-LE demonstrated significant higher DAS28-CRP improvement than to G-LE, although no significant difference demonstrated for mHAQ improvement among groups. G-UE to G-LE demonstrated significant higher DAS28-CRP improvement than to G-U, as well as G-U to G-LE demonstrated significant higher mHAQ improvement than to G-U.

**Conclusions:** From these results, it is suggested that mHAQ-UE and mHAQ-LE might be decreasing function. However, mHAQ-UE and mHAQ-LE showed by upper extremities joint tenderness, while mHAQ-LE can move more sensitively with knee swelling. Tight disease activity control may reduce mHAQ both of them, however, reduces more predominantly with mHAQ-UE than mHAQ-LE.

### AB0226 FUNCTIONAL DISABILITY IN RA PATIENTS TREATED WITH BIOLOGICS: HUR-BIO REAL LIFE RESULTS

**A. Sari, B. Armanag, A. Erden, L. Kılıç, O. Karadag, A. Akdoğan, S. Apras Bilgen, S. Kiraz, U. Kalyoncu, E. Erdem, Rheumatology, Hacettepe University School of Medicine, Ankara, Turkey**

**Background:** Rheumatoid arthritis (RA) is a chronic, erosive disorder which may lead to permanent joints damage. Health assessment questionnaire (HAQ) is frequently used for evaluating functional disability in RA patients.

**Objectives:** The aim of this study is to determine the effect of biologic treatment on functional disability in RA patients.

**Methods:** HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a prospective, monocentric database of biological treatments including 1219 RA patients by August 2016. 523 patients in whom HAQ assessment before biologics were available, was recruited in this retrospective analysis. HAQ score $>1.0$ was defined as severe functional disability. $^1$ HAQ assessment at last follow-up visit was evaluated. Improvement of HAQ score 0.22 points or more was considered as clinically significant response to treatment.

**Results:** Among 523 patients (80.5% female), mean age was 52.6±12.5 and mean disease duration was 9.4±7.3 years. Seropositivity for RF and/or CCP was present in 67.2% of patients. At baseline visit, HAQ score was $>1.0$ in 288 patients (51.2%). Baseline and last follow-up HAQ scores were 1.07±0.62 and 0.64±0.57. Minimal clinically significant improvement of HAQ score was observed in 238/377 patients (63.1%). Clinically significant response was more frequent in patients with baseline HAQ score of $>1$ (153/195 (78.4%) vs 85/182 (46.7%); p = 0.001). Table 1 represents features of patients according to baseline HAQ score. Mean follow-up time was 16±4±16.4 months. Data of at least one visit was available for 377 (72.0%) patients.

**Table 1. Comparison of demographic an clinical data of patients according to baseline HAQ score**

**Conclusions:** Functional disability was observed approximately half of patients. Clinically significant improvement was more frequent among patients with higher baseline HAQ scores particularly. Biologic treatment seems to be provide significant functional improvement. However significant functional disability persists in one fourth of patients.

immunological approach to the diagnosis of lesions of the nervous system in patients with rheumatoid arthritis

L.P. Gontar1, E.V. Briunov2, L.A. Mislakova1, A.S. Trolimenko1, O.V. Paramonova2, Clinical Immunology Lab, FSBSU Research Institute for Clinical and Experimental Rheumatology2, Department of Hospital Therapy, Volgograd State Medical University, Volgograd, Russian Federation

Background: Although S100 proteins represent 40% of the neutrophil cytoplasmic proteins, their physiological and pathological functions are still unclear. S100 protein concentrations are dramatically enhanced in synovial fluid and synovium of patients suffering from rheumatoid arthritis (RA). Their expression seems to correlate with disease activity and joint damage [1].

Objectives: Improvement of immunological detection of neurological involvement in RA by means of polyclayamide magnetic beads with immobilized S-100 protein.

Methods: The research was carried out in agreement with the principles of the World Medical Association Declaration of Helsinki. The informed consent had been signed by all involved persons, another obligation require was age 18 years or more. The patients were from the rheumatoid wards in Volgograd Municipal Hospital No. 25 and Volzhsky Municipal Hospital No. 1. Diagnosis of RA was established by ACR-EULAR criteria (2010), RA activity was evaluated using DAS28. Serum anti-S-100 protein antibodies were measured by ELISA, with S-100 protein immobilized on polyclayamide magnetic beads as an antigen. The antibody concentrations were expressed as optical density units (ODU) and were considered positive if the cutoff value (2SD of the reference group, 0.050 ODU) was exceeded. The results were expressed as mean±SD, differences were considered significant when p<0.05. Pearson correlation coefficient (r) was also used.

Results: 40 healthy persons (29 men and 11 women), and 95 female patients with RA and the neurological signs, appeared during active phase of the disease, were recruited for this study. Mean age of the healthy controls was 36±7 years, and for the RA group it was equal to 55±11 years. Mean RA duration was 4.2±2.9 years. 13 patients had low, 52 – moderate, and 8 – high disease activity. The most common types of neurological involvement were mononeuropathy (n=29), polyneuropathy (n=65), radiculopathy (n=80); cervicocranialgia (n=51), and trigeminal neuralgia (n=14). The symptoms of central nervous system damage (TIA, seizures, cerebellar ataxia, dysarthria) were found in 21 patients. In RA group, anti-S-100 protein antibodies were detected in 51 (32.4%) cases, with mean concentration 0.078±0.028 ODU. The patients with different neurological signs had mean anti-S-100 protein antibody concentration 0.138±0.046 ODU, the subgroup without any neurological signs had 0.060±0.024 ODU (p=0.022). In all cases analyzed index correlated with the degree of activity of the pathological process. High levels of antibodies to S-100 protein in RA associated with central nervous system (CNS) and peripheral nervous system (PNS).

Conclusions: We found an association between neurological involvement in RA and elevation of anti-S-100 protein antibody concentrations. These findings give us an opportunity to improve the diagnosis of minor neurological damage in RA and thus to make more precise adjustment of the treatment.

AB0232 MINIMAL CLINICALLY IMPORTANT IMPROVEMENT (MCI) OF RAPID3 (ROUTE ASSESSMENT OF PATIENT INDEX DATA 3), AN INDEX OF ONLY PATIENT SELF-REPORT SCORES, PERFORMS SIMILARLY TO TRADITIONAL RHEUMATOID ARTHRITIS (RA) INDICES, DAS28 AND CDAI

I. Castrejon1, M.M. Ward2, M.J. Bergman2, L.C. Guthrie3, M. Alba2, T. Pincus1, L. Rheumatology, Rush University Medical Center, Chicago, Chicago
2 Intramural Research Program, NIAMS/NIH, Bethesda, L. Rheumatology, Taylor Hospital, Ridley Park, United States

Background: No single “gold standard” measure is available to assess patients with rheumatoid arthritis (RA) in clinical trials and routine care, as in hypertension, diabetes, and other diseases. Therefore, an index of several measures, such as a DAS28 Disease Activity Score-28 and CDAI (Clinical Disease Activity Index), based on 7 RA core data set measures, is needed. However, the only quantitative data in many (most) patients in routine rheumatology care are laboratory test results. RAPID3 (routine assessment of patient index data), which includes only patient self-report scores, is considerably more feasible than DAS28 or CDAI for routine care, distinguishes active from control treatments in RA clinical trials similarly and is correlated significantly with these indices. A minimal clinically important improvement (MCI) to interpret changes in clinical trials and clinical care has not been established for RAPID3

Objectives: To estimate MCIs of RAPID3, and compare results to MCIs of DAS28 and CDAI

Methods: Post hoc analyses were performed of a reported longitudinal study of 250 patients with active RA (1). All 7 RA core data set measures were collected at baseline and after treatment escalation with prednisone 1 month later or with disease modifying medications or biologic agents 4 months later (1). Patient judgment of improvement in arthritis status was obtained as “improved”, “the same” or “worsened”, and analyzed in relation to changes in RAPID3, DAS28 and CDAI. RAPID3 is the sum of 0–10 measures; physical function on a HAQ recalculated from 0 to 10, pain and patient global estimate on 0–10 VAS (visual analog scales), total=0–30. DAS28-ESR (erythrocyte sedimentation rate) and CDAI were computed as described in the literature. Changes in all indices, standardized response means (SRM), MCIs as changes that had a specificity of 0.80 for improvement based on receiver-operating characteristic curves, and MCI as a proportion of the maximum score were computed.

Results: Among 250 patients, 167 (66.8%) reported improvement. RA activity and SRMs improved similarly per the 3 indices (Table), ROC curve areas were ≥0.77 (Table). MCIs with specificity for improvement of 0.80 were -3.5 for RAPID3, -1.17 for DAS28-ESR, and -12.5 for CDAI. MCIs were in a similar range of 11.6% to 16.8% of maximum score (Table).

Conclusions: MCIs for RAPID3, DAS28, and CDAI were in a similar range. Knowledge concerning MCI thresholds can improve interpretation of data from clinical trials and routine clinical care.

SRM = standardized response mean; CI = confidence interval.
Objectives: We investigated the effects of oral contraceptives (OCs) and menopause on RA in South Korean women using nationwide data.

Methods: We examined the proportion of patients in remission and 3 other disease severity categories according to RAPID3 at 3 sites at which MDHAQ is completed by all patients in routine care.

Results: Similar RAPID3 remission rates were seen at 3 USA sites (about 24%), comparable to results from France and Norway. Low severity ranged from 7–24%, moderate severity from 23–99%, and high severity from 21–46%. Age and sex were similar in the analyses. The proportion of patients in 4 RAPID3 categories, high severity (>12/30), moderate severity (6.1–12), low severity (3.1–6), and remission (<3), was computed. MDHAQ demographic and clinical measures and DOCGL were compiled into a 0–30 RAPID3, as well as scores for fatigue, RADAI (0–48), and DOCGL demographic and clinical measures, and self-report RADAI (0–10) in each site. The analyses included 420 RA patients from the 3 sites that were analyzed. Remission rates according to RAPID3 severity ranged from 23% to 26%, similar to reported rates from France and Norway. Low severity ranged from 7–24%, moderate severity from 23–99%, and high severity from 21–46%. Age and sex were similar in the disease severity categories at the 3 sites (Table). Patients in the moderate and high severity groups at each site had higher scores for fatigue, RADAI self-reported joint pain, and DOCGL.

Table 1. Table (SD) for demographic and clinical characteristic of patients in remission versus other disease severity categories according to RAPID3 at each site.

Methods: Data were collected from the 2008–2012 Korea National Health and Nutrition Examination Surveys. A total of 17,890 eligible participants were included. As there were significant differences in baseline characteristics between the patients on OCs and those not taking OCs, we used propensity score-matching to adjust for such differences. We calculated the odds ratios (ORs) and 95% confidence intervals (95% CIs) of OCs leading to RA development.

Results: The peak incidence of RA was between 50–59 years old. The overall rate of OC usage was 16.5% and mean duration of OC using was 18.4±28.78 (ranged from 0 to 360) months. Before propensity score-matching, using multivariable logistic regression adjusted for traditional risk factors, taking OC was a significantly associated with RA development (OR 1.18, 95% CI 1.19–1.19, p < 0.001). After propensity score-matching, taking OCs was not associated with RA (OR 1.05, 95% CI 0.83–1.34, p < 0.001). Menopausal status showed strongly significant increase in the risk of RA.

Conclusions: There was an association between menopausal status and RA development in South Korean women. However, usage of OCs did not show significant effects on the development of RA.

References:

Disclosure of Interest: None declared.
Conclusions: Pts with CDAL <35–36 at BL achieved sustained LDA more frequently and more rapidly than pts in the higher disease category at BL. In pts with higher disease activity at BL a more robust response was observed with bari 4 mg treatment.

AB0236 ASSOCIATION OF LYVE-1 PROTEIN IN EXOSOME WITH DISEASE ACTIVITY AS A NEW CANDIDATE BIOMARKER FOR RHEUMATOID ARTHRITIS
J. Yoo 1, S.K. Lee 2, M. Lim 1, D. Sheen 1, E.-H. Choi 2, S.A. Kim 1, 1School of Medicine, 2Eulji Medi-Bio Research Institute, Eulji University, Daejeon, Korea, Republic Of

Background: Exosomes, membrane-bound vesicles of 40–100 nm in diameter, have protein and lipid composition that depends on the cell origin, the state of activation, interaction and/or transformation of the parent cells. Those proteins and lipids may be a role in mediating inflammatory and autoimmune disease as well. Discovery of inflammatory marker to evaluate appropriate response of treatment could give effective timing to adjust treatment for rheumatoid arthritis patients.

Objectives: The aim of this study was to identify protein candidates in exosome being related with inflammatory parameters.

Methods: The study population consisted of 60 RA patients, in which there were 30 patients of clinical remission (rem) group with DAS28-ESR<2.6 and 30 patients of non-clinical remission (non-rem) group with DAS28-ESR>2.6. By exosome preparation with ExoQuickTM kit and protein identification with tandem mass tags labeling/mass spectrometry between the groups, potent protein markers were selected. Level of the proteins was measured by ELISA.

Results: We identified 6 proteins by proteomics approach. Amyloid A (AA) and lipid vascular endothelial hyaluronic acid receptor-1 (LYVE-1) was identified with different levels in exosome between CR group and non-CR group. AA levels of both serum and exosome were higher in non-CR group than CR group (p value<0.001). Significant positive correlations were found between exosome AA level and CRP as well as between serum AA level and CRP (p=0.614, p value=0.001 and p=0.624, p value=0.001). Though LYVE-1 level of serum was not different between non-CR group and CR group, LYVE-1 level of exosome was lower in non-CR group than CR group (p value<0.01). We found positive correlations between serum/exosome of LYVE-1 and CRP in only non-CR group (serum p=0.376, p value<0.04; exosome p=0.545, p value<0.002).

Conclusions: We suggest that LYVE-1 in exosome can be used as an additional marker of disease activity in RA patients and this study provides the evidence about the role of exosome for RA as the carrier of useful marker.

AB0238 THE INFLUENCE OF FATIGUE IN THE DEFINITION OF REMISSION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOLCILIZUMAB
J. Caetano 1, S. Oliveira 1, J. Delgado Alves 1,2, 1Systemic Autoimmune Diseases Unit, Department of Medicine IV, Fernando Fonseca Hospital, Amadora; 2CEDOC, NOVA Medical School, Lisbon, Portugal

Background: Achieving disease remission or low disease activity is the therapeutic goal in rheumatoid arthritis (RA) treatment. Disease activity is defined through established criteria requiring high values of inflammatory markers. Several studies have shown fatigue levels in patients with newly diagnosed malignancy. J Cancer. 2014:5(3):1907–20.

Objectives: To evaluate the relation between PBA and fatigue, and whether fatigue influences disease remission definition in RA patients treated with tocilizumab (TCZ), an anti-IL-6 receptor monoclonal antibody.

Methods: We prospectively recruited 18 consecutive patients with RA (ACR/EULAR 2010 criteria), on TCZ treatment (3 months), from a single referral centre. Disease activity was evaluated by disease activity score for 28-joints (DAS28), and the ACR/EULAR Boolean-based criteria for remission were calculated. Visual Analog Scale for Fatigue (VASF) and Multidimensional Assessment of Fatigue scale (MAF) were used to measure fatigue.

Results: 89% of the patients were female and mean age was 55.5±13.8 years (yrs). Mean disease duration was 8.8±6.8yrs and mean duration of TCZ treatment was 2.3±1.3yrs (50% 1st line). Mean PGA score was 3.3±2.0 (3 best-health) and mean DAS28 C-reactive protein (CRP) was 2.27. According to DAS28-3RD 44% of the patients were in remission, 22% had low disease activity and 33% had moderate activity. 3 patients (17%) fulfilled the ACR/EULAR Boolean criteria for remission. Considering all the composites of the Boolean criteria, PGA was the only reason for not achieving remission in 10 patients (56%). The mean fatigue scores were: VASF 6.6±2.3 (0-best health), Global Fatigue Index (GFI), calculated through MAF scale, 24.3±14.9 (1-best health). Amongst the 18 patients, PGA correlated with higher fatigue scores on VASF (r=0.50, p=0.0095) and on GFI (r=0.49, p=0.037). In the group of patients not fulfilling Boolean remission, a similar correlation between PGA and higher fatigue scores was found (VASF: r=0.54, p=0.036; GFI: r=0.79, p=0.0041). In the sub-group of patients in which PGA was the only factor for not achieving Boolean remission, there was a significant correlation between PGA and fatigue scores (GFI: r=0.79, p=0.009), that was not present in the other patients (GFI: r=0.24; p=0.49).

Conclusions: We found a positive correlation between higher PGA and fatigue
scores in RA patients treated with TCZ. PGA was the major limiting factor for higher PGA and fatigue scores was found, not present in the rest of the cohort. These results enhance the influence of fatigue in patients’ perspectives of disease and reinforce the limitations of using PGA to define RA activity and remission. Furthermore, considering the influence of TCZ in fatigue mechanisms, by blocking IL-6 receptor, we still found high fatigue scores in this cohort, which can enhance the complex physiopathology of fatigue in chronic inflammatory diseases, and the role of several other cytokines (IL-1, TNF-α). This effect and comparison with RA patients treated with anti-TNF-α can be explored further in larger prospective studies.

DKK1 IS NOT ASSOCIATED WITH INFLAMMATORY ACTIVITY INDEXES IN RHEUMATOID ARTHRITIS, BUT WITH FUNCTIONAL DISABILITY RELATED TO THE LONG EVOLUTION OF THE DISEASE

R. Girardo-Busto 1, E.L. Saldañarraga 1, A.M. Santos 1, J.I. Angarita 1, J.G. Ballesteros 1, J.C. Rueda-Sanchez 1, A. Vasquez 1, L. Valero 1, S. Arias 2, J. Londono 2 on behalf of Grupo de Espondiloartropatías Universidad de La Sabana – Hospital Militar Central. 1Department of Rheumatology; 2Universidad de la Sabana – Hospital Militar Central, Bogotá, Colombia

Background: Rheumatoid arthritis (RA) is a systemic chronic inflammatory disease characterized by joint destruction, deformity, lower functional status and decrease in life expectancy. Wnt signaling pathway recently it has been implicated in bone homeostasis. Studies suggest that overexpression of inhibitors of the Wnt signaling pathway, like the Dickkopf 1 protein (DKK1) has been implicated in bone destruction.

Objectives: To compare circulating levels of DKK1 in patients with RA to their disease activity and functional status.

Methods: 378 consecutive patients with early and established RA were evaluated at the Hospital Militar Central in Bogotá-Colombia, between March 2015 and November 2016. A complete medical history related to RA was obtained. Disease activity was evaluated by DAS28-PCR, CDAI, SDAI and RAPID3. functional status was measurement using MDHAQ and the Steinbrocker functional classification. DKK1 levels measured by ELISA using an Abcam® kit.

Results: The mean age was 60.7±13.1 years, disease duration 13.1±10.9 years, 80.4% were female. Higher levels of DKK1 were not associated with higher disease activity by CDAI (p=0.70), SDAI (p=0.84), DAS28 with CRP (p=0.80) or RAPID3 (p=0.70). Interestingly higher levels of DKK1 were significantly associated to greater disability and lower functional status according to the Steinbrocker functional grading (p=0.013) and with severe disability by MDHAQ (p=0.004), Table 1.

Other variables associated with joint destruction were osteoporosis, elevated rheumatoid factor, smoking, and hospitalization

Steinbrocker functional grading n (%) DKK1 (pg/ml) P

| Class I-II | 286 (75.2) | 4930.9±6801.5 | 0.013 |
| Class III-IV | 93 (24.5) | 7930.6±10811.8 |
| MDHAQ | | |
| Without or low disability | 334 (88.0) | 3192.0±2729.4 | 0.004 |
| Moderate or severe disability | 45 (12.0) | 4446.6±2821.0 |

Conclusions: Higher levels of DKK1 were found in patients with lower functional status. This association was not found in patients with greater disease activity according to CDAI, SDAI, DAS28 and RAPID3. This could be explained by greater structural damage though more studies would be needed to explore this possibility.

AB0240

ASSOCIATION BETWEEN LEPTIN CONCENTRATIONS AND CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS

J.A.D.J. Batún Garrido 1, E.E. Juárez Rojo 2, M. Salas Maña 2, É. Hernández Nuñez 1, F. Olán 1. 1Hospital Regional de Alta Especialidad Dr. Gustavo A. Rovirosa Pérez; 2Universidad Juárez Autónoma de Tabasco, Villahermosa, Tabasco; 3Hospital Regional de Alta Especialidad Dr. Gustavo A. Rovirosa Pérez, Villahermosa, Mexico

Background: It has been observed that leptin plays a role in the development of cardiovascular risk, independently associated with the development of atherosclerosis, as well as with traditional risk factors such as obesity and arterial hypertension, on the other hand, its participation in carbohydrate and lipid metabolism and in coagulation, makes leptin a promoter of the complications of obesity and therefore increase cardiovascular risk.

Objectives: Identify whether there is a relationship between serum leptin concentrations and cardiovascular risk assessed using the Framingham scale.

Methods: We studied patients with the diagnosis of rheumatoid arthritis (RA) according to the ACR/EULAR 2010 criteria; the leptin determination was through an enzyme immunoassay (ELISA) with the TECO® Test Kit. Cardiovascular risk was calculated using the modified Framingham score, as reported by EULAR, the result obtained was multiplied by 1.5. We considered as risk values of <1% as low; 1–2.5% moderate and >5% high. Statistical analysis was performed using the SPSS 22.0 package. A p<0.05 was considered a significant result. Categorical variables were compared with Chi square test. Continuous variables were compared with either the Student’s T test or the Mann-Whitney non-parametric test, according the case.

Results: We studied 77 patients. The traditional CVR factors that presented the highest prevalence were age, hyperlipidemia and obesity; with regard to the prevalence of non-traditional factors, hyperleptinemia, glucocorticoid use and positive RF were predominant. More than 1/3 parts of the study population consumed metohexate and hydroxyclooroquine, which have been considered as CVR protective factors. Serum leptin concentrations and CVR factors were compared and found that there was a significant difference between higher leptin values and disease activity (p=0.047), obesity (p=0.038), positive rheumatoid factor (p=0.009), Tobacco (0.009) and metabolic syndrome (p=0.001). Likewise, a significant relationship was found between lower leptin concentrations and hydroxyclooroquine consumption (p=0.023). Framingham CVR was calculated and the result obtained was multiplied by 1.5. The 35.5% of the population studied had a Framingham RCV, 38.3% moderate and 25.9% presented a high risk. We compared the level of CVR and serum leptin concentrations, finding that the highest CVR were the leptin values.

Conclusions: There is a positive association between CVR and serum leptin concentrations. It is also significantly associated with traditional and non-traditional risk factors.

AB0241

RELATIONSHIP BETWEEN LEPTIN AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

J.A.D.J. Batún Garrido 1, E.E. Juárez Rojo 2, M. Salas Maña 2, É. Hernández Nuñez 1, F. Olán 3. 1Hospital Regional de Alta Especialidad Dr. Gustavo A. Rovirosa Pérez; 2Universidad Juárez Autónoma de Tabasco, Villahermosa, Tabasco; 3Hospital Regional de Alta Especialidad Dr. Gustavo A. Rovirosa Pérez, Villahermosa, Mexico

Background: Increased concentrations of leptin have been observed during infectious processes and inflammation, in such a way that it plays a role in the inflammatory and the immune response.

Objectives: Determine the association between serum leptin and disease activity measured through DAS-28 PCR.

Methods: Patients with the diagnosis of rheumatoid arthritis (RA) according to the ACR/EULAR 2010 criteria were studied. Leptin was determined by enzyme immunoassay (ELISA) with the TECO® Test Kit, the values higher than 17 ng/mL were considered as hyperleptinemia. Disease activity was assessed by DAS-28 PCR, classifying as remission <2.3, low activity ≥2.3 to <3.8, moderate activity as ≥3.8 to <4.9 and high activity ≥4.9. Statistical analysis was performed using the SPSS 22.0 package. A p<0.05 was considered a significant result. A multivariate logistic regression model was used to determine the association between significant variables and leptin concentrations.

Results: 77 patients were studied, 93.5% were female. The activity of the disease was determined, finding that 40.3% of patients were in remission, 41.6% had low activity, 11.7% had moderate activity and 6.5% had high activity. The 46.8% had obesity, 65.5% were overweight, 18.2% had normal weight and 2.5% were underweight. The 37.7% of the patients studied had metabolic syndrome, being the main factor the presence of an altered abdominal perimeter. The 63.6% had positive rheumatoid factor. The 71.4% had leptin levels ≥17 ng/ml. A multivariate logistic regression was performed with leptin as dependent variable. The results show an independent association between higher concentrations of leptin and disease activity (OR 1.9; 95% CI 1.3–3.8; p=0.045), obesity (OR 3.63; 95% CI 1.1–11.9; p=0.033), the presence of metabolic syndrome (OR 2.74; 95% CI 1.7–10.4; p=0.038), and positive rheumatoid factor (OR 3.5; 95% CI 1.2–11.3; p=0.024). Leptin was also found at higher disease activity, there were higher concentrations of serum leptin. Patients with severe activity had higher leptin media than patients in remission

Conclusions: There is a positive relationship between the activity of the disease and the serum leptin concentration, likewise this hormone is related to other inflammatory processes such as metabolic syndrome and rheumatoid factor.

SERUM LEVELS OF ANGIOGENIC AND PROINFLAMMATORY factors. 

Background: The miRNAs, small non-coding RNA, regulate the genetic expression to posttranscriptional level, inhibiting the translation. The role of miRNAs in the evolution of RA is not clear. 

Objectives: To evaluate the variants rs2910164G/C in the evolution of RA and its extra-articular manifestations (EAM) 

Methods: 133 cases with RA were included (ACR/EULAR criteria 2010) and 430 healthy controls. There were evaluated EAM (rheumatoid nodules [RN], Raynaud phenomenon [RP], cutaneous vasculitis [CV], episceritis, sclerosis, peripheral ulcerative keratitis [PUK], multiple mononeuritis [MP]) and levels of ESR, CRP, RF and CCP. It was performed genotyping of single nucleotide polymorphisms (SNPs) rs2910164G/C in miR-146a, rs11614913C/T of miR-196a-2 and rs3746444A/G of miR-499. The descriptive and inferential statistical analysis was performed with the software SPSS and Finetti. 

Results: Patients with RA, women 126 (94.7%); age Me 48.9 (IQR 40–58); patients with EAM 23 (17.2%); women 22 [95.6%]; RN 14 [60.8%], RP 4 [17.3%], CV 1 [4.3%], episceritis 1 [4.3%], PUK 1 [4.3%], MM 1 [4.3%], MP 1 [4.3%]; ESR Me 37 (IQR 22–45), CRP Me 0.11 (IQR 0.03–0.27); positive RF 125 patients (93.9%, high positive 94.1%, negative 5.9%). The alleles and genotypic frequencies and the association with susceptibility and severity to Rheumatoid arthritis (RA) and its extra-articular manifestations (EAM) were shown in table 1

Conclusions: None of the evaluated variants in miRNAs are associated with susceptibility for RA, however, the SNP rs11614913C/T located in miR-196a-2 is associated with EAM.

AB0243 SERUM LEVELS OF ANGIOGENIC AND PROINFLAMMATORY CYTOKINES TO DISCRIMINATE BETWEEN 6 SETS OF REMISSION CRITERIA IN RA

J. Ramírez García, A. Cuervo, R. Celis, V. Ruiz-Esquide, M.V. Hernández, R. Sammarti, J.D. Cañete. Rheumatology, Hospital Clinic, Barcelona, Spain

Background: The ideal definition of remission in RA remains to be agreed. Angiogenic factors and proinflammatory cytokines are key in RA pathogenesis.

Objectives: The aim of this study was to analyze serum levels differences of angiogenic and inflammatory biomarkers between SDAI, CDAI, ACR, DAS28 and sonographic remission in patients with (RA). 

Methods: We selected patients with RA in clinical remission (DAS28-ESR <2.6 for <6 months). PDUS of knees and hands was performed. Serum levels of biomarkers of inflammation/angiogenesis were determined by Quantibody ® Human Array. Patients were classified according to 6 sets of remission criteria: RA with EAM, ACR50, DAS28, SDAI, CDAI, ACR, DAS28 and sonographic remission in patients with RA.

Results: 60 patients with RA were collected. 76% female, aged (mean) 53 years; disease duration 110 months. 47% (76%) patients, 27% (45%) biological therapies. At baseline, 67% of patients had PD signal and 48% fulfilled criteria for previously defined UdAS. Although patients in sonographic remission had lower levels of inflammatory biomarkers such as IL-6, IL-17 or IL-23, no significant differences were found between the 6 sets of remission criteria. Angiogenic biomarkers such as CXCL6 (0.025), ENA78 (0.007), SDF1 (0.047) and VEGF-R1 (0.025) were significantly lower in patients fulfilling CDAI remission. Patients with no PD signal (0.009) and no UdAS (0.006) had significantly lower levels of BFGF. 

Conclusions: RA patients in CDAI remission had significantly-lower levels of angiogenic cytokines. However, no differences in serum levels of proinflammatory cytokines were found between the 6 sets of remission criteria.

AB0244 MICROWAVE RADIOMETRY-DERIVED THERMAL CHANGES OF SMALL JOINTS AS POTENTIAL ADDITIONAL BIOMARKER IN RHEUMATOID ARTHRITIS: A PROSPECTIVE STUDY

K. Laskari1, G. Pentazos2, K. Prekas3, I. Raftakis4, E. Siroses5, P.P. Sklias6,1.1 Rheumatology Unit, 1st Dept. of Propaedeutic Internal Medicine and Joint Rheumatism Program, National & Kapodistrian University of Athens Medical School; 2Department of Rheumatology, Asklepiion General Hospital, Athens, Greece; 3Institute of Materials Research and Innovation, University of Bolton, Bolton, United Kingdom

Background: Microwave Radiometry (MR) is a rapid, non-invasive method that detects local tissue temperatures. Using joint ultrasound as reference method, in a proof-of-concept study, we have found that an increased temperature at the knee joint detected by MR in the absence of relevant clinical signs reflects the presence of subclinical synovial inflammation in rheumatoid arthritis (RA) [1].

Objectives: To test the hypothesis that temperature of small joints assessed by MR correlates to global disease activity levels in RA, a disease in which small joints are primarily affected.

Methods: Ten patients with active, untreated RA underwent clinical and laboratory assessments, joint ultrasound and MR of hand and foot small joints (RTM 01 RF5 microwave computer based system, Bolton, UK) at baseline, as well as 15, 30 and 90 days after treatment onset. Twenty aged-matched healthy individuals served as controls.

Results: Using 1248 separate MR-derived recordings from RA patients we created several thermo-scores involving different small joint combinations and compared them with clinical and ultrasound data. The best performing thermo-score involved the sum of temperatures of 16 small joints (2nd-5th metacarpal and proximal inter-phalangeal joints, bilaterally). This thermo-score correlated positively to DAS28 disease activity score (p<0.001), tender joint count (p=0.002), swollen joint count (p=0.001), patient's visual analogue scale (p<0.001), CRP
1. T. Okano 1, K. Orita 2, Y. Sugioka 3, K. Mamoto 1, T. Koike 3,4, M. Tada 5, correlated independently with the at 1 year. Multiple regression analysis revealed that the baseline MMP-3 level predictive value for baseline MMP-3 level in women in terms of structural damage. There was a weak correlation between the baseline MMP-3 level was performed, with

**AB0245 DISTRICT DIFFERENCES BETWEEN THE SEXES OF PREDICTIVE VALUE OF MATRIX METALLOPROTEINASE-3 AT BASELINE REGARDING CHANGES IN MODIFIED TOTAL SHARP SCORE AT 1 YEAR IN PATIENTS WITH RHEUMATOID ARTHRITIS**

K. Inui 1, T. Okano 1, K. Orita 2, Y. Sugioaka 3, K. Mamoto 1, T. Koike 3,4, M. Tada 5, H. Nakamura 1. 1Department of Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka; 2Department of Orthopaedic Surgery, Shirahama Hamayu Hospital, Shirahama; 3Center for Senile Degenerative Disorders, Osaka Ohi University Graduate School of Medicine, Osaka; 4Search Institute for Bone and Arthritis Disease, Shirahama Foundation for Health and Welfare, Shirahama; 5Department of Orthopaedic Surgery, Department of Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan

**Background:** Matrix metalloproteinase (MMP-3), also known as stromelysin-1, is expressed in inflamed synovium of patients with rheumatoid arthritis (RA). It degrades components of articular cartilage, such as proteoglycans. In Japan, MMP-3 has been used as a clinical biomarker of joint destruction and its predictive value for radiographic progression has been reported.

**Objectives:** W aimed to confirm a relation between baseline MMP-3 and radiographic progression at 1 year and to examine the association of the MMP-3 level with ultrasonography (US) findings.

**Methods:** A total of 259 (213 women) consecutive patients with RA were enrolled. We collected baseline data, that included the patient’s age, sex, disease duration, use of glucocorticoid or disease modifying antirheumatic drugs, Disease Activity Score-28, and modified total Sharp score (mTSS); MMP-3 and, C reactive protein levels;, rheumatoid factor or anti-citrullinated peptide antibody status,; and the power doppler score (PD) of US assessment of digits and wrists. Baseline MMP-3 level was analyzed in association with the baseline PD value and changes (Δ) in mTSS, erosion score (ΔERN), joint space narrowing (ΔJSN) at 1 year from baseline by Pearson’s correlation method. Changes between ΔMMP-3 and ΔmTSS, or ΔPD were also analyzed. Multiple regression analysis was performed, with ΔmTSS as the outcome for baseline variables. Statistical analysis was performed separately by sex because the upper normal limits of MMP-3 differ between the sexes (men: <121 ng/ml, women: <9.7 ng/ml).

**Results:** There was a weak correlation between the baseline MMP-3 level and PD score in men. There was also moderate correlations between baseline MMP-3 level and structural damage at 1 year only in men. There was no predictive value for baseline MMP-3 level in women in terms of structural damage at 1 year. Multiple regression analysis revealed that the baseline MMP-3 level correlated independently with the ΔmTSS only in men (p=0.0031), whereas in the women the baseline PD score was correlated independently with the ΔmTSS (p=0.0003).

**Conclusions:** The baseline MMP-3 level was a good predictor of deterioration of the mTSS at 1 year in male patients with RA, but not in female patients. On the other hand, the baseline PD score was a useful predictor of joint destruction in female patients with RA.

**AB0246 IMPACT OF TREAT TO TARGET STRATEGY WITH COMPLEMENTARY ULTRASOUND ON REAL WORLD RADIOPHIC OUTCOMES IN EARLY RHEUMATOID ARTHRITIS OVER THE PAST DECADE**

K. Kobayashi 1, K. Minegishi 1, S. Ohno 1, H. Nakajima 1. 1Center for Rheumatic Diseases, Yokohama City University Medical Center; 2Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan

**Background:** Treatment for rheumatoid arthritis (RA) has changed over the past decade. Early diagnosis and prompt aggressive treatment based on treat to target strategy, as well as complementary ultrasound have been adopted and proven to improve patient clinical and radiological outcomes in clinical trials.

**Objectives:** The aim of this study was to compare radiographic progression of early RA patients starting their first DMARD 10 years ago vs more recently in daily clinical practice.

**Methods:** We reviewed the medical records of consecutive patients with symptom of 3 years duration who fulfilled the 1987 ACR classification criteria or the 2010 ACR/EULAR classification criteria in a single center retrospectively. In the first cohort (2000s), 70 patients (55.3±13.3y.o, Female 77%) who were diagnosed with RA during 2003–2005 were included. in the second cohort (2010s), 71 patients (54.5±17.3y.o,Female90%) who were diagnosed with RA during 2013–2015 were included. Radiographs of hands were assessed at baseline and one year after according to the van der Heijde Sharp score (range 0–280) without clinical information and chronological orders of radiographs in the individual patients.

**Results:** Mean changes in radiographic joint damage for joint space narrowing score, erosion score, total radiographic score were higher in 2010s than 2000s (0.92±2.70 vs 0.28±1.86; p=0.010, 0.54±1.35 vs 0.35±0.99; p=0.390, 1.45±3.54 vs 0.68±2.55; p=0.015, respectively). Radiographic progression defined as total radiographic score >0 and ≤5 were 31.4% and 22.5% and 8.6% vs 8.5% between 2000s and 2010s (p=0.230 and p=0.970, respectively). Methotrexate (MTX) was frequently used for initial treatment in 2010s than 2000s (86% vs65%, <0.001), and initial dose and maximum dose of MTX were higher in 2010s than 2000s (9.1±2.09 mg/week vs 4.67±1.54 mg/week; p<0.001 and 12.0±4.73 mg/week vs 8.13±1.84 mg/week; p<0.001, respectively). The mean duration from symptom onset to diagnosis was earlier in 2010s than 2000s (5.75±5.04 months vs 7.85±6.85 months, p=0.001), CRP at baseline and 1 year after were lower in 2010s than in 2000s (2.74±1.90 mg/dL vs 3.35±9.4 mg/dL; p=0.001 and 0.60±1.19 mg/dL vs 1.20±1.99 mg/dL; p=0.003, respectively). There were no significant differences in sex, age, positive rate of RF and ACRA, the Sharp score at baseline, steroid use, and biological agents use between two cohorts.

**Conclusions:** In recent 10 years, early diagnosis with complementary ultrasound and appropriate MTX use based on treat to target strategy led to prevent joint destruction of RA patients in daily clinical practice.

**AB0247 EVALUATION OF RHEUMATOID ARTHRITIS CASES WITH HIGH ANTI-CCP ANTIBODY LEVEL**

K. Suzuki, M. Minami, Y. Nishio, N. Hara, S. Nakamura, Hokkaido Orthopedic Memorial Hospital, Sapporo, Japan

**Background:** Anti-cyclic citrullinated peptide antibodies (Anti-CCP Ab) are well-established serological markers that show high sensitivity and specificity in diagnosing early rheumatoid arthritis (RA). Furthermore, Anti-CCP Ab is reported to be associated with bone erosions of RA. Therefore, Anti-CCP Ab positive RA patient can be a candidate for intensive treatment.

**Objectives:** Upper measurement limit of Anti-CCP Ab increased recently up to 1200 units. High level of Anti-CCP Ab may be a predictor of the profound therapy for RA. To understand the importance of Anti-CCP Ab level, we evaluated RA patients with high titer Anti-CCP Ab in relationship to the other activity markers of RA and the intensity of the treatment for RA.

**Methods:** Total of 186 RA patients with Anti-CCP Ab higher than 30 units was included in this study. Baseline markers such as CRP, MMP-3, RF and anti-CCP Ab were measured at the entry of the study. Relationship among these markers were evaluated and examined using statistical significance for the single-factor ANOVA and the multiple comparison test. Among those cases 131 cases were treated conservatively with biologics and/or DMARDS and were followed up more than one year. We graded them from 1 to 4 by the intensity of the treatment.

Grade I: Biological agent. Grade II: Methotrexate (MTX) more than 12mg or combination with more than 3 DMARDS Grade III: MTX 6–11mg or combination
with two recommended DMARDs Grade IV: single use of DMARDs including MTX less than 5mg.

**Results:** There was no relationship between titers of Anti-CCP Ab and titers of RF. We found significant statistical correlation between anti-CCP antibody titers and inflammatory markers such as CRP and MMP-3. There was significant statistical correlation between CRP and MMP-3. In terms of treatment intensity, strong intensity group showed high titer of anti-CCP Ab and CRP. Titer of RF and MMP-3 level did not have any relationship with the treatment intensity. In cases treated with biologics, anti-CCP Ab and CRP were significantly higher compared to non-biologic case group. In 80% of cases treated with biologic treatment of anti-CCP Ab titers was more than 200 units. However, non-biologic treatment was continued in more than 50% of cases with anti-CCP Ab higher than 200 units.

**Conclusions:** Even though we treated cases based on the severity of the symptoms of the patient and response in laboratory data, high anti-CCP Ab titers and CRP at the base line were most associated with the treatment intensity after 1 year. The results of our study suggest that the titer of anti-CCP Ab can be better a predictor of the treatment intensity than MMP-3 and RF.

**IDENTIFICATION OF INFLAMMATORY- AND IMMUNE DISORDER-RELATED PROTEINS AS PUTATIVE BIOMARKERS FOR IMPROVING RHEUMATOID ARTHRITIS MONITORING**

L. González-Rodríguez 1, V. Calamia 1, L. Lourido 1, P. Fernández-Puente 1, M. Camacho-Encina 1, C. Ruiz-Romero 1, A. Julià 2, A. Fernández-Nebro 3, J. Tornero 4, S. Marsal 2, F.J. Blanco 1, 1Proteomics Group, Rheumatology Division, Hospital Universitario A Coruña; 2Rheumatology Research Group, Vall d’Hebron Hospital Research Institute, Barcelona; 3UGU Reumatología, Instituto de Investigación Biomédica (IBIMA), Hospital Regional Universitario de Málaga, Málaga; 4Hospital Universitario Guadalajara, Guadalajara, Spain

**Background:** Rheumatoid arthritis (RA) is a long-lasting inflammatory autoimmune disorder that ultimately leads to the destruction of joints. Potential biomarkers are needed for an early diagnosis and monitoring the disease.

**Objectives:** Using the DAS28 activity index, 80 RA serum samples (40 with low activity and 40 with high activity) were selected in order to be analyzed by mass spectrometry. The aim of this study was to find possible protein biomarkers that could discriminate patients with different RA activity in the daily clinical routine.

**Methods:** In order to facilitate the complex measurement of these serum samples, a simple, fast and reproducible albumin-specific depletion method using ethanol was optimized and applied to this study. Four independent pools of the 40 high RA activity samples (10 samples per pool) and 4 pools of the 40 low RA activity samples were firstly albumin-depleted, and then the remnant serum proteins were digested and differentially labelled with iTRAQ 8-plex reagents. Subsequently, the 8 labelled pools were combined and cleaned using StageTips-C18. Finally, the pool mixture was fractionated by HPLC (Zorbax-C18) and the resulting fractions were analyzed by nanoLC-MS/MS using two different equipments for validation (MALDI-TOF/TOF and TripleTOF).

**Results:** The mass spectrometry analysis led to the identification of 186 proteins. Among these, Haptoglobin, Kininogen-1, Alpha-2-HS-glycoprotein, Serum Amyloid A, Atamin and Histidine-rich-glycoprotein, exhibited a differential relative abundance depending on the RA activity of the patients (p<0.03) in both analysis. These proteins were also validated by other orthogonal techniques (western blot, ELISA and protein arrays).

**Conclusions:** In this proteomic study, 9 proteins were found to be modulated between patients with high and low RA activity. Most of these proteins are related with the RA process and the effects caused by this type of disease (inflammation and immune disorder in joints). Therefore, these proteins are possible biomarker candidates for improving RA monitoring. Future validation experiments and prospective studies are needed to facilitate their implementation in the clinical routine.

**AB0250**

**THE ADIPOSE TISSUE AS PREDICTIVE FACTOR OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS: EVALUATION OF BODY FAT COMPOSITION BY BIOELECTRICAL IMPEDANCE ANALYSIS AND ULTRASONOGRAPHY**

M.G. Anelli 1, C. Rotondo 2, R. Fanizzi 2, O. Magazzino 2, M. Giannotta 2, M. Giannini 2, O. Lorusso 2, E. Praino 3, M.T. Viggiani 3, F. Cacciapaglia 3, M. Barone 3, G. Lapadula 3, F. Iannone 2, 1DIM; 2DET, Unit of Rheumatology; 3DET, Gastroenterology Unit, Bari, Italy

**Background:** Adipose tissue (AT) is an endocrine organ able to secrete the adipokine" molecules that contribute to the low-grade inflammatory state in obese subjects and to the local inflammation that affects joints and bone (1,2). High-grade inflammation, in course of RA, leads to an altered body composition (3,4), characterized by the increasing of fat mass and the decreasing of lean mass, mostly not associated to body mass index (BMI) variations (3,5). The BMI is not able to differentiate visceral (VTH) and subcutaneous (STH) fat tissue and to distinguish between muscle mass and fat mass body composition (BC) (6,7). Alternative methods proposed for assessment of visceral fat deposition, are described in the present study.

**Objectives:** The aim of the study is to investigate if BC, assessed by BIA and US,
correlates with disease activity (assessed by the Disease Activity Score using 28 joint counts – DAS28) and affects the response to the therapy (DAS 28 variation from first evaluation).

Methods: 87 consecutive RA patients (pts) (72 women and 15 men; aged 52.4±13.2 years; disease duration of 10.7±8.6 years), treated with DMARDs and/or biologics (bDMARDs), were recruited during their regular visit. The inclusion criteria were the 1987 American College of Rheumatology (ACR) or ACR/EULAR 2010 classification criteria. The pts underwent to anthropometric measures (BMI); abdominal US to assess STH and VTH and derived computing of peritonal circumference (PC); and BIA to the indices of body composition (fat-free mass index (FFMI) and fat mass index (FMI)).

Results: We observed increasing values of BMI, FMI, VTH (fig. 1) and CP with the worsening of disease activity phases, evaluated by DAS 28. In particular, pts with DAS28≥5.1 had highest BMI (30.9±2; p=0.036), FMI (11.5±1.6; p=0.05), CP (92.7±12.5 cm; p=0.035) and VTH (24.8±5.8 mm; p=0.046) than pts in less severe disease activity. By linear regression analysis the predictor of higher DAS28 is the BMI (p=0.028). As regard the drug response, the predictors of DAS 28 improvement are higher FFMI (p=0.044) and lower BMI (p=0.015), independently by bDMARDs or DMARDs treatment.

A trend to higher FMI and US AT measures was observed in female with high disease activity, in particular in menopause pts.

Conclusions: An altered fat distribution is observed in active RA phases; in particular, the FMI increasing is attributable just to visceral AT (VTH and CP). An inflammatory hyperactivity of visceral adiposity could be supposed in RA. The body composition, in addition to BMI, seems to predict the disease activity and drug response in RA patients. The evaluation of VTH by US could be useful to not overestimate the disease activity; instead the BIA could be a useful tool to support the clinicians in a more aggressive treatment management.

AB0251 THE IMPACT OF THE RHEUMATOID FOOT ON FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS EVALUATED BY FFI AND LFIS

M. Erraoui, B. Amine, L. Tahir, I. El Binoune, J. Bahha, S. Fellous, Y. Boujermen, F. Allai, R. Bahri. Rheumatology, Mohammed V University, Faculty of Medicine and Pharmacy of Rabat. El Ayachi Hospital, SALE, Morocco.

Background: The impairment of function in patients with rheumatoid arthritis (RA) is determined by several factors related to the disease including joint damage. The foot, a location frequently affected during course of the disease, has a major impact on the lower limb and could cause functional disability.

Objectives: The purpose of this study is to evaluate the impact of the rheumatoid foot on function of patients with RA.

Methods: Cross-sectional study was conducted in 33 patients with RA. Patients with static lower limb disorder or foot injury from other origin were excluded. Demographic and clinical characteristics were collected: age, sex, BMI, disease duration, tender joint count, swollen joint count, foot pain evaluated on anVAS, foot squeeze test and various podiatric abnormalities observed clinically (forefoot, midfoot and rearfoot). Biological characteristics also collected: sedimentation rate in the first hour, C reactive protein, rheumatoid factor and anti-CCP.

Disease activity was evaluated by DAS28, CDAI, SDAI and DAS44. Functional repercussions were estimated by the French Functional Index (FFI), comprising 23 items, divided into 3 sections: pain, function and limitation of activity. Functional disability was studied by the Leeds Foot Impact Scale (LFIS), which includes 51 items (21 items specific to foot function alteration (LFIS-I) and 30 related to foot disability (LFIS-D)). Statistical analysis was performed using SPSS21 software.

Results: Thirty-three patients followed for RA were included. The mean age of our patients was 49.39±10.52 with a female predominance (87.9%). Mean disease duration was 9.96±7.49 years. In all patients; 21 (95.5%) were seropositive. The mean DAS28 was 5.5±1.38 and the mean HAQ was 1.37±0.83. 93.9% of our patients had bilateral foot pain; 69.7% in the forefoot, 18.2% in the midfoot and 42.4% in the hindfoot. The medial retromalleolar tufefaction was found in 21.2% of the patients and the lateral retromalleolar tufefaction in 45.5% of them.

The squeeze test was positive in 23 (69.7%) patients. Prevalences of Podiatric abnormalities were noted in the following ordre: hallux valgus (48.5%), quintus varus (12.1%), hallux rigidus (6.1%), claw toe (15.2%), triangular forefoot (9.1%), rearfoot valgus (27.3%) and rearfoot varus (27.3%).

Mean FFI was 52.35±25.63 (FFI-pain: 58.69±24.41, FFI-function: 53.63±30.48 and FFI- limitation of activity: 39.33±30.58). Mean LFIS-I was 1136. Mean LFIS-D was 19.96.

Conclusions: Joint destruction over time was more pronounced in the feet than in the hands. Baseline erosions limited to the feet were associated with low disease activity, suggesting that inflammation localized to the feet may not be reflected by DAS28. These observations may have relevance to the evaluating of disease activity and progression in the individual patient. Possibly inclusion of the feet to DAS28 might improve the validity of this disease activity measure.

TIPS ON SELECTION OF BIOLOGICS FOR PATIENTS WITH RHEUMATOID ARTHRITIS BASED ON TREATMENT PATTERNS

M. Kamiya 1, S. Soen 1, H. Kikuchi 2, N. Okada 3, 1 Department of Orthopaedic Surgery and Rheumatology, Kindai University Nara Hospital, Ikoma-City; 2 Department of Orthopaedic Surgery and Rheumatology, Kindai University Sakai Hospital, Sakai-City; 3Department of Orthopaedic Surgery, Sumoto Itsumi Hospital, Sumoto-City, Japan

Background: The emergence of biologics has led to innovation in the treatment of rheumatoid arthritis (RA). In the clinical setting, biologics are administered with careful consideration of complications and medical history in accordance with the treat-to-target recommendations. However, the progression of joint damage, the costs incurred before finding an effective biologic are serious concerns. It is therefore desirable to use biologics with long-term efficacy and less financial burden from the early stage.

Objectives: Participants were RA patients treated with one of three biologics having different mechanisms of action who achieved therapy targets with long-term treatment patterns were evaluated.

Methods: Between November 2004 and October 2016, 196, 57, and 85 RA patients were treated with etanercept (ETN), tocilizumab (TCZ), and abatacept (ABT), respectively, in first- or second-line therapy. These patients were divided into the continuation group, who underwent therapy with the same agent for ≥3 years without disease flare (DAS28-ESR ≥3.2) persisting 3 months, and the discontinuation group, who experienced primary failure resulting in discontinuation of the therapy within 3 months. Student’s t test or Mann-Whitney’s U test were used to compare therapy continuation rates and reasons for discontinuation among the three biologics. Finally, relative dose intensity (RDI) was calculated to evaluate the treatment patterns of the individual biologics.

Results: The Kaplan-Meier method showed that the 3-year continuation rates of therapy with ETN, TCZ, and ABT were 54.2%, 23.8%, and 35.8%, respectively: the continuation rate of ETN was significantly higher than that of the other two agents. The numbers of patients treated with ETN, TCZ, and ABT were respectively 46, 9, and 14 in the continuation group and 16, 12, and 11 in the discontinuation group. The proportion of patients treated with ETN plus concomitant MTX was significantly higher in the continuation group than in the discontinuation group (P<0.0057). No significant differences were found in patients’ background characteristics (disease duration, rheumatoid or anti-cyclical citrullinated peptide positivity, number of biologies previously used, and DAS28-ESR). Mean RDI values (median value, 95% confidence interval) over a 3-year period were as follows: 0.95 (0.92, 0.83–1.06) for 25 mg/week ETN therapy; 0.78 (0.90, 0.66–0.89) for 50 mg/week ETN therapy; 0.84 (0.84, 0.76–0.89) for TCZ therapy; and 0.76 (0.76–0.85) for ABT therapy. The cumulative costs for 3 years of the respective treatments were 19,700, 32,200, 27,300, and 39,000 euros (1 euro =115 Japanese yen). After targets were reached, the dose of ETN was maintained at 25 mg/week or reduced from 50 mg/week, while the TCZ and ABT therapies were continued over the long term with a longer dosing interval.

Conclusions: Treatment with ETN plus concomitant MTX showed high continuation rates, and long-term achievement of therapy targets was maintained at a lower dosage (and thus, lower costs). It is beneficial to choose this method over non-TNF inhibitors.

AB0254 COMPARISON OF DYNAMIC PEDOBAROGRAPHIC FINDINGS BETWEEN RHEUMATOID ARTHRITIS PATIENTS AND HEALTHY INDIVIDUALS

S. Ghadimy, M. Aarabi, N. Abdolahi, N. Nematollahi, M. Aghaei. Rheumatology Research Center, Gorgan, Iran, Islamic Republic of

Background: Foot involvement happens early in RA patients and situation hadn't happened yet. Since we excluded patients with severe deformities and those who couldn’t walk alone from the study, and our cases were relatively in early stages of disease, we didn't find any significant difference in pressure or force between symptomatic patients with and without radiographic findings. This can be explained by the fact that foot pressure alteration detectable in pedobarography is already begun in all RA patients with foot symptoms but radiologically evident pathologies had not happened yet.

Conclusions: RA has considerable effect on patients’ feet along with other physical and mental issues. While conventional radiological methods has a limited efficacy in predicting and diagnosing the pathologic changes in foot region, pedobarography can easily shows these changes in foot pressure values and can be used to detect RA patients that need simple interventions like using proper insoles to prevent surgical interventions.

AB0255 EVALUATION OF KINESIOPHIA IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS

Background: Fear avoidance behavior which is caused by painful injury resulting precision and extreme fear is defined as kinesiophobia. Rheumatoid arthritis (RA) is a chronic, inflammatory and systemic disease with symmetrical arthritis and visceral involvement. Ankylosing spondylitis (AS) is a chronic, inflammatory disease with involvement of peripheral or spinal joints.

Objectives: In our study, we aimed to evaluate the relationships between kinesiophobia and disease activity, quality of life (QoL), level of physical activity and emotional status in RA and AS patients.

Methods: We included 80 patients, with RA (8 males-M, 34 females-F) (group 1), 49 patients with AS (34 M, 15 F) (group 2) and 29 healthy controls (9 M, 20 F) (group 3) in our study. The QoL was assessed using the health assessment questionnaire (HAQ), kinesiophobia was assessed with Tampa scale of kinesiophobia (TSK), pain was assessed with visual analog scale (VAS), fatigue was assessed with VAS and emotional status was assessed with Beck depression inventory (BDI). Disease activity was assessed with Bath ankylosing spondylitis disease activity index (BASDAI) and functional status was assessed with Bath ankylosing spondylitis functional index (BASFI) in patients with AS. Disease activity was assessed with patients with RA.

Results: The mean age was 46.2 in group 1, 43.2 in group 2 and 40.17 in group 3. There was no difference among groups with respect to mean age (p>0.05). Kinesiophobia was present in 37 patients in group 1, 22 patients in group 2 and 7 patients in group 3. Statistically significant differences were found among groups.

with respect to the number of patients with kinesiophobia and to mean scores of pain intensity, fatigue, HAQ and BDI (p=0.05−0.001). Patients with RA had higher rates of kinesiophobia than patients with AS and healthy controls (p=0.001, p=0.001). Patients with RA had worse scores than patients with AS and healthy controls. Patients with AS had worse scores than healthy controls. In patients with RA and AS, kinesiophobia is associated with pain severity, fatigue, emotional status and QoL.

Conclusions: In our study, patients with RA and AS had higher rates of kinesiophobia. We found that kinesiophobia was related with pain severity, fatigue, depression, disease activity and QoL of the patients. The QoL can be improved through controlling kinesiophobia by reducing pain, depression and fatigue.

SERUM AND SYNOVIAL KYNURENIC ACID CONCENTRATION AND ITS CORRELATION WITH DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: CLINICAL AND ULTRASONOGRAPHIC STUDY

F. Elshabacy1, T. Fathy Mohammed1, M.A. Mortada2, H.A. EL-Saadany3, S.M. Farouk4, E.R. Amer5, 1Rheumatology, Benha Teaching Hospital, Benha; 2Rheumatology & Rehabilitation, Zagazig University, Zagazig; 3*Internal medicine and Rheumatology, Military Medical Academy, Cairo; 4Clinical Pathology, Benha Teaching Hospital, Benha, Egypt

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease. Kynurenic acid has anti-inflammatory effects, because it is the most important agonist of the orphan G-protein-coupled receptor (GPR35) which expressed on various types of cells associated with the immune system. Stimulation of these receptors by kynurenic acid lead to reduction in the synthesis of proinflammatory cytokines, nitric oxide, and reactive oxygen species (1).

**Objectives:** Detection and quantification of kynurenic acid in serum and synovial fluid obtained from the affected joints in patients with rheumatoid arthritis and its relation to different and synovial aspects of disease activity and signs of synovitis and synovial hyperplasia detected by musculoskeletal diagnostic ultrasound.

**Methods:** Thirty RA patients diagnosed according to ACR and EULAR revised criteria and thirty patients of idiopathic knee osteoarthritis as a control group were enrolled in the study. These patients were collected from outpatient clinic of rheumatology department Benha Teaching Hospital. Kynurenic acid was assessed in Serum samples from all patients and controls coupled synovial fluid samples aspirated from knee joint of all RA patients and fourteen OA patients after musculoskeletal ultrasonographic examination of these joints.

**Results:** Serum and synovial level of kynurenic acid was assessed in the studied groups. Comparison between RA and OA patients as regard serum kynurenic acid showed no differences where it’s level was 29.80±13.86 pg/ml in RA versus 30.98±11.03 pg/ml in OA patients), while synovial kynurenic acid was significantly lower in RA (16.38±6.45 pg/ml) than in OA patients (26.22±2.99 pg/ml (p<0.001). Kynurenic acid was significantly lower in synovial fluid (16.38±6.45 pg/ml) than in serum (29.80±13.86 pg/ml) in RA group of patients (p<0.001). Comparison among different grades of synovitis detected by grey scale U/S and by Doppler signals in RA patients as regard serum kynurenic acid showed that it was significantly lower in hypoperfused grade of synovitis (P<0.001). Synovial kynurenic acid level was negatively correlated with grades of synovitis and Doppler signals (p<0.001).

**Conclusions:** The negative correlation between Kynurenic acid concentration in the synovial fluid and both the synovial thickness detected by ultrasonography and the hyperaemia of synovial tissues as represented by the Doppler activity, may support its use as a local marker of the two faces of rheumatoid arthritis (chronicity and activity) at the joint level.

To the best of our knowledge, this is the first study that gives correlation between the serum and synovial levels of kynurenic acid concentrations and the grade of synovitis detected by grey scale and Doppler ultrasonography.

SCREENING OF DIFFERENTIALLY EXPRESSED SERUM PROTEINS FOR RHEUMATOID ARTHRITIS BY SURFACE-ENHANCED LASER DESORPTION/IONIZATION-TIME OF FLIGHT-MASS SPECTRA

N. Liang, L. Zhang, K. Xu. Shanxi academy of medical sciences Shanhui dayi Hospital, TaiYuan, China

**Background:** RA is a chronic inflammatory rheumatic disease, and early diagnosis and treatment can improve prognosis.(1) Surface-enhanced laser desorption/ionization-time of flight-mass spectrometry (SELDI-TOF-MS) combines a protein chip and mass spectroscopy technology own the advantages of low dosage of samples, direct point sample detection and high sensitivity.

**Objectives:** SELDI used to profile and compare the proteomes in serum samples of RA patients including complicated with Sjogren’s syndrome (SS), interstitial lung disease (ILD). Using Biomarker Wizard software and Biomarker Pattern Software established diagnostic model, and calculate sensitivity and specificity,which can simplify clinical procedures, save medical costs and explore the pathogenesis.

**Methods:** Using the Biomarker Wizard and Biomarker Pattern software to screen the differentially expressed serum proteins, then establish disease activity prediction model to predict RA disease progression between the following groups, including simple RA patients (n=44) and RA-SS patients (n=18), RA patients (n=44) and RA-ILD (n=22), RA patients (n=44) and RA-ONFH (n=6). Also 96 RA patients and 77 healthy control, which were randomly allocated to the training set (83 RA patients and 56 healthy controls) and test set (14 RA patients and 20 healthy controls) to develop and verify a pattern by means of decision treearoboom. Using the Biomarker Wizard and Biomarker Pattern software to establish the disease diagnosis model to predict RA disease progression between the following groups, including simple RA patients (n=44) and RA-SS patients (n=18), RA patients (n=44) and RA-ILD (n=22), RA patients (n=44) and RA-ONFH (n=6). Also 96 RA patients and 77 healthy control, which were randomly allocated to the training set (83 RA patients and 56 healthy controls) and test set (14 RA patients and 20 healthy controls) to develop and verify a pattern by means of decision treearoboom.

**Results:** 1. Comparison of RA patients and healthy controls: there are 22 up-regulated expression in RA, 36 down-regulated. The diagnostic model of M/23448.857.4716.712.8214.285 and 10645. The sensitivity and specificity is 91.566% and 92.857%, the area under the ROC curve was 0.937, to verify the diagnostic model, we use 95% confidence interval of 0.914−0.950. The diagnostic model of M/212595.86. The sensitivity and specificity is 86.4% and 84.1% and the area under the ROC curve was 0.856. 2. Comparison of the simple RA and RA-SS: The sensitivity and specificity is 77.8% and 78.5% and the area under the ROC curve was 0.794.

**Conclusions:** The serum protein fingerprinting by SELDI-TOF-MS could identify new biomarkers in RA. The biomarkers may play an important role in pathogenesis of RA. We could diagnose RA in early stage, predict disease progression and determine disease activity by these biomarkers.

AGE AND QUALITY OF LIFE AMONG RHEUMATOID ARTHRITIS PATIENTS TREATED WITH BIOLOGIC AGENTS

N. Ogura, N. Yajima, Y. Miwa. Rheumatology, Showa University School of Medicine, Nishinakano, Shinagawa Ward, Tokyo, Japan

**Background:** Rheumatoid arthritis (RA) is a common autoimmune disease of unknown etiology which is characterized by symmetric, chronic inflammatory, peripheral polyarthritis. If it is untreated or unresponsive to therapy, inflammation and joint destruction lead to loss of physical function, inability to carry out daily tasks of living.

In addition to problems related to pain and inflammation, patients with RA are also affected by psychological problems such as anxiety and depression. It has been a while since, the biologic agents have let RA patients to early remission, and improved their Quality of life (QOL).

A few studies show relevance between age and QOL among RA patients. Lambert et al. found that age was positively correlated with pain, indicating that increasing age made the situation worse.

**Objectives:** This study aimed to assess the relationship between age and QOL of RA patients who has been treated with biologic agents.

**Methods:** 149 RA patients who treated with biologic agents at Showa University Hospital, Showa University Northern Yokohama Hospital and Showa University Koto Toyo University Hospital were recruited from 2005 to 2016. This study design was retrospective cohort study. Loss to follow-up was eliminated. The patients were divided into two groups, whose age was 65 years old and over (elderly) and under 65 (adults). The primary outcome was the change of QOL in 6 months’. QOL was measured using SF-36, and we use physical component scale (PCS) and mental component scale (MCS). Logistic regression analysis was performed.

**Results:** Among 149 RA patients, the mean age was 57 years old and 85.9% was female. 92 out of 149 patients (61.7%) were adult group and 57 (38.3%) were elderly group. Adjusted with sex, disease duration, DAS28-ESR, HAQ, and with or without complications which are interstitial lung disease, diabetes mellitus, and chronic kidney disease, there was no significant difference in change of MCS in 6 months’. But those of PCS was significantly higher in adult’s group (regression coefficients -7.25; 95% Confidence Interval (CI) -11.7 to -2.77; p=0.0018).

**Conclusions:** There is a possibility that, younger patient who suffers with RA could achieve better quality of life than those of elderly patients after treatment with biologic agents.
from a dual X-ray absorptiometry database. Demographics and other risk factors, as well as fragility fractures, were recorded. Initially, those who had sustained a fracture were compared to those who had not sustained a fracture using chi-squared tests for categorical variables and T-tests for continuous variables. Following that, univariate and multivariable logistic regression models were fitted looking at the predictors of fracture. Variables included age at scan, height, weight, alcohol, smoking, family history, rheumatoid arthritis, secondary osteoporosis as defined by FRAX™, body mass index and steroid exposure, in addition to BMD in the lumbar spine and femoral neck.

Results: Of 2029 female patients were scanned in the referral period. The mean age at scan was 66 (SD 10.46), 356/2029 (17.5%) had sustained a fracture. Results of the univariate analysis are shown in table 1, significant predictors are indicated with an asterisk (*).

AB0261 CLINICAL AND STRUCTURAL RESPONSES OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS (RA) USING STEP-UP DOSAGES OF TOFACITINIB IN A TREAT TO TARGET APPROACH

N.B. Gaylis1, J. Saglani1, S. Nee dell2. *Arthritis and Rheumatic Disease Specialties, Aventura; 2Boca Radiology, Boca Raton, United States

Background: Tofacitinib has been shown to reduce the clinical signs and symptoms of some RA patients at an approved dose of 5 mg bid. Studies report that 10 mg bid is an effective dose. This is the first community practice trial to measure the clinical and structural benefits of stepping up the initial dose of 5 mg bid in non-responders to 10 mg bid in order to achieve a clinical response using a treat to target approach.

Objectives: This study evaluates the optimal dose of tofacitinib (5 mg bid VS 10 mg bid) needed to reach treatment target in a cohort of patients with active RA while comparing the corresponding structural findings measured by low field MRI.

Methods: 20 RA patients who were unresponsive to either methotrexate (10–25 mg weekly) or MTX plus up to 2 prior biologics with synovitis, osteitis or erosions on Baseline MRI (Esaote 0.3T) were treated with 5 mg bid tofacitinib with a treat to target goal of Low Disease Activity (LDA) or remission depending on the Clinical Activity Index (CDAI) score at Baseline. If the target was not met and sustained for 3 months, the dose of tofacitinib was increased to 10 mg bid in an attempt to reach target. MRIs of the hand/wrist were blindly read by a musculoskeletal radiologist using a rheumatoid arthritis MRI scoring system (RAMRIS). A CDAl score of >10 was needed at study entry.

Results: Of the 20 enrolled patients, 6 remained at 5 mg bid and 14 were dose escalated to 10 mg bid most at the 12 week period. Of the 5 mg bid group, 3 completed the trial at target and 3 early terminated (ET) for lack of efficacy, relapse and AE. Structurally, there was no change in erosions in all 3 patients; 2 showed regression of synovitis and 1 showed no change; 2 showed regression in osteitis and 1 no change. Of the 14 patients escalated to 10 mg bid, 11 completed the trial with 7 remissions, 2 LDA and 1 MDA. 3 patients missed due to lack of efficacy. In the 10 mg bid group, 9 patients showed no change in erosions, 1 reduction and 5 progression. 5 patients showed no change in synovitis and 6 showed progression, and 7 showed no change in osteitis, 3 showed progression and 1 showed progression. The CRP values correlated with the improvement of

AB0259 PREDICTORS OF HIGH DISEASE ACTIVITY IN A COHORT OF GREEK PATIENTS WITH ACPA POSITIVE EARLY RHEUMATOID ARTHRITIS

N. Papadopoulos1, A. Gkagkali2, E. Konstantinidou3, L. Mentisidou1, G. Tzatzarakis4, V. Galanopoulou1, 1Rheumatology Unit; 2Gastroenterology Unit, Papageorgiou General Hospital; 3Molecular Biologist, PRIVATE; 41st INTERNAL MEDICINE CLINIC, Papageorgiou General Hospital, Thessaloniki, Greece

Background: In Early Rheumatoid Arthritis, the presence of ACPA positivity is associated with increased disease activity.

Objectives: To investigate possible predictors, for high disease activity (DAS-28 >5.1), in a cohort of Greek patients with ACPA positive early RA.

Methods: From 2000 until December 2016, 156 patients with ACPA positive early RA, were diagnosed and subsequently followed up as outpatients at the Rheumatology Unit of our hospital. Demographic, clinical, laboratory and therapeutic parameters were evaluated during every follow-up. At the end of the study (last visit during 2016), all the above parameters were re-evaluated, considering the high disease activity (DAS-28 >5.1). The used methods were χ², ANOVA, Binary Logistic Regression (BLR) and ROC Curve.

Results: From 156 patients, 25% were males, 37.8% were current smokers, 16% with anemia of chronic disease (ACD). At the time of diagnosis, Univariate ANOVA, Binary Logistic Regression (BLR) and ROC Curve. Based on the previous results the severity of disease can be predicted with sensitivity for smokers 2.95, for RF positivity 3.397 and for CRP 1.066 respectively. Based on the previous abstract and it showed that the use of AIs significantly reduced lumbar spine BMD (p<0.001) compared to untreated RA patients (p=0.001, CI=0.723–0.878) using the ROC curve.

Conclusions: That 10 mg bid is an effective dose. This is the first community practice trial to measure the clinical and structural benefits of stepping up the initial dose of 5 mg bid in non-responders to 10 mg bid in order to achieve a clinical response using a treat to target approach.

AB0260 THE PREDICTORS OF FRAILTY FRACtURES IN PATIENTS ON OMAZTATINb: An OBSERVATIONAL STUDY

N. Meah1, R. Sinha2, M. Bukhari2. 1Lancaster Medical School; 2Rheumatology, Royal Lancaster Infirmary, Lancaster, United Kingdom

Background: The use of aromatase inhibitors (AIs), given after breast cancer, has been associated with a low bone mineral density (BMD) and as a risk factor for fragility fractures. We have reported on the risk factor for low BMD in a previous abstract and it showed that the use of AIs significantly reduced lumbar spine BMD and femoral neck BMD (1). The FRAX™ tool uses the femoral neck BMD to predict fractures on a population basis but ignores the lumbar spine. Some patients who have undergone bilateral hip replacements would not be able to estimate their risk of fractures. In the 20 mg bid group, 3 completed the trial at target and 3 early terminated (ET) for lack of efficacy, relapse and AE. Structurally, there was no change in erosions in all 3 patients; 2 showed regression of synovitis and 1 showed no change; 2 showed regression in osteitis and 1 no change. Of the 14 patients escalated to 10 mg bid, 11 completed the trial with 7 remissions, 2 LDA and 1 MDA. 3 patients missed due to lack of efficacy. In the 10 mg bid group, 9 patients showed no change in erosions, 1 reduction and 5 progression. 5 patients showed no change in synovitis and 6 showed progression, and 7 showed no change in osteitis, 3 showed progression and 1 showed progression. Conclusions: Our results suggest that a significant number of patients treated with the standard dose of 5 mg bid may potentially have improved outcomes including LDA or remission when treated at a higher dose (10 mg bid). As is evidenced by the results in this study, 11 of the 14 patients had significant improved response after treatment with the step up dose. It would appear that this improved result occurs by 3 months of therapy. Furthermore, the structural findings correlate in large part to the clinical findings showing stabilization or improvement in the majority of patients. A larger study is needed to validate these clinical and structural responses as well as to evaluate the safety outcomes using 10 mg bid for intervals of more than 12 months.

AB0262 EVALUATION OF PATIENT REPORTED OUTCOME USING RAPIDS AND HAQ-DI COMPARED TO DAS28: EXPERIENCE FROM ROUTINE CLINICAL PRACTICE IN MALAYSIA

N. Mohd Jamid1, B. D’Souza1, H.C. Hong1, N. Mohd Noor1, C.K. Cheah1, Y.L. Lee2, S.C. Gun1, 1Hospital Tuanku Jaafar, Seremban; 2PFIZER, Kuala Lumpur, Malaysia

Background: Patient reported outcome (PRO) is an important measure for physician in management of patient with rheumatic diseases. Health assessment questionnaire disability index (HAQ-DI) is the most widely used PRO tool in rheumatoid arthritis (RA) clinical trials. Previous studies have shown that HAQ-DI correlates well with disease activity score of 28-joints (DAS28). However, routine assessment of patient index data 3 (RAPID3) is much simpler and faster to use.

Objectives: This study aims to evaluate the correlation between RAPID3 and DAS28 compared to HAQ-DI and DAS28 in our population.

Methods: RA patients who received routine treatment in Hospital Tuanku Ja‘afar from March to November 2016 were included in this study. Validated RAPID3 and HAQ-DI questionnaire were made available in other languages; Malay, Chinese and Tamil, for patients who were not English literate. Descriptive analysis were conducted. Pearson correlation was used to measure the correlation between these PRO tools while area under the curve of the receiver operating characteristic (ROC) curves evaluate the sensitivity to detect disease activity. DAS28-ESR and DAS28-CRP were used as the reference variable in ROC analysis to stratified the disease activity into two groups; low (remission and low) and high (moderate and severe)

Results: A total of 400 patients completed PRO assessments were available for analysis. The median age of our cohort was 57 years old (range 22 to 88) and 73.5% were female. Ethnic distribution in this cohort were as follows: 38.5% Indian, 31.8% Malay and 27.8% Chinese. Both RAPID3 (r=0.74,p<0.001) and HAQ-DI (r=0.57, p=0.001) were correlated with DAS28-ESR. The area under the curve was significantly higher in RAPID3 (83%) compared to HAQ-DI (75%) which implied greater performance in discriminating low and high disease activity using DAS28-ESR as reference. We observed similar performance trend between RAPID3 (92%) and HAQ-DI (82%) compared to DAS28-CRP.

Conclusions: In conclusion, RAPID3 is an effective quantitative measure of disease activity compared to HAQ-DI in our population. Furthermore, RAPID3 and HAQ-DI correlates well with disease activity score of 28 joints (DAS28). However, routine assessment of patient index data 3 (RAPID3) is much simpler and faster to use.
Conclusions: MBDA score may be of additional value in predicting DAS28 flares but not in predicting medication escalations or physician-reported flares in RA patients on TNFi in stable low disease activity.

**AB0264 THE PERFORIN A91V GENE AND CLINICAL FEATURES ANALYSIS IN CHINESE SO-JIA CASES WITH MACROPHAGE ACTIVATION SYNDROME**

P. Wei 1, H. Zeng 2, 3, Department of Pediatric Allergy, Immunology and Rheumatology, 4 Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China

**Objectives:** Macrophage activation syndrome (MAS) is a severe, potentially fatal complication of rheumatoid disease, especially in the systemic onset juvenile idiopathic arthritis (SoJIA). We aimed to investigate the clinical characteristics of 31 SoJIA cases with MAS and the perforin A91V gene were detected in part context.

**Methods:** gene-specific polymerase chain reaction (PCR) primers were used to analyze the perforin A91V gene polymorphism.

**Results:** 31 SoJIA cases were associated with MAS.25 out of 31 cases (83%) had infections prior to MAS. Serum ferritin was significantly increased in 27 cases (87.10%). High concentrations of triglycerides (23 cases, 74.19%) and lactic dehydrogenase (27 cases, 87.10%) were observed. What is more, Creatine Kinase (CK) increased in all cases that had been checked. Well-differentiated macrophages phagocytosing hematopoietic elements were found in all cases (100%) 6 cases (19.35%) merged with multiple organ dysfunctions (MODS). The perforin A91V (NCBI: SNP rs35947132) variant gene was detected in twenty cases, but no mutation was found. Corticosteroids, immunosuppressant, cell cycle inhibitors, immunoglobulin, Tumor necrosis factor (TNF) antagonist and plasminogen were effective. After treatment, 28cases (90.32%) children were in remission, while 3 out of 31 cases died with mortality of 9.68%.

**Conclusions:** MAS is a life-threatening complication of systemic onset juvenile idiopathic arthritis. Most cases were preceded by infection. Unrelated levetiracetam, progressive hepatosplenomegaly, lymphadenopathy, cytopenias, elevated serum liver enzymes significantly increased serum ferritin are the main feature. Early diagnosis and treatment is the key to improve prognosis. The perforin gene mutations in our patients have not found yet.

**AB0265 THE SIGNIFICANCE OF EARLY DIAGNOSIS AND PROGNOSTIC EVALUATION OF FOUR KINDS OF ANTI-CCP ANTIBODIES IN VARIOUS TYPES OF JUVENILE IDIOPATHIC ARTHRITIS**

P. Zeng 1, H. Zeng 2, 3, 1 Department of Pediatric Allergy, Immunology and Rheumatology, 4 Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China

**Objectives:** To investigate the relationship between immunological parameters AKA, anti-CCP, the RF-FGIG, RF-IGM and the early diagnosis and prognosis in sub-JIA patients.

**Methods:** Collection of 76 JIA patients in our hospital with system treatment and adhere to the follow-up treatment for at least six months, detect the immunological parameters of AKA, anti-CCP, RF-FGIG, RF-IGM in the early diagnosis, compare the Positive rate in different subtypes and prognosis, and make the statistical analysis of sensitivity, specificity and relevant risk, compare to the normal control group of blood of 49 healthy children.

**Results:** There is a significant difference between various types of JIA and general JIA patients in AKA positive rate, relative risk OR is 3.514.

**Conclusions:** The effect of AKA, anti-CCP, RF-FGIG, RF-IGM in the different subtypes of JIA diagnosis are different, it is found that AKA, anti-CCP has good sensitivity and specificity in polyarticular JIA, AKA appears relate with refractory JIA, it is a large sample of the study to be confirmed that whether it can be a serological marker in the early diagnosis and prognosis of Polyarticular JIA.

**AB0266 EFFECTS OF PERIODONTAL BASIC TREATMENT ON PERIODONTAL CONDITION, CLINICAL RESPONSE AND SERUM INFLAMMATORY PARAMETERS IN RHEUMATOID ARTHRITIS (RA) PATIENTS WITH MODERATE TO SEVERE PERIODONTITIS**

F. Xiao, P. Zhang, X. Li, Y. Mou, H. Chen, Y. Cai. The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

**Background:** Periodontal disease (PD) shares several clinical and pathogenic characteristics with Rheumatoid Arthritis (RA). Some intervention studies have suggested that periodontal treatment can reduce serum inflammatory biomarkers such as C-reactive protein, or erythrocyte sedimentation rate. Periodontal disorders are not only a threat to dentition, but may also be an aggravating factor in patients with RA, its treatment may improve the RA outcomes. In this study we assessed the effect of periodontal basic therapy in relieving the PD symptoms and the clinical signs of RA in order to evaluate the importance of periodontal treatment in the control of inflammation.

**Objectives:** To evaluate the effects of periodontal basic treatment on periodontal condition, clinical response and serum inflammatory parameters in RA patients with moderate to severe periodontitis.

**Methods:** A total of 46 subjects with confirmed diagnosis of RA and moderate to severe periodontitis were included in the study. 18 subjects completing the study received periodontal basic treatment consisting of scaling/root planing and oral hygiene instruction at baseline and at 6 weeks; 28 subjects completing the study received no treatment as control group. Participants continued using their usual disease-modifying medications for RA without any changes in DMARD therapy during the study period. Periodontal indices and RA measurements, such as probing depth (PD), clinical attachment level (CAL), bleeding on probing (BOP), high-sensitivity C-reactive protein (hsCRP), erythrocyte sedimentation rate (ESR), disease activity scale (DAS28) and subjective symptom were recorded at baseline, 6 and 12 weeks for each participant.

**Results:** After periodontal basic treatment, significantly lower PD, CAL and BOP were observed in the treatment group (P<0.01), hsCRP, ESR, DAS28 and patients' subjective symptom improved significantly (p<0.05). Besides, the PD and BOP were statistically significantly between treatment subjects after therapy and controls (P<0.001). Although hsCRP was significantly lower in the treatment group after therapy than controls (P<0.01), there was no significant difference in the DAS 28 level between the two groups after periodontal basic therapy (P>0.05). Visual analog scale (VAS) was used to evaluate patients' subjective symptom, the results show that the improvement was much better in patients received periodontal therapy than controls (P<0.001).

**Conclusions:** Periodontal basic treatment can effectively improve periodontal status, patients’ subjective symptom and circulating inflammatory status.

**AB0267 TREATMENT PARADIGMS IN REAL-WORLD PRACTICE: BIOLOGIC AGENT USE PRIOR TO AND AFTER DISCONTINUATION OF ABATCEPT IN THE ACTION STUDY**

**Background:** ACTION is a 2-year, observational study of patients (pts) with moderate-to-severe RA who initiated IV abatacept (ABA) in Canada and Europe (NCT02109666).

**Objectives:** To determine pt biologic (b)DMARD use prior to initiation and after discontinuation of ABA overall and by treatment line in ACTION.

**Methods:** Pts with RA initiated IV ABA as first- or second-line therapy were enrolled during three periods between May 2008 and December 2013. Pts could switch administration routes (IV to SC) during treatment. Crude retention rates (Kaplan–Meier) were compared by log-rank test.

**Results:** Of the 2364 pts enrolled, 2350 were evaluable for analysis: 673 (28.6%) were biologic naïve and 1677 (71.4%) biologic failures. Baseline characteristics differed: biologic-failure pts had longer RA duration, higher CRP levels and prevalence of radiographic erosions, and lower rates of chronic obstructive
pulmonary disease and neoplasms vs biologic-naïve pts. Most biologic-failure pts (96.7%) had previously received ≥ 1 TNF inhibitor (TNFi): 48.7% had received 1 and 48.0% ≥ 2 TNFi; 56.6% had received ≥ 2 bDMARDs. The overall 2-year retention rate was 47.9% and was higher for biologic-naïve vs biologic-failure pts (54.5% vs 45.2%; p < 0.001); the most common reasons for ABA discontinuation were inefficacy (61.4 vs 67.7%) and safety (31.3 vs 21.2%). A small proportion of pts started a bDMARD ≥ 6 months after discontinuation (Table), most commonly ABA IV. Mean (SD) days from stopping ABA to starting a bDMARD was similar for biologic-naïve [93.4 [51.3]] and biologic-failure pts [93.6 [46.0]]. Among pts who restarted ABA, 62% (80.5%) biologic-naïve and 158 (85.0%) biologic-failure pts were considered to have discontinued as the time from last dose was ≥ 84 (IV) or > 28 (SC) days, and thus were no longer temporary discontinuations, as predefined in the protocol. Three pts continued for bad compliance, 3 for lack of efficacy, 3 for remission/major improvement, 12 for safety and 15 for other reasons (Table). EULAR moderate improvement and 10% experienced a good response. In all, 20% of pts at the last follow-up before ABA discontinuation and 58.3% at ABA restart; mean (SD) DAS28 (CRP) was 3.2 (1.1) and 3.8 (1.4), respectively.

Conclusions: Prior to abatacept treatment, over half of biologic-failure pts had received ≥ 2 bDMARDs and most had received a TNFi. After initial discontinuation (protocol defined), over one-third of pts restarted abatacept.

Disclosure of Interest: R. Alten Grant/research support from: Bristol-Myers set as 0.05.

Results: We included 63 RA patients (81% of women), with a mean (SD) age of 61 (10) years and a mean disease duration of 19 (10) years, 86% RF-positive and 87% ACPA-positive. Bone erosions were present in 86% of the patients. At baseline, the mean DAS28 was 5.79 (1.55). Combination therapy with methotrexate and with others cDMARDs was used in 48% and 30% of the patients, respectively; RTX monotherapy in 22% of our sample. Thirty percent of patients were previously exposed to other biologics. The magnitude of response was greater in ACPA-positive vs ACPA-negative patients in terms of DAS28 variation at 6, 12, and 18 (median of 1.09 vs -0.08; 2.03 vs 0.35 and 2.10 vs 0.19; p < 0.029, p < 0.039 and p = 0.044, respectively), without significant differences between groups in terms of initial DAS28 (5.91 [1.60] vs 5.00 [0.90], p = 0.051). The presence of ACPA was also significantly associated with EULAR response at 6 months. 18 (64%), 75% and 85% in ACPA-positive patients vs 25%, 16% and 25% in ACPA-negative patients; p = 0.034, p = 0.010 and p = 0.001, respectively.

Outcomes did not differ according FR status. There were no associations between the values of FR, ACPA and IgG at baseline with the clinical response (DAS28 variation). CD19+ cells depletion occurred in all patients (mean of 146.4/mm3 at baseline vs 10.6/mm3 at 6M). An increase of peripheral NK cells was seen at 6M (mean 231/mm3 at baseline vs 289/mm3 at 6M). We only have found a positive correlation between NK cells number at baseline and DAS28 variation at 6 M (r = 0.35, p = 0.023). There were no associations between, neither NK cells, nor CD19+ cells variations at 6M with clinical response to RTX.

Conclusions: Our data suggest that ACPA seroreactivity is associated with a better clinical response to RTX in RA patients. NK cells at baseline may be useful to identify early responders to RTX.

RAPID RADIOGRAPHIC PROGRESSION PROGNOSTIC FACTORS IN A LATIN AMERICAN COHORT OF RHEUMATOID ARTHRITIS

Background: Rapid Radiographic Progression (RRP) in Rheumatoid Arthritis (RA) patients predicts long-term disability (1), high related economic costs (2) and loss of working time (3). Detection of RRP predictors as a necessary tool for aggressive therapeutic interventions has been proved, but in Latin-American cohorts, no available data had been reported.

Objectives: To determine independent risk factors associated with RRP in a cohort of RA patients.

Methods: A prospective analysis of RA Almenara cohort (January 2015-April 2016), 500 patients followed up with annual evaluations (background clinical/epidemiology, clinimetric, laboratory, health questionnaires and X-rays) who meet ACR 2010 criteria’s, older than 16 years at diagnosis, sign information, treatment, and disease activity were evaluated. A blinded rheumatologist for the RA condition read all films. Associated factors were analyzed (gender, socioeconomic level, smoking, age at diagnosis, time disease, use of biological and non-biological DMARDs, DAS 28, current steroids, HAQ/functionality, RA, sharp/VDH score and CRP). Clinical response delay and CRP were included to analyze risk factors in the RRP group. Statistical analyses were performed using linear regression models with logitlink. SPSS v. 21.0 was used.

Results: 153 patients, 90.8% women, middle low (37.9%) and middle (35.3%) the most prevalent socioeconomic status. Age at diagnosis was 46.06 (12.73) years, time disease 14.25 (10.26) years. DAS28 average: 4.51 (1.33). Basal Sharp VDH:104.53 (90.09), CRP: 9.77 (10.35) UI/L, RF: 352.49 (538.08) UI/L, ACPA: 563.64 (782.2)UI/dL, PR annual rate was 7.64 (2.4 years of follow-under one-third of pts restarted abatacept.

AB0268

ACPA SEROPOSITIVITY AND PERIPHERAL NATURAL KILLER CELLS AS PREDICTIVE MARKERS OF CLINICAL RESPONSE TO RITUXIMAB IN RHEUMATOID ARTHRITIS PATIENTS

Background: The efficacy of B cell-depletion therapy confirms the importance of B lymphocytes in rheumatoid arthritis (RA) pathogenesis. Rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) are prognostic factors for a more severe disease. Others immune elements, namely natural killer (NK) cells, seems to influence RA clinical response to rituximab (RTX), but data are lacking.

Objectives: To analyze the influence of baseline status/levels of RF, ACPA and serum immunoglobulin G (IgG) level in RTX treatment. To study the effect of RTX on NK and CD19+ cell populations and their association with clinical response at 6, 12 and 18 months (M).

Methods: An observational retrospective study was conducted, including all the consecutive patients with diagnosis of RA under rituximab, followed at our Rheumatology department. Demographic and clinical data were obtained by using the shared database (ReumaD) and the analysis was limited until December 2016. RF, ACPA and IgG titles were evaluated at baseline. NK (CD56+CD16+) and B lymphocytes (CD19+) absolute counts were assessed by flow cytometry prior to the first RTX cycle and 6 M after. Clinical responses were assessed by DAS28 and EULAR criteria at 6, 12 and 18 M. Correlations were studied using Spearman correlation coefficient (Spearman coefficient 20.0). Significance level was set as 0.05.

Results: We included 63 RA patients (81% of women), with a mean (SD) age of 61 (10) years and a mean disease duration of 19 (10) years, 86% RF-positive and 87% ACPA-positive. Bone erosions were present in 86% of the patients. At baseline, the mean DAS28 was 5.79 (1.55). Combination therapy with methotrexate and with others cDMARDs was used in 48% and 30% of the patients, respectively; RTX monotherapy in 22% of our sample. Thirty percent of patients were previously exposed to other biologics. The magnitude of response was greater in ACPA-positive vs ACPA-negative patients in terms of DAS28 variation at 6, 12, and 18 (median of 1.09 vs -0.08; 2.03 vs 0.35 and 2.10 vs 0.19; p < 0.029, p < 0.039 and p = 0.044, respectively), without significant differences between groups in terms of initial DAS28 (5.91 [1.60] vs 5.00 [0.90], p = 0.051). The presence of ACPA was also significantly associated with EULAR response at 6 months. 18 (64%), 75% and 85% in ACPA-positive patients vs 25%, 16% and 25% in ACPA-negative patients; p = 0.034, p = 0.010 and p = 0.001, respectively.

Conclusions: Our data suggest that ACPA seroreactivity is associated with a better clinical response to RTX in RA patients. NK cells at baseline may be useful to identify early responders to RTX.

**AB0260** HOW DOES THE ACTIVITY OF RHEUMATOID ARTHRITIS AFFECT 2-T WAVE OF RECENT ONSET PATIENTS WITH A 5-YEAR FOLLOW-UP?

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory joint disease affecting 0.5% of Spanish population. This disease results in a significant radiological and functional deterioration, decreasing the quality of life and increasing health costs. RA specific treatment is not well established. Therefore, the radiological and functional deterioration progress slowly during the whole course of the disease, it has been proven that early and aggressive approach to the disease is important in order for its control because the final outcome can be improved with a close, intense and early follow-up.

**Objectives:** To describe the clinical characteristics and evolution during 5 years of disease activity in RA patients derived from a recent arthritis clinic.

**Methods:** A prospective longitudinal study was carried out of 154 patients diagnosed from 2003 to 2012. They included patients over 18 years old diagnosed with RA (ACR criteria 1987) and with 5 years of follow-up. Socio-demographic and clinical variables such as Rheumatoid Factor (RF) antibody, immunoglobulin G (IgG) rheumatoid factor (RF), anti-citrullinated peptide antibodies (ACPA) or disease activity (DAS28- VASG) as well as treatment were assessed in those patients. Mean and standard deviation of quantitative variables and frequencies and percentages of qualitative variables were calculated.

**Results:** Of the 154 patients, 66.2% were females with a mean age at diagnosis of 52.8±14.64 years. Only 18.8% (29) patients were smokers; 67.5% (104) of patients were RF positive and 57% (88) of them were ACPA positive. Clinical remission measured by means of DAS28- VASG (<2.6) was achieved in 84 patients (54.5%), 92 patients (59.7%) and 95 patients (61.7%) after 1, 2 and 5 years, respectively. Mean values of DAS 28 were 2.58 (2.02) at first year, 2.61 (1.99) at two years and 2.59 (2.02) at 5 years. Of the 154 patients, 108 (78.8%) started treatment with monotherapy (mostly methotrexate) and after 5 years only 18 (25.7%) patients were on biological treatment. No differences were found when remission was compared at first, second and 5 years of follow-up.

**Conclusions:** These results suggest that achieving an early control of the disease is of importance, since control of the disease becomes more difficult as the delay of the diagnosis increases.

**AB0272** THE PERFORMANCE OF A SINGLE CENTRE INTERVENTIONAL CLINIC IN EARLY RHEUMATOID ARTHRITIS

**Background:** In early rheumatoid arthritis (RA), first assessment by a rheumatologist and/or initiation of disease-modifying anti-rheumatic drugs (DMARD) within 12 weeks of symptom onset are associated with a significant benefit in long-term disease outcome.

**Objectives:** Our objective was to determine the proportion of patients with newly diagnosed RA in whom first rheumatologist assessment and/or initiation of DMARD therapy was within the desired time frame.

**Methods:** A retrospective chart review of adult patients diagnosed with RA during 2014 and 2015 was performed at the rheumatology department of an integrated secondary/tertiary teaching hospital that provides rheumatology services for a population of more than 500,000 residents. Potential cases were identified by searching the electronic medical records for ICD-10 codes M05.7 and M06.* Electronic and paper records of patients were then thoroughly reviewed.

In addition to demographic and clinical data, dates were recorded for onset of inflammatory joint symptoms, referral to rheumatologist, initial assessment by a rheumatologist and/or initiation of DMARD therapy. The percentage of patients assessed by a rheumatologist and/or treated with a DMARD within 12 weeks of symptom onset and the median times for delay were then calculated.

**Results:** Between January 1st 2014 and December 31st 2015, 243 new cases of RA were identified at our Department of Rheumatology. Of those, 197 (81.1%) were referred to our early interventional clinic. Of the remaining 46 patients, 37 (80%) were not referred due to the lack of patients. The characteristics of the 111 (45.7%) new RA patients who were examined by a rheumatologist and/or initiated DMARD therapy were as follows: M05.7% and M06.* Time from symptom onset to DMARD initiation, weeks (median) 13.0 (IQR 4.6–27.8) weeks, median time from referral to consultation was 1.0 (IQR 1.3–3) days and median DMARD treatment delay was 15.7 (IQR 8.7–31.9) weeks.

</tr>
</tbody>
</table>

**Conclusions:** 46% of new RA patients were assessed by a rheumatologist and 36% were treated with a DMARD within the recommended time frame of 12 weeks. Most of the treatment delay was due to the time elapsed between symptom onset and referral to a rheumatologist. These results substantiate the efficacy of our early interventional clinic in diagnosing and treating patients with early RA; despite the heavily protracted nationwide waiting times for first rheumatologist assessment and significantly (40%) lower number of rheumatologists per capita compared to European Union average, the percentage of timely treated patients was comparable to recent results from international studies.

VERY HIGH, BUT NOT LOWER, RADIOGRAPHIC PROGRESSION LEADS TO AN INCREASE IN HAQ-DI. RESULTS FROM THE SWISS SCQM RA COHORT

1Division of Rheumatology, Kantonsspital St. Gallen, St. Gallen; 2Graf Biostatistics, Winterthur, Switzerland; 3Rheumaethn, Klinikum der Universität München, Campus Innenstadt, Munich, Germany

Background: Numerous predictors of radiographic progression in RA patients have been identified over the last years. In general, analyses of radiographic progression in RA rather focus on radiographic non-progression or repair. High radiographic progression in spite of therapy has, to our knowledge not been analysed in detail in the last years, neither in RCTs nor in cohort studies.

Objectives: To analyse radiographic, demographical and clinical data in RA patients with high radiographic progression before and after the individual peak radiographic progression.

Methods: We included all RA patients from the Swiss registry SCQM with at least two subsequently scored radiographs. Radiographic destruction was scored using the Ratingen erosion score. To analyse high radiographic progression we selected for the highest (peak) radiographic progression in every individual patient for the analysis. The individual peak radiographic progression was analysed in groups as change of Ratingen scores/year: 0–≤10, 10–<20, 20–≤30, >30 (groups 1–4, follow up 1998–2015). The baseline disease characteristics were compared using standard descriptive statistics (Kruskal-Wallis or Chi-square tests). The change of DAS 28 and HAQ-DI scores before and after peak progression was analysed with the Wilcoxon signed rank tests.

Results: 3 patients were included in the analysis. 3’049 patients had a peak radiographic progression between 0 and <10/year; 773 between 10 and <20, 150 between 20 and <30, and 61 of >30. All patient groups were within the same age range (mean: 56.5 – 60.5 years). Rheumatoid factor and ACPA were more frequent in patient groups with higher peak radiographic progression (RF: 73.6, 80.0, 88.9, 90.0; ACPA: 68.8, 73.4, 74.3, 82.1, groups 1–4, respectively). When the rate of radiographic progression before and after peak progression was analysed, 69.7%, 74.7%, 76.9%, and 93.3% of the patients had a radiographic progression of 25% or lower as compared to peak progression before and 76.1%, 81.8%, 91.1%, and 93.8% after this peak progression, respectively for patients in groups 1 to 4 (Figure A).

The disease activity, as assessed by DAS 28, was significantly higher in all patient groups before peak progression and lower thereafter (Figure B, p<0.001). Average HAQ-DI scores increased after peak radiographic progression in group 4 (Figure C, p=0.005) whereas it is stable or even decreases among the patients of the other patient groups.

Conclusions: These data show that higher disease activity precedes radiographic peak progression, which is, if high, overall rare. Radiographic progression before and after the individual peak radiographic progression was far lower as compared to the time of radiographic peak progression. Only the highest individual peak (change of Ratingen score >30/year) radiographic progression was followed by an increase of HAQ-DI scores.

THE ASSOCIATION BETWEEN REPEATEDLY INFECTION AND DISEASE OUTCOME IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Zhang1, J. He2, C. Li2, J. Li2, J. Chen2, Y. Jin2, Yan Gan2, Z. Li2.
1Department of Rheumatology and Immunology; 2Peking University People's Hospital, Beijing, China

Background: Some publications shows some therapies in rheumatoid arthritis (RA) could cause infections and it also can react the disease prognosis. But there was no report about the relationship between the repeatedly infections during the disease duration and its disease outcome.

Objectives: Our study was to evaluate the association between the history of repeated infectious agents that occurred more than three times during the duration of RA and the current disease status of RA, such as disease activity and physical disability.

Methods: 688 pure RA patients were selected from December 2015 to June 2016 in Peking People's hospital and divided into two groups according to their current disease status. Clinical data were collected including DAS28, HAQ, disease duration and therapies. Infectious agents occurred repeatedly during the duration were identified as history repeated infectious agents. T test, ANOVA, chi-squared test and multivariate analysis of covariance were used for analyzing the association between the infections and disease outcome.

Results: 688 RA patients were divided into two groups based on whether their DAS28 reached 3.2 (active or inactive). The HAQ score and the incidence of airway infection has a significant difference among these two groups (P=0.000; P=0.002). Logistic regression analysis shows that smoking, airway infection and age were the risk factor for RA active (OR=4.844, 95% CI (0.193,1.001); OR=1.326, 95% CI (0.655,2.687); OR=1.013, 95% CI (0.989,1.037)), and the disease duration and the therapy were also affect the disease outcome (OR=0.650,OR=1.560). Than we divided these patients into four groups based on their infectious site such as airway, urinary, intestinal and no-infection. After adjusting for the disease duration, only airway infection incidence has statistically significantly different (P=0.000). DAS 28 has statistical different only among the groups whether they have airway infectious agents after adjusting the smoking and therapy (P=0.002; P=0.002). Compared with infection free group, patients with airway infection has a higher DAS28 because they have more swollen or painful joints, while patients with urinary infection perform a higher scores because they have a high level of ESR.

Conclusions: The repeated infectious agents during the disease duration might lead to poor outcome. We should pay more attention to those patients who have repeatedly infectious agents during their disease duration in order to improve their prognosis.

THE CORRELATION OF CARTILAGE OLGOMERIC MATRIX PROTEIN WITH SONOGRAPHIC KNEE CARTILAGE THICKNESS AND DISEASE CHARACTERISTICS IN RHEUMATOID ARTHRITIS

1Medicine, Universiti Kebangsaan Malaysia, Kuala Lumpur; 2Medicine, Putrajaya Hospital, Putrajaya; 3Radiology; 4Microbiology, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia

Background: Cartilage Oligomeric Matrix Protein (COMP) is an extracellular protein which is primarily found in the cartilage and to a lesser extent in ligaments, meniscus, tendons and synovium. Experimental models of rheumatoid arthritis (RA) and osteoarthritis have pointed out that serum COMP levels are reflective of the cartilage turnover rate.

Figure 1. Levels of clinical data include HAQ, abnormal joints number, CRP and ESR were compared among subgroups of infection free (n=469), airway (n=121), urinary (n=173) and inactive infection (n=85). This figure shows that clinical factors contribute to the difference among these two disease groups.

Conclusions: The repeated infectious agents during the disease duration might lead to poor outcome. We should pay more attention to those patients who have repeatedly infectious agents during their disease duration in order to improve their prognosis.

References:

Disclosure Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.3976
Objectives: To investigate the correlation of serum COMP levels with the articular cartilage damage based on sono graphical knee cartilage thickness (KCT) and disease characteristics in RA.

Methods: A total of 61 RA patients and 27 healthy controls were recruited in this study. Serum samples were obtained from all subjects to determine the COMP levels. All subjects had bilateral ultrasound scan of their knees performed by a single radiologist; who was blinded to the details of the subjects. The KCT was based on the mean of measurements at 3 sites; the medial condyle, lateral condyle and intercondylar notch (Figure 1). Besides, the RA patients were assessed for their disease activity based on DAS 28.

Results: Serum COMP concentrations were significantly elevated in the RA patients compared to the controls (p<0.001). The serum COMP levels had an inverse relationship with bilateral KCT in RA subjects and the healthy controls. However, the association was statistically insignificant for bilateral knees in the control arm. COMP correlated significantly with disease activity based on DAS 28 (r = 0.299, p = 0.010), disease duration (r = 0.439, p = 0.05) and mean left KCT (r = 0.285, p = 0.014) in RA (Table 1). Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) which are the traditional markers of inflammation; demonstrated a significant positive correlation with the DAS 28 scores (r = 0.372, p = 0.003 for ESR; r = 0.305, p = 0.017 for CRP) comparable to the serum COMP. However, neither ESR nor CRP had a significant association with the KCT, as opposed to the serum COMP.

Table 1. Correlation of Serum COMP levels with Clinical Parameters in RA

KCT: knee cartilage thickness.

Conclusions: The serum COMP is a promising biomarker in RA which reflects disease activity and damage to the articular cartilage. Serum COMP appeared superior to the traditional markers in RA i.e ESR and CRP in predicting sono graphical cartilage.

response and ACR 70 criteria were determined after 12 weeks of treatment with a fixed schedule methotrexate and prednisone. Physician perceived remission (PhR) was defined as a global assessment of ≤20 on a visual analogue scale, phrased: “How active do you think the RA of your patient is today?”. Patient perceived remission (PatR) was phrased as: “Would you say that, at this moment, your disease activity is as low as it has ever been?”. In patients in PhR, the change in components of the DAS28 and questions of the Rheumatoid Arthritis Impact of Disease (RAID) and Health Assessment Questionnaire (HAQ) were compared between patients in and not in self-perceived remission.

Results: The agreement on remission between patients and physicians was 64% and was dependent of the definition of remission. In Boolean remission, EULAR good response and ACR70 remission agreement was: 86%, 63% and 80% respectively (table). Patients in PhR, the patients in PatR had more improvement on all RAID subdomains. There were no significant differences in clinical outcomes (ESR was significantly different at baseline, but not after 12 weeks; see figure).

AB0278 ULTRASOUND EXAMINATION IN DIAGNOSIS OF EARLY RHEUMATOID ARTHRITIS

W. Hamdi1, S. Miladi2, K. Matallah, M. Bouaziz, D. Kaffel1, I. Zouch1, M.M. Kchir1.

Background: Fortunately, management of RA at the early stage has become possible thanks to the emergence of new biotherapies and the strategy treat to target. Musculoskeletal ultrasound (US) is a potent tool for the detection of synovitis, effusion and bone erosion in RA.

Objectives: The aim of this study was to assess the contribution of US in diagnosing RA at the early stage of the disease.

Methods: A cross-sectional study was performed during 2 years. Patients with a history of inflammatory joint pain for <6 weeks and <2 years with synovitis of at least one joint were enrolled in this study. All patients underwent clinical assessment, laboratory tests and plain radiography of hands and feet. US was assessed within one week of clinical examination. Synovitis and erosion were defined according to the OMERACT.

Results: One hundred patients were included in this study with an average age of 51 ± 14.6 years old. Female outnumbered male with a sex ratio of 3.8. The mean duration of the disease was 10 ± 7.4 months. When admitted to our department and after clinical examination it was found that 31% of patients presented polyarthritis, 4% had oligoarthritis and 7% suffered from monarthrosis. US findings: US was found to be more sensitive than clinical examination to detect synovitis. Among the 2200 joints assessed by US, a synovitis was detected in 81% patients, an intra-articular effusion in 96% patients and PD signals in 51% patients. Also, flexor tenosynovitis were present in 55% patients and extensor tenosynovitis in 59% patients. Erosions were more detected in plain radiography (70%) than in US (41%). Clinical parameters (VAS, duration of morning stiffness, number of night awakens, TJC) were not correlated with most US findings. Nevertheless, correlation was detected for US effusion (r=0.250, p=0.028) and for US Dopper (r=0.289, p=0.011) with SJC. PDUS examination correlated with CRP results (r=0.302, p=0.023) but not with ESR results. A significant, positive correlation was observed between erosions in X-rays or US assessment (r=0.342, p=0.002). The US detected synovitis in 25% of patients who had no swollen joint at the clinical examination when admitted to our department and had detected erosions in 9% of patients having negative plain X-rays.

Conclusions: Ultrasound appears as a sensitive tool to detect subclinical synovitis (25%) and infra- radiological erosions (9%). It helps us to make an early diagnosis and start appropriate treatment before the onset of irreversible joint destruction.
Results: The mean age of our population was 49.17±11.21 years (age 24–78). The disease average duration was 7.4±4.22 years (4 months - 29 years), 82.71% of RA were women and 17.29% were men. Seropositive RA were 80.24%, and 71.6% of RA have anti CCP positive antibody. Univariate analysis of the presence of anti-CCP antibodies in conjunction with HLA DRB1 and DQB1 was performed. Complete HLA typing of HLA DRB1 0401 and 1501 were significantly associated with the presence of anti-CCP antibodies (p<0.0001). Four DRB1 0401 carriers were homozygotes with three of them having anti-CCP antibodies.

Garriship of HLA DQB1*0201, 0301, 0302,0501 and 0601 was associated with the presence of anti-CCP antibodies and so was HLA-DQB1*0401*, but with a less significant association.

Conclusions: Although no formal conclusions on causality can be drawn from this association study, these findings suggest that anti-CCP antibodies are associated with different phenotypes; which suggest that various pathogenic mechanisms underlie the positivity for anti-CCP in RA.

AB0282 RHEUMATOID ARTHRITIS PATIENTS ACHIEVED BETTER QUALITY OF LIFE THAN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS AT SUSTAINED REMISSION: THE IMPACT OF DISEASE DIAGNOSIS ON HEALTH-RELATED QUALITY OF LIFE OUTCOMES

V. Pascual Ramos, I. Contreras-Yáñez, L. Llorente, K.R. Valencia-Quíones, J. Romero-Díaz. Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Background: Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) impact the health-related quality of life (HRQoL) of the patients. The 2004 update of the Disease Activity Score (DAS28) allows comparison of outcomes among different conditions. Whether remission represents similar status in terms of QoL in RA and SLE patients is unknown. In 2004 and 1999, respectively, recent-onset RA and SLE cohorts were initiated in a referral center for rheumatic diseases in Mexico City; the SF-36 was applied beginning from enrollment.

Objectives: To compare the SF-36v2 scores between patients from both cohorts who achieved for the first time sustained remission (SR) and to define the role of disease diagnosis as associated to SF-36v2 normative data in SR patients.

Methods: First SR was considered when RA and SLE patients achieved at least 12 months of continuous follow-up with either SLE disease activity index 2000 update >0 or Disease Activity Score (28 joints) <2.4, respectively. Up to December 2015, updated data from 172 RA patients and 211 SLE patients with at least one year of follow-up were reviewed. In the SLE cohort, SF-36 was incorporated to routine assessments from 2005 onwards, while in the RA cohort it was applied since the beginning of enrollment. The SF-36v2 license re-scored the SF-36 used in the SLE cohort. In all the cases, Spanish versions were used and scoring was adjusted by gender and age. SF-36v2 scores were available for the majority of RA patients. Logistic regression models were used to investigate factors associated with normative SF-36v2. Written informed consent was obtained from all patients.

Results: Cohorts were integrated primarily by middle-aged females (89%), with recent-onset disease (5.3±3.2 months); at inclusion, RA patients were older and less educated; follow-up was longer in SLE patients (10.6±2.9 vs. 7.5±3.3 years; p<0.001) and a higher number of them died (15% vs. 2%, p<0.001).

A higher proportion of patients achieved SR sooner in the recent-onset RA cohort than in the SLE cohort: 58% vs. 30.6% of the patients, after 30.8±23.9 vs. 59.4±37.5 months, respectively, p<0.001. At SR, RA patients achieved better scores in 6 out of 8 SF-36v2 domains and in the physical health component summary (PHCS) compared with SLE patients; also, a greater proportion of RA patients achieved normed scores in five domains and in the PHCS; SLE patients achieved more frequent roles (physical and emotional) norms and scored higher mental health component summary than their counterpart. Finally, at SR RA patients had greater improvement in the majority of SF-36v2 domains and both summary components, despite having worse SF-36v2 scores at baseline evaluation.

In SR patients from both cohorts, age (β: 1.08, 95% CI: 1.02–1.1, p<0.003) and SF-36v2 score (β: 9.64, 95% CI: 3.61–25.75, p<0.001) were predictors of not achieving normative PHCS.

Conclusions: RA patients who achieved SR had better HRQoL than their SLE counterparts. Age and SLE diagnosis were associated with not achieving HRQoL norms in RA patients.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.1187
Results: At baseline the mean scores of HAQ-DI and RAQoL did not differ greatly among patients on csDMARDs and bDMARDs (1.29±0.75SD vs 1.13±0.54SD, p=0.063; 16.31±8.26SD vs 15.03±7.13SD, p=0.219, respectively). However, the mean physical component summary score of SF-36 was significantly higher in bDMARDs compared with csDMARDs (32.98±5.97 vs 31.50±7.82, p=0.039), while in the mental component of this scoring system not such a difference was found (p=0.983). After 6 months subjects treated with bDMARD showed a significant decreasing of the means of the HAQ-DI and RAQoL, as opposed to the other treatment group (0.86±0.55SD vs 1.17±0.76SD, p<0.01; 10.96±6.53SD vs 14.55±7.96SD, p<0.01 respectively). Similar results were obtained for both physical and mental component summary scores of SF-36 (39.49±6.43SD vs 48.8±6.04SD, p<0.01; 43.69±7.96SD vs 59.66±10.19SD, p=0.001 respectively). At month 12 a significant improvement of QoL measured by the three assessment tools was registered in patient receiving bDMARDs compared with the csDMARD treatment group (p<0.001).

Conclusions: Patient treated with bDMARDs showed better results for QoL than on therapy with csDMARDs within a period of 12 months of treatment. Current management strategies should focus on improving the symptoms of activity and maintaining physical function in order to increase QoL in patients with RA.

AB0284 ASSESSMENT OF DISEASE ACTIVITY BY DAS28-CRP, CDAI, SDAI AND RESPONSE TO TREATMENT WITH CSDMARDS AND BDMARDS AFTER ONE-YEAR FOLLOW-UP IN RHEUMATOID ARTHRITIS PATIENTS FROM BULGARIAN POPULATION

V.V. Boyadzhieva, N. Stolov, M. Ivanova, R. Stolov, R. Rashkov. Rheumatology, University Hospital “St. Iv. Rilski” Medical Faculty - Medical University, Sofia, Bulgaria

Background: The assessment of disease activity is an essential component in the selection of therapeutic approach for the prevention of disability of patients with RA.

Objectives: The current study was conducted to evaluate the disease activity in patients on csDMARDs and bDMARDs after 6 months to 1-year of treatment and to determine whether the benefits of different therapies were sustained over time.

Methods: A total of 260 patients for the study were selected 220 patients with a mean age 55.05±10.63SD years, meeting the 1987 ACR classification criteria for RA. Patients were stratified according to the 1987 ACR classification criteria for RA were included in the study. The other treatment group (p<0.001). Unlike results reported in 48 recent onset RA patients and in the serum from 20 healthy control (n=20) at baseline and 6 months after initiation therapy with non-biological disease modifying anti-rheumatic drugs (DMARDS). In the patients Disease activity was calculated by the 28 joint counts (DAS28) and muscleskeletal ultrasonod examination (MSUS) was performed at baseline and after 6 months using a 12-joint score (bilateral elbow, wrist, 2nd metacarpophalangeal (MCP), 3rd MCP, knee, ankle) [2]; immunoglobulin-M rheumatoid factor (IgM-RF) titre, and cyclic citrullinated peptide (anti-CCP) antibodies titre and C-reactive protein (CRP). Levels were measured and the health assessment questionnaire (HAQ) scores were recorded.

Results: Serum and SF GITRL levels were highly significantly increased in RA (39.38±16.78 ng/mL and 30.6±16.79 ng/mL respectively) compared to serum level in the healthy controls (10.3±5.46 ng/mL, p<0.001). In RA patients, baseline serum and SF levels of GITRL significantly correlated with DAS28 (r=0.52 and 0.56 respectively, p<0.05). anti-CCP titres (r=0.46 and 0.51 respectively, p<0.05), grey scale (GS) (r=0.5 and 0.52 respectively, p<0.05) and power Doppler (PD) (r=0.65 and 0.88 respectively, p<0.001) synovitis scores. Also, serum and SF levels of GITRL at 6 months follow up significantly correlated with the DAS28 (r=0.42 and 0.48 respectively, p<0.05), GS score (r=0.46 and 0.51 respectively, p<0.05), PD signal (r=0.43 and 0.45 respectively, p<0.05). Logistic regression analysis showed that baseline serum levels of GITRL were predictive of follow up DAS 28 and PD synovitis score (p=0.009 and 0.03 respectively).

Conclusions: Rheumatoid arthritis patients have significantly increased serum and synovial levels of GITRL that remarkably correlated with the DAS28 and MSUS parameters of inflammations suggesting that it could be a useful marker to reflect RA disease activity. GITRL could be a useful biomarker to predict treatment outcome in RA patients.

AB0296 14 CASE STUDY OF MACROPHAGE ACTIVATION SYNDROME (MAS) IN SYSTEMIC ONSET JUVENILE IDIOPATHIC ARTHRITIS

X. Chen1, H. Zeng2. 1Department of Pediatric Allergy, Immunology and Rheumatology; 2Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children’s Medical Center, Guangzhou, China

Background: Macrophage activation syndrome (MAS) is a severe, potentially life-threatening syndrome.

Objectives: We aim to review the precipitating events,clinical features, treatment, and outcomes of macrophage activation syndrome (MAS). Part patients were analysed the Polymorphisms of Perforin A191V (NCBI:SNP rs35347132) using special primers by polymerase chain reaction (PCR).

Results: Fourteen patients (10 girls, 4 boys) were concluded to have evidence of MAS. The primary diagnosis was systemic onset juvenile idiopathic arthritis, with age ranged from 5 months to 12 years. No medication was identified as trigger. Eleven had infections prior to MAS,specific infectious agents were identified in four. High grade fever, new onset hepatosplenomegaly, lymphadenopathy, dysfunction
of liver, abnormal fat metabolism and hemophagocytosis were common clinical features. Two cases were with ARDS and MOF in three and three died. The perforin A91V (NCBI:SNP rs35947132) gene was detected in seven systemic onset juvenile idiopathic arthritis complicated with MAS cases, but no mutation were found. Glucocorticoid, intravenous immunoglobulin, immunomodpressive therapy were effective and HP (Plasmodiapheresis) used in one serious case was also effective.

**Conclusions:** MAS is a rare and potentially fatal complication of childhood rheumatoid diseases, especially systemic onset juvenile idiopathic arthritis. Most of our patients were male, and most cases were preceded by infection. Bone marrow studies support the diagnosis. MOF may be a poor prognostic sign. Aggressive early therapy is essential.

**MUTUAL ASSENT TOWARDS COMPREHENSIVE DISEASE CONTROL: THE RELATIONSHIP BETWEEN US MEASURES AND PATIENT REPORTED OUTCOMES IN EARLY RHEUMATOID ARTHRITIS**

Y. El Miedany 1, M. El Gaafary 2, N. El Arousi 3, S.S. Youssef 3, A. Nasr 4

1Rheumatology, Darent Valley Hospital, Dartford, United Kingdom; 2Community and Public Health; 3Rheumatology and Rehabilitation; 4Radiology, Ain Shams University, Cairo, Egypt

**Objectives:** Assessment of the relationship between US measures of joint inflammation/damage and patient reported outcomes (PROs): HAQ, pain and patient global assessment in early rheumatoid arthritis (early RA) patients over 5-years follow up period.

**Methods:** This longitudinal cohort of 261 patients with early RA was derived from the US monitoring study [1]. Adopting OMERACT definitions; correlations between total US scores (synovial hypertrophy, synovial fluid, Power Doppler, bone erosion and tenosynovitis) and PROs [2] namely functional disability (HAQ), pain and 5-years was not associated with changes in PROs. Radiological damage was assessed using modified Total Sharp score (mTSS). Univariate correlations as well as correlations between interval changes were assessed. Multivariable regression models were used to evaluate the associations across all time-points and their relationship to clinical disease activity measures.

**Results:** There were significant correlations (p < 0.01) between total US score and HAQ (r=0.71), pain (r=0.69) and patient global scores (r=0.66) at all timepoints. Correlation 0.12 at baseline, 0.22 at 1-year and 0.41 at 5-years). Change in mTSS HAQ (r=0.71), pain (r=0.69) and patient global scores (r=0.66) at all timepoints.

**Conclusions:** There were significant correlations (p < 0.01) with the US score of the affected joints. US total score at 1-year predicted subsequent 5-year HAQ score (R2=0.17). At 0, 1- and 5-years, total US scores were higher in patients whose HAQ score was > 1 (9.26) compared to those below 1 (4.16, p < 0.01). The link between joint inflammation/structural damage and PROs is of critical importance to the care of patients with inflammatory arthritis. US measures of inflammation and structural damage correlated independently with functional physical, pain and patient global assessments. A clear relationship between radiographic structure damage and the patient's perceived remission/flare and in each of the two groups, the levels of CRP and ESR were determined. Patients with elevated levels of Nampt had the following laboratory parameters (Mm): ESR – 37.8±5.1, CRP – 56.0±9.37 (rate - less than 5.0 mg/l). The second group had following data: ESR 22.4±5.56, CRP 21.65±1.38. Thus, patients with elevated levels of nicotinamide phosphoribosyltransferase had significantly higher concentrations of ESR and CRP (p < 0.001). There is the relationship between the level of nicotinamide phosphoribosyltransferase serum and laboratory markers of inflammation in RA (CRP and ESR). The data indirectly confirm the hypothesis that increased levels of nicotinamide phosphoribosyltransferase in RA patients is associated with disease activity.

**PREDICTOR OF THE SIMPLIFIED DISEASE ACTIVITY INDEX 50 (SDAI 50) AT MONTH 6 DURING BDMARDS TREATMENT IN PATIENTS WITH LONG-ESTABLISHED RHEUMATOID ARTHRITIS: A SINGLE-CENTER, RETROSPECTIVE STUDY**

Y. Miwa, A. Nishimi, S. Nishimi, T. Tokunaga, S. Ishii, T. Kasama on behalf of ASHURA Registry Group. Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan

**Background:** The simplified disease activity index (SDAI) 50 has good agreement with the EULAR response measures for early rheumatoid arthritis (RA). Although there are reports on early RA, there have been no reports on long-established RA.

**Objectives:** In this study, we analyzed the relationships between various baseline factors and SDAI 50 after six months of biological disease-modifying antirheumatic drugs (bDMARDs) treatment to determine the prognostic factors for long-established RA.

**Methods:** The subjects were 332 RA patients who had been treated with bDMARDs for 6 months. The following characteristics were investigated: age, gender, disease duration, smoking history, body mass index, steroid and methotrexate dosage, previous bDMARDs use, combined csDMARDs use, ESR, CRP, serum matrix metalloproteinase-3 levels, SDAI score, health assessment questionnaire disability index score (for daily living activities) and short-form 36 score (for quality of life). As a primary outcome index, SDAI response was defined as a 50% reduction in SDAI score between baseline and 6 months (SDAI 50).

**Results:** The group of RA patients who achieved SDAI 50 (Group A: 204 patients) had a higher tender joint count (p = 0.041), swollen joint count (p = 0.001), evaluator’s global assessment (p = 0.027) and SDAI (p = 0.006) than did those who did not achieve SDAI 50 (Group B: 152 patients). Before the start of the treatment, steroid dosage (p = 0.018, odds ratio: 1.119, 95% CI: 1.029–1.229) and SDAI (p = 0.0003, odds ratio: 0.953, 95% CI: 0.928–0.978) were determined based on logistic regression analysis. Comparisons were performed between Groups A and B and between before treatment and after 6 months of SDAI. Group A showed a significant improvement compared to Group B by repeated measure analysis of variance (ANOVA) (Interaction: p = 0.000, Group A vs. Group B: p = 0.000, before vs. after treatment: p = 0.000). Our study demonstrated that RA patients with a lower steroid dosage and higher SDAI baseline are more likely to achieve SDAI 50 with bDMARD treatment.

**LABORATORY MARKERS OF INFLAMMATION AND SERUM NICOTINAMIDE PHOSPHORIBOSYLTransFERASE LEVEL IN RHEUMATOID ARTHRITIS PATIENTS**

Y. Akhverdyan 1, B. Zavadovsky 1, J. Polyakova 1, L. Seewodoro 1, I. Zborovskaya1, T. Rogatkina2.

1Rheumatology, Darent Valley Hospital, Dartford, United Kingdom; 2Community and Public Health

**Objectives:** To study relationship between serum levels of nicotinamide phosphoribosyltransferase and laboratory markers of inflammation in patients with rheumatoid arthritis (RA).

**Methods:** We determined nicotinamide phosphoribosyltransferase level in sera of 140 patients with RA (96 women and 44 men) by indirect enzyme-linked immunosorbent assay (RaiBiotech, cat No. EIA-VIS-1). The control group consisted of 20 women and 10 men aged 22 to 55 years without complaints of pain in the joints throughout life. The mean duration of disease was 5.9±0.37 years.

**Results:** We divided all RA patients into 2 groups: one group (118 patients) with elevated levels of nicotinamide phosphoribosyltransferase serum (more than 3.9 ng/ml) and second group (22 patients) - with normal range.

In each of the two groups, the levels of CRP and ESR were determined. Patients with elevated levels of Nampt had the following laboratory parameters (Mm): ESR – 37.8±5.1, CRP – 56.0±9.37 (rate - less than 5.0 mg/l). The second group had following data: ESR 22.4±5.56, CRP 21.65±1.38. Thus, patients with elevated levels of nicotinamide phosphoribosyltransferase had significantly higher concentrations of ESR and CRP (p < 0.001).

**Conclusions:** There is the relationship between the level of nicotinamide phosphoribosyltransferase serum and laboratory markers of inflammation in RA (CRP and ESR). The data indirectly confirm the hypothesis that increased levels of nicotinamide phosphoribosyltransferase in RA patients is associated with disease activity.

**PULMONARY AMYLoidOSIS IN RHEUMATOID ARTHRITIS – A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 161 PATIENTS**

A. Apalzy 1, M. Bély 2, 1Department of Rheumatology, St. Margaret Clinic Budapest; 2Department of Pathology, Hospital of the Order of the Brothers of Saint John of God, Budapest, Hungary

**Background:** AA amyloidosis (AAa) is one of the most insidious systemic complications (RAa) of rheumatoid arthritis (RA), which fortunately may lead to death [1].

**Objectives:** The aim of this study was to determine the prevalence and location of amyloid A deposition in the lungs of RA patients at the time of death.

**Methods:** A randomized autopsy population of 161 in-patients with RA was studied. AAa complicated RA in 34 (21.1%) cases [1].
At least four tissue samples of lungs (from apical and basal regions of both lungs) were available for histologic evaluation in 33 of these 34 patients. RA was confirmed clinically according to the criteria of the ACR. The presence of amyloid A deposits in various structures of the lungs was determined histologically by amyloid specific Congo red staining, according to Romhányi [2]. The extent of amyloid A deposition was evaluated by semi-quantitative, visual estimation on a 0 to 3 plus scale, based on the number of involved tissue structures per light microscopic field [1]. "0": no amyloid deposits, "1": sporadic, minimal amyloid deposits on different tissue structures, "2": less than five, "3": five or more involved tissue structures per microscopic field at objective magnification of x20.

Results: Amyloid A deposition in the lungs was detected in 24 of 33 (72.2%) patients. Amyloid deposition in various structures does not begin at the same time. In the early stage of systemic amyloidosis there were histologically detectable amyloid deposits only in a few structures (arterioles, interstitial collagen fibers, peribronchial and perilobular basement membranes). In other structures (small and medium size arteries, peribronchial basement membranes, small veins, collagen IV reticulin fibers, venules, medium size veins and nerves) deposits were seen only in late stages of amyloidosis (with massive involvement of the mentioned structures).

Conclusions: Amyloidosis is a progressive, cumulative process, involving in its early stage only a few structures in some organs, and increasingly more in the later stages of the disease [1]. Amyloid A deposition starts in the most frequently involved structures of the most frequently involved organ [1].

In the lungs amyloid A deposition starts in the wall of arterioles and in interstitial collagen fibers. As time progresses, basement membranes of peribronchial and peripheral regions of lobules, small and medium size arteries become involved. Still later panlobular deposition of basement membranes, small veins, reticulin fibers (collagen IV) of subpleural fat tissue, venules and medium size veins become involved. The involvement of nerves indicates advanced stages of amyloid deposition in the lung. This chronology of amyloid A deposition allows an indirect assessment of the stage of amyloidosis. Based on the involvement of structures in lung biopsy specimens the pathologist may be able to estimate involvement of the other structures, even if not present in the sections. Involvement of arterioles alone (without involvement of small arteries) indicates an early stage of amyloidosis, whereas amyloid A deposits in veins or peripheral nerves suggests an advanced stage with massive involvement of other pulmonary structures.

Whereas amyloid A deposits in veins or peripheral nerves suggests an advanced stage of amyloidosis. Based on the involvement of structures in lung biopsy specimens the pathologist may be able to estimate involvement of the other structures, even if not present in the sections. Involvement of arterioles alone (without involvement of small arteries) indicates an early stage of amyloidosis, whereas amyloid A deposits in veins or peripheral nerves suggests an advanced stage with massive involvement of other pulmonary structures.

AB0291 EPIDEMIOLOGY AND COMORBIDITY OF RHEUMATOID ARTHRITIS IN UPPER EGYPT, A HOSPITAL BASED STUDY
A.M. Elsaman, A.R. Radwan, M.H. Abu Dahab, A.M. Shefif, E.M. Abu Al-Fadil. Rheumatology, Sohag University Faculty of Medicine, Egypt, Egypt

Background: Rheumatoid arthritis (RA) is one of the commonest autoimmune diseases. It affects about 1% of the population worldwide (1). The prevalence of RA varies widely between different countries (2). Not only the prevalence of the disease which differs among different continents, races, ages and socioeconomic levels but also the disease pattern. Studies explaining the epidemiology of RA in Egypt in general and in upper-Egypt, in particular, are very limited (3).

Objectives: To estimate the comorbidity of rheumatoid arthritis and its relation to disease activity, duration, disease pattern and demographic features of RA patients in upper Egypt.

Methods: This study was carried out on 923 patients who fulfilled ACR/EULAR criteria 2010. All of them live in Sohag governorate and aged 18 years or older DAS28-ESR score, first involved joint, joint distribution, disease pattern, extra-articular comorbidities including gastrointestinal, urinary, cardiac, haematological and neurological were estimated. The activity of daily living was valued by Erlangen score (E-ADL).

Results: The mean age of the participants was 45±10.9 years, with a range (19–70). The median of the disease duration was 5 years, with a range (0.5–40 years). Most of the participants were female (691, 74.9%). Disease onset was gradual or insidious in 94.3% of cases and acute in 5.7% of them. First joint group affected were the small joints of the hands (MCPS and MPJs), recorded in 48.9% of cases, followed by wrist joints (29.3% of cases), then knees (9%), ankles and small joints of the foot (6%) and lastly other joints collectively recorded in only 6.8%. The commonest extra-articular comorbidities were haematological, seen in 323 cases; 35%, followed by gastrointestinal in 290 cases (31.4%), then ophthalmological in 31%, entrapment syndromes in 29.4%, pulmonary in 21.7%, urological in 12.4%, rheumatoid nodules in 11.4%, liver cirrhosis in 8.7%, renal impairment in 8.5% and cardiovascular diseases in 6.5%. The activity of daily living (E-ADL) showed that most of the cases fell in score 4 (58.2%). Regarding DMARDs treatment of the study population, Methotrexate (MTX) was used regularly by 78.3% of cases, hydroxychloroquine (HCO) by 78.1%, followed by Leflunomide (LEF) by 26.4% and sulfasalazine (SSZ) by 13.1%. The majority of cases used combination therapy of either MTX+HCO, MTX+SSZ, MTX+HCO+SSZ or MTX+LEF. Regarding other drugs, 99% of cases used NSAIDs (regularly in 30.2% and on demand in 68.8%). Steroids were regularly used by 26.8% of cases.

Conclusions: The commonest comorbidities were haematological, gastrointestinal, ophthalmological and neurological ones; respectively. Erosion, deformity and DAS28-ESR score have a great impact on E-ADL score.

AB0292 CLINICAL FEATURES OF RHEUMATOID ARTHRITIS AT 75 YEARS OF AGE AND OLDER IN JAPAN – COMPARISON WITH POLYMYALGIA RHEUMATICA IN THE SAME AGE GROUP
A. Aoki1, H. Oka1, I. Aoki2. 1Dept. of Rheumatology, Tokyo Medical University Hachiōji Medical Center, Tokyo; 2Dept. of Pathology, Kanagawa Prefectural Ashigarakami Hospital, Kanagawa, Japan

Background: As Japan is a super-aged society, we have many chances to care for elderly patients in our hospital. Elderly-onset rheumatoid arthritis (RA) (onset age >60 years) may present similar symptoms to those of polymyalgia rheumatica (PMR). We consider that differential diagnosis of RA and PMR is more difficult in patients over 75 than those under 74 in clinical practice. Anti-cyclic citrullinated peptide antibody (ACPA) was reported to be a helpful tool in the differential diagnosis of EORA from PMR. However, when elderly patients with negative ACPA complained of bilateral shoulder and/or girdle pain, it was difficult to differentiate PMR from RA.

Objectives: The study aimed to explore clinical features of RA and PMR at onset age 75 years. For the present investigation, we used a novel diagnostic
tool to distinguish ACPA-negative elderly RA patients from PMR patients at initial presentation.

Methods: From April 2011 to December 2016, 21 RA patients and 24 PMR patients in our hospital, whose onset age was over 75 years, were recruited for this study. PMR patients did not have any evidence of giant cell arteritis. The diagnosis of RA was made based on 2010 ACR/EULAR RA classification criteria. The diagnosis of PMR was made based on 2012 EULAR/ACR classification criteria or Bird’s criteria. Data were obtained from medical records under informed consent. Statistical analysis was performed using the Mann-Whitney U-test to compare median values and Fisher’s exact test to compare frequencies (IBM SPSS version 24). P < 0.05 indicated statistical significance.

Results: RA patients (6 men and 15 women) consisted of fifteen ACPA+ (11 RF+, 4 RF–), six ACPA– (1 RF+, 5 RF –). PMR patients consisted of 12 men and 12 women. All of them were ACPA–RF– and did not meet 2010 RA criteria. Twenty patients (10 RA, 10 PMR) had a 7-year follow-up. No bilateral shoulder pain met Bird’s criteria. Clinical features and statistical results are shown in the Table. Sixty-seven percent of RA patients and 13% of PMR patients had left-right differences in joint pain.

Scoring was performed based on clinical findings. Tenderness and/or swelling joint counts among wrists, fingers, ankles, and knees – each 1 point, left-right difference = 1 point, no bilateral shoulder pain = 1 point, no girdle pain = 1 point, no fever = 1 point; the maximum score was 8. The mean score in RA patients was 4.8 (SD = 1.44), whereas in that PMR patients was significantly lower at 1.5 (0.98) (P = 0.001). Receiver operating characteristic (ROC) curve analysis was used to determine the most suitable cut-off level to find RA. The area under ROC curve score over 3 was 100% sensitivity and 87.5% specificity. All 6 ACPA-negative RA patients showed a score over 4.

Table: Clinical features in patients with rheumatoid arthritis (RA) and polymyalgia rheumatica (PMR)

Conclusions: Pease et al studied RA at onset 60 years and over and PMR, and reported that arthritis of wrists and fingers was suggestive of RA1. However, in our study, small joint swelling was rare in RA patients 75 years and older. The scoring system we made might be useful for the differential diagnosis of ACPA-negative RA and PMR in elderly patients 75 years and older.

The average pregnancy length was 36.36 weeks and the mean birthweight was 2878.90 grams. Growth restriction was identified in several patients, even in those with a normal body mass index.

13 patients never had new flare postpartum and in the others the mean time of postpartum flare was 12.1 weeks.

Objective: Patients with RA have a high risk of postpartum flare, and in every center, the local rheumatologists provided RA pts to be examined by US. All the US machines were identical both for type and controlateral sonographers (rheumatologists with a special interest in US that were performing US as their usual activity for many years). In every center, the local rheumatologists provided RA pts to be examined by US. All the US machines were identical both for type and US examination was performed bilaterally on wrists, MCP and MTP joints, looking for synovitis, effusion, synovial proliferation and PD signal and bone erosions. The positive findings were scored according to a 0–3 score for synovitis components and presence/absence for erosions; the number and size of the largest erosion was also recorded.

Results: Descriptive and demographic data of the 433 pts examined are reported in Table 1. Pts were divided on the basis of the DAS28 result. Statistically significant differences in age and disease duration were registered between the group in CR and the group with DAS28 >3.2 (p=0.019 and p=0.012, respectively), while no differences were found for HAQ or MTX use. Disease activity was assessed by the disease activity score of 28 joints (DAS28), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and visual analog scale (VAS). Disease activity, lipid profile and intra-media thickness (IMT) of common carotid arteries were measured before and after 85 days (6 months) of treatment.

Methods: The study included 82 patients in the Specialized Course Out-patient Therapy Department of the 1st Clinic of Tashkent Medical Academy of age group between 44 and 65 years (mean 52±8.4), predominantly female gender (n=57, 69.5%), with early RA (mean disease duration 9.2±2.4 months).

Objectives: To investigate the US characteristics of RA pts presenting either CR or low disease activity (LDA).

Methods: In 2015 an educational event focused on the added value of US in RA pts was held in 22 rheumatology centers in Italy. After a brief presentation on the evidence of US added value for the clinician given by expert sonographers (rheumatologists with a special interest in US that were performing US as their usual activity for many years), in every center, the local rheumatologists provided RA pts to be examined by US. All the US machines were identical both for type (Logiq E R7, General Electrics, with a 4.2–13 MHz linear probe) and settings (both for grey-scale and power Doppler (PD)). Pts signed an informed consent and a brief history of them was collected by the local rheumatologists (previous and current therapy, DAS28, HAQ score). The US examination was performed bilaterally on wrists, MCP and MTP joints, looking for synovitis (effusion, synovial proliferation and PD signal) and bone erosions. The positive findings were scored according to a 0–3 score for synovitis components and presence/absence for erosions; the number and size of the largest erosion was also recorded.

Results: Descriptive and demographic data of the 433 pts examined are reported in Table 1. Pts were divided on the basis of the DAS28 result. Statistically significant differences in age and disease duration were registered between the group in CR and the group with DAS28 >3.2 (p=0.019 and p=0.012, respectively), while no differences were found for HAQ or MTX use. Disease activity was assessed by the disease activity score of 28 joints (DAS28), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and visual analog scale (VAS). Disease activity, lipid profile and intra-media thickness (IMT) of common carotid arteries were measured before and after 85 days (6 months) of treatment.

Methods: The study included 82 patients in the Specialized Course Out-patient Therapy Department of the 1st Clinic of Tashkent Medical Academy of age group between 44 and 65 years (mean 52±8.4), predominantly female gender (n=57, 69.5%), with early RA (mean disease duration 9.2±2.4 months), divided into 2 groups: Group 1 (n=40) received methotrexate (MTX); 7.5 mg/week; plus prednisolone with the same previous doses plus rosuvastatin (40 mg/day). Lipid profile assessment comprised triglycerides, total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C). Disease activity was assessed by the disease activity score of 28 joints (DAS28), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and visual analog scale (VAS). Disease activity, lipid profile and intra-media thickness (IMT) of common carotid arteries were measured before and after 85 days (6 months) of treatment.

Results: 4 patients receiving rosuvastatin were excluded due to abnormal liver function test parameters (De Ritis ratio >9), further assessment was thus performed on 78 (Group 2, n=38) early RA patients. Overall ESR (Group 1: 24.4±7.26; Group 2: 37.4±12.3) and CRP (Group 1: 5.5±6.05; Group 2: 25.8±23.4) were significantly lower during the treatment. The mean DAS28, unconditionally considered as the most important index of clinical disease activity in RA, was found to be lower (p=0.05) in the adjunct statin-treated group (Group 2: 3.68±0.77) than that of the conventional DMARD treated group (Group 1: 4.5±1.08). Statin significantly reduced LDL-C (0.9±2.1 mmol/l to 3.3±0.6 mmol/l; p<0.05) and increased HDL-C (1.3±0.6 mmol/l to 2.0±0.4 mmol/l; p=0.06) after 6 months of treatment. However, rosuvastatin therapy showed no significant improvement in VAS score (6.7±1.5 to 6.9±0.6; p=0.41) and IMT (1.04±0.09 to 1.08±0.07; p=0.05).

Conclusions: Statins ameliorate RA activity, reduce potential cardiovascular risk in the context of atherosclerosis and mediate clinically apparent anti-inflammatory effects, but long-term effects and benefit-risk profile should be addressed in the management of elevated risk of cardiovascular events in RA patients.

1. V. Odin1, O. Inamova2, V. Tyrenko1, M. Toporkov1. Faculty therapy, Military Medical Academy Named After S.M. Kirov; 2Clinical Rheumatic Hospital No. 25, St. Petersburg, Russian Federation

Background: Specific antibodies, including antibodies to cyclic citrullinated peptide (ACCP) and modified citrullinated vimentin (AMCV) are markers of severe course of rheumatoid arthritis (RA). At the same time, rheumatoid arthritis often associated with autoimmune thyroiditis (Hashimoto’s thyroiditis, HT).

Objectives: Evaluate the role of antibodies to ACCP and AMCV on the clinical and laboratory features of rheumatoid arthritis in association with autoimmune thyroiditis.

Methods: The study included two groups of patients. The first group of patients included 16 patients (14 men and 2 women, mean age - 62.37±2.12 years) with RA in combination with HT and detection in the blood only ACCP (group 1).

The second group also included 16 patients (14 men and 2 women, mean age – 52.31±4.94 years) with RA in combination with HT and detection of ACCP and AMCV in the blood (group 2). In the first group of patients 10 patients had euthyreose, from 5 - hypothyroidism, compensated reception L-thyroxine, 1 patient - thyrotoxicosis ongoing medical euthyreose. In the second group of patients was observed in 14 patients euthyreose, from 2 - hypothyroidism, compensated reception L-thyroxine.

Results: Both groups of patients differed on the following parameters studied: erosion detected in 68% in group 1 and 50% in group 2 (p<0.05), in the first group of patients predominated (62%) the high degree of activity of RA by DAS-28, in while in group 2 - the average (56%, p<0.05).

By using correlation analysis Spearman correlation relationships among the studied attracted attention significant (R=-0.62, p<0.05) relationship between erosions and detection in the blood of antibodies to ACCP in the second group of patients (a combination of RA and HT and identifying in blood ACCP and AMCV), which was repeatedly weakened and unreliable in group 1 (combination of RA and HT and only detection of ACCP) in the blood.

Conclusions: Second group patients (a combination of RA with HT and detection in blood ACCP and AMCV) are closer correlations with indicators of joint destruction than group 1 patients, that in the future may use as a prognostic marker of a more severe course of RA in combination with HT.

ATLANTOAXIAL SUBLUXATION AS A PROBLEM IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Mishevska Percikovna 1, A.A. Kuchi 2.
1Dept. for Inflammatory Rheumatic Disease, University Rheumatology Clinic; 2Dept. for Internal Medicine, PHO City Health Centre Skopje 1, Skopje, Macedonia, The Former Yugoslav Republic Of

Background: Atlantoaxial subluxation (AAS) is important and potentially life threatening complication of Rheumatoid arthritis (RA). It is defined when the space between odontoid process from C2 and arch of the atlas exceeds more than 3 mm. Instability in atlantoaxial joint may result with numerous neurological symptoms, compression of spinal cord and ultimately quadriparesis or quadriplegia.

Objectives: Aim of the study was to determine the frequency and the characteristics of atlantoaxial instability among our patients with RA and its dependence on the nature of the disease.

Methods: 92 outpatients from University Rheumatology Clinic in Skopje, with classical RA (ACR criteria 1988) were examined for the AAS. In all cases were analysed the duration of the disease, haematological and serological tests, disease activity (DAS 28), visual analogue scale (VAS) for the degree of articular pain and verbal rating scale (VRS), for cervical-occipital pain. All patients underwent native and functional x-ray, CT scan and MRI of cervical spine. A complete neurological examination was obtained, with SEP of the n. medianus et n. tibialis. Results: Atlantoaxial instability, with expressed cervical-occipital symptomaticology, occurred in 54 from 92 (58.69%) patients with RA. AAS appeared significantly more often in patients with longer duration of the disease (p<0.0001), in cases with significant cervical-occipital pain (VRS p<0.0001), with stronger joint pains (VAS), with higher values of SR (p=0.002), CRP (p=0.023), RF (p=0.000005), anti CCP (p=0.000003), and DAS 28 (p=0.0001). Anemia and thrombocytosis (p=0.0008) appeared significantly more in cases with AAS. Anterior AAS, (mostly combined with other types) was the most frequent type, presented in 41 participants (75,92%). In one case posterior AAS was detected, what is very rare finding. Positive SEP was significantly higher in the group with AAS.

Conclusions: AAS is serious extra-articular manifestation of RA. Cervical subluxation may be a general anesthetic risk and risk for a neck injury. Routine cervical radiographs with the head in flexed position should be recommended in need of general anaesthesia and in situations with risk for a neck injury.

Acknowledgements: Rheumatoid arthritis, atlantoaxial subluxation.

ASSOCIATION OF VITAMIN D STATUS WITH RHEUMATOID ARTHRITIS DISEASE ACTIVITY AND UV INDEX

C. Lopes 1, J.L. Gomes 1,2, T. Costa 1, M. Mateus 1, F. Pimentel-Santos 1,2, J.C. Branco 1,2, 1Rheumatology Department Unidade Hospital de Egas Moniz | CHLO; 2CEDOC, NOVA Medical School | Faculdade de Ciências Médicas - NOVA University of Lisbon, Lisbon, Portugal

Background: Lower serum vitamin D levels have been shown to be associated with various autoimmune disorders, including Rheumatoid Arthritis (RA). Vitamin D deficiency is common in RA patients, despite profiling from a sunny country.

Objectives: The aim of the study is to evaluate (1) – the association between vitamin D serum levels and disease activity in patients with RA; (2) – seasonal distribution of vitamin D levels.

Methods: Patients fulfilling the 2010 EULAR/ACR Rheumatoid Arthritis Classification Criteria, which had serum vitamin D [25(OH)D3] levels measured between January 2013 and December of 2016 were included. Demographic data, disease activity scores, including DAS28v-CP and DAS28v-ESR, vitamin D supplementation with cholecalciferol and other therapeutic approaches were recorded. Vitamin D insufficiency was considered between 25–75 nmol/L and deficiency if <25 nmol/L. Radiographs of the cervical spine, chest, knees and hands were utilized to assess erosive damage.

Results: A sample composed by 95 patients, 79 females (83.16%), with an average age (SD) of 68.57 (11.92) years within 40–88 years range were included. Average disease duration was 13.46 (11.41) years. The average age at diagnosis was 57.10 (14.25) years. The average vitamin D levels were 78.13 (60.98) nmol/L in a range between 20–400 nmol/L. Vitamin D levels were not significantly different in male v.s. females patients. The prevalence of vitamin D insufficiency and deficiency was 53.68% and 8.42% respectively, despite 57.89% of the patients taking supplementation (average 6141 (4800) UI/week). The univariable analysis showed that although vitamin D levels presented a negative poor correlation with DAS28v-CP (rho=-0.348, p-value<0.001) and DAS28v-ESR (rho=-0.271, p-value<0.0001), there was a direct reduction in dispersion of the vitamin D values for increasing values of DAS28v-CP and ESR. It was observed that vitamin D levels increase with patient age and decrease with disease duration. Sazonality and supplementation didn’t affect vitamin D levels in our population.

Correlation between vitamin D and DAS28v-CP

Conclusions: Vitamin D insufficiency/deficiency was frequent among RA patients (62.1%), independently of seasonality or supplementation. An interesting pattern
behavior was observed in this study, which indicates that the likelihood of encountering a very narrowband of vitamin D values for patients with high disease activity is very high, and thus, the forecast capability of vitamin D values for patients with increasingly active disease is quite good. Future research will aim at strengthening the statistical parameters of relevance, identifying and characterizing the driving factors of the effects of the global pattern.

AB0301 CARDIOVASCULAR RISK AND END ORGAN DAMAGE IN AN ITALIAN GROUP OF PATIENTS WITH RHEUMATOID ARTHRITIS

C.A. Valena1, S. Barbosa2, G. Erba3, R. Facchetti3, A. Maloberti3, P. Villa1, I. Boggion1, M. Riva3, G. Grassi3, M.R. Pozzi1, 1Clinica Medica Università Milano Bicocca; 2Dipartimento di Medicina Clinica e Prevenzione, Università Milano Bicocca, Monza, Italy

Background: The elevated cardiovascular burden of rheumatoid arthritis is well known and the recent update of EULAR recommendations for cardiovascular disease management (1) establish as overarching principle that the rheumatologist is responsible for CVD risk management in patients with RA. They highlight the need of optimal disease activity control, regular CVD risk assessment, lifestyle counseling, appropriate prescription of NSAIDs, corticosteroids, antihypertensives and statins. Screening for asymptomatic atherosclerotic plaques by use of carotid ultrasonography is also suggested: the presence of carotid plaques is associated with poor CVD-free survival and is strongly linked to future acute coronary events in RA patients.

Objectives: We performed an overall cardiovascular assessment to evaluate the presence of end-organ damage in a group of RA patients.

Methods: We carried out non-invasive 24 hours ambulatory blood pressure monitoring, echocardiography, carotid doppler ultrasound and pulse wave velocity (PWV) in a group of RA patients to optimize non-DMARDs therapy and to evaluate end-organ damage.

Results: 55 RA patients, 76.4% female, mean age 62.8±9 yrs were examined. The median disease duration was 12 yrs. 84% were RF +, 80% ACPA + and 51% had erosions. Mean DAS 28 CRP was 2.8±1.23 and HAQ 0.54±0.6. All pts were treated with cDMARDs and/or bDMARDs (54%) and Pd mean dosage was <5 mg/day. Only 3 patients had previous CV event. 49% were hypertensive, 25% had high cholesterol, 13% diabetes and 16% were smokers: median BMI was 25. MAP monitoring revealed that 43/55 (78%) pts were hypertensive: 13 of them had unknown or not/under treated hypertension: 63% had dipper profile and only 12% were reverse dipper. We did not find increased left ventricular mass and wall thickness, but left ventricular diastolic dysfunction grade I-II was found in 26/55 pts, not related to hypertension nor to RA activity. The IMT median value was 655 mm; only in 3 pts was >900 mm: no relation with disease activity was found. In 11 pts carotid plaques were present and related with age, BMI and ambulatory mean pressure values, but not with RA activity or duration. In one patient the plaque required carotid endarterectomy. The PWV median value was >10m/s in 16 pts, all hypertensive.

Conclusions: The accurate evaluation of cardiovascular involvement of this small group of RA patients shows that hypertension is frequent and often not appropriately treated and seems to be the main cause of the increased PWV. Low grade LV diastolic dysfunction was found in half of patients, with no relation with hypertension or RA features, except for CCP presence, but the small numbers do not allow any speculation. Carotid artery involvement was present in 20% of pts, but only in 1 was clinically significant. Once again no relation with RA features was found: the small number of patients, the low disease activity and the tight and overall clinical control could be partial explanations. The clinical tight control of patients with RA is an unique opportunity to fulfill EULAR recommendations.

DOI: 10.1136/annrheumdis-2017-eular.4127

AB0302 WORKABILITY IN PATIENTS WITH SEROPOSITIVE RHEUMATOID ARTHRITIS

C. Berner1, T. Lamprecht2, K.H. Fenzl1, G. Erlacher1, T.E. Dorner3, 1Medical Division, Rheumatology, Kaiser Franz Josef Hospital, SMZ-Süd; 2Karl Landsteiner Society, Institute for Autoimmune Illnesses and Rheumatology; 3Institute of Social Medicine, Centre for Public Health, Medical University of Vienna, Vienna, Austria

Background: Rheumatoid arthritis (RA) and other rheumatic conditions can lead to work disability, and temporary or permanent exit from the labour market. The indirect costs related to work disability are higher than direct treatment costs, and pose an economic burden on patients and society. Workability in RA is influenced by many factors, including symptoms, such as pain, swelling and stiffness, muscle strength, or physical or mental exhaustion, which are components of the frailty syndrome.

Objectives: This study aimed to determine the association of workability with disease activity, pain, functional disability and frailty in patients with seropositive rheumatoid arthritis.

Methods: We conducted a monocentric cross-sectional study at a rheumatologic outpatient clinic and day hospital including 100 seropositive RA patients (according to 2010 EULAR classification) in the working age (<65 years). Workability was assessed with the self-administered Work Ability Index questionnaire. For disease activity, we used the Clinical Disease Activity Index (CDAI), a Visual analogue scale for pain assessment and functional impairments, and the Work Ability Index (WAI). The self-administered Health Assessment Questionnaire Disablement Index (HAQ-DI) and for the degree of frailty the SHARE Frailty Instrument (SHARE-FI). After testing for normal distribution, bivariate correlations between workability and associated variables were calculated using Spearman’s correlation coefficients.

Results: Of 100 patients for 58 the workability index could be assessed. The remaining 42 were either unemployed, on disability pension, or employed but currently not working. These 58 patients, 37 women and 21 men, had an average age of 64.8 years (min-max=22–59, SD=9.3) and an average disease duration of 12 months (range: 0–123 months, SD=60.9). 83% of patients reported moderate workability, 27 good workability, 16 moderate workability and 7 poor workability. The workability was weakly correlated with age (rs=−0.37, p<0.004), and moderately correlated with pain intensity (rs=0.42, p<0.001), disease activity (rs=0.40, p<0.002), functional disability (rs=0.64, p<0.000) and frailty (rs=0.632, p<0.000). The workability was not significantly related with sex and country of origin.

Conclusions: A considerable portion of employed RA patients reported poor or moderate workability, which is significantly associated with disease activity but also with other the parameters assessed. An adequate therapy may therefore not only improve well-being and state of health in RA patients but also provide socioeconomically advantage by maintaining patients’ workability.

AB0303 DOES COMORBIDITY ADVERSELY IMPACT ON TREATMENT RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

C.D. Hughes, N. Gulick. Rheumatology, King’s College Hospital, London, United Kingdom

Background: The burden of comorbid illness in Rheumatoid Arthritis is high. Whilst there can be coincidental existence of comorbidity, it can be attributed to the disease process itself or therapeutic agents. Recent EULAR guidelines recommend reporting, screening and prevention of six common comorbidities (cardiovascular, malignancy, infections, gastrointestinal, osteoporosis, depression). Limited research is available evaluating the impact of comorbidity on disease response following biologic treatment.

Objectives: To analyse retrospective data from the King’s College Hospital (KCH) Virtual Biologic Clinic (VBC) to assess the impact of comorbidity on disease response following treatment with biologics.

Methods: Retrospective patient note review data was collected for patients referred to the VBC from May 2013 to July 2016. The following data was recorded: age, sex, disease duration, smoking status, BMI, presence or absence of Anti CCP antibody +/- Rheumatoid factor and the six specified comorbidities. Disease Activity Score in 28 joints (DAS28) at time of referral for biologic and within 6 months of commencing treatment was also recorded in order to calculate treatment response.

The impact of comorbidity and disease variables on 6 month EULAR response were analysed using logistical regression (SPSS version 23).

Results: The database contained 150 patients. 18 patients were excluded due to no follow-up DAS28, leaving 132 for analysis. Mean age and disease duration were 58 years and 10.45 years respectively. Comorbidity was present in 70% of patients. 70% of patients achieved a EULAR moderate response (improvement of >1.2 of DAS28) and 36% of this group achieved EULAR good response (DAS28<3.2). The most prevalent comorbidities were infection, cardiovascular disease and depression.

Logistic regression analysis was run analysing EULAR moderate response against presence of comorbidity and dataset variables (age, gender, serumostatus, baseline DAS, HAQ and polypharmacy). The resulting model was not statistically significant (p=0.975).

Logistic regression analysis looking at EULAR good response against presence of comorbidity was also not statistically significant (p=0.149). Analysis looking at EULAR good response against three variables (HAQ, baseline DAS and serumostatus) was found to be statistically significant (p<0.001)

Conclusions: Comorbidities were present in the majority of patients assessed
AB0304 SERUM LEVELS OF SCLEROSTIN AND DICKKOPF-1, AND THEIR CORRELATION WITH BONE MINERAL DENSITY AND BONE MARKERS IN RHEUMATOID ARTHRITIS

Background: Sclerostin (SOST) and dickkopf-1 (DKK1) are involved in the development of primary osteoporosis. Although to date, it is controverted does exist about if serum levels of these molecules may reflect adequately a subgroup of patients with decrement of Bone Mineral Density (BMD) being useful as clinical biomarkers. Some non-conclusive observations made in postmenopausal osteoporosis have shown abnormalities in serum levels. To date, there is a lack of information about if serum molecules are associated with decrement of BMD in RA. This information is relevant for if the measurement of these serum molecules could be useful in the clinical care to identify a subgroup of patients with low BMD.

Objectives: To evaluate if serum levels of SOST and DKK1 correlate with bone mineral density and other bone markers in RA.

Methods: In this cross-sectional study, we included 115 women with RA ≥40 years old. All patients were assessed for clinical characteristic disease activity (DAS28) and functioning (HAQ-DI). BMD was measured in lumbar spine, hip and forearm using DXA. According to Pearson's results, osteoporosis was identified if the BMD in a patient had a T-score with a decrement of ≤−2.5 standard deviation (SD). According to their results we classified these patients in two groups: a) low BMD (T-score<−1SD on lumbar spine or total hip) and b) normal BMD (T-score≥−1SD). Serum SOST, DKK1, including serum Receptor Activator of NF-κB Ligand (sRANKL) and osteoprotegerin (OPG) were quantified by ELISA. We compared serum levels between the groups using Student t-tests. For comparisons between proportions we performed Chi-square test (or Fisher exact test if required). Correlation between serum levels of SOST, DKK1, with BMD, clinical variables, sRANKL, and OPG were performed using Pearson correlation tests.

Results: From the 115 women with RA, 58 patients had low BMD (50.4%), from them 44 patients (38.3%) had osteoporosis. Patients in the group with low BMD had higher age (63.8±14.9 vs 53.9±1.6, p<0.0001), DAS28 (4.1±1.5 vs 3.3±1.4, p<0.001), and HAQ-DI score (0.69±0.53 vs 0.36±0.47, p<0.001) compared with normal BMD; whereas lower serum levels of sclerostin was observed in the low BMD group (128.5±75.0 vs 178.2±103.3, p=0.004). SOST levels were correlated with BMD in hip or lumbar spine (r=0.393, p<0.0001), DAS28 (r=−0.311) and seronegativity, and low baseline DAS28 and seronegativity contribute towards good treatment response. The limitations of this study include gaps in clinical records, absence of patient reported questionnaires, and small size of database.

AB0305 FACTORS CONSIDERED BY RHEUMATOLOGISTS TO DECIDE TREATMENT DURING RHEUMATOID ARTHRITIS PATIENT’S FOLLOW-UP

C. Sifuentes-Cantu, I. Contreras-Yañez, M. Gutierrez, V. Pascual-Ramos. 1. Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán; Division of musculoskeletal and rheumatic diseases, Instituto Nacional de Rehabilitación, Mexico, D.F., Mexico

Background: Disease activity (DA) is the most important factor in the treatment decision during rheumatoid arthritis (RA) patient’s follow-up. In routine clinical practice, it is recommended to regularly evaluate DA and musculoskeletal ultrasound has been suggested to add value to establish the level of DA. Nevertheless, the final treatment proposal also requires considering additional factors. In a previous clinical study performed in the setting of an early arthritis clinic, we found that in 20% of the clinical scenarios evaluated, the German ultrasound score of 7 joints (GUS-7) (1) findings impacted the rheumatologist is treatment proposal; the impact was more frequent among the trainee in rheumatology (TR) than among the senior rheumatologist (SR).

Objectives: To determine and rate, which among the following factors were determinant to recommend a treatment in the same population of RA patients above described: the clinical assessment, the GUS-7, comorbidities, treatment-related adverse events, DMARDs costs/availability, patient’s preference and DMARD maximum dose. We also compared if factors differed between both physicians.

Methods: Eighty-seven consecutive and randomly selected RA outpatients were invited to participate; 2 patients denied and 85 patients underwent 170 assessments (85 each by the SR and the TR). At first, both physicians (blinded to each other) performed a clinical evaluation that included DAS28 scoring and recommended a RA-treatment. Then, patients underwent GUS-7 by a blinded (to clinical evaluations) rheumatologist. In the final step, the TR and the SR integrated the US findings to their previous evaluation and reviewed their prescription; also, both physicians recorded and rated on a standardized format which of the factors above described were determinant in the final treatment proposal. Patients signed informed consent and were instructed about the process. Only the SR met each patient’s prescription. Descriptive statistics are reported as frequencies (percentages) and 2-tailed p-values. Clinical assessment (DAS28) was rated as determinant in the majority of the clinical scenarios (100%), followed by GUS-7 in 84.7%, DMARD maximum dose in 41.2%, comorbidities in 23.5%, DMARD cost/availability in 21.2%, treatment-related adverse events in 20% and patient’s preference in 14.1% of them. The SR and the TR differed in their selection: GUS-7 and treatment-related adverse events were more frequently considered determinant for the TR (45.9% vs. 38.8%, p<0.01 and 12.9% vs. 7.1%, p=0.08), meanwhile the opposite figure was true for DMARD cost/availability (4.7% vs. 16.5%, p<0.001) and DMARDs maximum doses (17.1% vs. 24.1%, p=0.08).

Conclusions: In a real clinical setting, DA assessed by DAS28 and by musculoskeletal ultrasound were the most important factors to determine the treatment of RA outpatients; additional factors were considered and differently rated by TR and SR.

AB0306 CAPLAN’S SYNDROME, CADMIUM AND CHINA CLAY: COULD OCCUPATIONAL KAOLIN INHALATION ENHANCE CADMIUM EXPOSURE TO EXPLAIN THE SIXTY YEAR CONUNDRUM OF CAPLAN’S SYNDROME FIRST REPORTED IN COAL MINERS?

D. Murphy, K. Bellis, D. Hutchinson. 1. Rheumatology, Royal Cornwall Hospital; 2. University of Exeter Medical School, Cornwall Campus, Truro, United Kingdom

Background: Caplan’s syndrome was first described in the coal miners of South Wales (UK). The specific cause for rheumatoid pulmonary nodules associated with coal dust exposure remains unknown. Coal dust exposure alone does not appear to explain Caplan’s syndrome as almost all of these men were also smokers. Cigarette smoke is the most important environmental cause of cadmium exposure. We describe Caplan’s syndrome in an ex-smoking kaolin worker associated with a significantly raised urinary cadmium level.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.5652

References:

AB0307 TREATMENT DURING RHEUMATOID ARTHRITIS PATIENT’Socupation ever reported. Elevated cadmium levels of 11.2–15.9 mg/kg have been observed in kaolin.2 Fifty fold higher than those reported in coal.4 Cadmium contains variable amounts of clays and minerals such as kaolinite. Cadmium content in coal is strongly associated with levels of kaolinite contamination.4 Cadmium
nanoparticles have been observed to cause lung parenchyma inflammation and granuloma formation in an animal model.5

Conclusions: Kaolinite mineral capacity for adsorption of heavy metals, in particular cadmium, could explain the scale and pattern of Caplan’s syndrome incidence seen in Welsh coal miners and Cornish kaolin workers, and further explains the interactive risk seen in sequential dust and cigarette smoke exposure.

AB0307 DIFFERENTIAL ASSOCIATION OF AGE AND DISEASE ACTIVITY WITH CAROTID INTIMA-MEDIA THICKNESS IN MEN AND WOMEN WITH RHEUMATOID ARTHRITIS

D. Taverner 1, S. Paredes 1, R. Ferre 1, L. Masana 2, A. Castro 2, J.C. Valles 2, 
1Rheumatology; 2Internal Medicine; 3Biologist, Hospital Sant Joan de Reus, Reus, Spain

Background: Rheumatoid arthritis (RA) is the most common chronic inflammatory condition and is characterized by an increased risk in cardiovascular (CV) disease. Carotid intima-media thickness (cIMT) is a surrogate marker of CV disease and many studies have evaluated the relationship between cIMT and RA disease activity with contradictory results.

Objectives: To evaluate in RA patients the association between both cIMT and carotid plaque presence and clinical RA features and analytical measurements.

Methods: We selected 214 RA patients according to the American College of Rheumatology criteria. Conventional clinical evaluation and analytical measurements were performed, including a standard lipid profile. We used My Lab 50 X-Vision sonograph to measure cIMT and atherosclerotic plaque presence.

Results: No differences between men and women regarding age, body mass index, glycemia, LDL-C and TG were observed. However, men had a significantly higher waist circumference, systolic and diastolic BP and lower levels of HDLC. On the other hand, women had significantly higher values of DAS28 (3.7 vs 2.99), HAQ, and VSG with no differences in other inflammatory variables (rheumatoid factor, ACPR, CRP or fibrinogen). Moreover, 74% of patients had pathological cIMT without gender differences and 43% had plaque presence in the carotid artery with a significant higher percentage in men (57%) than women (36%). Overall, men had significantly higher cIMT (0.678 vs 0.627 mm) but when disease activity (DAS28) was considered, we observed that such difference was due to patients that were in remission or in low activity. Men and women with moderate and high disease activity had no statistical differences in cIMT. Furthermore, across women cIMT was significantly higher in those with high disease activity compared to women with remission. This effect was not observed in men. Multivariate linear regression with cIMT showed a significant interaction between age and gender, so that the effect of age on cIMT was significantly more pronounced in men than in women.

Conclusions: We have described that in our RA cohort, disease activity measured with DAS28 and age are differentially associated with cIMT in men and women. Our results could explain the contradictory results published in the literature and it can be justified by a higher incidence of RA in women and by the hormonal-genetic status.

AB0308 DISEASE ACTIVITY, GRIP STRENGTHS AND HAND DEXTERITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Palamar 1, G. Er 1, R. Terlemez 1, U. Ioji 2, G. Can 3, M. Saridogan 1, 
1Department of Physical Medicine and Rehabilitation, Istanbul University Cerrahpasa Medical Faculty; 2Physical Medicine and Rehabilitation Clinic, Bagcılar Training Hospital; 2Department of Public Health, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease affecting hand joints, and leading impairment in hand functions. To date many studies have evaluated the disease activity of patients with RA, but little attention has been carried out to assess hand functions, and dexterity (1–2).

Objectives: The purpose of this study was to determine the clinical relevance of the Quick Disabilities of Arm, Shoulder and Hand (QuickDASH), hand dexterity with the Purdue Pegboard Test (PPT), and grip and pinch strengths of RA patients.

Methods: Eighty-two women with a diagnosis of RA according to the 2010 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) criterion were recruited to the study. The disease activity scores were determined by using Disease activity score-28 (DAS-28). Grip strengths were measured with a Jamar dynamometer, and pinch strengths were measured by the Purdue Pegboard Test (PPT). Multivariate linear regression with the PPT, and functional outcomes were assessed with the QuickDASH questionnaire.

Results: The mean age of the study group was 49.27±10.69 years. Average values of DAS-28, the QuickDASH values were found to be 4.22±1.28, 38.33±18.76, respectively. High correlation was observed between DAS-28 and the QuickDASH values (p<0.001). The mean grip strengths were significantly correlated with the QuickDASH and DAS-28 values (p<0.01) (Table 1). The mean lateral pinch strengths were correlated significantly with DAS-28 and the QuickDASH scores (p<0.001). DAS-28 was correlated with PPT performance just in women with remission hand (p<0.05). The QuickDASH values were not correlated with all PPT performances (p<0.05). Grip strengths were positively correlated with the PPT performances (p<0.05).

AB0309 LIPID-LOWERING INTERVENTION OF A PREVENTIVE CARDIO-RHEUMA CLINIC IN MEXICAN MESTIZO PATIENTS WITH RHEUMATOID ARTHRITIS

D.A. Galazar-Delgado 1, J.R. Azpiroz-López 2, I.J. Colunga-Pedraza 1, E.R. Ramos-Cázares 1, F.J. Torres-Quintanilla 4, A. Valdivinos-Bañuelos 4, R.I. Arvizu-Rivera 4, A. Martínez-Moreno 4, J.A. Cárdenas-de la Garza 4, R. Vera-Pineda 4, J. García-Colunga 4, M.A. Garza-Elizondo 4, G. Elizondo-Ríos 4, 1Rheumatology; 2Cardiology; 3Internal Medicine; 4Radiology, Universidad Autónoma de Nuevo León, Monterrey, Mexico

Background: Patients with rheumatoid arthritis (RA) have a significantly increased risk for cardiovascular (CV) morbidity and mortality when compared to general population (1). Preventive cardio-rheuma clinics have been created in recent years and proven to be effective to manage CV risk in patients with inflammatory joint diseases around the world (2).

Objectives: To evaluate the need for lipid-lowering intervention in Mexican mestizo patients with RA.

Methods: We initiated a preventive cardio-rheuma clinic for appropriate CV disease prevention in patients with RA in our population. A complete evaluation and CV risk stratification was performed to our patients, including blood tests and ultrasound examination of both carotid arteries. Each patient was classified to lifestyle changes only, a lifestyle improvement plus lipid-lowering treatment, or to have a low risk with no need for intervention, in accordance to the 2012 European Guidelines on cardiovascular disease prevention in clinical practice and the 2016 ESC/EAS Guidelines for the Management of Dyslipidemias.

Results: A total of 100 patients were evaluated, patient characteristics and intervention group distribution are shown in Table 1. Among these patients, 49 were found not to need any intervention. The remaining 51 were classified into lifestyle change (n=18, 35.3%) or lipid-lowering drug regimens (n=33, 64.7%). A significant difference between intervention groups was only found regarding age (p<0.001). A multiple regression analysis was performed to predict the kind of intervention needed from age, disease duration, disease...
activity and autoantibody levels, only age added statistically significantly to the prediction.

Conclusions: There was indication for preventive intervention in more than half of our patients. Age is a determinant factor that increases CV risk in RA patients independently from disease-specific factors. Treatment to lipid targets is essential to reduce their risk of CV morbidity and mortality (3). A prospective study evaluating treatment success rate is needed to further evaluate the intervention of the clinic.

AB0310 PREVALENCE OF COMORBIDITIES OF RHEUMATOID ARTHRITIS IN A MEXICAN MESTIZO POPULATION

D.A. Galarza-Delgado 1, J.R. Azpiri-López 2, I.J. Colunga-Pedraza 1, R.E. Ramos-Cázares 1, F.J. Torres-Quintana 1, A. Valdovinos-Barluenos 1, R.I. Arvizu-Rivera 1, A. Martínez-Moreno 1, J.A. Cárdenas-de la Garza 2, R. Vera-Pineda 1, Rheumatology; 2Cardiology; 3Internal Medicine, Universidad Autónoma de Nuevo León, Monterrey, Mexico

Background: Patients with rheumatoid arthritis (RA) have an increased risk of developing comorbid conditions which are associated to increased mortality, hospital admissions, higher costs of care and inability to work (1, 2).

Objectives: To evaluate the prevalence of comorbidities in a Mexican mestizo population of RA patients.

Methods: We performed a cross-sectional study in which RA patients who were admitted to our outpatient clinic between August 2014 and December 2016 were consecutively enrolled. We collected data regarding demographics, disease characteristics (activity, severity, treatment), comorbidities (cardiovascular, infections, cancer, and osteoporosis), and performed blood tests at the time of the patient’s visit to the clinic.

Results: We analyzed 225 patients. Their characteristics are shown in Table 1. Age, 55.7±8.3 years (mean ± SD); disease duration, 9.5 (4 – 15.5) (median (IQR)); female gender, 93.7%; Disease Activity Score using 28 joints – C-reactive protein (DAS28-CRP), 3 (2 – 4) (median (IQR)); past or current use of any other conventional disease modifying anti-rheumatic agents.

Conclusions: This study confirms the high prevalence of comorbidities in RA patients. Among our cohort, 63.5% had at least one comorbidity, being those associated with cardiovascular disease the most common. With a systematic assessment (3) including a thorough physical examination, vital signs and laboratory tests, it is possible to detect comorbid conditions that would otherwise remain unrecognized.

AB0311 RESULTS OF SCREENING FOR TUBERCULOSIS INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS BEFORE AND ON TREATMENT WITH BIOLOGICAL DMARDS

D. Karatsev 1, S. Boriso 2, T. Fonina 2, G. Loukina 2, E. Luchkhnina 2, L. Guntupova 2, A. Satybaldev 2, 1Nasonova Research Institute of Rheumatology; 2Moscow Centre against tuberculosis; 3Moscow clinical scientific center; 4Early arthritis department, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: The prevalence of tuberculosis infection in Russia is much higher than in Western Europe. Therefore, screening for TB infection in patients with RA before therapy with biological agents is of particular importance. At the same time, reliable information on the results of screening are very few.

Objectives: Explore the results of the application of different methods of diagnosis of tuberculosis infection in RA patients before and during treatment with biological agents.

Methods: We used the data from the Russian register “Observational REgister of arthritis in Clinical practice” (OREL). 1471 RA patients were screened for TB infection before prescribing biologics, of whom 829 patients were exposed to TB infection monitoring on therapy by biologics. The group included 21.1% men, 78.9% women; at the time of initial screening age was 50.0±5.4 years, the duration of the disease 8,5±3.8 yrs, 68.3% RF +, 85.1% anti-CCP +, DAS28-ESR 5.7±7.1, 95.7% used synthetic DMARDs, 60.1% used systemic steroids.

We used PPD ( Mantoux) test, Diaskin test (intradermal test with tuberculosis antigens CFP10-ES38) and QuantiFeron-TB Gold (QFT) test (in some patients), chest X-ray, chest CT scan (if needed), all the patients were consulted by phthisiatrician. PPD and Diaskin test results were considered positive if the papule was ≥ 5 mm. Duration of treatment with biologics (anti-TNFs and others) varied widely (2–154 months), making a total of 2552 patient-years.

Results: At screening, we got 40.3% positive results of PPD test (significantly more in younger patients and patients who did not receive steroids), 16.5% positive results of Diaskin test (with no significant correlations with age and steroids). Positive results matched in 19.9% of cases, negative - in 51.9%. Discordant results in 217 patients were in 92.2% cases related to negative results of Diaskin in PPD-positive persons. Active TB was found after additional examination in 3 (0.2%) patients, inactive TB-related changes were revealed in 124 (8.8%) patients. Positive PPD and Diaskin results, but not QFT, correlated with signs of inactive TB lesions. Positive results of PPD and QFT tests matched in 36.5% of cases, negative - in 18.7%. Diaskin and QFT – in 33.6% and 41.1% of cases resp. As a result of screening, 224 pts were treated by isoniazid or combination of anti-TB drugs before initiation of biologics. On treatment with biologics, 114 (13.7%) pts became PPD-positive and 56 (6.8%) Diaskin positive, active TB was diagnosed in 8 (0.97%) pts.

Conclusions: In carrying out TB screening before prescribing biologics in high-
risk population of TB infection it is reasonable to use both PPD and Diaskin tests, and repeat them every 6 months on treatment.

U83 SCORING SYSTEMS FOLLOW-UP 48 WEEKS TNF-A ANTAGONISTS PLUS MTX TREATMENT FOR HIGH DISEASE ACTIVITY REFRACTORY RHEUMATOID ARTHRITIS

D.F. Lin 1, X. Gu 1, J. Cao 2, Y. Pan 2, J. Gu 1. 1Rheumatology department; 2Ultrasound department, the 3rd Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: US7 score is the ultrasound scoring system for rheumatic ailments (RA). This scoring system has shown good evidence so far. Several reports accessed its inter-rater, intra-rater agreement, its specificity, sensitivity and practical possibility compared to more complex scoring systems such as 72-joints scoring systems, which showed it is an convenient tool for clinical use. Our goal is to explore U83 to investigate the ultrasonic changes during biological agents plus MTX treatment in high disease activity refractory RA patients in Yellow people.

Methods: All cases were diagnosed as RA fulfilling 2009 ACR/EULAR classification criteria and evaluated as high disease activity for DAS28≤5.1 with MTX+HCO=SSAP or MTX+LEF invalid therapy for more than 3 months before baseline. Biological TNF-a antagonist or IL-6 antagonist plus with MTX 10mg qw were then given and ultrasound was performed by 2 observers blinded to physical examination and blood test results at 0, 12, 24, 48 weeks. US examination referred to US7 scores by Backhaus et al. DAS28 were employed to blinded to physicial examinations and blood tests at 0, 4, 12, 24, 48w. US examination referred to US7 scores by Backhaus et al. DAS28 were employed to blinded to physicial examinations and blood tests at 0, 4, 12, 24, 48w. US examination referred to US7 scores by Backhaus et al. DAS28 were employed to blinded to physicial examinations and blood tests at 0, 4, 12, 24, 48w. US examination referred to US7 scores by Backhaus et al. DAS28 were employed to blinded to physicial examinations and blood tests at 0, 4, 12, 24, 48w. US examination referred to US7 scores by Backhaus et al. DAS28 were employed to blinded to physicial examinations and blood tests at 0, 4, 12, 24, 48w. US examination referred to US7 scores by Backhaus et al. DAS28 were employed to blinded to physicial examinations and blood tests at 0, 4, 12, 24, 48w. US examination referred to US7 scores by Backhaus et al. DAS28 were employed to blinded to physicial examinations and blood tests at 0, 4, 12, 24, 48w.

Results: 1) 26 subjects were enrolled in the program up to now. 22 were given TNF-a antagonists and 4 were given IL-6 antagonists. 17 finished 24 weeks follow-up. 1 withdrew for TB infection at 12 week and 1 withdrew for fungi pneumonia at 8 weeks. Mean age of 17 was 44.3±11.8 years old, female-male ratio was 15:2, and disease duration was 71 months. All were RF and ACPA positive.

Conclusions: Only 42.8% of the sample had all CV risk factors requested and registered in the clinical record, so should promote improvement in the health team to increase this. The average 10-year CV risk in all people with RA was 12.42%, and in patients who met the criteria to be multiplied by the factor 1.5 increased to 13.03%, which means that these patients should be reported this and followed up. In addition, the questionnaire regarding obesity and cholesterol levels. Despite population receiving biologics are younger, they had lower CV risk. We need more research to confirm this results

HIGH INFLAMMATORY ACTIVITY AS A PREDICTOR OF INCREASED ARTERIAL STIFFNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Trotskaya, S. Velmakin, S. Villevalde, Z. Kobalava. Propaedeutics of internal disease, RUDN University, Moscow, Russian Federation

Background: Patients with rheumatoid arthritis (RA) have a high risk of cardiovascular (CV) morbidity and mortality. Arterial stiffness (AS) is a known predictor of CVD. Relationships between inflammation and arterial stiffness in patients with RA are not well understood.

Objectives: The aim of the study was to evaluate parameters of AS and their associations with inflammatory activity in patients with RA.

Methods: 62 patients with RA (EULAR 2010) without known CV events were examined (73% females, age 58.5±15.4 (M±SD) years, 13% smokers, 61% with AH, 34% with dyslipidemia). Median duration of RA is 8 years (IQR 3–17). Seropositive RA was found in 69% of patients compared with 58% in our controls. Mean CIMT 0.7±0.2 mm), p<0.05, except 0w:4w, sig<0.05), synovitis Power Doppler scores (0w:4w:12w:24w = 8.5±4.9:3.8:2.7, all sig<0.05, except 4w:12w:24w, 12w:23w, sig=0.361,0.227,0.235), tenosynovitis grey scale scores (0w:4w:12w:24w = 0.63±0.25:0.25:0.07, all sig<0.05, except 4w:12w:24w:12w, 4w:24w, 12w:24w, sig= 1.0, 0.26, 0.26), tenosynovitis Power Doppler scores (0w:4w:12w:24w = 1.00±0.19:0.00 all sig<0.05, except 4w:12w:24w:12w, 4w:24w, 12w:24w, sig< 0.18, 0.18, 1.0), bone erosion scores (0w:4w:12w:24w = 1.2±0.1:0:94:0.53, all sig<0.05 except 0w:4w:12w:4w:24w, 12w:24w, sig< 0.083, 0.317, 0.102, 0.102). The above data showed the scores found biological agents improved thoroughly the whole course as Dass8 did. Synovitis seemed to be eliminated faster than tenosynovitis and the repair of bone erosion was the latest event compared to decreased synovitis and tenosynovitis.

Conclusions: It is recommended U83 used in clinic for US7 scoring system could reflect more excessively than Dass8 in more refined aspects including the changes of tendon, joint, bone at different phases during biological agent treatment for RA. However, more samples and those with positive and negative anti-cyclic citrullinated peptide (anti-CCP)

Methods: We conducted an observational descriptive study of patients who attended a specialized rheumatology clinic in Bogotá, Colombia from 2010 to 2015. Patients with RA were enrolled who had completed at least 5 years of follow-up. The information required to estimate CVD risk was obtained from medical records. Other variables included were biological therapy and test result of anti-CCP. For the calculation of CVD risk, the Framingham estimator was used and adjusted for the Colombian population. Additionally, patients who had 2 or more of these criteria: More than 10 years of evolution of RA, positive rheumatoid factor and/or extra-articular compromise, the risk was adjusted by multiplying by 1.5. Nonparametric statistics (Mann-Whitney U test) was used.

Results: We identified 273 eligible patients with RA with mean age 61, 66% women. Only 117 (42.8%) had recorded in their charts all variables to calculate CVD risk. We found that 32% had high blood pressure, 7% type II DM, 11% Obesity and 13% smoking. The population evaluated, 10-year CVD risk median was 12.42% and for Colombia was 8.69%, adjusting this risk according to the disease in Colombia, increased to 13.03%. When we compare the 10-year CVD risk in anti-CCP positive patients (median: 11.15) and anti-CCP negative (median: 12.42) we found not find differences. However, we found differences in the 10-year CVD risk median 9.04 vs. 23.25, 10-year CVD risk adjusted to Colombia median 6.32 vs. 16.31 and 10-year CVD risk adjusted to Colombia and RA median 6.81 vs. 13.39 between patients using biological therapy versus patients without receiving respectively (p<0.001).

Conclusions: Only 42.8% of the sample had all CV risk factors requested and registered in the clinical record, so should promote improvement in the health team to increase this. The average 10-year CVD risk in all people with RA was 12.42%, and in patients who met the criteria to be multiplied by the factor 1.5 increased to 13.03%, which means that these patients should be reported this and followed up. In addition, the questionnaire regarding obesity and cholesterol levels. Despite population receiving biologics are younger, they had lower CV risk. We need more research to confirm this results

CARDIOVASCULAR RISK, BIOLOGICS AND ANTI-CYC KLITULATED PEPTIDE POSITIVITY IN RHEUMATOID ARTHRITIS

E.A. Jauregui, C.A. Agudelo, C. Aldana, Y.A. Muñoz. Rheumatology, Riesgo de fractura S.A-CAYRE, Bogotá, Colombia

Background: Co-factors and traditional cardiovascular disease (CVD) risk factors contribute to atherosclerosis in rheumatoid arthritis (RA). Several records since 1984 have reported an increase of 4 to 5 times the CVD risk and mortality in RA patients. Physicians who evaluate these patients forget to perform or record this assessments in medical records. Since 1948, the Framingham Heart Study became an ambitious project in health research, to identify the general causes of this assessments in medical records. Since 1948, the Framingham Heart Study became an ambitious project in health research, to identify the general causes of...
Objectives: To describe hospital admissions and contributing factors in patients with rheumatoid arthritis (RA) treated biological DMARD (b-DMARD) and conventional synthetic DMARD (cs-DMAR).

Methods: We systematically searched literature (via Pubmed, Cochrane and abstracts from recent ACR and EULAR congresses) up to March 2016 for observational studies providing data concerning the presence of a traditional cardiovascular risk factor. For each cardiovascular risk factor, results were described with the relative risk (RR) and 95% confidence interval (CI) and with p-value. The RR were calculated for both RA patients and for patients with RA in the control group. A random effect model was used to pool the results.

Results: Out of 5714 screened references, 13 studies were included. Due to lack of data, atherosclerosis studies could not be included in this meta-analysis. For hypertension and diabetes, an increased risk was observed: RR =1.35 [95% CI 1.27–1.45], p<0.0001 and RR=1.11 [1.04–1.19], p=0.001, respectively. On the contrary, hypertension was not associated with dyslipidemia (RR=0.93 [0.77–1.2], p=0.63) and diabetes with dyslipidemia (RR=0.93 [0.92–0.94], p=0.0003).

Conclusions: This meta-analysis highlights a moderate excess risk of hypertension and diabetes among patients with RA relative to the general population. A comprehensive identification of cardiovascular risk profile of RA is an opportunity to improve health management of these patients. Future research is crucial in order to establish to what extent the control of modifiable risk factors can improve cardiovascular outcome of these patients.

HOSPITAL ADMISSIONS OF PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH DMARD

E.C. Cervantes Pérez, J.R. Maneiro, A. Souto Vilas, J.A. Mera Varela, J.J. Gómez-Reino. Ramón Domínguez Foundation, University Hospital Complex of Santiago de Compostela, Santiago de Compostela, Spain

Objectives: To describe hospital admissions and contributing factors in patients with rheumatoid arthritis (RA) treated biological DMARD (b-DMAR) and conventional synthetic DMARD (cs-DMAR).

Methods: Retrospective observational study of RA patients admitted to the hospital for any cause from 2010 to 2015. Demographic, clinical and therapeutic characteristics were collected from the medical charts. Multivariate and univariate models were used to identify variables associated with admissions for any cause, major adverse cardiovascular events (MACE), and infection. The statistical program Stata 14.0 was used for the analysis.

Results: In the period 2010–2015, 26% of all RA patients were treated with b-DMARD. There were a total of 1251 hospital admissions for any cause in 600 patients; 1055 admissions in 477 patients treated with cs-DMAR and 196 admissions in 123 patients treated with b-DMARD. Of the 1251 admissions, 251 were due to infections and 60 to MACE. Demographic, clinical and therapeutic characteristics were collected from the medical charts. Multivariate and univariate models were used to identify variables associated with admissions for any cause, major adverse cardiovascular events (MACE), and infection.

Conclusions: infections and MACE are a significant cause of hospital admission in patients with rheumatoid arthritis. Comorbidities as diabetes, hypertension and dyslipidaemia but not b-DMARD are significantly associated with admission for infection or MACE.

THE POTENTIAL ASSOCIATION BETWEEN RHEUMATOID ARTHRITIS AND TRADITIONAL CARDIOVASCULAR RISK FACTORS: A META-ANALYSIS OF CONTROLLED STUDIES

E. Fitoh, C. Gaujoux-Viala, B. Combe, J. Morel, C. Hua, A. Nutz, C. Lukas, F. Fräsière, Lapeyronie Hospital, Montpellier, Nîmes Hospital, Nîmes, France

Background: Systemic inflammation is the cornerstone of both rheumatoid arthritis (RA) and atherosclerosis. RA is currently considered as a cardiovascular risk factor.

Objectives: The aim of this systematic review was to assess the association between RA and the traditional cardiovascular risk factors (hypertension, dyslipidemia, diabetes mellitus, and atherosclerosis) in RA patients in comparison to the general population.

Methods: We systematically searched literature (via Pubmed, Cochrane and abstracts from recent ACR and EULAR congresses) up to March 2016 for observational studies providing data concerning the presence of a traditional cardiovascular risk factor (among hypertension, dyslipidemia, diabetes mellitus, atherosclerosis) in patients with RA and in a control group. A meta-analysis of the relative risk (RR) concerning patients with RA in relation to the control group was performed for each cardiovascular risk factor.

Results: Out of 5714 screened references, 13 studies were included. Due to lack of data, atherosclerosis studies could not be included in this meta-analysis. For hypertension and diabetes, an increased risk was observed: RR =1.15 [95% CI 1.07–1.24], p=0.0003 and RR=1.11 [1.04–1.19], p=0.001, respectively. On the contrary, not any association was found with the dyslipidemia (RR=0.93 [0.77–1.2], p=0.43).

Conclusions: This meta-analysis highlights a moderate excess risk of hypertension and diabetes among patients with RA relative to the general population. A comprehensive identification of cardiovascular risk profile of RA is an opportunity to improve health management of these patients. Future research is crucial in order to establish to what extent the control of modifiable risk factors can improve cardiovascular outcome of these patients.

RHEUMATOID ARTHRITIS IN BRAZIL – THE “REAL “ STUDY:
COMORBIDITIES IN ECUADORIAN PATIENTS WITH
1, A.B. Vargas-Santos1, C. Albuquerque2, R. Amorim 1,
progress. Ninety-four (41.4%) obstetricians participated in
this survey. They had 22±6.16 years of practice. Thirty-nine
(90.7%) rheumatologists participated in this survey. They
had 26±12.8 years of practice. Figure 1 displays the
percentage of physicians who consider the selected RD medications detrimental
to/not compatible with fertility, pregnancy and breastfeeding.
Average score in accordance with EULAR/BSR guidelines was
0.65±0.154 and results were significantly different between specialties (p<0.001):
rheumatologists scored between 0.41 and 1, with an average of 0.777±0.152
and obstetricians scored between 0.36 and 1 with an average of 0.603±0.124.
Multivariable analysis showed that the scores reflecting adherence to recommen-
dations were significantly associated with type of specialty (rheumatology vs obstetrics) and number of pregnant patients with RD seen per month.

Conclusions: Advices given to RD patients who plan on becoming pregnant in
Lebanon vary largely, especially among the physicians’ specialty and experience in
RD, which highlights the urgency of disseminating the EULAR/BSR guidelines
among rheumatologists and obstetricians alike.

AB0318 CLINICAL AND SEROLOGIC CHARACTERISTICS OF A COHORT OF ECUADORIAN MEN WITH RHEUMATOID ARTHRITIS
1Universidad Espíritu Santo; 2Universidad Católica Santiago de
Guayaquil; 3Universidad Católica Santiago de
Guayaquil; 4Universidad Espíritu Santo; 5Centro de Reumatología y
Rehabilitación, Guayaquil, Ecuador

Background: Rheumatoid arthritis (RA) is an inflammatory and disabling disease whose expression and clinical course is influenced by gender. In developed countries the prevalence of RA is 0.5–1%, with a ratio 3:1 female:male.

Comparative gender studies have shown that women have greater functional
disability, disease activity and pain than men1.

Objectives: The purpose of this study is to describe and compare the clinical and serological characteristics of a cohort of men with RA.

Methods: A cross-sectional study was conducted in patients with established RA in 2013 in 2 hospitals (Vernaza Hospital and a private rheumatology center (CERER). The data included demographics, comorbidities, habits, treatments, laboratory exams, number of swollen and tender joints, Visual Analog Scale (VAS), activity and disability index (DAS28 and HAQ-DI) and PHQ-9 for depression. The statistical program SPSS V. 22 was used to analyze the data and calculate frequencies, percentages, means, ranges, Spearman correlation and ANOVA coefficient. Statistical significance used was 0.05, with a 95% reliability.

Results: 402 patients with a mean age of 50 years were included, 67.8% (353) women and 12.2% (49) men. 93.8% (377) were mestizos, 3.5% (14) White, 1.5% (6) indigenous and 1.2% (5) Afro-Ecuadoreans. As for comorbidities, 55.5% (223) were married, 15.4% (62) cohabiting, 12.4% (50) divorced, 8.5% (34) singles and 8.2% (33) widowers. 9.7% (39) of the patients smoked, 7.5% (30) ingested alcohol and 0.5% (2) drugs. The average age of onset of the disease was 41 years, with a median time from onset of symptoms and the first rheumatology visit of 28.7 months, median follow-up time of 51.8 months and average disease duration of 11 years. For comorbidities, 54.8% (147/269) had dyslipidemia, 28.4% (114) gastric ulcer, 23.6% (95) hypertension, 20.1% (81) obesity, 19.6% (79) depression, 15.2% (61) thyroid disease, 12.4% (50) of the sexual involvement, 10.7% (43) allergies, 10.4% (32/307) hypertransaminasemia, 9.3% (21/225) anemia, and 6.7% (27) diabetes mellitus. 32.3% (114) of women had at least one abortion. The PHQ-9 medium was 5.3; according to this 11.2% (45) corresponded to mild depression, 4.5% (18) moderate depression, 3.2% (13) moderately severe depression and 0.7% (3) severe depression. As for the other indicators of disease activity, the average for the number of painful joints was 5 (0–28), swollen joints 4 (0–26), patient VAS 3.9 (0–10) and doctor VAS 3.4 (0–10). In laboratory data, 67.4% (215/319) had positive ESR, 64.8% (149/230) C-reactive protein, 90.5% (182/201) anti CCP positive, and 94.4% (286/307) RF.

Conclusions: This is the first study of comorbidities in patients with RA in Ecuador. Patients with RA have a high prevalence of comorbidities and risk factors, which is why physicians should be prepared to prevent them and offer an early treatment.

AB0320 RHEUMATOID ARTHRITIS IN BRAZIL – THE “REAL” STUDY: A NATIONWIDE PROSPECTIVE STUDY

1Universidade de São Paulo, São Paulo; 11Universidade de São Paulo – Ribeirão Preto; 10Universidade de Brasilia, Brasilia; 9Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo; 4Universidade Federal do Paraná, Curitiba; 7Universidade Federal de Santa Catarina, Florianópolis; 6Universidade Federal de Minas Gerais, Belo Horizonte; 2Universidade Estadual de Campinas, Campinas; 8Universidade de São Paulo - Ribeirão Preto, Ribeirão Preto; 3Universidade Federal do Pará, Belém; 5Universidade de São Paulo, São Paulo; 11Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

Background: Early diagnosis and immediate treatment are critical in achieving optimal outcomes in rheumatoid arthritis (RA). However, anecdotal evidence suggests that in Brazil there is still a significant delay in patient referral, RA diagnosis and DMDAR initiation. The lack of national data hinders effective advocacy for proper public health policies, which led the RA commission of the Brazilian Society of Rheumatology to create a nationally-representative multicenter RA cohort to provide the necessary data.

Objectives: To describe the development process and baseline characteristics of a large, nationally-representative multicenter cohort of RA patients in Brazil.
Methods: Twelve public rheumatology centers from all of the 5 regions of Brazil enrolled ~100 consecutive RA patients each (1987 ARA or 2010 ACR-EULAR). This cohort is being followed prospectively for 1 year, with systematic data collection at time 0, 6±1 months and 12±1 months, and registration of all other visits during this 1-year period. Data collection began in 08–2015, using a single online electronic medical record, and included demographic, socioeconomic, clinical, laboratory, radiographic and therapeutic characteristics, along with functional status, quality of life and adherence to treatment information.

Results: 1125 patients were enrolled (Table). -90% were female, with a mean age of 56 years and median disease duration of 13 years. Median BMI was 27 kg/m², with 64% of the patients classified as overweight or obese. The interval between symptoms and diagnosis varied from 1 to 457 months (median 12 months). Almost half of the patients were on glucocorticoids, 96% on DMARDs, with 36% on biologics. Only 7% were seronegative for both rheumatoid factor and ACPA. Median HAO-DI was 0.075 and median DAS28-ESR was 3.5, with 58.6% of patients presenting moderate or high disease activity.

Conclusions: The delay in diagnosis may explain the high percentage of patients with moderate or high disease activity and erosive disease. The low level of physical dysfunction observed in this established, predominantly seropositive RA population may be explained by the large proportion of patients on glucocorticoid and biologic therapy. Our findings suggest that, despite current treatment concepts being well known and accepted by Brazilian rheumatologists, there is still a gap in early diagnosis and management of RA.

AB0321 RELATIONSHIP OF CAROTID FEMORAL PULSE WAVE VELOCITY WITH AGE AND TIME OF EVOLUTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. Ramos1, G. Alarcon1, D. Cardona2, S. Totsuka1, E. Cardona1, F. Perez1, A. Coldar1, J. Gomez1, M. Vazquez del Mercado1.1Physiology, University of Guadalajara,2Physiology, University of Guadalajara, Guadalajara, Mexico

Background: Early vascular aging occurring in Rheumatoid Arthritis (RA) may be a consequence of chronic inflammation. The measurement of Carotid-femoral pulse wave velocity (cfPWV) is the gold standard to evaluate arterial stiffness. Early vascular aging occurring in Rheumatoid Arthritis (RA) may

Objectives: The aim of this study was to evaluate variations in the Carotid-Femoral Pulse Wave Velocity (cfPWV) and its association to age and time of disease evolution in patients with rheumatoid arthritis.

Methods: RA patients were matched for age and sex with healthy controls. Subjects with a history of smoking, cardiovascular disease, hypertension, diabetes mellitus, cancer, liver disease, thyroid disease and kidney disease were excluded. The cfPWV was calculated using the PulsePen® (Diatrace, Italy) device.

Results: We included 76 women with RA and 28 healthy women, mean age (44.3±10.92 vs. 43.0±16.26, P=0.654). cfPWV demonstrated good correlation with age (r=0.459, P<0.01), disease evolution time (r=0.311, P<0.008), triglycerides (r=0.289, P=0.03), total cholesterol (r=0.421, P<0.001) and atherogenic index (r=-0.320, P=0.02). No association with disease activity was found. cfPWV was higher in those patients with RA >10 years evolution compared to patients with <10 years of disease evolution and to controls (P<0.05).

Conclusions: A significant association between cfPWV was seen in patients with RA, and was also correlated to age and to a disease evolution >10 years long without finding a significant association with increased disease activity.

References:
was significantly higher compared to patients in GCPT group – 7 (10.3%) and 6 (8.8%) respectively (p < 0.038 and p < 0.049). Baseline C-peptide was elevated in patients who developed IGT after a course of GCPT (850 pmol/l before GCPT, 4099 pmol/l 4–6 hours after GCPT and 1904 pmol/l after a 3-days course of GCPT) or DM (1050 pmol/l, 3170 pmol/l and 1796 pmol/l before GCPT, at peak blood glucose level and after a 3-days course of GCPT, respectively) (p < 0.05). C-peptide remained normal in the absence of CMD and in IGT patients. Baseline HOME-IR index was elevated in patients with IGT (4.52, 17.47, 9.67 before GCPT, at peak blood glucose level and after a 3-days course of GCPT, respectively) and DM (5.04, 15.2, 10.4 respectively) (p < 0.05), and normal in patients without CMD (2.5, 5.84 and 4.01 respectively) and patients with impaired fasting glucose (IFG) (2.46, 7.08 and 5.46).

HOME-iel anti index analysis revealed that in the absence of CMD and at earlier stages of CMDs (IFG, IGT) insulin resistance is compensated via an increase of β-cell secretory activity, which is associated with a significant decrease of HOME-iel index to 64.6 at peak blood glucose levels after GCPT compared to baseline level (170) (< 0.05). C-peptide, HOME-IR and HOME-iel index levels in OGCT patients demonstrated same trend as in GCPT patients. Significant differences were observed in patients with IGT and DM before and after oral glucose tolerance test (OGTT) on C-peptide (1042 pmol/l vs. 1978 pmol/l in IGT; 1306 pmol/l vs. 2286 pmol/l in DM) and HOME-IR (4.53 vs. 9.81 in IGT; 5.6 vs. 11.27 in DM patients), whereas in patients without CMD and in patients with IFG, C-peptide before OGTT was 489 pmol/l vs. 742 pmol/l, after - 1295 pmol/l vs. 1488 pmol/l, HOME-IR was 3.9 vs. 2.88 before OGTT and 2.88 vs. 5.85 after the test in the absence of CMD and in IFG patients, respectively. A significant decrease of β-cell function was observed in DM patients, reflected by a decrease of HOME-iel after OGTT compared to baseline (147 vs. 78.4).

Conclusions: C-peptide in IGT and DM in patients with increased IR both during GCPT and long-term OGCT. Long-term OGCT is associated with more CMDs compared to GCPT.

AB0324 IS LOW SERUM VITAMIN D LEVEL ASSOCIATED WITH INCREASED NEUROPATHIC PAIN IN RHEUMATOID ARTHRITIS PATIENTS? A CROSS-SECTIONAL STUDY

1, Physical Medicine and Rehabilitation, Afyon Kocatepe University, Afyonkarahisar; 2, Afyon Kocatepe University, Afyonkarahisar, Turkey

Background: Rheumatoid arthritis (RA) is a systemic, autoimmune, progressive condition characterised by progressive synovitis with resultant joint destruction, functional disability and significant pain. Recent experimental data indicates that there may be a neuropathic component of pain perception in RA.

Objectives: The aim of this study was to examine the development of neuropathic pain (NP) in patients with RA and its relationship with vitamin D.

Methods: We used the Leeds assessment of neuropathic symptoms and signs (LASNSS) questionnaire to evaluate NP in 93 patients with RA. Clinical parameters included general demographics, and disease activity scores were evaluated. The patients also completed Short form-36 survey, and Health Assessment Questionnaire.

Results: Of all the patients who were eligible for the study, 75 were female (80.6%). Mean serum vitamin D level of the participants was calculated to be 22.8±11.9 ng/ml. According to the LANSS questionnaire 31 patients (33.3%) were classified as having NP. There was a negative correlation between vitamin D levels and LANSS value (p<0.001). We have determined that vitamin D serum levels below 20 ng/ml have significantly higher NP positivity rate (p<0.012), besides they have 5.8 times more risk of developing NP when compared to patients with vitamin D serum levels ≥30 ng/ml.

Conclusions: We conclude that Vitamin D deficiency is prevalent in RA patients with NP. However, it is the right diagnosis, Vitamin D deficiency treatment is relatively easy, safe, inexpensive and with satisfactory outcomes; therefore, an underlying vitamin D deficiency should be explored in the etiology of NP in patients with RA.

AB0325 TREAT TO TARGET AND THE REAL LIFE EXPERIENCE – DATA FROM A COHORT OF RHEUMATOID ARTHRITIS PATIENTS IN SOUTH EAST ROMANIA (CONSTANTA COUNTY)

V.C. Suta1, T. L. Andronache1, M. Suta2, I. Rheumatology Department, IInd Internal Medicine Clinic, “St. Apostol Andrei” Emergency Clinical County Hospital Constanta; 2 Faculty of Medicine, “OVIDIU” University Constanta, Constanta, Romania

Background: Treatment target in rheumatoid arthritis (RA) is remission or low disease activity. Considering that there is no quantitative “gold standard” for measuring disease activity, monitoring and evaluation of RA patients is made through composite scores, which have an important subjective component. Moreover, the laboratory investigations used (ESR and CRP) are commonly discordant with the clinical findings.

Objective: To evaluate patient disease activity and establish relations between disease activity scores and their components in RA patients.

Methods: We performed a transversal study which included 447 RA patients (aged 18 to 86-years-old) admitted to our Rheumatology Department between January 2014 and December 2015. Patients’ evaluation was performed by the rheumatologist. All the data obtained from the medical history, clinical examination, laboratory tests and imaging studies was recorded at the same date. All patients signed a dated informed consent at the time of admission.

Results: The study included 447 patients, mean age 62.13±11.44, 85% women, accounting for a female: male ratio (F:M) of almost 6:1 (5.7:1) with an average disease duration of 49% of 10.75±9.85 years. 48% of our patients presented with normal CRP values (<0.5mg/dl) and values of ≤1mg/dl for CRP; compatible with Boolean remission, were present in 66.6% of the patients. A significant percentage of our sample population (194 patients: 43.4%) registered normal ESR values (<28 mm/h).

Remission and LDA were registered in 18.1% up to 29.8% of the patients, depending on the score used. The lowest rate of remission and low activity is registered through the DAS28 ESR evaluation (18.1%). The other three scores outline similar percentages for T27 group of patients: 27.1% (SDAI), 29.7% (SASSA) and 29.7% (DAS28 4.4). The DAS28 ESR score is characterized in our study by a small number of swollen joints (<1), medium-normal ESR values (<30mm/h) and CRP values ≤1mg/dl (with the exception of SDAI). Consequently, patients with low activity based on the afore mentioned scores meet remission according to Boolean definition.

Conclusions: The disease activity and implicitly the remission rate are appreciated differently depending on the scale used. The limit between remission and low disease activity is fragile, influenced mainly by the purely subjective components of the assessment instruments. The important differences between the subjective and objective components of the evaluation scales recommend the supplementation of methods used in order to emphasize the real degree of joint inflammation.

AB0326 INFLUENCE OF NONSTEROIDAL ANTI-INFLAMMATORY DRUGS ON ARTERSINAL STIFFNESS IN PATIENTS WITH RHEUMATIC DISEASES

J.N. Kim, J.-Y. Choe, S.-K. Kim, S.-H. Park, H. Lee, C.U. Lee, J.-W. Kim. Division of Rheumatology, Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, Korea, Republic Of

Background: The association with adverse cardiovascular (CV) events and NSAIDs has been the topic of much debate.

Objectives: The aim of the present study was to investigate the effects of continuing NSAIDs therapy on predictable parameters for CV events.

Methods: We enrolled 155 patients with variable rheumatic diseases (95 rheumatoid arthritis, 49 systemic lupus erythematosus, 3 behceth’s disease, 3 gout, 5others.) who were free from established CV diseases and had taken cardiovascular function tests from June 2015 to June 2016. They were divided into two groups depending on whether or not to have taken NSAIDs therapy for at least 5 years: NSAIDs taking group (91 patients) vs. non NSAIDs taking group (64 patients). For evaluating heart function, thoracish echocardiography was used. Arterial stiffness was assessed using brachial-ankle pulse wave analysis.

Results: There were no significant differences in blood pressure, serum creatinine, serum hemoglobin, total cholesterol, erythrocyte sediment rate, C-reactive protein, disease duration, age, and smoking history between the groups. The NSAIDs
taking group had a higher median (95% CI) baPWV (brachial-ankle pulse wave velocity) and median (95% CI) mean pulmonary artery pressure (mPAP) than non-NSAID taking group: baPWV 13.72 (12.77–15.52) vs. 15.29 (13.93–17.63) m/s, p=0.005; mPAP 26.5 (22.8–30.5) vs. 30.5 (27.3–32.3) mmHg, p=0.011. But baPWV and mPAP were not significantly different between selective cyclooxygenase-2 inhibitor (22 patients) and nonselective NSAIDs (69 patients): baPWV 15.33 (13.98–17.63) vs. 14.83 (13.82–17.39) m/s, p=0.191; mPAP 29.0 (24.5–34.5) vs. 30.0 (26.0–33.0) mmHg, p=0.960.

Conclusions: Our study suggests that continuing NSAIDs therapy is associated with increased arterial stiffness in patients with rheumatic diseases, independently noted to increase the incidence of cardiovascular disease.

**FEAR OF FALLING AND FOOT PAIN, IMPAIRMENT AND DISABILITY IN RHEUMATOID ARTHRITIS**

J. Bahha, B. Amine, M. Erraoui, Y. Boujenane, S. Fellous, I. El Binoune, R. Bahin. Rheumatology, Mohammed V University, Faculty of Medicine and Pharmacy of Rabat, El Ayachi Hospital, sale, Morocco

**Background:** Fear of falling, foot pain and functional disability are commonly reported in rheumatoid arthritis. Moreover, the relationship between the fear of falling and foot pain, impairment and disability has rarely been studied.

**Objectives:** To evaluate the relationship between fear of falling and foot pain, impairment and disability in patients with established RA.

**Methods:** A cross-sectional study that included patients with rheumatoid arthritis. We collected the following data: age, sex, duration of disease, foot pain assessed by the Visual Analogue Scale (VAS), Disease activity assessed by DAS 28, HAQ disability index (HAQ-DI). Fear of falling was assessed by Falls Efficacy Scale-International (FES-I) which consists of 16 different activities, scored using a four point scale (1=not at all concerned, 2= somewhat concerned, 3=fairly concerned and 4=very concerned). The summed scores for the 16 activities for each participant were calculated. Scores of ≥23 indicated a significant fear of falling. Foot disability and impairment were measured using the Leeds Foot Impact Scale (LFIS), Foot disability was represented by the total score of the LFIST; range 0 to 51) of the LFIS and foot impairment by the first subscale (LFISIF; range 0 to 21). Correlations were used to assess the relationship between fear of falling and foot pain, impairment and disability.

**Results:** Thirty-three patients were included. The mean age was 49.3±10.5 years with female predominance (n=29 (87.9%)). The mean disease duration was 9.9±7.5 years. The mean HAQ-DI was 1.02±1.7 and the SDCI was 1.86±2.7. The mean FES-I score was 37.4±15.1 and 69.7% (n=23) of patients had significant fear of falling. The mean VAS pain was 5.3±2.5, the PGA was 6.2±2.1 and the EGA was 5.7±1.7. The mean DAS28 score was 5.5±1.3. The mean CDAI was 29.9±13.6 and the SDI was 31.6±13.7.

Fear of falling was significantly correlated with TJC28 (r =0.52, p=0.001), PGA (r=0.56, p=0.001), EGA (r =0.39, p=0.025), HAQ-DI (r =0.40, p=0.001), DAS28 (r ≥0.38, p=0.029), CDAI (r =0.48, p=0.005) and SDI (r ≥0.52, p=0.002).

**Conclusions:** Our study suggests that continuing NSAIDs therapy is associated with increased arterial stiffness in patients with rheumatic diseases, independently noted to increase the incidence of cardiovascular disease.

**DO ANXIOUS OR DEPRESSIVE RHEUMATOID ARTHRITIS PATIENTS ON BIOTECHNOLOGIC THERAPY HAVE WORSE DISEASE ACTIVITY, FUNCTION AND QUALITY OF LIFE?**

J. Borges 1, N. Madeira 1, A. Cardoso 2, L. Cunha-Miranda 1, F. Barcelos 1, C. Miguel 1, C. Silva 1, S. Fernandezes 1, R. Trinca 3, D. Medeiros 1, A. Manelino-Marques 1, H. Santos 1, R. Leitão 1, A. Faustino 1.

Rheumatology; 2Nutrition; 3Nursing, Instituto Portugues de Reumatologia, Lisboa, Portugal

**Background:** Depression, anxiety and fatigue are common symptoms in rheumatoid arthritis (RA) patients, and seem to influence disease activity, pain, quality of life (QoL), and treatment response.

**Objectives:** To assess disease activity, function and QoL in RA patients with symptoms of anxiety/depression.

**Methods:** Observational, cross-sectional study including RA patients on bDMARD followed at our centre, registered at Reuma.pt with ≥1 evaluation from 2015/11 to 2016/07. Clinical data including DAS28, CDAI, SDAI, TJC, SJC, patients’ and physicians’ pain/global assessments (VAS), ESP, CRP, HAQ, EQSD. HADS score (anxiety and depression domains, cutoff >8) and FACIT-F were collected. Data were analyzed using Mann-Whitney, Qui-Squared and Spearman correlation, p<0.05.

**Results:** 182 patients enrolled, 84.6% female, mean age: age at 1st bDMARD 53.8±11.1; time since diagnosis 16.2±9.3 years; DAS28 3.5±1.3; CDAI 10.2±9.6; SDI 11.2±10.4; HAQ 0.97±0.6; HADS-Anxiety 7.1±3.5; HADS-Depression 6.62±4.54, FACIT -F 35.1±9.2, EQ-5D 0.36±0.2. 77 (44.5%) patients scored ≥8.1 evaluation from 2015/11 to 2016/07. Clinical data including DAS28, CDAI, SDAI, TJC, SJC, patients’ and physicians’ pain/global assessments (VAS), ESP, CRP, HAQ, EQSD. HADS score (anxiety and depression domains, cutoff >8) and FACIT-F were collected. Data were analyzed using Mann-Whitney, Qui-Squared and Spearman correlation, p<0.05.

**Results:** Thirty-three patients were included. The mean age was 49.3±10.5 years with female predominance (n=29 (87.9%)). The mean disease duration was 9.9±7.5 years. The mean HAQ-DI was 1.02±1.7 and the SDCI was 1.86±2.7. The mean FES-I score was 37.4±15.1 and 69.7% (n=23) of patients had significant fear of falling. The mean VAS pain was 5.3±2.5, the PGA was 6.2±2.1 and the EGA was 5.7±1.7. The mean DAS28 score was 5.5±1.3. The mean CDAI was 29.9±13.6 and the SDI was 31.6±13.7.

Fear of falling was significantly correlated with TJC28 (r =0.52, p=0.001), PGA (r=0.56, p=0.001), EGA (r =0.39, p=0.025), HAQ-DI (r =0.40, p=0.001), DAS28 (r ≥0.38, p=0.029), CDAI (r =0.48, p=0.005) and SDI (r ≥0.52, p=0.002).

**Conclusions:** This study suggests that fear of falling is frequent in patients with rheumatoid arthritis and demonstrated that fear of falling is significantly correlated with disease activity.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.6029
Conclusions: Anxious or depressive patients showed higher disease activity, especially in measures with some subjectivity (such as TJC and PGA) but not regarding ESR or CRP and worse function and QoL. This fact must be taken into account when evaluating therapeutic efficacy.

AB0330 RHEUMATOID FACTOR AND RO52kDA ANTIBODIES ARE INDEPENDENT PREDICTORS OF INSULIN RESISTANCE IN RHEUMATOID ARTHRITIS

J. Aguilar-Arregui1, F.D. Perez-Vazquez2, E. Gomez-Bañuelos2, G.-I. Diaz-Rubio3, S. Duran-Barragan2, F.-I. Corona-Meraz2, A. Saldaña-Millán2, R.-E. Navarro-Hernández2, M. Vázquez-Del Mercado2, 1Servicio de Reumatología, División de Medicina Interna, Ppcc 004086, CONACyT, Hospital Civil, “Juan I. Menchaca”; 2Instituto de Investigación en Reumatología y del Sistema Musculoesquelético, Universidad de Guadalajara, Guadalajara, Mexico

Background: The rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) autoantibodies in rheumatoid arthritis (RA), have been used as diagnostic and prognostic tools [1]. However, this traditional perspective has changed toward a major role in RA pathogenesis. Several studies have demonstrated that FR and ACPA autoimmune positivity beyond its level, might influence disease activity, bone erosions and development of comorbidities. Anti-Ro52kDa antibodies have also been associated with disease severity in RA and might influence the development of comorbidities such as insulin resistance (IR) in RA.

Objectives: To evaluate the association between RF, ACPA and anti-Ro52 kDa and IR in RA patients.

Methods: We included 83 RA patients classified according to ACR 1987 and ACR/EULAR 2010 criteria and 90 controls matched for age, gender and body mass index (BMI). Homeostasis Model Assessment-Insulin Resistance (HOMA-IR), anthropometric parameters and antibody positivity (RF, ACPA, Ro52 kDa) were evaluated. Multivariate regression analysis was used to assess the contribution of autoantibodies, adiposity and disease activity to insulin resistance in RA.

Results: Patients positive for RF or anti-Ro52 kDa showed higher levels of basal insulin (P=0.009, P=0.006) and HOMA-IR. DAS-28 ESR was correlated with basal insulin (r=0.31, P=0.01) and HOMA-IR (r=0.29, P=0.02). We also observed positive correlations between serum triglycerides (r=0.47, P=0.01) and HDL-c (r=-0.38, P=0.02) and basal insulin. Multivariate analysis showed that Triglycerides, HDL-c, DAS-28, RF and anti-Ro52 kDa were independent predictors of basal insulin and HOMA-IR in patients with RA.

Conclusions: In RA, RF or anti-Ro52 kDa are independent predictors of IR. This phenomenon might be linked to the network of inflammation, adipokine secretion, since disease activity was also precipitous of higher basal insulin. Both RF and anti Ro52 kDa, along with disease activity are independent predictors of IR in RA patients without comorbidities.

References:
[4] Matsudaira R, Tamura N, Sekiya F, Ogasawara M, Yamanaka K, Takasaki Conclusions: The value of RDW does not appear to significantly change its value regarding ESR or CRP and worse function and QoL. This fact must be taken into account when evaluating therapeutic efficacy.

AB0331 BEHAVIOR OF THE VALUE OF RED CELL DISTRIBUTION WIDTH IN PATIENTS WITH RHEUMATOID ARTHRITIS IN TREATMENT WITH DAILY DOSE OF METOTREXATE

J.E. Espinoza Martínez, M.U. Martinez Martínez, C. Abud-Mendoza, Unidad de Reumatología y Osteoporosis, Hospital Central Dr. Ignacio Morones Prieto, San Luis Potosí, Mexico

Background: Recently the relationship between inflammatory biomarkers such as C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) has been found, with the increase in the percentage of red cell distribution width (RDW) events related to increase in cardiovascular risk in patients with rheumatoid arthritis (RA). RDW is a parameter that represents the heterogeneity of erythrocyte size and is calculated by an automatic blood analyzer, translates anisocytosis and in turn is related to atherosclerosis, is a predictor of mortality in patients with cardiovascular diseases such as acute myocardial infarction (AMI) and Congestive Heart Failure (CHF) plus it has the advantage of being very cheap. In patients with RA who receive treatment with methotrexate (MTX), particularly those with good therapeutic response with decreased disease activity, the values of ESR and CRP decrease.

Objectives: The aim of this study is to verify if there is a decrease, increase or neither change in the value of RDW in the patients receiving or not MTX comparing the value prior to the start of treatment and the last value measured during their therapy.

Methods: In this descriptive, non-experimental cross-sectional study, men and women older than 18 years of age with a diagnosis of rheumatoid arthritis according to ACR criteria (Aletaha et al., 2010) who were or not treated with methotrexate and other DMARDs. We excluded patients with less than two visits in this unit and the elimination criteria were patients who did not have baseline or last RDW test. The records of all patients included name, age, sex, date of diagnosis of RA, comorbidities, baseline and final laboratory exams during follow-up that included tests with RDW and medications.

Results: A total of 403 all with a diagnosis of RA and an average of 4.62 years of evolution, of which 51 they do not take methotrexate in daily dose and 352 receive treatment and only 4.2% suffered from a cardiovascular event. The comparison was made grouping the patients in whom they received and not treatment with methotrexate and correlated with the value of baseline and final RDW as shown in Table 1.

<table>
<thead>
<tr>
<th>Table 1</th>
</tr>
</thead>
<tbody>

<tr>
<td><strong>Baseline RDW</strong></td>
</tr>
<tr>
<td>Minimum</td>
</tr>
<tr>
<td>Median</td>
</tr>
<tr>
<td>Mean</td>
</tr>
<tr>
<td>Maximum</td>
</tr>
</tbody>
</table>

The results shown in Table 1, do not appear to reveal a significant change in RDW values between the different subgroups; in the figures we compared the median of RDW for each group of patients who take methotrexate from all patients included in this study.

Conclusions: The value of RDW does not appear to significantly change its value when taking methotrexate at a daily dose in RA patients. The value of RDW may have weight in the assessment of the risk of suffering a cardiovascular event in patients with rheumatoid arthritis.

AB0332 DOES A COMMUNITY INTERFACE RHEUMATOID ARTHRITIS ANNUAL REVIEW IMPROVE PATIENT CARE?

J. Mcdonald R, Haign, D. Murphy. Rheumatology, Royal Devon and Exeter Hospital, Exeter, United Kingdom

Background: Patients with rheumatoid arthritis are known to have a long term disability and increased risk of extra-articular comorbidities. EULAR guidelines suggest annual review of cardiovascular risk in patients with rheumatoid arthritis [1] whilst UK national (NiCE) guidelines suggest a more holistic annual review to look at the impact of the disease on quality of life as well as co-morbidities [2].

1AB0331

2AB0332
Objectives: Our aim was to look at the annual reviews currently taking place in primary care to see how frequently patient co-morbidities were assessed and documented. We then implemented a formal community rheumatology interface review to assess whether this improved patient care.

Methods: A large primary care practice (16,000 patients) was offered a community rheumatology interface review by a secondary care clinician. A search was undertaken for patients with rheumatoid arthritis who had attended for an annual primary care review between December 2015–2016. Of these 30 reviews were selected and we assessed how frequently the following were recorded: DAS28, HAQ score, FRAX score, Q-Risk2 (CV risk assessment tool) and screening for depression. Once we had analysed these results we implemented a community rheumatology interface review and assessed compliance with the above outcomes had improved compared to standard primary care management.

Results: In patients assessed prior to implementation of interface review, we found that a DAS28 score was recorded in 0%, HAQ score in 0%, FRAX in 13%, Q-Risk2 in 10% and depression screening in 23%. In comparison, patients assessed by a community rheumatology interface clinician recorded DAS28 in 100%, HAQ score in 100%, FRAX in 100%, Q-Risk2 in 100% and depression screening was recorded in 100%. Based on improved interface review 7 patients (23%) were sent for DEXA scanning or started on a bisphophonate, we discussed cardiovascular risk and starting a statin in 8 patients (26%) and 7 patients (23%) required follow-up for mental health. Of the 30 patients in this cohort all patients reported full adherence to their anti-rheumatic regime.

Conclusions: 1. An annual review with a rheumatology interface practitioner is of benefit in holistic patient care and improved compliance with all domains of the annual review.

AB0334 KNEE FUNCTION AFTER TOTAL KNEE ARTHROPLASTY IS INFLUENCED BY DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Harigane1,2, K. Kumagai2, Y. Mochida1, K. Ishii1, Y. Miyama1, H. Choe2, A. Nagatoki1, Y. Inaba1, N. Hitsuji1, T. Saito1, 1Center for Rheumatic Diseases, Yokohama City University Medical Center; 2Department of Orthopaedic Surgery, Yokohama City University; 3Department of Orthopaedic Surgery, Yokohama City University Medical Center, Yokohama, Japan

Background: Several studies reported that development of pharmaco-medicolegal treatment for rheumatoid arthritis (RA) contributed to decreased number of orthopaedic surgery. [1–3] Surgical treatment is, however, still required in many cases, and the impact of orthopaedic surgery on disease activity remain unclear.

Objectives: The aims of current study was to evaluate the effect of total knee arthroplasty (TKA) with capsulosynovectomy on changes of disease activity and knee function after TKA in patients with RA.

Methods: Seventy-seven serial patients with RA (61 female and 16 male) who underwent primary TKA with more than one year of follow-up were retrospectively reviewed to assess postoperative disease activity and knee function. The mean age at the time of surgery was 68.3 years. The disease activity of RA was measured using Disease Activity Score in 28 Joints (DAS28). Clinical outcome was measured by treatment score for RA knee of the Japanese Orthopaedic Association (JOA) score. To evaluate the effects of disease activity on knee function, outcomes at before and one year after surgery were separately investigated following two groups; patients who had remission or low disease activity in DAS28-CRP (good controlled group), and patients who had moderate or high disease activity (poor controlled group) one year after surgery.

Results: The disease activity of RA was significantly decreased in DAS28-CRP one year after surgery. (3.9 vs. 2.7, p < 0.01) Postoperative knee function was significantly improved in JOA scores one year after surgery. (48.9 vs. 86.0, p < 0.01). As for differences of knee function between good and poor controlled group, the mean JOA score in good controlled group was significantly better than in poor controlled group. (90.4 vs. 82.1, p < 0.01) Postoperative knee function was negatively correlated with RA disease activity. (R^2=0.21, p < 0.01)

Conclusions: TKA with capsulosynovectomy improves both knee function and disease activity in patients with RA. Based on the results, knee function after TKA is influenced with disease activity.

DOI: 10.1163/1875418X-0001
EFFECT OF TOTAL KNEE ARTHROPLASTY ON MEDICATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Harigane 1, 2, Y. Mochida 3, K. Kumagai 2, K. Ishii 1, Y. Miyamae 1, N. Mitsugi 3, Biological Therapy in Severe Peripheral Ulcerative Disease. (3.9 vs. 2.7, p < 0.01) As for difference of the disease activity in same and change groups, DAS28-2CRP was significantly decreased after surgery (same group; 3.7 vs. 3.2, p < 0.01) as well as change group; 3.7 vs. 3.2, p < 0.01) DAS28-2CRP in change group was significantly higher both before and after surgery compared with those in same group. (p < 0.01)

Conclusions: TKA with capsulosynovectomy improves disease activity after surgery in patients with RA. Based on the results, patients with higher disease activity before surgery required further medication after surgery.

References:

Objective: This study evaluated the effect of total knee arthroplasty (TKA) with capsulosynovectomy on changes of disease activity and medication in patients with RA.

Methods: Seventy-seven serial patients with RA (61 female and 16 male) who underwent primary TKA with more than one year of follow-up were retrospectively reviewed to assess postoperative disease activity and drug administration. The mean age at the time of surgery was 68.3 years old. The disease activity of RA was measured using Disease Activity Score 28 joints (DAS28). To evaluate the effects of medication on preoperative and postoperative disease activity, outcomes at before surgery and one year after surgery were separately investigated following two groups; patients who were treated with the same or reduced medication (same group) and patients who were administered with additional or alternative medication (change group).

Results: Seventy-two patients (97.3%) were administered with at least one DMARDs before or after surgery. The mean dose of methotrexate (MTX) was 7.7mg/week before surgery and 8.0mg/week after surgery respectively. The number of patients treated with biological DMARDs was increased after surgery (17 patients vs.21 patients), however there was not significant differences. RA disease activity was significantly decreased in DAS28-CRP one year after surgery (17 patients vs.21 patients), however there was not significant differences.

Conclusions: TKA with capsulosynovectomy improves disease activity after surgery in patients with RA. Based on the results, patients with higher disease activity before surgery required further medication after surgery.

AB0336 MAGNETIC RESONANCE IMAGING-ASSESSED SYNOVIAL AND BONE CHANGES IN HAND AND WRIST JOINTS OF RHEUMATOID ARTHRITIS PATIENTS

Background: Magnetic resonance imaging (MRI) is a sensitive and useful method for the detection of synovitis and joint destruction in rheumatoid arthritis (RA) patients. However, the patterns of MRI-detected bone erosion, bone marrow edema (BME), synovitis, and tenosynovitis have received insufficient attention.

Objectives: Therefore, this study evaluated the patterns of bone erosion, BME, synovitis, and tenosynovitis and calculated the RA-MRI score (RAMRIS) of patients with RA at the carpal and metacarpophalangeal (MCP) joints using MRI.

Methods: MRI datasets from 43 RA patients were analyzed. All patients had undergone MRI of one wrist. In addition, 36 patients had MCP joint images taken, and 5 had also received MRI of the contralateral wrist and MCP joints. The MR images were evaluated for bone erosion, BME, and synovitis in consensus by 2 blinded readers according to the OMERACT RA-MRI score (RAMRIS). The MRI-detected tenosynovitis was evaluated based on Haavardsholm’s tenosynovitis score.

Results: The capitale, lunate, triquetrum, and hamate bones were the most common sites of erosion and BME and showed the highest RAMRIS erosion and BME scores. Moreover, MRI-detected tenosynovitis was present in 78.3% of all patients with RA, and the extensor compartment 4 and flexor digitorum profundus and superficialis were frequently affected.

Conclusions: This study identified the distribution and prevalence of MRI-detected bone erosion, BME, synovitis, and tenosynovitis of the wrist and MCP joints in RA patients. The patterns of the MRI-detected abnormalities may help to select sites for the application of MRI protocols in clinical trials and practice.

AB0337 BIOLOGIC THERAPY IN SEVERE PERIPHERAL ULCERATIVE KERATITIS (PUK). MULTICENTER STUDY OF 27 PATIENTS

García Aparicio 4, A. Juan Ma 5, N. Palomu 5, M. González-Gay 1, R. Blanco 1, H. LMV Santiago 2, H. Donostia 3, H. Pezet 6, Valencia; 7H; H Río Carmón, Palencia; 6H San Carlos, Madrid; 6C Hospitalario, Zamora; 9H; Toledo; 1H S Lázter, P Mallorca, Spain

Background: Peripheral Ulcerative Keratitis (PUK) is a severe infection that may lead to ocular perforation. PUK may be primary or associated with systemic conditions. Treatment is based on corticosteroids and conventional systemic immunomodulating drugs.

Objectives: To evaluate biologic therapy in cases with severe and refractory PUK.

Methods: Multicenter study of 9 hospitals. Patients presented inadequate response or intolerance to conventional therapy with corticosteroids and at least 1 systemic traditional immunomodulating drug.

The main outcome measures were visual acuity, signs of inflammation, progression to corneal thinning, central keratolysis and ocular perforation. Comparisons were made between baseline and 1st week, 1st month, 6th month and 1st year. Statistical analysis was performed using the software STATISTICA (StatSoft). Results were expressed as means±SD for variables with a normal distribution, or as median [IQR] when they were not normally distributed. The comparison of continuous variables was performed using the Wilcoxon test and categorical variables with chi-square test.

Results: We studied 27 patients/35 affected eyes (7 men/20 women), mean age, 57.2±16.3 years (range 28–89). PUK was primary in 1 case whereas in the 26 remaining cases, the underlying diseases were Rheumatoid Arthritis (RA) (n=19), Psoriatic Arthritis (n=2), RA+Felty syndrome (n=1), Behçet Disease (n=1), Type I diabetes mellitus (n=1), granulomatous panarteritis (n=1), and microscopic polyangiitis (n=1). They received the following biologic drugs: rituximab (n=16), oral doxycycline (3), azathioprine (3) and ascorbic acid (2). Moreover, 10 patients required surgery: amniotic membrane (n=7), penetrating keratoplasty (n=4), conjunctival resection (n=3), tissue adhesives (n=2), conjunctival flap (n=1) and lamellar keratoplasty (n=1).

Anti-TNFα drugs were the most common biologic agents used in these cases (n=19): Adalimumab (ADA) (n=10; 37%), Infliximab (IFX) (n=8; 29.6%). In the remaining 8 cases the biologic agents were rituximab (n=7; 25.9%) and tocilizumab (n=1; 3.7%). The main outcome measures are summarized in the Table. After a mean follow-up of 23.7±20 months, all objective outcomes had improved with a reduction of the median prednisone dose from 33.7 [17.5–52.5] mg at baseline to 0 [0–2.5] mg (p=0.028). The main observed adverse effects were supraventricular tachycardia (n=1) and pulmonary Tuberculosis (n=1).

AB0338 HEADS-UP! SARCOIDOSIS AND RHEUMATOID ARTHRITIS CO-EXIST
L. Zickuhr, R. Hajj-Al, Rheumatology, Cleveland Clinic Foundation, Cleveland, United States

Background: Sarcoidosis and rheumatoid arthritis (RA) uncommonly co-occur. How dual diagnosis affects these patients' clinical phenotype is unknown.

Objectives: To characterize the clinical and comorbid phenotype and to increase awareness of the coexistence of sarcoidosis and RA.

Methods: We searched PubMed from 1980–2016 for relevant articles using key words “sarcoidosis” and “rheumatoid arthritis,” excluding cases with tumor necrosis factor inhibitors. We found 12 cases, omitted 5 lacking clinical detail, and added 2 from our experience at the Cleveland Clinic. Clinical features, laboratory and imaging findings were reviewed and summarized.

Results: Females comprised 7/9 cases (77%). Our cases are the first to describe men with dual diagnosis. Of the 8 cases reporting ethnicity, 4 (50%) were white. The mean age at time of diagnosis was 35.3 years for RA and 51.0 years for sarcoidosis. In 5/9 cases (55.6%), RA preceded sarcoidosis. RA affected the hands in 8/9 patients (88.9%). Of the 8 cases reporting symptoms of sarcoidosis, 5 (62.5%) had dyspnea. All cases (100%) had elevated rheumatoid factor (RF) and, when checked, anti-citrullinated peptide (anti-CCP) antibodies. Angiotensin converting enzyme (ACE) was elevated in 6/9 patients (66.6%). Of the 5 patients with joint imaging, 4 (80%) had inflammatory changes. All sarcoidosis (100%) was biopsy-proven. One case (11.1%) demonstrated concomitant pulmonary RA and sarcoidosis.

Conclusions: Sarcoidosis and RA coexist in seropositive patients, most commonly in women in their fourth through sixth decades of life. RA preceded sarcoidosis about half the time. Hand arthritis and dyspnea were the most common symptoms for RA and sarcoidosis, respectively. Awareness of this dual diagnosis may help identify RA and sarcoidosis earlier and prevent treatment delay.

AB0339 COMORBIDITIES AND RISK FACTORS OF CARDIOVASCULAR DISEASES IN RHEUMATOID ARTHRITIS PATIENTS
L.V. Khimion1, I.V. Klymas1, I.M. Naishetik2. 1Department of Family Medicine, Shupyk National Medical Academy of Postgraduate Education; 2Kyiv Regional Clinical Hospital, Kyiv, Ukraine

Background: It is well known, that atherosclerosis associated cardiovascular diseases in many cases determine the life expectancy in RA patients. At the same time, risk factors which promote the development of premature atherosclerosis, including comorbidities, remain uncertain.

Objectives: to analyze comorbidity conditions in RA patients under age of 50 years and assess their impact on the vascular wall (evaluated by ultrasound investigation of the carotid arteries).

Methods: The study was conducted at the Department of Family Medicine, Shupyk NMAPE at the Kyiv Regional Clinical Hospital. The study included 128 RA patients, aged from 18 to 49 years (women - 102 (81%), men - 24 (19%), average age 43.8±8.8 years, who provided written consent to participate in research. As a control group 30 persons without any autoimmune diseases (women - 25 (83.3%) men - 5 (16.7%), average age 42.4±8.6 years) were examined.

All RA patients and control group underwent comprehensive clinical, laboratory and instrumental examination to identify comorbid conditions including evaluation of atherogenesis by use of ultrasound examination of the carotid arteries with intima-media thickness (IMT) measurement and atherosclerosis plaques (AP) assessment.

Results: The frequency of identified comorbid conditions and diseases in RA patients and control group are presented in Table 1. The average number of comorbid diseases/conditions per RA patient significantly exceeded its number in controls (4.13 and 1.67 respectively, p<0.05); most frequently among RA patients was determined: dyslipidemia (60.32%), nonalcoholic fatty liver disease (61.1%), chronic cholecystitis (36.51%), cholesteroles of the gallbladder (30.16%), hypertension (37.30%), autoimmune thyroiditis (27.77%), spinal osteoarthritis (33.33%).

The study of lipid metabolism included: determining the level of total cholesterol and triglycerides, HDL and LDL cholesterol. Patients with RA had significantly higher total cholesterol, triglycerides, HDL and LDL cholesterol values (p<0.05) at the same time as in the comparison group had a tendency to decrease. Noted a reduction parameters: CRP (83.3%), ESR (81.3%), GLU (81.3%) and BUN (79.7%). RA patients had a higher frequency of comorbid conditions and diseases than controls without RA; some of comorbidities have significant influence on atherogenesis; RA patients require a multidisciplinary and holistic approach for effective management of their health related problems.

AB0340 CLINICAL EFFICACY OF STATINS IN PATIENTS WITH RHEUMATOID ARTHRITIS
L. Mikulet, T. Ilashchuk. Department of Propedeutics of Internal Diseases, Higher State Educational Establishment of Ukraine “Bukovinian State Medical University”, Chernivtsi, Ukraine

Background: Cardiovascular disease (CVD) is a major cause of mortality in patients with rheumatoid arthritis (RA), in the literature there are conflicting data on the role of statins in patients with RA, indicated lack of awareness. The study of lipid metabolism included: determining the level of total cholesterol. An analysis of the relationship between the use of statins in the treatment of patients with RA and cardiovascular complications, the influence of statins on atherogenesis; a detailed assessment of the lipid profile. The study of lipid metabolism included: determining the level of total cholesterol, HDL cholesterol and low density (LDL), atherogenic index (AI), triglycerides (TG). The study confirmed the positive effect of statins on atherogenesis; a detailed assessment of the lipid profile. The study of lipid metabolism included: determining the level of total cholesterol, HDL cholesterol and low density (LDL), atherogenic index (AI), triglycerides (TG). The study confirmed the positive effect of statins on atherogenesis; the study included 43 patients with RA. A survey conducted by the protocol patients (DAS28 index, visual analog scale (VAS), morning stiffness). The study of lipid metabolism included: determining the level of total cholesterol. The study included 43 patients with RA. A survey conducted by the protocol patients (DAS28 index, visual analog scale (VAS), morning stiffness). The study of lipid metabolism included: determining the level of total cholesterol. The study included 43 patients with RA. A survey conducted by the protocol patients (DAS28 index, visual analog scale (VAS), morning stiffness). The study of lipid metabolism included: determining the level of total cholesterol. The difference between groups is significant, p<0.05.
for cervical spine subluxation it was higher patient age. Logistic regression confirmed early final awakening and short sleep respectively (HR 1.109, 95% CI 1.120–1.260, p<0.05) and (HR 1.095, 95% CI 0.991–0.998, p<0.005) as independent predictors of anterior atlanto-axial subluxation. The main risk factors for incident hypervascular atlantoaxial joint active pannus was disease activity score (DAS28) at early follow-up. The frequency of early final awakening and short sleep were higher in relation to cervical spine involvement. Male sex, CRP positivity, and older age were risk factors for incident anterior atlantoaxial subluxation.

Conclusions: Cervical spine involvement is common and may be asymptomatic indicating routine cervical spine imaging is needed in patients with RA specially with patients with sleep disturbances and high disease activity

AB0334 THE RHEUMATOID FOREFOOT: WHICH FREQUENT INJURY? WHAT IMPACT ON WALK?

M. Erraoui, B. Amine, L. Tahiri, I. El Binoune, J. Bahha, S. Fellous, Y. Boujenane, F. Allali, R. Bahiri. Rheumatology, Mohammed V University, Faculty of Medicine and Pharmacy of Rabat, El Ayachi Hospital, SALE, Morocco

Background: Foot involvement is the most common cause of disability in patients with rheumatoid arthritis (RA). The forefoot remains the most affected location.

Objectives: Investigate the forefoot injuries in patients with RA and evaluate its impact on walking.

Methods: Cross-sectional study of 33 patients with rheumatoid arthritis. Patients with static lower limb disorder or foot injury from other origin were excluded. Demographic and clinico-biological characteristics were collected: age, sex, BMI, disease duration, tender joint count, swollen joint count, foot pain evaluation on aVAS, percentage of patients with such discordance is not clear. The frequency of early final awakening and short sleep were higher in relation to cervical spine involvement. Male sex, CRP positivity, and older age were risk factors for incident anterior atlantoaxial subluxation.

Conclusions: Cervical spine involvement is common and may be asymptomatic indicating routine cervical spine imaging is needed in patients with RA specially with patients with sleep disturbances and high disease activity

**AB0345** PSYCHIATRIC DISORDERS RELATED TO HYPERLEPTINEMIA AND RHEUMATOID ARTHRITIS: CLINICAL ACTIVITY MEASURED BY DAS28

M. Vázquez-Del-Mercado 1, A.-M. Rodríguez-Ramírez 2, E. Chavarría-Avilia 3, F. Sandoval-García 3, B.-T. Martín-Marquez 3, R.-E. Navarro-Hernandez 3, F. Corona-Meraz 3, E. Gomez-Baruellos 2, 1 Servicio de Reumatología, División de Medicina Interna, Pnn 004086, CONACYT, Hospital Civil Juan I. Menchaca; 2 Instituto de Investigacion en Reumatología y del Sistema Musculoesquelético, Universidad de Guadalajara, Guadalajara, Mexico. 3 Instituto de Investigación en Reumatología y del Sistema Musculoesquelético, Instituto de Investigación en Reumatología y del Sistema Musculoesquelético, Universidad de Guadalajara, Guadalajara, Mexico.

**Background:** Leptin is an adipose-derived hormone with a role in depression related to chronic stress, anxiety and pain disorders, disturbs with a high prevalence in RA patients. In previous studies, it has been demonstrated the role of leptin in the pathogenesis of RA, in particular, its association with anti-CCP. The purpose of this study was to evaluate the psychiatric disorders risk related to serum soluble leptin levels with clinical activity in RA patients.

**Objectives:** To evaluate the association between psychiatric disorders and serum leptin (sLep) levels and RA disease activity.

**Methods:** 76 outpatients diagnosed with RA (ACR1987/ ACR/ EULAR2010) were evaluated with clinical, laboratory and image assessment. Disease activity was measured using DAS28 CRP. The Mini International Neuropsychiatric Interview Plus (M. I. N. I. Plus) was used for the psychiatric evaluation. sLep levels were measured by ELISA method.

**Results:** sLep levels were significantly higher in RA patients M.I.N.I. plus (+) (n=46) DAS28 CRP (n=50) compared to M.I.N.I. plus (-) (n=18) DAS28 CRP (n=26). The sLep level was significantly higher in patients with a psychiatric disorder (P=0.006) with an odds ratio of 1.6 [1.04–2.46] P=0.03 for present psychiatric comorbidity. After adjustment with age and years of RA diagnosis, the odds ratio increased to 1.72 [1.08–2.73] P=0.02. Also, DAS28 CRP had a moderate correlation with the number of psychiatric diagnosis present, past and for lifetime r=0.485, P=0.001, IC95% [0.30–0.633].

**Conclusions:** sLep levels and DAS28 CRP were associated with symptoms of depression, such as anxiety and pain disorder in RA patients.

**Disclosure of Interest:** None declared

**AB0347** EVALUATION OF THE IMPACT OF RHEUMATOID ARTHRITIS ON SEXUAL FUNCTION

M. Brahimi 1, H. Hachi 1, S. Ben Hammouda 1, I. Haddada 1, M. Marouai 2, M. Jiguirim 2, M. Younes 3, 1 Rheumatology, Taher Star Hospital Mahdia, mahdia; 2 Rheumatology, Fattouma Bourguiba Hospital Monastir, Monastir, Tunisia.

**Background:** Rheumatoid arthritis (RA) may affect all aspects of life including sexual functioning. The percentage of arthritic patients who experience sexual problems ranged in various studies from 31% to 76%. The reasons for disturbing sexual functioning are multi-factorial and comprise disease-related factors as well as therapy. It can occur before, during and after sexual activities, and can affect sexual health in different perspectives.

**Objectives:** The aim of our study is to evaluate the impact of the RA in sexual function and its associated factors.

**Methods:** This is a cross-sectional and descriptive study during a period of the year 2016, including 37 patients followed in the department of Rheumatology in Mahdia Tunisia. All patients were diagnosed with RA based in ACR 1987/EULAR 2010. We evaluated for each patient the parameters of activity of the disease, the quality of life by the HAQ questionnaire and the mood disorders using the Hospital Anxiety and Depression Scale (HAD).

**Results:** The age of the RA patients (32 females/5 males) ranged from 21 to 76 years. The mean age was 51.6 years. The mean duration of the disease was 11±10 years [1–34]. The mean number of tender joints was 13.2±9.6 and swollen joint was 5.9±7. The mean DAS28 was 5.5±1.5 [2.9–8.2] and the HAQ was 1.6±0.9 [0–2.8]. 51.3% of patients had specific joint deformations, 83.8% had radiologic involvement and 29.7% had osteoporosis.

The biologic analysis showed that the mean ESR was 45±27.1 and the CRP was 13.7±25.3. Rheumatoid factors were positive in 37.8% of cases, the ACPA were positive in 32.4% of cases. 81.1% of RA patients were treated by methotrexate and 13.5% were treated by biologic treatments.

The average score of depression was 9.2±4.2 [0–20]. 12 patients (32.4%) didn’t have signs of anxiety (score ≥8). 12 patients (32.4%) had probably an anxiety (score between 8 and 10) and 13 patients (35.2%) presented a certain anxiety (score >10). We found a significant correlation between the score of anxiety and the number of tender joints, the anxiety score and the HAQ (Health Assessment Quality).

**Conclusions:** Our study showed that the majority of our RA patients suffered from mood disorders; 67.5% had signs of depression and 65.6% had signs of anxiety. So, it’s important to evaluate the mood disorders in RA patients to ameliorate their quality of life.

**AB0346** MOOD DISORDERS (ANXIETY AND DEPRESSION) IN RHEUMATOID ARTHRITIS

M. Brahimi 1, M. Marouai 1, H. Hachi 1, S. Ben Hammouda 1, I. Haddada 1, M. Jiguirim 2, M. Younes 3, 1 Rheumatology, Taher Star Hospital Mahdia, mahdia; 2 Rheumatology, Fattouma Bourguiba Hospital Monastir, Monastir, Tunisia.

**Background:** In addition to recurrent pain, fatigue, and increased rates of physical disability, individuals with rheumatoid arthritis (RA) have an increased prevalence of some mental health disorders, particularly those involving affective or mood disturbances. Many researchers have shown that mood disturbance and disability may serve as important pathways through which disease burden contributes to poor health functioning in RA.

**Objectives:** Our aim is to estimate the mood disorders (anxiety and depression) in patients with RA and to evaluate the associated factors.

**Methods:** This is a cross-sectional and descriptive study during a period of the year 2016, including 37 patients followed in the department of Rheumatology in Mahdia Tunisia. All patients were diagnosed with RA based in ACR 1987/EULAR 2010. AB0348 SLEEP DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Brahmi 1, S. Ben Hammouda 2, H. Hachfi 1, M. Marouli 1, I. Haddada 1, M. Jqurin 2, M. Younes 1, 1 Rheumatology, Algerian Society for Rheumatology, Algeria; 2 Rheumatology, Fattouma Bourguiba Hospital, Monastir, Tunisia

Background: Rheumatoid arthritis (RA) is one of the most common autoimmune diseases known to be one of the leading causes of disability. Sleep disorders have direct influence on patient’s life. But the exact nature of relationship between sleep disorders and Rheumatoid arthritis is not completely understood.

Objectives: The aim of our study is to evaluate the impact of RA in sleep quality and to establish associated factors.

Methods: This is a cross-sectional and descriptive study during a period of the year 2016, including 37 patients followed in the department of Rheumatology in Mahdia Tunisia. All patients were diagnosed with RA based on ACR 1987/EULAR2010. We evaluated for each patient the parameters of activity of the disease, the quality of life by the HAQ questionnaire and the quality of sleep using two scales: Epworth (ESS) and Pittsburg scale (PSQI) which is composed from 7 components rated each one from 0 to 3.

Results: The age of the RA patients (32 females/5 males) ranged from 21 to 76 years. The mean age was 53.1 ±12 years. The mean duration of the disease was 11±10 years [1–34]. The mean number of tender joints was 13.2 ±9.6 and swollen joint was 5.97. The mean DAS28 was 5.51±1.5 [2.9–8.6] and HAQ was 1.60±0.9 [0–2.8]. 51.3% of patients had specific joint deformations, 83.8% had radiologic involvement and 29.7% had osteoporosis.

The biologic analysis showed that the mean ESR was 45±27.1 and the CRP was 13.7±25.3. Rheumatoid factors were positive in 37.8% of cases, the ACPA were found to be associated with high score of HAQ. The biologic parameters of RA.

The mean ESR score was 9±5.7 [0–23]. 56.8% of patients had no sleep debt, 32.4% had a sleep deficit and only 10.8% had signs of somnolence. Our study confirmed a significant correlation between the Epworth score and the number of tender joints, the ESR, the Health assessment questionnaire (HAQ) score. The average of the subjective sleep quality was 1.35, latency to sleep was 1.81, “sleep duration” was 1.24, “habitual sleep efficiency” was 1.08, “sleep disorders” was 1.62, “the use of a sleep medicine” was 0.27 and finally the average of the 7th component about “poor form during the day” was 1.11 out of 3. So the latency to sleep and sleep disorders were the most affected components.

We had a significant correlation between PSQI and the number of swollen joints, the HAQ score. The value of the ACPOA was found to be associated with high score of ESR and CRP.

Conclusions: Our study showed that the sleep disruption wasn’t rare in patients with RA. This can be related to the disability and pain caused by this disease. Further studies with large sample size, as well as more careful tools of sleep disorders, would help to generalize results and suggestions. By providing adequate health care, and recognition of the patients’ pain conditions we would ameliorate sleep quality and increase the QOL of RA patients.

AB0349 THE SERUM LEVEL OF IRISIN IS DECREASED IN THE PATIENTS WITH RHEUMATOID ARTHRITIS

A.T. Kalkan 1, M. Ozmen 2, B. Birlik 3, D. Kozaci 4, I. Turkmen 5, D. Solmaz 2, O. Gerck 2, S. ‘Guencem 2, S. Akar 2
1Department of Internal Medicine; 2Department of Internal Medicine, Division of Rheumatology; 3Department of Radiology, Imam Kadi Celebi University, School of Medicine; 4Department of Medical Biochemistry; 5Department of Musculoskeletal System and Regenerative Medicine, Ankara Yildirim Beyazt University, School of Medicine, Izmir, Turkey

Background: Adipokines are proteins that are synthesized by and secreted from both skeletal muscle and adipose tissue, and show their effects through autocrine, paracrine or endocrine pathways (1). Irisin, a novel adipokine, is secreted in association with exercise from the skeletal muscle, and from the white adipose tissue to help the brown fat tissue gain the energy expenditure phenotype (2).

There is evidence that the irisin is associated with metabolic syndrome (MetS) and cardiovascular risk (3,4).

Objectives: Rheumatoid arthritis (RA) is associated with an increased risk of cardiovascular disease (CVD) and MetS compared with the general population (5,6).

The aims of this study were to assess the serum level of irisin, and the possible relationships of irisin with disease activity in patients with RA.

Methods: Eighty four consecutive RA patients fulfilling the 2010 ACR/EULAR RA Classification Criteria were included in the study. Fifty age- and sex-matched healthy volunteers were enrolled as the control group. Disease duration, medications, history of traditional risk factors of CVD and demographic data of patients were noted. Body Mass Index (BMI) was calculated as “weight (kg)/height (m)²”. HbA1c, lipid profile, insulin were measured. Insulin resistance was assessed with the Homeostasis Model Assessment (HOMA) Index. RA disease activity was assessed by disease activity score based on evaluation of 28 joints (DAS28). Serum irisin level was assessed by ELISA. Measurement of carotid intima media thickness by carotid doppler ultrasonography was performed by a radiologist for cardiovascular risk assessment.

Results: There was no significant difference between the groups in terms of BMI (p=0.20), HbA1c (p=0.15), lipid profiles (p<0.05), insulin resistance (p=0.72) and carotid intima-media thickness (p=0.216). Serum irisin levels were found to be significantly lower in RA patients (20.65 (minimum:16.94- maximum:99.35) ng/mL) than healthy controls (37.56 (18.37–84.70) ng/mL) (p<0.001). There was no relationship between RA disease activity and irisin levels.

Conclusions: This study showed that irisin was significantly lower than controls. Irisin may be responsible for increased cardiovascular risk in RA patients. But before a definite judgment, prospective studies with a larger sample size assessing the exercise behaviour of patients and the presence of CVD are necessary.

AB0350 FUNCTIONAL DISABILITY MEASURED BY HEALTH ASSESSMENT QUESTIONNAIRE (HAQ) CORRELATES WITH DISEASE ACTIVITY IN ELDERLY RHEUMATOID ARTHRITIS PATIENTS

N. Alpay-Kanitez 1, O. Pehlivan2, A. Omma 3, S. Can-Sandikci 3, S. Yilmaz-Onel 1, C. Bes 1, S. Celik 1, 1Bakirok Dr. Sadi Konuk Research and Training Hospital; 2Umuriye Research and Training Hospital, Istanbul; 3Ankara Numrese Research and Training Hospital, Ankara, Turkey

Background: Rheumatoid arthritis (RA)’s prevalence increases with age and the recognition of functional disability related to RA could be challenging in elderly patients.

Objectives: In this study, we aimed to look at the correlation between disease activity and the functional disability by using HAQ score in elderly RA patients.

Methods: Elderly RA patients, ≥65 years old at their routine visits were included to the study. The composite “disease activity score” in 28 joints (DAS-28) and “Physician Global Assessment” (PhGA) were used to determine disease activity. Health assessment questionnaire (HAQ) scores were calculated to describe the functional disability and compared across the disease activity groups according to DAS-28.

Results: Two hundred and fifty eight RA patients with the mean age of 71±5...
(65–90) were included. Seropositivity rate was 71% and 47% of the patients had erosive disease. Joint deformity was seen in 72 (28%) of patients and 28 (11%) patients had undergone total arthroplasty. Lung involvement (8.5%) and Sjogren’s syndrome (7.4%) were found as the most frequent extra-articular manifestations. Hypertension (68%) and osteoporosis (36%) were the common co-morbidities. The proportion of IVRT patients with high and moderate disease activity was found as 70%. HAQ and PhGA scores were significantly correlated with the disease activity (Figure).

Conclusions: We provided a novel data concerning the usefulness of HAQ for prediction of disease activity in RA patients who are elderly as well. In the future, our report will be supported by the studies which suggest that HAQ score improve with effective treatment in elderly RA patients.

AB0351 PROTEIN ANTIBODIES AND SUBCLINICAL CARDiac AFFECTION IN RHEUMATOID ARTHRITIS PATIENTS
A. Helal1, G. Younis1, N. Hussein1, E. Elsharkawy2, N. Abdelhady Abdelsadek1, 1Physical Medicine, Rheumatology and Rehabilitation, Alexandria University Hospital; 2Cardiology and Angiology, Faculty of Medicine, Alexandria, Egypt

Background: Cardiovascular disease (CVD) is a major cause of morbidity and mortality in rheumatoid arthritis (RA) patients. It has been postulated that chronic inflammatory activity is important for the development of CVD even after adjustment for traditional cardiovascular risk factors. One of the changes occurring in the context of inflammation is citrullination. Development of anti-citrullinated protein antibodies (ACPA) is implicated in higher frequency of extra-articular manifestations including cardiovascular complications.

Objectives: To assess the relation of ACPA to subclinical cardiac affection in RA patients.

Methods: Thirty RA patients fulfilling the 2010 ACR-EULAR classification criteria for RA with no clinically evident CVD were subjected to full history taking and clinical examination. Disease activity was assessed by 28-joint disease activity score based on C-reactive protein (DAS28-CRP) (4 variables). The levels of ACPA, CRP, total cholesterol, triglycerides, high density lipoprotein cholesterol and low density lipoprotein cholesterol were measured. The patients were subjected to M-mode and colour Doppler echocardiographic examination. Patients were subdivided into two subgroups according to ACPA positivity (ACPA positive patients represented “group A” and ACPA negative patients represented “group B”).

Results: The frequency of subclinical cardiac affection by echocardiographic examination was significantly higher among group A patients (4 patients had valvular lesion and 9 patients had diastolic dysfunction) than in group B patients (3 patients had diastolic dysfunction), (p=0.011). ACPA level showed significant positive correlation with isovolumic relaxation time (IVRT) in group A patients (prolongation of IVRT is a sign of diastolic dysfunction), (p<0.001).

Conclusions: The presence of ACPA is related to development of subclinical cardiac involvement in RA patients and all RA patients with high level of ACPA should be routinely evaluated with echocardiography to assess their cardiovascular status.

AB0352 RISK FACTORS AND SUBCLINICAL ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS FEMALES COMORBID WITH HYPERTENSION

Background: Rheumatoid arthritis (RA) associates with accelerated atherosclerosis and high cardiovascular mortality. Cardiovascular risk management in RA comorbid with HT is of a great importance. Our report will be supported by the studies which suggest that patients with RA comorbid with HT were characterized by higher frequency of subclinical atherosclerosis with unstable atherosclerotic plaques in compare with controls.

Methods: The study included 112 RA females with comorbid HT (mean age of 54 (50.5; 61.5) years) and 105 RA females without HT (control group). All pts received stable therapy of RA for more than 6 months. Pts with coronary artery disease were excluded. The risk of fatal cardiovascular disease was calculated using mSCORE (EULAR 2010); RA disease activity was measured using DAS28 scale. Carotid ultrasound with stiffness indexes detection and endothelial-dependent flow mediated vasodilatation (EDVD) by Celermajer method were performed. The levels of adiponectin, insulin were measured using ELISA kit test, insulin resistance was estimated using HOMA2 index.

Results: Subclinical manifestations of atherosclerosis were established in 88 (78.5%) RA females with HT and 55 (52.4%) control group pts. The majority of main group pts have atherosclerotic plaques - 62 (55.4%), unstable plaques had 26 (23.2%) pts. While only 33 (29.5%) patients were high and very high cardiovascular risk assessed by mSCORE. In compare, 35 (33.3%) control group pts have atherosclerotic plaques, unstable plaques had only 14 (13.3%) control pts (p<0.05). The presence of atherosclerotic plaques in RA females with HT was associated with age, RA disease activity, endothelial dysfunction, carotid stiffness, LDL cholesterol level, insulin resistance, adiponectin level, duration of steroid therapy. AUROC index for adiponectin and HOMA2 were 0.83 (95% CI 0.74–0.95; p<0.05 and 0.75 (95% CI 0.68–0.91; p=0.05 respectively, that indicate a good quality of diagnostic models.

Conclusions: RA females with comorbid HT are characterized by higher frequency of subclinical atherosclerosis with unstable atherosclerotic plaques in compare with controls. Endothelial function, insulin resistance, adiponectin level,
carotid stiffness determination may be useful additional tools for cardiovascular risk evaluating in this pts.

ASSOCIATED FACTORS FOR FALLS AND FEAR OF FALLING IN AMBULATORY PATIENTS WITH RHEUMATOID ARTHRITIS: A COMPARATIVE STUDY WITH HEALTHY SUBJECTS

A. Yesim 1, Y. Ulus1, T. Berna1, L. Tomak2, Y. Zahiroglu1, A. Bilgici1, O. Kung1

1 Department of Physical Therapy and Rehabilitation, Faculty of Medicine; 2 Department of Biostatistics, Faculty of Medicine, Ondokuzmayis University, Samsun, Turkey

Background: Rheumatoid arthritis (RA) is a chronic disease that affects the bone and joints. Patients with RA might be considered to be at increased risk of falls and FOF for a variety of reasons, including the presence of muscle weakness and stiffness or painful joints of the lower extremities resulting in impaired physical activity, disability, and postural stability (1,2).

Objectives: The aim of the present study was to compare fall history and fear of falling (FOF) in RA patients with healthy controls, and to investigate their relationships between the demographic features, severity of pain, disability, disease activity, walking velocity, balance and emotional status in patients with RA.

Methods: One hundred-twenty patients with RA and 60 healthy volunteers were included in the study. Their fall history (yes, no) and the number of falls within the last year were questioned. FOF by presence of FOF (yes/no) and by Falls Efficacy Scale-International (FES-I) walking time by 10 Meter Walk Test (10MWT), balance by One-Leg Stand Test (OLST) and Berg Balance Scale (BBS), emotional status by Beck Depression Inventory (BDI) and Beck Anxiety Inventory (BAI) were performed in both groups. Pain severity and global assessment (PGA) by Visual Analogue Scale (VAS), disability by the Health Assessment Questionnaire (HAQ), disease activity by Disease Activity Score-28 (DAS-28) were evaluated in patients with RA.

Results: There was no statistically difference between the RA patients and controls in terms of presence of fall history while presence of FOF and FES-I scores were significantly high in patients. PGA, 10MWT, pain VAS, HAQ, BAI, and BDI scores were significantly high in patients. BBS score and OLST were significantly low for fallers compared to the non-fallers in the patients (p<0.05). In the patient group, FES-I score was significantly correlated with pain VAS, PGA, DAS-28, HAQ, BAI, and BDI positively and BBS, OLST negatively (p<0.05).

In regression analysis, the number of falls, HAQ, BBS and BDI scores were detected to be independent risk factors affecting variations in FES-I scores (p<0.001).

Conclusions: According to the results of our study, ambulatory patients with RA have increased FOF, disturbed balance, increased walking time and impaired emotional status compared with controls. On the other hand, walking time, pain severity, disability, scores of emotional status and PGA were higher, while the balance scores were lower in the RA patients with fallers. There were relationships between FOF and increased pain, high disease activity and anxiety level, impaired PGA, increased walking time but the most important factors associated with FOF were impaired balance, increased disability and depression, and number of falls in RA patients. Strategies for preventing falls, maintaining balance, improving emotional status and againts FOF are of the utmost importance in patients with RA.

PREVALENCE OF SIGNS OF CONNECTIVE TISSUE DYSPLASIA IN PATIENTS WITH RHEUMATOID ARTHRITIS AND CHARACTERISTICS OF THE COURSE OF COMBINED PATHOLOGY

R. Demidov, S. Lapshina, L. Nysoutova. Kazan State Medical University, Kazan, Russian Federation

Background: Connective tissue dysplasia (CTD) has a common pathogenesis with rheumatoid arthritis (RA). Question of peculiarities in such combination remains little known.

Objectives: To analyze the peculiarities of RA in patients with signs of CTD. Methods: Among the 107 patients with RA, seen in the rheumatology departments in Kazan city, 18 (16.8%) patients (15 women and 3 men, mean age 47.9±12.89 years) with reliable signs of CTD were selected, identified clinically and the agreement of their documentation was performed. By DAS28 low RA activity was detected in 1 (5.6%) patients, average - 13 (72.2%), high - 4 (22.2%). The clinical-laboratory and instrumental methods of diagnosis, standardized and independently developed questionnaire for the presence of CTD in selected group of patients were used

Results: The most frequently following signs of CTD syndrome - vegetative-vascular dystonia - 14 (77.7%), myopia - in 9 (50%), mitral valve prolapse- in 6 (33.3%), small heart abnormalities - in 8 (44.4%), flat feet - 6 (33.3%), scoliosis - in 5 (27.7%), hyperkyphosis - in 2 (11.1%), hypermobility of joints - in 2 (11.1%), anomaly of kidney structure- in 2 (11.1%), rhythm and conduction disturbances- in 7 (38.8%). Osteoporosis was observed in 11 (61.1%) patients. We select two group of patients: the first (n=9) from 1 to 5 CTD signs and the second (n=9) - from 6 to 9 dysplasia symptoms. In the second group RA activity by DAS28 was significantly (p<0.05) higher (4.52±1.20) than in the first (DAS28 =3.95±0.81). Obtained differences in RA activity, depending on the availability of myopia (DAS28 =4.68±0.87) and osteoporosis (DAS28 =3.78±1.06); flatfoot (DAS28 =4.53±1.05) or its absence (DAS28 =4.04±1.02) were evaluated. A significant (p<0.05) difference was found in patients with osteoporosis, the availability for activity (DAS28 =4.68±0.97), pain intensity VAS (1.44±m 6.90), compared with normal bone density tissue (DAS28 =3.36±0.36, pain VAS =5.83±2.22 cm).

Conclusions: Among patients with RA CTD signs occur more frequently than in the population (16.8% versus 10%). The most frequently detected are myopia, vegetative-vascular dystonia, cardiac diseases, osteoporosis. Patients with signs of dysplasia had a trend towards a higher activity of RA.

MUSCLE POWER AND FALL RISK IN RHEUMATOID ARTHRITIS

P. Dieterl, D. Felsenberg, G. Armbricht. Centre of Muscle and Bone Research, Charite, Berlin, Germany

Background: One of the serious consequences of aging is the gradual loss of neuromuscular function, such as gait speed, in order to the ability to generate high-velocity movements and current evidence suggests that it declines earlier with advancing age [1] and is more strongly related to functional status than muscle force [2]. A decreased capacity for high-velocity movements in the legs has been linked to delayed responses in maintaining postural stability and thus with age-associated fall risk [3]. People with rheumatoid arthritis (RA) may be at high risk of falling due to disease-related impairments such as pain, joint deformity, muscle weakness, altered gait and decline in postural stability.

Objectives: As role of muscle power in fall-risk assessment of RA patients has not been investigated, so far, the aim of the present study was to determine the association between muscle power, muscle force, functional performance and falls in the last 12 months in RA patients.

Methods: 98 subjects with RA older than 60 years from a cross-sectional study on the prevalence of corticosteroid-induced osteoporosis in Germany (PSIO-B Berlin) and 98 age-matched controls without inflammatory disease, randomly chosen from a cross-sectional study collecting reference values for body composition, were analyzed in this case-control study. Muscle function was determined by muscle power body mass in vertical countermovement jumps (ZUPlm, on a force plate, the chair rise test (CRT), gait speed, grip strength and the Short Physical Performance Battery. Differences in muscle function measures between the RA group and the healthy reference were derived separately by sex with Student-T test or Mann-Whitney-U test. Using logistic regression adjusted for age and the association between muscle function and falls was determined.

Results: In bivariate analysis RA patients showed significantly weaker performance in all muscle function tests compared to controls in both sexes. Applying logistic regression, age (OR 1.10, 95%-CI 1.00–1.24) and female sex (OR 5.99, 95%-CI 1.25–28.57) were significantly associated with retrospective falls in RA subjects but not in controls. Gait speed (OR 0.09, 95%-CI 0.01–0.88) remained a significant correlate for falls independent of age and sex in RA patients. In controls only the CRT (OR 1.13, 95%-CI 1.02–1.26) could differentiate individuals who had past fall events in the age and sex adjusted model. No association was found for the ZUPlm and retrospective falls.

Conclusions: The results of the present study could not confirm an association between fall risk and muscle power in RA patients, but they highlight the importance of monitoring neuromuscular function such as gait speed, in order to decrease falls and consequently to prevent fractures, contributing to a better prognosis of rheumatic disease.

**AB0356** ASSOCIATION BETWEEN CARDIOVASCULAR RISK FACTORS AND CAROTID INTIMA-MEDIA THICKNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. González Mazarío1, J.J. Frago Gil1, J. Ivorra Cortes1, C.M. Feced Olmos1, F.M. Ortiz-Sanjuan1, E. Grau García1, E. Labrador Sánchez2, S. Huerta Barberá3, K. Arévalo Ruales4, R. Negueroles Albuixech5, I. Martínez Cordellat1, I. Chalmeta Verdejo1, E. Labrador Sánchez1, S. Huerta Barberá2, K. Arévalo Ruales1, R. Negueroles Albuixech1, J.E. Oller Rodriguez1, V. Forneres Ferrer3, J.A. Román Ivorra1,2,2, Rheumatology Department, HUP la Fe1,2, Medical School, UCV, BIOstatistic Unit, IIS la Fe, Valencia, Spain

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease which affects 0.5% of adults, especially women. This disorder is associated with increased morbidity and mortality due to atherosclerotic cardiovascular diseases. In addition to traditional cardiovascular risk factors, inflammation plays a key role in this fact. Intima-media thickness (IMT) measured by carotid ultrasound is currently used to detect the presence of atherosclerotic disease and its value could be a predictor of subclinical cardiovascular disease.

**Objectives:** To study cardiovascular risk factors, disease activity and carotid IMT in a RA patients series.

**Methods:** Cross-sectional observational study of patients diagnosed with RA according to ACR/EULAR 2010 criteria. Patients with age under 75 years old and up of 5 years of disease evolution were included. Cardiovascular established disease patients were excluded. During a unique visit, anamnesis, physical examination, laboratory test, electrocardiogram, chest X-ray and carotid ultrasound with Esaote-MyLabClassC equipment. Statistical analyses were performed using software R (version 3.3.2).

**Results:** A total of 31 patients (57.1±9.7 years, 83.6% female, with 19.2±11.2 years of average disease course) were included. In relation to the classic cardiovascular risk factors, 19.4% were active smokers, 41.9% hypertensives and 45.2% had hyperlipidemic treatment (85.7% with a statin), three of the patients were diabetic (9.7%). All patients were treated with monotherapy or combination therapy and 4.8% were also given glucocorticoids at low doses during the last 6 months. The mean of the right carotid IMT was 0.9±0.7mm (1° Q=0.8; 3° Q=1.3) with an average HAQ of 0.88±0.68. As for articular-manifestations, 45.2% had xerophasia, 29% xerostomia, and 19.4% had rheumatoid nodules. The median total cholesterol was 195 mg/dL (174–221) and LDL of 116 mg/dL (96.5–138). The median of the right carotid IMT was 576.13±118.78 mm and the carotid left IMT was 616.32±134.31 mm, resulting in 12 determinations higher than values expected to their age and sex provided by the ultrasound developer (38.7%). Using the SCORE table (modified by EULAR), only 5 patients (16.1%) had moderate-to-high cardiovascular risk. Statistical analysis showed a significant association between an increased IMT and tobacco consumption (Pearson correlation risk factor) (p=0.028) and the modified SCORE (p=0.04). Neither years of evolution disease nor the analytical biomarkers showed a significant association.

**Conclusions:** Our study shows that in patients with good disease control data, classic cardiovascular risk factors are related to increased carotid intima-media thickness. However, these factors may underestimate overall cardiovascular risk over other measures of subclinical cardiovascular disease, such as carotid IMT.

**AB0358** PATIENTS WITH EARLY RHEUMATOID ARTHRITIS HAVE INCREASED CARDIOVASCULAR RISK AT THE TIME OF DIAGNOSIS

R. Davies1, C.R. Thompson1, H.S. Jin1, E.A. Ellins2, J.P. Halcox2, A.S. Williams1, E.H.S. Choy1, CREATE centre, Institute of Infection and Immunity, Cardiff University, Cardiff, Institute of Life Sciences, Swansea University Medical School, Swansea, United Kingdom

**Background:** Cardiovascular (CV) mortality in patients with rheumatoid arthritis (RA) is up to 50% higher than the general population. Whilst traditional CV risk factors such as smoking, diabetes and hypertension contribute to this increased mortality in RA, they do not fully explain the increase in risk. The British Society for Rheumatology, National Institute for Health and Clinical Excellence and European League Against Rheumatism (EULAR) recommend annual assessment of CV risk in RA patients. Furthermore, EULAR recommends modifying such traditional CV risk scores by 1.5 for RA patients who meet two of three criteria consisting of (1) disease duration >10 years, (2) positive rheumatoid factor or anti-cyclic citrullinated peptide (anti-CCP) serology, (3) presence of severe extra-articular manifestation, to account for the unexplained increased CV risk in RA.

**Objectives:** This study assessed CV risk by QRISK2 score and used carotid ultrasound to determine cardiovascular risk and prevalence of subclinical atherosclerosis at the time of diagnosis of RA.

**Methods:** Patients >18 years-old with early RA, defined by ACR/EULAR 2010 criteria and diagnosis of RA <6 months were recruited from The University Hospital of Wales, Cardiff. Exclusion criteria included definite or autoimmune or inflammatory rheumatic disease, ACR Classification of Functional Status stage IV, previous history of CV disease and diabetes mellitus. Demographic details were collected, blood pressure, body mass index, ESR, CRP and lipid profile were measured. The study was approved by Research Ethics Committee for Wales (11/WA0306).

**Results:** 40 patients, 10 males and 30 females with early RA were recruited. Mean age was 55.7±14.8 years. Rheumatoid factor and anti-CCP antibodies were positive in 62% and 80% of patients respectively. Mean BMI was 27.2±5.9. Twenty-nine percent were current smokers. Mean DAS28 was 3.8±3.1. According to the QRISK2, 54% of patients had >10% risk of CV disease over 10 years. Carotid ultrasound was conducted in 35 patients. Mean CIMT was 0.71±0.19 mm. 10 patients (29%) had carotid plaques. Fourteen patients (40%) had either plaque or CIMT >0.9mm, both considered markers of high CV risk. These patients were termed “ultrasound positive” patients. The sensitivity and specificity of the QRISK2 to predict US positive patients was 82% and 56% respectively. The positive predictive value of the QRISK2 was 63% and the negative predictive value of the QRISK2 was 88%. No patients met >1 criteria for EULAR adjustment of risk as all patients had early RA and none had severe extra-articular manifestations.

**Conclusions:** Many patients with early RA have significant CV disease at the time of diagnosis. This suggests subclinical CV disease may be developing before patients become symptomatic. More than half of the patients with early RA fulfill current NICE guidelines for starting lipid-lowering therapy, although of these, over one-third had no subclinical disease on carotid ultrasound. There is scope to improve the sensitivity and specificity of the QRISK2 calculation in RA patients, perhaps with a biomarker.

**ASSESSING DEPRESSION IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS—HOW DO DIFFERENT APPROACHES COMPARE?**

S.L. Hider1, 2, S. Ryan1, N. Dale1, N. Stanney1, A. Machin2, C.A. Chew-Graham2, 3, Haywood Academic Rheumatology Group, Haywood Hospital, Staffordshire; 2Research Institute Primary Care and Health Sciences, Keele University, Keele; 3Collaboration for Leadership in Applied Health Research and Care (CLARHC), West Midlands, United Kingdom

**Background:** Depression is common in patients with rheumatoid arthritis and negatively impacts on their quality of life and disease outcomes, including disease activity and treatment response. Several case-finding tools for depression are available, including the PHQ2, which is both valid (1) and easy to use. The presence of depression was assessed in 3 ways a) PHQ2 score b) Self-recorded “ever” depression using the self-administered report comorbidity questionnaire (2) and c) Self report health status using the EQSD - which includes a statement regarding current anxiety/depression (dichotomised into no anxiety/depression vs. slight/moderate/severe/extremely anxious or depressed. Ethical approval was obtained (15-W5-0063).

**Results:** 179 RA patients provided data. Of these 119 (66%) were female and the mean (sd) age was 67.1 (11.7) years. 59 patients (33%) reported they had ever had depression using the self-report comorbidity questionnaire and 25 (14%) indicated they were currently receiving treatment. 68 (38%) indicated they were currently slightly (or more) anxious or depressed when assessed with the EQSD. 37 (21%) scored positively on the PHQ2. There was good concordance between the PHQ2 and EQSD at higher levels of depression, in that all those with severe or extreme anxiety or depression on EQSD also scored positively on the PHQ2. However, of those with moderate anxiety/depression on EQSD, 4/14 patients scored less than 3 using the PHQ2 score.

**Conclusions:** Depression is common in patients with established RA. Use of the PHQ2 case-finding questions in patients with established RA, may help clinicians identify patients who may benefit from more detailed assessment of mood and interventions to improve their outcomes. Reliance should not be placed on a single tool, and exploration of mood should be part of routine assessment of a patient with RA.

AB0361  
**BODY COMPOSITION AND PHYSICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS (AR)**

**Objectives:** To describe the body composition and physical activity of patients with RA.

**Methods:** Design: Observational case-control study. Population: 31 consecutive RA-patients (ACR/EULAR 2010 criteria) selected from a prospective inception cohort (diagnosis of RA between 2005 and 2012), and 31 sex and age-matched voluntary controls. Protocol: We included 62 subjects who were assessed using body-composition measurements obtained with a dual-body X-ray absorptiometry (DESA) for the assessment of body composition at study entry. Other clinical measures were also collected from the onset of the disease. The level of physical activity was assessed according to the abbreviated protocol of the International Physical Activity Questionnaire (IPAQ). Main outcome: Fat mass index (FMI) and fat free mass index (FFMI). FMI was defined as fat mass (kg)/height (m²) and FFMI as lean mass (kg)/height (m²).

**Secondary outcome:** Description of the anthropometric parameters: BMI (body mass index), waist-hip index. Variables: Demographic, treatment, clinical-analytical variables: Disease Activity Score of 28 joints (DAS28-ESR), Clinical Activity Disease Index (CdaI) and Simplified Disease Activity Index (SDAI); Anti-cyclic citrullinated peptide antibody (ACPA), Rheumatoid factor (RF), Health Assessment Questionnaire (HAQ) and erosions. BMI was categorized according to the OMS classification. Waist-hip index (central obesity: 1 for men and >0.8 for women). Statistical analysis: Descriptive and paired T-test or ranks test and Wilcoxon signed rank, as required.

**Results:** We included 62 subjects, 31 RA (50%) and 31 controls (50%). The mean duration of the disease of RA patients was 84.4 months. With a DAS28 mean of 3.04 (0.8), mean HAQ 1.77 (0.6). The majority presented erosions (64.5%) RF (83.3%), and ACPA (77.4%) positive. Differences in clinical and densitometric anthropometric parameters between cases and controls are shown in Table 1. Significant differences were observed in the proportion of overweight subjects between cases and controls (p=0.03). A higher percentage of controls had moderate to high physical activity compared with the patients (65.5% vs. 34.8%). The majority of patients with RA patients had low physical activity (74.2%). These had a mean (SD) of HAQ higher than patients with moderate-high physical activity [1.2 (0.9) vs 0.66 (0.6); p=0.09] Finally, patients performing moderate-high physical activity had less inflammatory activity than those performing low physical activity, with a DAS28 mean of 2.69 (0.7) vs 3.08 (0.9) p=0.03, respectively.

**Conclusions:** Patients with RA compared to controls show more overweight and less physical activity.

**Disclosure of Interest:** None declared

AB0360  
**CLINICAL AND HIGH RESOLUTION CT STUDY OF THE LUNGS IN 96 EGYPTIAN PATIENTS WITH RHEUMATOID ARTHRITIS**

S. Tharwat, D. Shahin, A. Abdesalam, A.F. Barakat. *Internal Medicine (Rheumatology & Immunology), Mansoura University Hospital, Mansoura, Egypt*

**Background:** Lung involvement is a common extra-articular manifestation of rheumatoid arthritis (RA) that confers significant morbidity and mortality. However, this issue has not been sufficiently studied in Egyptian patients.

**Objectives:** To assess the prevalence of pulmonary abnormalities by high resolution computed tomography (HRCT) chest in RA patients and their association with clinical variables.

**Methods:** Ninety-six patients with RA were assessed regarding their age, gender, duration of RA disease, sicca symptoms, presence of subcutaneous rheumatoid nodules, rheumatoid factor, respiratory symptoms, use of medications, disease activity of RA using Disease Activity Score 28 (DAS28), basic laboratory investigations and pulmonary abnormalities in plain x-ray and HRCT.

**Results:** HRCT abnormalities were identified in 25% of the patients: 58.3% had respiratory symptoms while 41.7% were subclinical. Dyspnea and cough were the most frequent symptoms. HRCT abnormalities were interstitial lung disease (ILD) in 11 patients (11.5%), pleural involvement in 8 patients (8.3%), consolidation in 4 patients (4.2%), diffuse alveolar hemorrhage in 3 patients (3.1%), bronchiectasis in 2 patients (2.1%), and apical fibrosis with cavitation in only 1 patient (1%). Patients with dyspnea, cough, chest rales, cutaneous rheumatoid nodules, and who received disease modifying antirheumatic drugs (DMARDs) combination were more likely to have HRCT abnormalities.

**Conclusions:** Pulmonary involvement is not uncommon in RA patients, and HRCT is a sensitive tool in pulmonary evaluation.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.5996

---

**Image:**

- Chest x-ray shows reduced lung volumes with bilateral reticular opacities.
- HRCT chest shows diffuse reticulo-nodular shadows suggestive of interstitial lung disease.
ANALYSIS OF INSULIN RESISTANCE IN A RHEUMATOID ARTHRITIS INCEPTION COHORT: CASE-CONTROL STUDY

S. Manrique-Arja 1, N. Mena-Vázquez 1, I. Ureña 1, S. Abad 2, M. Rojas-Gimenez 1, L. Ginel 1, L. Cano-Garcia 1, C. Fuego 1, C. Domic 1, M.C. Ordoñez-Cañizares 1, F.G. Jimenez-Nuñez 1, G. Diaz-Cordova 1, A. Belmonte 1, V. Coret 1, M.V. Iriyog 1, A. Fernandez-Nebro 1,1 Department of Reumatology at the University Regional Hospital of Malaga (HRUM), Malaga University; 2Ciudad Jardín (Guadalmedina) Health center. Hospital Regional de Málaga, Málaga, Spain

Objectives: To describe insulin resistance (IR) in patients with rheumatoid arthritis (RA) and compare it with healthy controls and to analyze the association between the accumulated inflammatory burden in patients with RA and IR.

Methods: Design: Observational case-control study. Population: consecutive RA-patients (ACR/EULAR 2010 criteria), > 16 years, selected from a prospective inception cohort (diagnosis of RA between 2007 and 2011). Patients with Diabetes Mellitus (according to ADA 2010 criteria) were excluded. Controls: sex- age and BMI -matched controls were collected from a health center in our hospital area. Protocol: Cases and controls were evaluated by a rheumatologist. Clinical data of disease activity (RA patients), analytical values and oral glucose tolerance test (OGTT) were determined. All participants signed informed consent.

Main outcome: IR measured by the homeostasis model for insulin resistance (HOMA-IR) ([IR-2.29 μU * mmol/ml])/2. Secondary outcome: IR measured by quantitative insulin sensitivity check index (QUICKI) (< 0.3 - < 0.5 μU * mmol/ml) and β-cell function by a homeostatic model assessment of β-cell function (HOMA β). Variables: Demographic, clinical-analytical variables, Disease Activity Score of 28 joints (DAS28-ESR), Health Assessment Questionnaire (HAQ), BMI (according to OMS classification) and glucose in insulin and after OGTT values. Statistical analysis: Descriptive and paired T-test or Chi-square test followed by binary logistic regression in RA patients (Dependent variable: Insulin Resistance).

Results: Sixty-two subjects were studied, 8 of them were excluded after OGTT (4 diabetic patients and their respective controls). Finally, 54 subjects were included: 27 RA and 27 healthy controls. The mean age of patients with RA was 52.2 (12.1) years. Most of them were women (88.9%), with seropositive (FR 81.5% and ACPA 74.1%) and erosive (63%) RA. The mean duration of the disease was 85.6 months (27.1) and mean DAS 28 index since the onset of the disease of 2.98 (0.9).

Differences between clinical characteristics and in relation to IR between cases and controls are shown in Table 1. No significant differences in the proportion of subjects with IR in cases and controls were observed. 33.3% of patients with RA had IR. In multivariate analysis, the only independent variable associated with IR in RA patients was disease activity score (DAS28) (OR [95% CI] = 3.6 [1.0–12.9], p=0.045).

Conclusions: The only predictor of IR in RA patients was the inflammatory activity measured by DAS28. We did not find a higher IR in RA patients than in healthy controls, it could be because the patients were well treated and the inflammatory activity was controlled in the most of them.

Disclosure of Interest: None declared

CHARACTERISTICS OF BLOOD PRESSURE PHENOTYPES IN PATIENTS WITH RHEUMATOID ARTHRITIS - EULAR

S. Velmakin, E. Troitskaya, S. Villevalde, Z. Kobalava, Propaedeutics of Internal Diseases, Rudn University, Moscow, Russian Federation

Background: Patients with rheumatoid arthritis (RA) have increased cardiovascular risk. Arterial hypertension (AH) is highly prevalent, and seems to be under-diagnosed and under-treated among patients with RA. Data on ABPM profile in patients with rheumatoid arthritis are lacking.

Objectives: The aim of the study was to evaluate ABPM parameters and characterize phenotypes of blood pressure in patients with RA.

Methods: 82 patients with RA (EULAR 2010) without known cardiovascular disease were examined (73% females, age 58.5±15.4 (M±SD) years, 13% smokers, 61% with AH, 34% with dyslipidemia). Median duration of RA was 8 years (IQR 3–17),. Seropositive RA was diagnosed in 69% of patients. Median CRP was 12.1 mg/dl (IQR 2.2–23.4 mg/dl), median rheumatoid factor (RF) was 32.5 IU/ml (IQR 8.3–173 IU/ml), All patients received disease-modifying antirheumatic drugs (DMARDs), 22% (38%) - biological treatment. Median duration of AH was 6.1 years (IQR 0–10 years). All patients with AH received antihypertensive treatment. 24-hour peripheral and central BP monitoring was performed (BPLab Vasotens, “Petr Telejen” – P<0.05 was considered significant.

Results: Mean office BP was 130±15/80±10 mmHg (peripheral) and 123±21/80±10 mmHg (central), 10 (17%) patients had elevated office BP (>140/90 mmHg), Mean BP values for peripheral and central BP were as follows: 125±15/72±9 and 116±14/75±9 mmHg for 24-h BP; 127±15/74±9 and 117±14/77±3 mmHg for daytime BP. 119±15/69±10 and 112±15/70±10 mmHg for nighttime BP. AH according to daytime BP was found in 15 (24.2%) pts, nighttime BP – in 29 (46.8%) pts, 24-h BP - in 19 (30.6%) pts. Phenotypes of BP were as follows: sustained normotension – in 38 (61.2%), masked hypertension in 15 (23.8%), sustained AH in 10 (16.1%), white-coat hypertension in 2 (3.2%) patients. Isolated systolic AH was observed in 12 (19.4%) pts. 10 (16.1%) patients had isolated elevated central BP. 20 (32.3%) pts had elevated central SBP according to individual reference values; all patients with high office BP had elevated central BP.

Conclusions: Patients with RA free of CVD are characterized by high prevalence of with the satisfactory control of office BP in the majority of patients. Relatively high prevalence of masked and isolated nocturnal hypertension despite antihypertensive treatment is observed in this population. These findings may help to optimize hypertension treatment in patients with RA.
Henoch-Schönlein purpura (HSP) is a non-thrombocytopenic leukocytoclastic acute systemic vasculitis of the small vessels with IgA-immunocomplex deposits, most commonly affecting the skin, joints, gastro-intestinal tract and the kidneys. It commonly affects the children aged between 4 to 10 years. The primary goal of treatment for rheumatoid arthritis (RA) is to maximize health-related quality of life (HRQOL) through symptom and damage control, and normalize function and participation in social and life activities. Although fatigue is recognized as one of the most debilitating symptoms of RA, little is known about how fatigue impacts participation.

**Objectives:**
We hypothesized that fatigue, along with pain, mood, disease activity, and pain medication use would be associated with participation.

**Methods:**
RA patients enrolled in an observational study at an academic center completed PROMIS measures assessing fatigue, physical function, mood (depression and anxiety), pain interference, sleep disturbance, and participation. RA clinical indicators were also collected at the visit. Variance inflation factors were examined to evaluate collinearity among variables. Covariates/confounders independently associated with participation included pain, mood (depression, anxiety), sleep, disease activity (CDAI), and physical function. Multiple regression models that did and did not include pain were compared using likelihood ratio tests with SPPS and R.

**Results:**
Participants were mostly female (82%) and white (83%) with mean (SD) age of 56 (13) years; 24% had ≥ high school, 29% had RA <5 years with 13% ≥ 2 years, and 22% were disabled. Mean CDAI was 7.9 (7.8). Most were in CDAI remission (n=56; 32%) or LDA (n=67; 38%); 39 (22%) were in MDA and 14 (8%) in HDA. Mean PROMIS fatigue was 53.9 (10.0); fatigue increased across CDAI levels from 46.2 (8.6) in remission to 64.0 (9.6). Only those with HDA had mean sleep, depression or anxiety scores ≥ 55 (i.e., above population norms). In the full model, fatigue, depression, CDAl, and physical function were significant independent predictors of reduced participation in social roles and activities (F (2, 169), p < 0.001, adj R2 = 0.55). Contrary to our hypothesis, pain was not associated with participation in univariate or multivariate models.

**Conclusions:**
Our results suggest that in RA patients, high levels or fatigue are common; conversely, depression, anxiety, and sleep disturbance were elevated only in patients with HDA. Disability and fatigue appear to have the greatest impact on participation in social roles and activities. RA treatments and interventions that attenuate fatigue and improve mood in people with active RA may improve their ability to participate in social and life situations restoring a sense of normalcy and improving HRQOL.

AB0368 PREDICTORS OF NEUROPATHIC PAIN IN RHEUMATOID ARTHRITIS
T. Martins Rocha 1, S. Pimenta 1, M. Bernardes 1, A. Bernardo 1, M. Barbosa 2, R. Lucas 3, L. Costa 1. 1Rheumatology; 2Pain Unit, Centro Hospitalar de São João; 3Clinical Epidemiology, Faculty of Medicine University of Porto (FMUP), Portugal

Background: Significant pain persists in a substantial proportion of Rheumatoid Arthritis (RA) patients in spite of disease remission. Recent evidence indicates that features suggestive of neuropathic pain (NP) are present in RA patients with a prevalence range of 33–38% using the painDETECT questionnaire (PDQ).

Objectives: To estimate the clinical predictors of NP in a cohort of RA patients.

Methods: Observational, cross-sectional study was performed with RA patients followed at our Rheumatology department with unchanged DMARD treatment during the last 3 months. Patients with diagnosed neuropathy or non-RA risk factors for NP were excluded. Selected patients were evaluated in a medical visit. Demographic, clinical and laboratory data were collected and disease activity and functional measures were evaluated. Two questionnaires were applied to assess NP: the Leeds Assessment of Neuropathic Symptoms (LANSS) and the PDQ. Univariate and multivariate logistic regression were performed to identify the predictors of NP. Significance level was set as <0.05.

Results: 112 RA patients were included. 86 (77%) were females, with a mean (SD) age of 55.1 (10.8) years and median disease duration of 13 years (range: 2–41). 84% patients were seropositive for Rheumatoid Factor and/or ACPA. 102 (92%) of RA patients were treated with Current MTX and previous/current Hydroxychloroquine (HCQ) treatment. Number of analgesics and current NSAIDs treatment were excluded because they did not respond correctly to a dominant choice for patients to weigh the pros and cons related to each of the treatment options in order to develop a preference.

Conclusion: The purpose of the study was to define representative patient preference phenotypes to enable patient-physician dyads to effectively incorporate patient preferences at the point-of-care.

AB0370 DEVELOPMENT OF PATIENT PREFERENCE PHENOTYPES FOR RHEUMATOID ARTHRITIS
W.B. Nowell 1, C. Wiedmeyer 2, G. Herath 2, G. Michel 3, L. Fraenkel 3. 1Global Healthy Living Foundation, Upper Nyack; 2Yale University School of Medicine; 3Yale University, New Haven, CT, United States

Background: Many important treatment decisions for patients with rheumatoid arthritis (RA) are conditional on patient preferences and, according to the U.S. National Academy of Medicine, mandate a shared decision making approach (SDM). Furthermore, SDM is being increasingly recognized as an important quality measure. One of the most common preference sensitive decisions in RA is how to escalate care when response to methotrexate monotherapy is inadequate. However, the number of RA medications currently approved makes it challenging for patients to weigh the pros and cons related to each of the treatment options in order to develop a preference.

Objectives: The objective of this study was to develop representative patient preference phenotypes to enable patient-physician dyads to effectively incorporate patient preferences at the point-of-care.

Methods: People living with RA were invited to complete a Choice-Based Conjoint analysis survey including seven attributes (route of administration, time to onset of action, bothersome adverse events (AEs), serious AEs, extremely rare AEs, duration of time on the market and affordability) developed iteratively based on patient feedback. Each attribute was described across three or four levels using plain language. Preference phenotypes were identified by applying latent class analysis to the conjoint data. Class solutions were replicated five times from random starting seeds. A five-group solution was chosen based on Akaike's information criterion. We calculated the percentage of importance assigned to each attribute and performed simulations to estimate preferences for triple therapy, SC and IV biologics, or tocilizumab.

Results: 1100 U.S. subjects recruited via the CreakyJoints online patient community completed the survey. Of these, 49 were eliminated because they completed the survey in less than 10 minutes and an additional 45 people were excluded because they did not respond correctly to a dominant choice task. The mean age was 51.7 (11.2). The majority were female; (95%) and Caucasian (93%). Preferences (assuming low cost across options), and the reasons underlying each respondent’s preference, clustered into five groups (Figure 1). There were no differences in the distribution of demographic or clinical characteristics across the five groups. Phenotypes were created based on the stated preference data.

Conclusion: Preferences vary and can be categorized into distinct phenotypes. Ongoing research is evaluating whether enabling patients to identify with a preference phenotype facilitates SDM at the point-of-care.

Disclosures of Interest: This research was supported by a grant from the Rheumatology Research Foundation.

DOI: 10.1136/annrheumdis-2017-eular.5024
Disclosures: Achieving REM or LDA is not the ultimate goal of treatment for patients with painful callosity and footwear problems caused by typical forefoot deformity. Recently, patients have expressed a desire to achieve functional REM or LDA just before surgery. The patient-reported outcomes (PROs) were assessed using the Health Assessment Questionnaire-Disability Index (HAQ-DI), EuroQol-5 Dimensions (EQ-5D), Beck Depression Inventory-II (BDI-II), and Patient’s General Health using a visual analogue scale of 100 mm (Pt-GH). The 28-joint Disease Activity Score using C reactive protein (DAS28-CRP), the Japanese Society of Surgery of the Foot (JSSF) standard rating system (JSSF) for the RA foot and ankle scale\(^6\), and the Time Up&Go test (TUG) were also assessed. All of these items were investigated just before surgery (baseline) and again at 6 and 12 months after surgery.

Results: Overall, the physical function (JSSF, TUG), QOL (EQ-5D), and mental wellness (depression) (BDI-II) were significantly improved at 6 and 12 months after surgery compared to the baseline values (p<0.05). In the REM/LDA group, significant improvement was noted in the physical function (JSSF), QOL (EQ-5D) both at 6 and 12 months after surgery; however, we did not observe any significant changes in the Pt-GH or DAS28-CRP (Table 1).

AB0372 ASSOCIATED FACTORS OF CERVICAL AND LUMBAR SPINAL INSTABILITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Sugimura\(^1\), M. Miyakoshi\(^2\), T. Kashiwagiura\(^3\), M. Kobayashi\(^4\), T. Aizawa\(^5\), H. Abo\(^6\), Y. Shimada\(^7\),\(^\)1 Orthopedic Surgery, Akita University Graduate School of Medicine; \(^2\) Orthopedic Surgery, Akita City Hospital, Akita; \(^3\) Orthopedic Surgery, Hiraka General Hospital, Yokote; \(^4\) Orthopedic Surgery, Kita Akita Municipal Hospital, Kitaakita; \(^5\) Orthopedic Surgery, Kakunodate Municipal Hospital, Senboku, Japan

Background: Few studies have compared rheumatoid arthritis (RA)-related disorders of the cervical and lumbar spine.

Conclusions: The objectives of this study were to examine the prevalence of and risk factors for cervical and lumbar spinal instability in patients with RA.

Methods: From a total of 1,843 patients registered in the Akita Orthopedic Group on Rheumatoid Arthritis (AORA), 135 patients [118 women, 17 men; mean age, 68 (41–84) years; mean disease duration, 14 (1–63) years] who underwent a radiographic examination were enrolled in this study. In the cervical spine, we defined instability as one of the following characteristics: (1) atlantodental interval (ADI) > 3 mm, (2) Ranawat value < 13 mm on a neutral plain radiograph, or (3) anteroposterior translation > 3 mm at the subaxial cervical spine on an anteroposterior bending plain radiograph. In the lumbar spine, instability was defined as anteroposterior translation > 3 mm on a neutral plain radiograph.

At the time of radiographs evaluation, demographic characteristics, clinical variables, medical history and current medications were investigated. The patients were classified into two groups: with both cervical and lumbar spinal instabilities and without. The independent risk factors for both cervical and lumbar spinal instabilities were then determined using multivariate logistic regression analysis.

Results: Forty-six (34.1%) patients exhibited cervical spinal instability, and 50 (37.0%) patients exhibited lumbar spinal instability. Twenty-four patients (17.8%) exhibited both cervical and lumbar spinal instability. The presence of both cervical and lumbar spinal instability was significantly and independently associated with disease duration (OR: 1.06; 95% CI: 1.01–1.12).

Conclusions: The prevalence of both cervical and lumbar spinal instability in patients with RA was 17.8%. Disease duration was independent risk factor for presence of both cervical and lumbar spinal instability in this study.

AB0373 ANALYSIS OF RISK FACTOR FOR LOCOMOTIVE SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM CHIKARA STUDY

Y. Yamada, M. Tada, K. Mandai, N. Hidaka. Department of orthopedics surgery, Osaka City General Hospital, Osaka City, Japan

Background: Patients with rheumatoid arthritis (RA) are at a higher risk for sarcopenia due to joint destruction and chronic inflammation\(^1\), which can lead to locomotive syndrome (LS), i.e., being restricted in the ability to walk or lead a normal life owing to a dysfunction in one or more of the parts of the musculoskeletal system\(^2\). The present observational CHIKARA study (Correlation research of sarcopenia, skeletal muscle and disease activity in rheumatoid arthritis; registration number UMIN000023744) was begun in 2016 to investigate the correlation between RA disease activity and sarcopenia and LS.

Objectives: We investigated the relationship between LS and disease activity at baseline in patients with RA.

Methods: One hundred patients (78% women; average age, 66y) enrolled in the CHIKARA study were examined for body weight, muscle mass, fat mass, predicted bone mass, basal metabolic rate (BMR), leg muscle score, etc., using a body composition analyzer. Laboratory data, disease activity, Health Assessment Questionnaire (HAQ) and treatment were also investigated. LS was diagnosed using a questionnaire called Locomo-5. We investigated the correlation between LS and each status using univariate and multivariate analyses.

Results: Fifty-two percent of the patients with RA that we examined had LS. Mean disease duration was 5.5 years and mean DAS28-ESR was 3.55. Table 1 shows the risk factors for LS. Univariate analysis showed that age, percent body fat, body weight, visceral fat rating, leg muscles score, rheumatoid factor status and HAQ had significant associations to LS. Leg muscle score and HAQ were detected as significant factors by multivariate analysis. Patients whose leg muscle score was less than 90 had a significantly higher prevalence of LS by ROC curve analysis (Odds ratio 3.77, p<0.001). Disease activity and use of glucocorticoids or biological agents showed no significant relationship.

Conclusions: Lower leg muscle score and higher HAQ score are independent risk factors for LS among patients with RA.

Rheumatoid arthritis - anti-TNF therapy

1Rheumatology; 2Immunology, Hospital la Paz, Madrid, Spain

Background: Anti-TNF are nowadays widely used for the treatment of Rheumatoid Arthritis (RA), which has dramatically changed the prognosis of the disease, carrying an important healthcare expense. This is why optimisation seems a successful strategy that should not be linked to a worse become of our patients’ clinical evolution.

Objectives: Describe a population of patients with RA under optimised treatment with Adalimumab (Ada) and Infliximab (Ifx). Study the incidence of flares and establish predictive factors of flares at baseline and pre-optimization.

Methods: Observational study of the prospective cohort RA-Paz. All the patients diagnosed of RA under treatment with Ifx and Ada between Jan.2000 and Dec.2016 of the day-care unit of La Paz Hospital, were included. Demographic data, clinical activity and blood sample results were collected at baseline, pre-optimization (pre-op) and at 3, 6, 9, 12, 18 and 24 months. Drug serum trough levels were measured under ELISA in each visit. Optimal range for Ifx was described as drug concentration between 1000-4000 ng/mL and 1500-5000 ng/mL for Ada. Optimisation was defined as drug use below standard dose. Flares were collected from the pre-op visit. Flare was described as clinical worsening which led to a therapeutic change or a DAS28 > 3.2. DeltaDAS28 > 0.6. Predictive factors of flare at baseline and pre-op were evaluated with a univariate and multivariate analysis. Statistical study was performed with the statistical program SPSS.

Results: Of the 271 patients diagnosed of RA, 74 patients were optimised (44 under Ada and 30 under Ifx). Baseline demographic characteristics are shown in the table below. During the 24 months after the pre-op visit, 55.4% (41) of the patients presented at least one flare with an average of 1.38 flares [1–5]. Most of the patients (53.7%, 22/41) were controlled with the adjustment of non biological treatment. Only 39.0% (16) of the patients, had to go back to the previous optimised dose and 7.3% (3) to the standard dose. 88.9% (39/41) were controlled after the dose modification. 104 flares were collected, 33% (34) at the pre-op visit. Flares were described as clinical worsening which led to a therapeutic change or a high DAS28 values in relationship to the MTX dose, statistical differences are observed with use of HD (≥ 20 mg/week) (3.1±1.3 with HD vs 3.9±1.1 without MTX, p=0.001). A least proportion of patients with flares were in supra-optimal range (13.3% with flares vs 26% without p=0.007). At baseline, no clinical factors were predictive of flare. Nor were blood sample results. In contrast, a higher disease activity, measured by DAS pre-op (p=0.004), a worse EULAR answer (p=0.027) and not being in supra-optimal range (p=0.032) were statistically correlated with flares development at the univariate analysis. Time to the optimisation tended to the significance (OR=1.152; p=0.08). In the multivariate analysis, only a higher DAS pre-op (OR=2.00, 1.08–3.73) and being in optimal (OR=5.90, 1.38–25.2) and sub-optimal range (OR=6.05, 1.28–28.7) were independently correlated.

Conclusions: In our cohort of optimised patients, we noted a high proportion of flares. However, flares were controlled with dosage readjustment without needing a treatment change. Independently correlated predictive factors for flares were a higher disease activity measured by DAS and not being in therapeutic range in the pre-optimisation visit.

Rheumatoid arthritis - anti-TNF therapy

1Rheumatology, University Hospital la Paz, Madrid, Spain

Background: Several publications in rheumatoid arthritis (RA) have demonstrated a beneficial effect of concomitant methotrexate (MTX) use with TNF inhibitors (TNFi), mainly because of the MTX effect in reducing immunogenicity. In a previous work in the RA-La Paz cohort, we found that the concomitant use of MTX had a positive effect on the pharmacokinetics of serum TNF levels, decreasing the immunogenicity of these drugs. Furthermore, the MTX effect was dose-dependent, being greater at high MTX dose. Currently, we investigate the effect of concomitant MTX use on the clinical response.

Objectives: To investigate the MTX influence on the clinical response in the RA-La Paz cohort treated with Infliximab (Ifx), Adalimumab (Ada) or Etanercept (Etn) at one year of treatment.

Methods: This is an observational study from a prospective cohort from the Rheumatology Unit of the University Hospital La Paz, Madrid, Spain that analysed a total of 150 RA patients (112 with RA patients. ARA (71 patients) and Etn (110 patients). Patients were grouped according to the MTX dose: no MTX, low dose (LD: ≤2.5 mg/week), intermediate dose (ID: 15–17.5 mg/week) and high dose (HD: >20 mg/week). For this study, the clinical response was evaluated by DAS28-ESR and the clinical improvement by sDAS28. Data were collected at baseline (BL) and 1 and 2 years of treatment. Statistical analysis was performed using GraphPad Prism 6.0 software.

Results: Out of 293 RA patients (pts) under TNFi treatment, 184 (71 with Ifx, 40 with Ada and 73 with Etn) were included. In this cohort, 128 (70%) pts used concomitantly MTX (91% oral administration) and 56 (30%) pts were in monotherapy. No differences in DAS28 were found at baseline between patients with or without MTX (p=0.8). After one year of treatment, pts with TNFi +MTX have a significantly lower DAS28 than patients without MTX (3.3±1.3 vs 3.9±1.1, p=0.004). When analyzing the DAS28 values in relationship to the MTX dose, statistical differences are observed with use of HD (≥ 20 mg/week) (3.1±1.3 with HD vs 3.9±1.1 without MTX, p=0.001) but not with intermediate (3.4±1.2 with HD vs 3.9±1.1 without MTX; p=0.08) or low MTX dose (3.6±1.6 with LD vs 3.9±1.1 without MTX; p=0.4) at 1 year of therapy.

Clinical improvement by sDAS28 was higher in patients with TNFi +MTX than in patients without MTX (1.7±1.4 vs 1±3.0, p=0.007). This effect was observed with all MTX doses (1.7±1.5 with HD vs 1±3.0 without MTX, p=0.01; 1.6±1.3 vs with HD 1±3.0, p=0.03) and being in optimal (OR=1.38–25.2) and sub-optimal range (OR=6.05, 1.28–28.7) were independently correlated.

Conclusions: We demonstrated a positive effect of any MTX dose on the clinical improvement at one year of treatment.

DOI: 10.1136/annrheumdis-2017-eular.2884
Results: of the 64 patients included in the study, 59 (92.2%) were women and 5 (7.8%) men, mean age 57.5±9.42 years. After 6 months, 7 patients were declared nonresponders, 38 achieved a moderate response and 19 good response.

Following baseline COMP titres and the EULAR response at 6 months, general tests were performed for all patients, the results were compared. Lower baseline titres had predictive value for achieving a good response (746.0±130.095 ng/ml) compared with moderate responders (1032.8±186.671 ng/ml) and nonresponders (1042.2±181.717 ng/ml, p=0.0000).

After 12 months 11 patients achieved moderate response, 44 a good response and just 1 patient was declared nonresponder. At this visit, even if we didn’t find significant differences between baseline COMP titres and the EULAR response (p=0.1430), we observed lower baseline titres for good responders (917.8±219.943 ng/ml) versus moderate responders (1042.7±193.117 ng/ml).

Grouping patients in 2–3 categories (good responders, moderate responders, nonresponders) there were no differences between groups at 6 months (937.2±218.106 ng/ml versus 1042.2±181.717 ng/ml, p=0.227) or 12 months (942.8±219.025 ng/ml versus 896.5±0.000 ng/ml, p=0.9755).

Following the status pretreatment of COMP and EULAR response at 6 months, we identified differences between groups (p=0.0001), all 7 patients declared nonresponders were COMP positive and only 13/19 (68.4%) of good responders were tested positive. At 12 months there were no differences between pretreatment status of COMP and response to treatment (p=0.2085).

Regarding the evolution of serum levels, we noticed a decrease statistically significant from baseline (948.7±215.683 ng/ml) to 12 months (740.8±227.04 ng/ml, p=0.0000).

Conclusions: COMP could be one of the biomarkers for identifying pretreatment the patients who will respond to biologic therapy in Rheumatoid Arthritis.

SWITCHING FROM BIO-ORIGINAL ETANERCEPT TO BIOSIMILAR ETANERCEPT SB4: PATIENT ACCEPTABILITY AND OUTCOMES IN THE REAL WORLD

C. Holroyd 1, D. Wallis 1, S. Bennett 1, P. Clayton 1, C.J. Edwards 2,
1Rheumatology; 2NHWR Wellcome Trust Clinical Research Facility, University Hospital Southampton, Southampton, United Kingdom

Background: A number of studies have demonstrated the efficacy of biosimilar therapies including SB4 (a biosimilar-etanercept). However, real world data of the process of switching, acceptability to patients, efficacy and safety is lacking.

Objectives: To obtain real world data of the acceptability and outcomes of patients with severe (eligible for TNFi therapy as defined by UK NICE) rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) who switch from bio-original etanercept (boDMARD-ETN) to the bsDMARD etanercept SB4 (bsDMARD-ETN).

Methods: Adult patients, with RA, PsA & AS, currently enrolled in the SmART study and switching from boDMARD-ETN to bsDMARD-ETN were followed for 6 months. Primary outcome was change in DAS28, PsARC response or BASDI following switching. Additional outcomes included: % change of remission rate, HAQ-DI, CRP or ESR levels, patient satisfaction, PDUS and SAEs leading to discontinuation. All patients had severe disease and were receiving boDMARD-ETN as per local guidelines of UK NICE. Analysis was performed in a similar way to a cross-over RCT trial design where patients act as their own control with respect to treatment.

Results: 462 patients were enrolled and 255 patients completed the study. Mean age was 53.9 (±12.1) yrs; 82.2% of enrolled patients were female; average disease duration was 7.8 (±7.5) yrs. DAS28 decreased from 6.1 (±1.1) at baseline to 2.9 (±0.1) at study end, whereas the mean HAQ-DI from 1.6 (±0.6) to 0.7 (±0.5). The proportion of patients in LDA and REM at study end was 56.0% and 31.1%, respectively. Total SQUASH score increased from 4772 (±4132) to 6104 (±5492), representing 28% improvement in overall physical activity. The largest score improvements were seen in the SQUASH domains of leisure time and sport (by 43%), followed by household activities and activities at work and school (each by 19%). The correlations between the total SQUASH score and its subscores with DAS28 were weak (r=-0.1 to baseline and study end). A significant correlation between the total SQUASH and HAQ-DI scores was seen at baseline (r=-0.30), but not at the study end (r=-0.22). Correlations between SQUASH subscores and HAQ-DI were not significant. The percentage of work disabled subjects decreased from 22% to 17%. According to linear regression analysis, sociodemographic factors did not substantially influence habitual physical activity.

Conclusions: Treatment with adalimumab in clinical practice in CEE resulted in clinically meaningful improvements in disease activity and physical function as well as improvements in physical activity. The correlation between the scores for disease activity, physical function and physical activity were however poor and there was no clear influence of the standard sociodemographic factors on physical activity.

AB0379 EFFICACY OUTCOMES FOR ORIGINATOR TNF INHIBITORS AND BIOSIMILARS IN RHEUMATOID ARTHRITIS AND PSORIASIS TRAILS: A SYSTEMATIC LITERATURE REVIEW

R. Moots,1 C. Curiale,2 D. Peterse2, C. Rolland3, H. Jones4, E. Singh2, E. Mysser4,1 University of Liverpool, Liverpool, United Kingdom; 2Pfizer, Collegeville, United States; 3Envision Pharma Group, London, United Kingdom; 4Organización Médica de Investigación, Buenos Aires, Argentina

Background: Regulatory approval of biosimilar versions of innovator biotherapeutics requires that new biological products be highly similar to innovator biologicals, with no clinically meaningful differences in safety, purity, and potency.1,2 Pre-specified margins for equivalence in efficacy have been met in comparative trials of biosimilars of tumour necrosis factor inhibitors (TNFis) in rheumatoid arthritis (RA)1 and plaque psoriasis (PsO).4,5 Supporting biosimilarity, but differences in treatment responses between originator pivotal trials and biosimilar trials have posed some interesting questions.

Objectives: To compare American College of Rheumatology 20% response (ACR20) and Psoriasis Area Severity Index 75% (PASI75) responses to originator TNFis in pivotal trials with those to originator TNFis and TNFi biosimilars in biosimilar trials in RA and PsO.

Methods: Historical data from originator pivotal trials (averaged across trials) were obtained from published systematic literature reviews. Searches were conducted to identify comparative randomized clinical trials of approved or proposed biosimilars of adalimumab (ADA), etanercept (ETN), and infliximab (INF) sourced from the European Union (EU). The databases were Embase®, MEDLINE®, the Cochrane Central Trials Register and Database of Systematic Reviews, and other Cochrane Library databases, and 2015/16 congress abstracts. To reduce variability, only studies conducted in disease-modifying antirheumatic drug-experienced patients treated with the same biologic dosages and assessed at the same time points were selected for analysis.

Results: Of 83 publications initially identified, 16 publications were included for analysis (RA: originators, n=4; biosimilars, n=6; PsO: originators, n=3; biosimilars, n=3). Higher proportions of ACR20 responders were found among RA patients receiving the originator biologics and biosimilars in biosimilar trials, than among patients receiving the originator biologics in pivotal trials (Table). Insufficient data were available from ADA and INF biosimilar studies in PsO; in ETN studies in PsO, a difference was also observed in the proportions of PASI75 responders between biosimilar and pivotal trials.

Conclusions: Differences were observed in treatment response rates between originator pivotal trials and more recent trials of originator biologics and their respective biosimilars. Such differences in outcomes may be attributable to fundamental differences in study design and/or baseline patient characteristics, which require further analysis. Additional research is also needed to explore the clinical relevance of these differences.

AB0380 RESULTS FROM A RANDOMIZED, SINGLE-BLIND, SINGLE-DOSE, PARALLEL-GROUP STUDY IN HEALTHY SUBJECTS DEMONSTRATING PHARMACOKINETIC SIMILARITY BETWEEN ABP 710 AND INFliximab

Background: ABP 710 is being developed as a biosimilar with the same amino acid sequence as infliximab, an anti-tumor necrosis factor therapy. Analytical and functional comparisons between ABP 710 and infliximab have been conducted and confirmed no clinically meaningful differences in terms of purity, safety, and potency.1,2

Objectives: This report describes the results of analyses comparing the pharmacokinetics (PK), safety, and immunogenicity of ABP 710 and infliximab sourced from the European Union (EU).

Methods: This was a single-blind, single-dose, parallel-group study among healthy adults, 18 to 45 years of age and with a body mass index of 18 to 30 kg/m². Subjects were randomized to receive a 5 mg/kg intravenous infusion of either ABP 710 or infliximab. The primary objective of this analysis was demonstration of PK similarity of ABP 710 to infliximab based on area under the serum concentration-time curve from 0 extrapolated to infinity (AUC(∞); primary endpoint). PK equivalence was deemed achieved if the geometric mean (GM) ratio and its 90% confidence interval (CI) for AUC(∞) was within the range of 0.80 to 1.25. Secondary endpoints included maximum observed serum concentration (Cmax), area under the serum concentration-time curve from time 0 to last quantifiable concentration (AUC(0-τ)), safety, and immunogenicity.

Results: A total of 49 subjects received ABP 710 and 49 subjects received infliximab. Following a single dose, the adjusted least square (LS) GM of AUC(∞), Cmax, and Cmax for ABP 710 was 33559 μg·h/mL, 31789 μg·h/mL, and 123 μg/mL, respectively. The adjusted LS GM of AUC(∞), Cmax, and Cmax for infliximab was 33706 μg·h/mL, 31847 μg·h/mL, and 121 μg/mL, respectively. Ratios of adjusted LS GMs (90% CIs) between ABP 710 and infliximab for AUC(∞), AUC(0-τ), and Cmax were 0.996 (0.904, 1.096), 0.998 (0.918, 1.086), and 1.021 (0.962, 1.083), respectively.

Safety: There was one subject in the infliximab group who developed polyarthritis that resolved with treatment and the subject completed the study. There were no deaths, other serious adverse events, or treatment-emergent adverse events (TEAEs) leading to discontinuation from the study. The incidence of TEAEs was similar in the two treatment groups (ABP 710: 83.7%; infliximab: 83.7%); the majority of TEAEs were mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and leucytosis. Immunogenicity: All subjects tested negative for antidrug antibodies (ADAs) prior to receiving any investigational product.

Conclusions: The study was designed to demonstrate PK similarity between ABP 710 and infliximab sourced from the EU among healthy subjects. The safety and immunogenicity profile were comparable between the two treatment groups.

DOI: 10.1136/annrheumdis-2017-eular.3281
to RTX (6.6). The demographic and response data DAS 28 are shown in Table 1. There are no differences in the years of evolution,% of women, FR or ACPA positive, erosions and disease activity, as measured by DAS 28, before the switch, between the two groups (anti-TNF vs non-anti-TNF). Patients in the anti-TNF group were slightly younger than non-anti-TNF:When the DAS 28 response is evaluated at 3 and 6 months, the modifying treatment is effective (DAS 28 beginning 4.4 vs DAS 28 6 months 2.8 ± 0.001). When assessing the response to change, there is no difference in the DAS 28 response at 3 months or 6 months, if you switched to anti-TNF or non-anti-TNF (3.18 vs 2.52 ± p=0.122).

When comparing the patients with anti-TNF alpha vs TCZ, 62.5% of the patients with TCZ are in remission compared to 38%, 5% (p=0.047).

Conclusions: In this retrospective study in daily clinical practice, it is evident that the change in treatment after failure of the first biological one, without differences if the change is to an anti TNF or another treatment. The percentage of patients who switched from anti-TNF at 6 months is higher if the change is at TCZ. Given the small number of patients, larger studies would be needed to confirm the results.

AB0382 OUTCOMES OF ETANECOTER THERAPY IN ELDERLY RHEUMATOID ARTHRITIS PATIENTS: AN INVESTIGATION OF THE AKITA ORTHOPEDIC GROUP ON RHEUMATOID ARTHRITIS REGISTRY

H. Anumam, T. Kashiwagura, M. Urayama, M. Kobayashi, T. Aizawa and 24 patients discontinued treatment. The AE and LOE cohorts contained 12 and 7 patients, respectively. The AE cohort had a mean age of 75.5 years at the start of treatment, with a mean disease duration of 20.7 years, 8.3% of patients switching from another biologic agent, 16.7% performing ADL independently, and a comorbidity rate of 100%. Corresponding values for the LOE cohort were: mean age, 71.4 years; disease duration, 12.7 years; switching from another biologic agent, 42.9%; performing ADL independently, 57.1%; and comorbidity rate, 28.6%. Efficacy was noted for 81.8% of all patients with 52 weeks of ETN therapy, achieving good efficacy in 21 cases and moderate efficacy in 24 cases.

Conclusions: Retention rate and efficacy were considered satisfactory in elderly RA patients receiving ETN therapy. The risk of adverse events was suggested to increase with increasing age and the presence of comorbidities. These factors require attention when prescribing ETN therapy.

AB0383 SUBCLINICAL BRAIN DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ITS RELATIONSHIP TO TNF BLOCKER THERAPY

S. Sağ, I. Tekeoğlu, M.S. Sağ, A. Kamanli, K. Nas. Department of Physical Medicine and Rehabilitation, Rheumatology, Faculty of Medicine, Sakarya University, Sakarya, Turkey, sakarya, Turkey

Background: RA is a chronic disease with a yet unclarified etiology, which causes the activation of pro-inflammatory pathways that bring about joint and systemic inflammations (1). In recent years, the pathophysiology of brain damage that can occur in RA has drawn attention. Emphasis is being put on the possibility that brain damage occurs due to blood-brain barrier (BBB) damage that is linked to chronic inflammation.

Objectives: In this study, we aimed to investigate the peripheral blood levels of brain-specific proteins such as S100 beta and GFAP (glial fibrillary acidic protein), the differences in these proteins in patients who did and did not undergo TNF blocker therapy and their relationship with cranial MR lesions, disease activity and cognitive functions with the purpose of determining CNS (central nervous system) damage in patients with rheumatoid arthritis (RA).

Methods: 59 RA patients (47 (81.0%) females, 11 (19.0%) males) and 34 healthy controls (24 (70.6%) females, 10 (29.4%) males) were included in the study. All RA patients were on synthetic DMARD therapy at the beginning. While 30 patients continued sDMARD therapy, 28 patients with high disease activity were started on TNF blocker therapy. All demographic characteristics of the patients were recorded. Disease activity was evaluated using DAS28. The Mini-Mental State Examination (MMSE) was used to evaluate cognitive functions, and the Fazekas Scale was used to assess the cranial MRI lesions. The peripheral blood S100 beta, GFAP, claudin, IL-17, IL-1 beta levels of the patients were measured at the beginning and on the 6th month.

Results: Demographic characteristics were similar between the two groups and no statistical difference was detected between the patient group and the control group except age. RA patients that was started on TNF blocker therapy, S100 beta and GFAP levels were higher to a significant degree compared to the control group. (p<0.05) In the group that was started on TNF blocker therapy, S100 beta and GFAP levels were detected to have decreased significantly 6 months after treatment compared to the start of treatment. (p<0.05) No difference was found between the RA and control groups in terms of hyperintense lesions seen in the cranial MRI. (p>0.05) As the lesions in the deep white matter seen in the cranial MRI of RA patients increased, their S100 beta levels were also seen to increase. (p<0.05)

Conclusions: In conclusion, next to decreasing disease activity and joint erosions by suppressing inflammation, anti-TNF therapy in RA can also suppress potential brain damage linked to subclinical BBB (blood-brain-barrier) dysfunction. Further studies with broader participation and longer patient follow-up are needed to reinforce this hypothesis.

AB0384 CLINICAL AND RADIOLOGICAL EVOLUTION IN RHEUMATOID ARTHRITIS (RA) PATIENTS AFTER DEINTESIFICATE BILOGICS

J. Uceda, R. Hernandez, J.L. Marenco. Rheumatology, Valme University Hospital, Seville, Spain

Background: RA is the most common chronic inflammatory arthritis. About 30% of patients need treatment with biologic therapy (BT). Deintensification of BT for patients in clinical remission, is a strategy used in clinical practice to reduce side effects and burden.

Objectives: The primary endpoint was evaluate clinical and radiological behavior of the RA in patients receiving BT at reduced doses.
The secondary endpoint was to analyze the characteristics of patients who remain for a longer period of time in an optimized dose regimen.

**Methods:** In our Rheumatology Unit we are treating 271 RA patients with BT, the dose was deintensified for 62 (23%) patients in remission or low disease activity for at least 6 months. We have selected 32 patients with BT reduced for at least 6 years in an observational, longitudinal, retrospective study. Disease activity was measured by the DAS 28 index. Structural damage was evaluated by SENS method.

**Results:** We analyze 32, 20 female, 12, male mean age at diagnosis 42.6 years old; BT was started after RA evolution of 98.63 months. Drug reduction was performed after full BT for 62 months, mean DAS 28 was 2.47.

Patients were 75% FR positive and 56.7% ACPA positive. Etanercept was the BT more commonly reduced 59.4%, followed by adalimumab 21.9%, infliximab 12.5% and certolizumab 6.3%.

For 21 patients remaining on reduced doses, the mean DAS28 at time for analysis was 2.67. BT reduction as different drugs: none infliximab reduced dose patients required return to normal dose. All certolizumab reduced (2 patients) patients needed to back to normal dose. Etanercept in 36.8% and adalimumab 28.6%.

The mean of SENS score before the optimization was 8.78 and at time for analysis 10.67 for both kind of patients, who continued reduced and those who returned to increase BT dose.

For the secondary endpoint 10 out of 12 male continue with deintensificated BT (83%) in the other hand only 11 out of 20 female (55%) maintained reduced dose.

More negative for FR (69.2%) and ACPA (75%) patients keep on reduced dose regimen.

**Conclusions:** We have deintensificated 62 out of 271 RA patients on BT (23%).

All patients were in clinical remission at the beginning of BT dose reduction for more than 6 months.

Most patients (65%) analyzed remain long time with reduced BT in clinical remission.

We have not observed significant X-ray progression for reduced patients, even if they increase disease activity and need to back to the original BT dose.

The increase in disease activity was the main reason to interrupt the optimization regime.

Infliximab was the drug that remained more time optimized.

According to the results of our study, male patients negative for ACPA and FR remain longer with reduced doses.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.5273
OBJECTIVES: To investigate and compare etanercept monotherapy versus combination with sDMARDs in RA patients regarding survival on drug, efficacy, quality of life and reason for discontinuation.

METHODS: Observational, open, long-term study of patients from the ATTRGA registry starting the ETN therapy since 2010 either on monotherapy or in combination with sDMARDs (n=406). 461 patients (80.7%) were females. Mean ± SD at baseline was 74.5% ± 15 years. A multidisciplinary team of rheumatologists and clinical pharmacists in a third-level hospital was involved in decision-making on treatment and dose reduction, which invovled the application of protocols and the follow-up of patients at least every hospital was involved in decision-making on treatment and dose reduction, which involved the application of protocols and the follow-up of patients at least every 3 months of duration on November 1, 2013, constituted the cohort of patients who were optimized for 3 years. None of the differences reach statistical significance.

CONCLUSIONS: The strategy of dose reduction of biological therapies in patients with established RA that achieve sustained remission is possible in 37.3% of cases in real clinical practice (CREATE Registry) and it was maintained for 3 years.

The probability of occurrence of relapse decreases after 2 years of treatment with an optimized regimen in those patients who have not relapsed before.

This strategy is possible in patients with persistently controlled disease and in view of our results, it is independent of the drug administered (antiTNF versus non-antiTNF).

After 3 years of follow-up, all patients maintained clinical remission (DAS 28 <2.6) despite relapses, and after resumption of the usual dose, all of them reached the therapeutic goal again.

Patients who maintain clinical remission for 3 years achieve DAS28 values statistically lower than those who did not after 2 years.

DISCLOSURE OF INTEREST: None declared.

RESULTS AT 3 YEARS OF AN OPTIMIZATION GUIDELINE OF BIOLOGICAL THERAPIES IN RHEUMATOID ARTHRITIS. CREATE RECORD RESULTS

P. Font1, M.C. Castro2, M. Romero3, R. Ortega3, L. Calvo3, D. Ruiz3, M. Cardenas2, R. Alejandre2, P. Carreto1, E. Collantes2, 1Hospital Reina Sofia - Imibic-Universidad de Cordoba; 2Hospital Reina Sofia - Imibic-Universidad de Cordoba, Cordoba; 3MFyC de Valladolid, Area Este, Valladolid, Spain

BACKGROUND: Dose optimization, such as dose reduction or dose spacing, is nowadays presented as a therapeutic strategy to be followed in patients with rheumatoid arthritis (RA) who have managed to reach and maintain clinical remission for a while. This strategy reduces the frequency of adverse effects and promotes cost savings.

METHODS: Patients with RA (Criteria ACR 1987) of the CREATE registry (patients who were treated in real life conditions) who had clinical remission (DAS28 <2.6) on a 6 months of duration on November 1, 2013, constituted the cohort of patients who were optimized for the dose received. According to the consensus of the Spanish Societies of Rheumatology and Hospital Pharmacy, the optimization of doses meant the reduction of between 20 and 50% of the same. A multidisciplinary team of rheumatologists and clinical pharmacists in a third-level hospital was involved in decision-making on treatment and dose reduction. There are many evidences that Th9 lymphocytes take part to the immunogenicity of biologic agents.

We aimed to evaluate the immunogenicity of branded and biosimilar infliximab by detecting changes in Th9 percentages following an “in vitro” stimulation test.

RESULTS: PBMCs from 55 consecutive RA outpatients (15 drug-free, 20 successfully treated with branded infliximab and 20 failing branded infliximab) and from 10 healthy controls were collected. PBMCs were cultured with/without 50 μg/mL infliximab originator (Remicade®) or 50 μg/mL infliximab biosimilar (Remisima®), 50 μg/mL Human IgG1kappa and 50 μg/mL recombinant Human IgG Fc for 18 hours. Th9 lymphocytes were identified by means of flow cytometry as Pu.1+, INF-γ, IL-9+ CD4+ cells. Furthermore, the markers CCR7 and CD45RA were used to distinguish naive from memory IL-9-producer cells.

Despite the variety of stimuli tested, changes in Th9 percentages were not statistically significant.

CONCLUSIONS: The results are consistent with the findings of previous studies that Th9 lymphocytes are implicated in the immunogenicity of biological therapies. However, further studies are needed to confirm these data.

DISCLOSURE OF INTEREST: None declared.

THE IMMUNOGENICITY OF BRANDED AND BIOSIMILAR INFLIXIMAB IN RHEUMATOID ARTHRITIS ACCORDING TO TH9-RELATED RESPONSES

R. Talotta1, A. Berzi2, A. Doria3, A. Batticciotto1, M.C. Ditto1, D. Trabattoni1, A. Batticciotto1, A. Berzi2, A. Doria3, M.C. Ditto1, D. Trabattoni1, A. Berzi2, A. Doria3, M.C. Ditto1, D. Trabattoni1, A. Berzi2, A. Doria3, M.C. Ditto1, D. Trabattoni1

BACKGROUND: There are many evidences that Th9 lymphocytes take part to the immunogenicity of rheumatoid arthritis (RA), however it is unclear whether these cells are implicated in the immunogenicity of biologic agents.

OBJECTIVES: We aimed to evaluate the immunogenicity of branded and biosimilar infliximab by detecting changes in Th9 percentages following an “in vitro” stimulation test.

RESULTS: PBMCs from 55 consecutive RA outpatients (15 drug-free, 20 successfully treated with branded infliximab and 20 failing branded infliximab) and from 10 healthy controls were collected. **AB0390** EFFICACY AND SAFETY OF YISAIPU, A RECOMBINANT HUMAN TUMOR NECROSIS FACTOR-α RECEPTOR II IGG FC FUSION PROTEIN IN CHINESE PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS

R. Wu, Department of rheumatology, the First Affiliated Hospital of Nanchang University, Nanchang, China

**Background:** Rheumatoid arthritis (RA) is characterized by chronic autoimmune diseases of progressive synovitis and joint destruction, which can eventually lead to joint deformation and disability. A number of clinical studies showed the effectiveness of tumor necrosis factor antagonist combined with methotrexate in the treatment of RA. Yisaipu used in this study is produced by CPGC Company (Shanghai, China), which was approved to treat RA by Chinese Food and Drug Administration, in 2005, which is biosimilar of etanercept (a soluble recombinant TNF receptor antibody fusion protein, an immunoglobulin molecule which connects two TNF receptors (p75) to the human IgG1 FC division). Etanercept had been confirmed the effectiveness in rheumatoid arthritis already in many clinical trial. However, there is however randomised controlled study published regarding Yisaipu in international journals. We conducted an open-label, randomized controlled study for 24 weeks to evaluate the efficacy and safety of Yisaipu in combination with DMARDs in comparison with low or medium dose of glucocorticoid in patients with moderate to severe RA.

**Objectives:** to evaluate the efficacy and safety of Yisaipu in combination with DMARDs in comparison with low or medium dose of glucocorticoid in patients with moderate to severe RA.

**Methods:** Eighty-four patients with moderate to severe rheumatoid arthritis were randomly assigned into 4 groups: group 1: methotrexate plus Yisaipu; group 2: methotrexate plus medium-dose prednisone (30mg/d, reduced to 15 mg/d after 2 weeks); group 3: methotrexate plus low-dose prednisone (7.5mg/d); group 4: methotrexate alone. Each group was treated with MTX (12.5mg once weekly, the next day with folic acid 10mg) and hydroxychloroquine sulfate (200 mg twice a day) concomitantly. The primary endpoint was ACR20 response rate at week 24. Secondary efficacy endpoints were ACR70, ACR70, DAS-28, Higher Health Assessment Questionnaire (HAQ) and EULAR remission rate at week 4, 12 and 24.

**Results:** At week 24, a higher proportion of patients in group 1 and group 2 than the other two groups met the ACR20 response criteria (85.7% in group 1 and 71.4% in group 2 vs. 62.5% and 58.9% in group 3 and group 4, P<0.05). The reductions of HAQ at week 24 showed significant improvement in group 1 and group 2 compared to group 3 and 4 (-2.96 and -2.69 respectively, P<0.05). Reduction of DAS-28 in group 1 and group 2 were significantly higher than the other two groups (P<0.05). The percentage of EULAR remission rate of group 1 and group 2 is significantly higher than group 3 and group 4 at week 24 (47.6% in group 1, 33.9% in group 2, 23.8% in group 3 and 14.3% in group 4, P<0.05). There were no significant differences of adverse event among four groups.

**Conclusions:** Yisaipu plus MTX or GCs plus MTX in Chinese patients with moderate to severe RA is safe and effective in our study. More studies are needed to compare the long-term safety and cost-effectiveness between Yisaipu and GCs in treatment with RA.

**Background:** CT-P13 is approved in both European Union and United States, and licensed for use in 79 countries around the world as a biosimilar to innovator infliximab (INFx). The independent registries of CT-P13 have been conducted in a number of European countries and Korea [1].

**Objectives:** to evaluate safety and effectiveness of CT-P13 when administered in a real-life setting in active RA patients.

**Methods:** This study collected data of patients who were treated with CT-P13 from 2013 December to 2016 June. Efficacy was assessed at baseline and every 6 months thereafter using DAS28 (ESR) and/or DAS28 (CRP) and collection of adverse events (AEs) was performed. Infliximab was assessed at baseline, Week 30 and every year during CT-P13 treatment period.

**Results:** Total 125 patients were enrolled; 104 patients started treatment with CT-P13 (Naive group) and 21 patients (8 from INX, 13 from other anti-TNFs) switched treatment to CT-P13 (Switched treatment group). The mean (SD) duration since RA diagnosis was 6.5 (±6.85) years for all patients. Of all patients treated with CT-P13, only 4.8% (6/125) of patients changed to other RA diagnosis was 6.5 (±6.85) years for all patients.

**AB0393 ADVERSE SKIN REACTIONS IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING TUMOR NECROSIS FACTOR ALPHA INHIBITOR – AN ANALYSIS OF DATA FROM THE SLOVENIAN BIOLOGICAL REGISTRY**

S. Drliča, A. Podovčnik, Ž. Rotar, A. Hočevar, S. Praprotkin, M. Tomšič on behalf of rheumatologist participating in BioRx.si registry.

1. Department of Internal medicine, Izola General Hospital, Izola. 2. Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia

Background: Paradoxical skin reactions (PSR) are defined as a new onset or worsening of skin conditions during treatment with tumour necrosis factor alpha (TNF-α) inhibitors that generally improve or respond to this therapy. The list of PSR is growing. The most commonly reported are psoriasis skin eruptions. Objectives: To evaluate the frequency of PSR in the group of rheumatoid arthritis (RA) patients treated with TNF-α inhibitor at the time of development of skin eruption. Methods: We conducted the analysis of the data from the mandatory Slovenian national registry of patients treated with bDMARDs (BioRx.si) which includes spontaneous adverse reaction reports between 01.01.2008–31.05.2016. The analyses were limited to patients with RA.

Results: During the observation period, 1,046 RA (82% female; median (IQR) age at initiation of TNF-α inhibitors 56 (49–63) years) patients treated with TNF-α inhibitors for 3,140 person years. We identified 14 cases with PSR (71% female, median age (IQR) 45 (53–62)). There were 6 PSR cases on adalimumab, 4 on etanercept, 3 on certolizumab – pegol, and 1 on infliximab. 10 patients developed psoriatic/psoriasiform eruptions, 2 patient leucocytoclastic vasculitis, one had lichen planus, and one undifferentiated skin changes. The incidence rate of new psoriatic/psoriasiform eruptions, 2 patient leucocytoclastic vasculitis, one had lichen planus, and one undifferentiated skin changes. The incidence rate of new psoriasiorm PSR, which is in line with published data.

**AB0394 TAPERING TNF INHIBITORS IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE STUDY**

A. Hacigüllü, G. Hatemi, S.N. Esatoglu, Y. Ozgurlu, S. Ugurlu, E. Seyahi, M. Melikoglu, I. Fresko, H. Ozdogan, S. Yurdakul, Y. Hamuryudan. Division Rheumatology, İstanbul University Cerrahpasa Medical Faculty, İstanbul, Turkey

Background: Increasing evidence suggests the feasibility of biologic DMARD tapering in RA patients after achieving and maintaining good control of disease activity. Current guidelines on RA treatment also recommend tapering of biologic and non-biologic DMARDs for patients in remission. Data on biologic DMARD tapering reflecting real life settings are limited.

Objectives: To collect information on biologic DMARD tapering and its outcome in RA patients who are followed-up in a rheumatology outpatient clinic.

Methods: In this retrospective study we used the hospital administrative database to identify patients with a diagnosis of RA and a first time prescription of a biologic DMARD (TCZ was specifically limited to one of the 3 TNF inhibitors (etanercept, adalimumab, infliximab)) between January 2012 and the end of December 2013. Demographics and information regarding treatment and outcome were taken from the medical charts.

Results: Of the 125 patients identified at the database search, 104 were belonging to our clinic and had available follow-up data until June 2016. Seventy-nine of them were women and 25 were men. Their mean age was 47.7±13 SD years and their mean disease duration was 7.4±6.9 years. 60% were prescribed etanercept, 23% adalimumab, 17% infliximab. After a mean duration of 14.0±7.6 SD months a dose reduction of TNF inhibitors was made in 44 patients (42%). This was in the form of spacing in 39 patients (Etanercept +16, Infliximab +14, Adalimumab +9) and dose tapering in 5 (all Etanercept). All of these were due to good clinical response except for 1 patient’s own request for fear from adverse effects. Following dose reduction increased disease activity was seen in 16 patients (36%) mandating restoration to original dose within a mean of 8.8±9.7 SD months with good response. Twenty-eight patients (64%) preserved their good clinical response during a mean follow-up of 46.1±8.3 SD months which enabled further dose reductions in 20 patients. There was also reductions in the mean number of synthetic DMARD’s (1.4±0.8 SD at the initiation of TNF inhibitors and 0.7±0.8 SD at the end of follow-up) and in the percentage of patients using steroids (78% to 33%). At the end of the follow-up, among the whole group of 104 patients, only 73 (70%) were using biologics (TNF inhibitors +49, non-TNF biologics +24). The reasons for stopping biologics in the remaining 31 patients were ongoing remission (16 patients), pregnancy (1 patient), non-compliance (4 patients), injection site reactions (3 patients), fear from adverse events (1 patient).

Conclusion: Tapering of TNF inhibitors was possible in 40% of RA patients during their routine follow-up. Half of the patients maintained good clinical response after tapering allowing further dose reductions in one third.

**Rheumatoid arthritis - other biologic treatment**

**AB0395 SUBCUTANEOUS TOCILIZUMAB AS MONOTHERAPY OR IN COMBINATION WITH A CSDMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS: 24 WEEKS RESULTS OF THE FRENCH PHASE II STUDY, TOSCA**

Background: After the two global pivotal studies, which evaluated the safety and efficacy of subcutaneous tocilizumab (TCZ-SC) in combination (como) with conventional synthetic disease-modifying antirheumatic drugs (cDMARDs), it was important to understand the efficacy and safety profile of TCZ-SC both as monotherapy (mono) and in combo with csDMARDs in patients (pts) managed in conditions less strict than those of pivotal clinical trials.

Objectives: To evaluate the efficacy and safety of TCZ-SC 162 mg once weekly (qw) as mono and in combo with csDMARDs over 24 weeks in adult pts with moderate to severe RA. The primary efficacy criterion was the change in DAS28-ESR from baseline to week 24 (W24).

Methods: TOSCA is a national, multicenter, open-label phase IIb study, part of the international umbrella study (TOZURA). It aimed to enroll TCZ-naïve patients who were csDMARDs inadequate responders (IR) and/or biologic DMARD-IR. Pts received TCZ-SC 162 mg qw for 24 weeks, administered at the investigator’s discretion as mono or in combo with a csDMARD. Stable oral corticosteroids (CCS), ≤10 mg/day prednisone or equivalent (eq.pred), were allowed.
Results: The baseline characteristics of the 139 included patients were: mean age 57.3 years (±13.8), 74.1% female, mean RA disease duration 10.8 years (±9.2), immunonpositivity 85.5%, structural joint damage 65.6%, mean DAS28 5.8 (±1.1). 52.5% of patients were bDMARD-IR. TCZ-SC was initiated in mono TCZ in 30.9% of pts and in combo in 69.1% (79.1% MTX). Oral CCS were used by 50% of pts (mean 7.4 mg/d eq/pred.±2.7). In comparison with mono pts, the mono pts were older (58.7 vs 56.7 years), with a higher mean DAS28 (6.1 vs 5.7), a longer disease duration (11.5 vs 10.6 years), and a higher CCS mean dose (8.3 vs 6.9 mg/d eq/pred.). At W24, the mean DAS28 score variation vs baseline was -3.1 overall (p<0.0001); -3.0 in mono TCZ vs -3.1 in combo TCZ (p=0.07) (Fig.). The proportion of pts who achieved DAS28 remission was 51.1% (41.9% in mono vs 55.2% in combo (p=0.14)). CDAI remission, which does not include acute phase reactants, was achieved in 17% pts, 16% in mono vs 17% in combo (p=0.95). At W24, 27.9% of pts receiving >5 mg CCS at baseline decreased the daily dose of pred. (30.1% in mono TCZ and 26.7% in combo. Out of the 23 pts (16.5%) who withdrew, 13.0% did so for lack of efficacy and 52.1% for safety reasons; one death occurred following a septic shock after surgery for gastric volvulus, not related to TCZ. At W24 95.7% of pts had experienced at least one adverse event (AE) and 10.1% at least one serious AE with similar rates between groups.

Conclusions: TCZ-SC demonstrated at 6 months comparable efficacy, safety and steroid sparing results in mono- and combo therapy consistent with the known profile of TCZ-IV.

Conclusions: TCZ I.V. treatment over two years resulted in improvements of all disease activity parameters. Contrary to csDMARDs and TNF-blockers, the results show that smokers benefit from TCZ I.V. to the same extent as non-smokers and ex-smokers. The similar effectiveness of TCZ I.V. was confirmed by distinctly improved patient reported outcomes (PROs) in all subgroups. On the other hand, smoking seems to coincide with a higher rate of adverse events and an increased risk of infections. However, due to differences in baseline characteristics between the subgroups, this has to be interpreted with caution.

AB0397 ABATACEPT SHOWS BETTER SUSTAINABILITY THAN TNF INHIBITORS WHEN USED FOLLOWING INITIAL BIOLOGIC DMARD FAILURE IN THE TREATMENT OF RHEUMATOID ARTHRITIS: 8 YEARS OF REAL-WORLD OBSERVATIONS FROM THE RHUMADATA® CLINICAL DATABASE AND REGISTRY

D. Choquette 1, L. Bessette 2, E. Alemao 3, B. Harauoi 1, F. Massicotte 1, M. Mitibaa 4, E. Muratti 4, J.-P. Pelletier 1, R. Postema 5, J.-P. Raynauld 1, M.-A. Rémillard 1, D. Sauvageau 1, A. Turcotte 4, E. Villeneuve 4, L. Coupal 1, M.-A. Rémillard 1

1Rheumatology, Institut de recherche en rhumatologie de Montréal (IRRM), Montréal; 2Rheumatology, Centre d'ostéoporese et de rhumatologie de Québec (CORQ), Québec, Canada; 3Bristol-Myers Squibb, Princeton, United States; 4Bristol-Myers Squibb, Montréal, Canada; 5Bristol-Myers Squibb, Uxbridge, United Kingdom

Background: In the absence of biomarkers predicting response to a specific therapy, the choice of second biologic is based mostly on habit and availability of an alternative agent. Traditionally, a second anti-TNF was the preferred option, but recent registry data point to better responses and retention if a drug with a different mode of action is prescribed.

Objectives: Assess the long-term retention of abatacept (ABA) and TNFi following first biologic (b)DMARD inadequate response in RHUMADATA® registry patients (pts) with RA.

Methods: Data from RHUMADATA® pts with RA prescribed either ABA or TNFi as the second DMARD after 1 January 2006 were analysed. Pts were followed until treatment discontinuation or 9 January 2017 cut-off. Pt characteristics were compared using descriptive statistics, bDMARD discontinuation rates using Kaplan-Meier methods, and proportional hazard models were used to identify predictors of treatment discontinuation.

Results: Data for 92 and 194 pts prescribed ABA or a TNFi, respectively; as second-line treatment were examined. No clinically significant differences in baseline characteristics were noted between treatment groups. Most pts were women (76.2%), average age (SD) was 45.1 (13.3) years at diagnosis and disease duration 10.8 (9.0) years. Most pts were stopping an anti-TNF agent: 97% of those who were switched to ABA and 83% of those who were prescribed a second anti-TNF. Overall, 77.6% of pts stopped their first bDMARD after >6 months of treatment (secondary failure). Significant differences in retention between ABA and TNFi groups (log-rank p=0.0002) were observed (Figure). Results remained unchanged for pts treated with TNFi only in first line, and primary/secondary failure of the first bDMARD did not affect sustainability of the second agent. Lack of efficacy (57.7%) and AEs (16.5%) were the most commonly cited reasons for treatment discontinuation.

Conclusions: Abatacept has better sustainability over a second line TNFi in RA patients having failed one prior bDMARD.

AB0398 IMPACT OF BODY COMPOSITION ON RESPONSE TO BIOThERAPY IN RHEUMATOID ARTHRITIS

S. Bouden, D. Kaffel, W. Hamid 1, 2, M.M. Kchir. Rheumatology, Institut kassab, Tunis, Tunisia

Background: Biological therapies had greatly improved the treatment of rheumatoid arthritis (RA). The response to biologics may be influenced by many factors. Little is known about the impact of body composition in RA biologics.

Objectives: We aimed to investigate the impact of obesity (BMI≥30) and body composition (lean mass/fat mass) on response to biologics in RA.

Methods: A retrospective study was performed over a period of 11 years (2006–2016). Patients diagnosed RA (according to the ACR 1987 criteria) and treated by biologics were enrolled. Body composition (lean mass/ fat mass) was measured by X-ray biophotonic absorption (DXA). The threshold of significance was set for a value of p<0.05.

Results: Fifty patients were enrolled, including 5 men and 45 women (sex ratio=0.11). The mean age was 66 years [38–79]. The mean duration of RA was 5 years [1–30]. The mean duration of treatment with biologics was 38 months [6–120]. Thirty nine patients were treated by TNF inhibitors (25 etanercept, 7 adalimumab, 6 infliximab and 1 certolizumabpegol), 6 rituximab and 5 tocilizumab. Nine patients had a normal weight (18%), 17 had overweight (34%) and 24 had obesity (49%). The average percentage of fat mass was 44.8% (23–54), with a median of 46. While comparing obese patients with others, we did not notice a significant difference in the mean variation of the DAS28 at 6 months for TNF alpha inhibitors nor for all biotherapies combined (respectively p=0.6 and p=0.9). The same result was observed while comparing the DAS28 according to the body composition (relative to the median of the percentage of the fat mass: for TNF alpha inhibitors (p=0.6) and for all biotherapies combined (p=0.03)).

Conclusions: In our study, there was no change in response to biologics in patients with RA. Further prospective studies with a larger size will be required to confirm or reverse these results.

AB0399 RITUXIMAB TREATMENT AND IMMUNOGLOBULIN LEVELS MONITORING

G. Kasavkar, S. Kamath. Rheumatology, Haywood hospital, Stoke on Trent, United Kingdom

Background: Rheumatoid arthritis is a well-known inflammatory condition with a prevalence around 1% in females and 0.5% in males in UK (as per NOAR study). In the past decade use of biologic therapy has helped clinicians to treat rheumatoid arthritis more effectively. Rituximab is one of the biologics which is used commonly for treating rheumatoid arthritis. Rituximab is chimeric monoclonal antibody targeting CD20 molecule of B cells. First trial of rituximab in treating rheumatoid arthritis was published in 2004 and since then it has shown promising results in clinical trials and is now the standard of care for treating rheumatoid arthritis. Little is known about the impact of body composition in RA biologics.

Objectives: To assess whether patients receiving Rituximab are appropriately monitored with pretherapy evaluation of immunoglobulin levels
To assess the effects of rituximab on immunoglobulin levels and incidence of infection among patients on rituximab

**Methods:** Data was collected of all (N=105) patients who received Rituximab between May 2014 until April 2015 at the Haywood Hospital where patients attend for Rituximab injections. Data was collected retrospectively from the Diamond System, Medisec system and Clinical Information System and entered onto an excel spread sheet which included following details

- Start date of Rituximab
- IgG levels prior to Rituximab and current IgG levels
- Total doses of rituximab and frequency of IgG monitoring
- Intermittent infections and type of infections.

**Results:** We observed that 82 out of 105 patients were started on rituximab after February 2011 when the BSR guidance was published and 53 out of 105 patients had their immunoglobulin levels checked prior to commencing treatment. 35/76 (46%) patients had 1 or more episodes of infections whilst on Rituximab which required treatment. Of these, 16 (46%) had recurrent infections. 39 patients had dropped their IgG levels after starting rituximab 18 (46%) of these suffered from infections.

17 patients had a drop in IgG ≥20% and 6 of these (36%) had recurrent infections and 1 patient had 1 episode of infection. None of the patients had dropped their IgG levels below 5

**Conclusions:** A significant number of patients (35/76 ≥46%) had 1 or more episodes of infections despite IgG levels being above lower normal limit Among patients who dropped their IgG level, had increased number infections. Also they had more than 1 episodes of infection Patients who dropped IgG levels ≥20% suffered with recurrent infections

**AB0400 EFFICACY AND SAFETY OF INTRAVENTOUS AND SUBCUTANEOUS TOCILIZUMAB IN A COHORT OF PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS IN REAL-LIFE**

**Background:** Tocilizumab (TCZ) is a humanized monoclonal anti-interleukin-6 receptor antibody, used for the treatment of moderate to severe rheumatoid arthritis (RA). Although TCZ has been proved to be highly effective and safe in RA patients in large clinical trials, few data are available from real-life practice [1].

**Objectives:** To evaluate efficacy, safety and retention rate of intravenous (IV) and subcutaneous (SC) TCZ in a real-world setting.

**Methods:** We evaluated patients affected by moderate-to-severe RA and treated with IV-TCZ from April 2010 to January 2017. Data of patients treated with IV-TCZ and SC-TCZ from January 2015 were collected retrospectively, while patients treated with either IV-TCZ or SC-TCZ from April 2010 to January 2017. Data of patients treated with IV-TCZ was estimated by Kaplan-Meier method.

**Assessment and paired t test was used for statistical analysis. Treatment retention rate was estimated by Kaplan-Meier method.**

**Assessment:**

- DAS28-CRP, CDAI and SDAI scores were used for disease activity assessment.
- CD3+, CD4+, CD8+ T, CD19+ B, CD20+ B, CD45RA+ B cells, CD69+ T cells and IFN-γ and Th17/Th1 ratio were used to assess disease activity, treatment discontinuation and/or onset of adverse events (AEs).
- Baseline immunoglobulin IgG, IgM, IgA, IgE with baseline the therapy in two group, and clinical adverse events (CRP, ESR, FER, ALT/AST, WBC, Hb, Ht, platelet) were used to assess disease activity, treatment discontinuation and/or onset of adverse events.

**Results:**

- CRP, ESR, FER significantly reduced in IV-TCZ group (P<0.05) at 12 weeks.
- There was no significant difference in frequencies of other risk factors, signs of disease activity, treatment discontinuation and/or onset of adverse events (AEs).
- After 12 weeks, tocilizumab + DMARDs group, CRP, ESR, FER significantly decreased, the most frequently occurring adverse reaction was infection, mostly upper respiratory tract infection, followed by elevated transaminase, cholesterol, low-density lipoprotein High-density lipoprotein triglyceride levels increased; two groups no serious adverse events (three-line reduction, severe infections, etc.).
- The proportion of CD4+ T, CD19 B cells in Tocilizumab group were lower than baseline (P<0.05), CD8, CD3+ T cells were increasing in comparing with baseline, however, no significant change with CD16+ 56-NK cells (P<0.05), and immunoglobulins IgG, IgM, IgA lower than baseline (P<0.05).

**Conclusions:** Tocilizumab can significantly reduce inflammatory markers (CRP, ESR, FER), but affect lipid metabolism and ALT/AST.Blocking IL-6 can be adjusted hyperthyroidism humoral and regulate CD4+ T, CD19 B cells, reduce joint destruction. Tocilizumab can effectively control the development of DMARDs poor efficacy SJIA.

**AB0402 RITUXIMAB MAY DELAY THE MOVEMENT OF RHEUMATOID ARTHRITIS PATIENTS ON CARDIORENAL CONTINUUM: RESULTS FROM A PROSPECTIVE OBSERVATIONAL SINGLE-CENTRE COHORT STUDY**

J.R. Gaisin1, L.V. Ivanova2, A.A. Trukchina3, A.A. Tukmacheva4, Y.A. Volkova1, A.A. Tebenkova1, N.I. Maximov1,1, Izhevsk State Medical Academy;2 Clinical Diagnostic Centre of the Udmurt Republic, Izhevsk, Russian Federation

**Background:** Similarities in risk factors, initial stages, progression and final stage of both atherosclerotic cardiovascular disease (CVD) and chronic kidney disease (CKD) allowed formulating a concept of cardiological continuum.1,2 CVD and CKD remain the main causes of mortality in rheumatoid arthritis (RA) patients.

**Objectives:** We aimed to evaluate the effects of rituximab biologic therapy on cardiological continuum of RA patients.

**Methods:** Biologics-naïve RA patients (n=50; age 55.1±10.3) were followed up for 72 months after commencing and continuing rituximab therapy (1–10 standard courses) compared with 30 control RA patients (age 53.2±9.8) followed up for 12 months. Comparing immunoglobulin IgG, IgM, IgA and IgE between baseline and after 12 weeks treatment. Comparing immunoglobulin IgG, IgM, IgA with baseline the therapy in two group, and clinical severe infections, etc.).

**Results:**

- After 12 weeks, tocilizumab + DMARDs group, CRP, ESR, FER were significantly decreased, the most frequently occurring adverse reaction was infection, mostly upper respiratory tract infection, followed by elevated transaminase, cholesterol, low-density lipoprotein High-density lipoprotein triglyceride levels increased; two groups no serious adverse events (three-line reduction, severe infections, etc.).
- The proportion of CD4+ T, CD19 B cells in Tocilizumab group were lower than baseline (P<0.05), CD8, CD3+ T cells were increasing in comparing with baseline, however, no significant change with CD16+ 56-NK cells (P<0.05), and immunoglobulins IgG, IgM, IgA lower than baseline (P<0.05).

**Conclusions:** Tocilizumab can significantly reduce inflammatory markers (CRP, ESR, FER), but affect lipid metabolism and ALT/AST.Blocking IL-6 can be adjusted hyperthyroidism humoral and regulate CD4+ T, CD19 B cells, reduce joint destruction. **ADHERENCE AND ACCESS TO BIOLOGICAL THERAPY AND TOFACITINIB IN A COHORT OF COLOMBIAN PATIENTS WITH RHEUMATOLOGICAL DISEASES**

**Background:**
Biological disease-modifying antirheumatic drug (bDMARD) and tofacitinib are highly effective, but with different pharmaceutical forms, adverse reactions and cost that could affect adherence therapy and drug access.

**Objectives:**
To determine patient adherence and administrative access to the treatment with bDMARDs and tofacitinib in patients with rheumatological diseases in Colombia.

**Methods:**
A retrospective cohort study, which included all patients in management with bDMARD and tofacitinib initiated between July 1, 2015 and June 30, 2016. A monthly follow-up of the administrative adherence were evaluated by holding or applying the medication, as well as the application of Morisky-Green test. Adherence was better with self-administered oral and subcutaneous therapies (non-adherent patient was considered when at least one doses is lost), other variables such as sociodemographic, comorbidities, and co-prescriptions were evaluated. A descriptive analysis, $x^2$ for comparison and multivariate logistic regression were performed.

**Results:**
Among 1,020 patients were evaluated, with a mean age of 52.8±15.4 years and a female predominance (72.8%). The most frequent comorbidities were hypertension (22.6%) and dyslipidemia (15.9%). The most prescribed drugs studied were adalimumab (31.9%), etanercept (22.2%) and tofacitinib (12.5%). 52.8% use conventional DMARDs and 42.2% use glucocorticoids. Global adherence was 66.3% as measured by Morisky-Green test. Adherence to treatment with bDMARDs and tofacitinib was associated with a greater probability of presenting delays in access after adjustment of variables.

**Conclusions:**
Subcutaneous other applications of bDMARD have better adherence rates compared to oral drug. However, the limitations in access to treatment decreased the adherence. On the other hand, the impact of the adherence could be major in the case of self-administered DMARD when weekly or longer intervals doses are lost, compared with the loss of one daily dose of tofacitinib.

**SIMILAR REMISSION RATES AMONG RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ANTI TNF AND NON-ANTI TNF THERAPIES: REAL-LIFE DATA**

J.A. Gómez-Puerta 1,2, N. Duque 1, M. Saldarriga 1, L.A. González 1,2, C. Cerón 1, L. Uribe Botero 1, O.J. Felipe-Díaz 1, 1Medicarte IPS; 2Grupo de Reumatología, Universidad de Antioquia, Medellin, Colombia

**Background:**
Several biological DMARD (bDMARD) therapies have been approved for use in rheumatoid arthritis (RA) and are classified according to their respective therapeutic target: Anti TNF therapies and non-Anti TNF therapies. They are very effective in most of patients but their comparative efficacy in daily clinical is less well known.

**Objectives:**
Our aim was to compare the efficacy of anti-TNF therapies vs non-Anti TNF therapies in a cohort of Colombian RA patients followed in different arthritis clinics under daily clinical practice conditions.

**Methods:**
We conducted a cross-sectional study including with RA patients treated at Medicarte IPS from March 2009 to December 2016. Medicarte is a referral center for the integral medical care and pharmaco-surveillance of patients under biologic therapies in 13 cities in Colombia for inflammatory arthropathies, mainly RA, psoriatic arthritis and spondyloarthropathies. Clinical information was obtained from electronic clinical records and medical claims. Only those patients with disease activity scores (DAS-28) at baseline and at the last visit were included. Remission was defined as DAS-28 <2.6 on the last visit. Patients treated only with conventional DMARD and/or tofacitinib were excluded.

**Results:**
A total of 1,020 patients with RA were identified. 844 patients (88% female) were included in the final analysis, 416 patients with anti TNF and 428 with non-anti TNF therapies (Rituximab 199, Tocilizumab 125 and Abatacept in 104 patients). The mean age was 55.2±11.8 years, with a mean disease duration of 10.4±9.5 years. The percentage of patients with DAS-28 <2.6 was 61% in the anti TNF group and 51% in the non-anti TNF group.

**Conclusions:**
Subcutaneous other applications of bDMARD have better adherence rates compared to oral drug. However, the limitations in access to treatment decreased the adherence. The other hand, the impact of the adherence could be major in the case of self-administered DMARD when weekly or longer intervals doses are lost, compared with the loss of one daily dose of tofacitinib.
of 15.2±9.5 years. bDMARD therapy was used for a mean time period of 3.2±2.5 years. Eighty three percent of patients were treated in combination therapy and 80% of patients were seropositive (CCP and/or RF). Both groups did not differ significantly on baseline clinical characteristics (see Table), with 2 exceptions: patients who received Anti-TNF therapies were treated more frequently as first line therapy (79.2% vs 53.2%, p=0.001) and received in a higher proportion combined therapy (90.9% vs 75.0%, p<0.001). A total of 59% of patient achieved remission at the last visit. Three year remission rates were slightly higher but not significant in patients treated with non-anti TNF therapies vs anti-TNF therapies (59.6% vs 53.3%, p=NS). We did not find significant differences in remission rates according serological status.

Conclusions: In real-life setting, a meaningful proportion of RA patients achieved remission on the last visit. Patients treated with anti-TNF and non-anti TNF therapies had similar baseline characteristics and after a mean time period of treatment of 3 years, achieved similar remission rates.

SAFETY OF RITUXIMAB THERAPY IN AUTOIMMUNE DISEASES:SYSTEMATIC REVIEW AND META-ANALYSIS

K. Kobayashi1, K.M. Minigishi1, N. Horita1, S. Ohno1, H.N. Nakajima3, Center for Rheumatic Diseases, Yokohama City University Medical Center; 2Department of Pulmonology; 3Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan

Background: Treatment with rituximab (RTX), a chimeric CD20 monoclonal antibody, has demonstrated efficacy for patients with several autoimmune diseases. There is a growing concern, however, safety evidence of RTX is still lacking.

Objectives: We conducted to evaluate the safety of rituximab (RTX) for autoimmune diseases.

Methods: A literature review was performed based on the randomized clinical trials (RCTs) that assessed adverse events by comparing RTX and placebo or no treatment for autoimmune diseases. The same add-on treatment for both arms were allowed. Study selection and data extraction were independently conducted in duplicate. Meta-analyses were performed for each outcome separately using fixed model and generic inverse variance method.

Results: In the primary analysis, 16 eligible RCTs, with a total of 4147 patients for five autoimmune diseases (n=8: rheumatoid arthritis, n=3: Sjogren syndrome, n=1: systemic lupus erythematosus, multiple sclerosis, ulcerative colitis, Graves orbitopathy, immune thrombocytopenia) were analyzed. The incidence of infection related reactions and the human antichimeric antibody (HACA) were higher in RTX group than placebo/no treatment group (OR 1.49, 95% CI 1.25–1.77 and OR 2.25, 95% CI 1.35–3.76, respectively). However, there were no significant differences the odds of total adverse events, serious adverse events, withdrawal for adverse events, infections, serious infections, malignancy, and all-cause death between two groups.

Conclusions: Our meta-analysis revealed that RTX was not associated with an increased risk of adverse events except for infusion related reactions and the incidence of HACA compared with placebo.

AB0406

STABLE EFFICACY AND SAFETY AFTER SWITCHING FROM TOCILIZUMAB INTRAVENOUS TO SUBCUTANEOUS IN RHEUMATOID ARTHRITIS: RESULTS OF A COHORT OF 200 PATIENTS

1Rheumatology, University Hospital, Orleans; 2Rheumatology, General Hospital, Orleans; 3Rheumatology, University Hospital, Tours; 4Rheumatology, University Hospital, Brest; 5Rheumatology, University Hospital, Reims; 6Rheumatology, University Hospital, Angers; 1LITEC, Immunology Laboratory, Poitiers, France

Background: Intravenous tocilizumab has been used since 2009 in Europe for the treatment of active rheumatoid arthritis. Since 2015, a subcutaneous formulation is available. The switch from a monthly, intravenous, with dose adjusted for bodyweight treatment to a weekly, subcutaneous, fixed dose, leads to various questions about efficacy and toxicity.

Objectives: The objectives were to evaluate the efficacy maintenance (mainte-
nance rate and DAS28 variation), the safety, the dose variation after the switch and the characteristics of patients switching to the subcutaneous form respect to those following with the intravenous tocilizumab.

Methods: A retrospective study was performed from a cohort of 203 patients undergoing intravenous tocilizumab from the rheumatology unit of 7 university hospitals between September 2015 and May 2016. Assessment has been done on the records, effectiveness was assessed using the DAS28, adverse events and reasons for staying on IV form were reported.

Results: On the 203 records analyzed, 3 were secondarily excluded. Of the 200 patients, 77 have switched for the subcutaneous form. Mean age of the 200 patients was 58 years (+/- 13.3) with 155 women (78%) and the mean duration of rheumatoid arthritis was 14 years (+/- 10.4), 72% of patients received a standard intravenous dose (8mg/kg/month) at baseline.

At the first visit after the prescription of the subcutaneous treatment, 58 patients on 65 (99%) maintained the treatment. The mean DAS28 was 1.53 (+/-1.00) at baseline and 1.19 (+/-0.78) at T1 (45 patients). Three patients received a reduced subcutaneous dose of 162mg/2 weeks following a reduced IV dose (<8 mg/kg/month) and maintained the subcutaneous treatment.

About safety, there was on new case of neutropenia.<1000/mm³. One severe adverse effect occurred (gastrointestinal perforation).

Regard to the dose variation, for the 77 patients switching, the mean difference between intravenous and subcutaneous dose was + 29mg/week (+/35mg) with the same previous tocilizumab dose.

Reasons for staying on IV form were essentially: the subcutaneous tocilizumab was not proposed in 55% of the cases and 17% of patients refused the subcutaneous form.

Conclusions: 89% of patients maintained the subcutaneous treatment after 4 months; efficacy was maintained in patients who received a reduced subcutaneous dose. Despite the higher dose after the switch (>28mg/week), there was no new case of neutropenia.

COMPARATIVE EFFECTIVENESS OF TOCILIZUMAB (TCZ) MONOTHERAPY WITH TUMOR NECROSIS FACTOR INHIBITORS (TNFI) IN COMBINATION WITH VARYING DOSES OF METHOTREXATE (MTX) IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. R. Harold1,2, G.W. Reed1,2, J. Best3, S. Zlotnick3, G. Persuitte2, J.M. Kremer2,4.
1Corrona, LLC, Southborough; 2Genentech, Inc, South San Francisco; 4Albany Medical College and The Center for Rheumatology, Albany, United States

Background: Clinical studies have shown that the efficacy of TCZ monotherapy and TCZ in combination with MTX is superior to that of TNFi monotherapy and comparable to that of TCZ in combination with MTX.

Objectives: To compare the effectiveness of TCZ mono vs TNFi plus varying doses of MTX in patients with rheumatoid arthritids (RA) and prior exposure to TNFi in routine clinical practice.

Methods: Eligible participants were TCZ-naïve patients from the Corrona RA registry who had prior exposure to ≥1 TNFi, initiated TCZ mono or a TNFi + MTX between 2010 and 2016 and had a 6-month follow-up visit. The primary outcome was mean change from baseline in Clinical Disease Activity Index (CDAI) at 6 months. Secondary outcomes included achievement of low disease activity (LDA; CDAI ≤ 10) at 6 months. Patients initiating a TNFi + MTX were grouped by MTX dose (<10 mg; >10 to <15 mg; ≥15 to <20 mg; >20 mg); outcomes in each group were compared with those initiating TCZ mono using trimmed populations, excluding patients outside the propensity score (PS) distribution overlap (not on common support). The PS included age, gender, body mass index, smoking status, American College of Rheumatology functional class and baseline modified Health Assessment Questionnaire, CDAI and patient pain scores. As a sensitivity analysis, propensity-matched populations were created (stratified by 1 vs >2 prior biologics, then matched on PS). Linear and logistic regression models were estimated in the trimmed populations, adjusting for the same covariates as in the PS.

Results: Baseline demographics were generally comparable between the TNFi + MTX groups and their matched TCZ mono groups. Overall, the mean age was 54 to 59 years, and the mean disease duration was 10.5 to 15 years. A higher proportion of patients initiating TCZ mono had received ≥3 prior biologics compared with those initiating TNFi + MTX. Patients initiating TCZ mono had significantly longer mean disease duration than those initiating TNFi + MTX ≥15 to <20 mg, ≥20 mg or TNFi + MTX > 20 mg (12.3 vs 9.3 years) and a higher mean baseline CDAI than those initiating TNFi + MTX <10 mg (28.1 vs 25.4). Patients in all groups had improvement in CDAI scores at 6 months. In adjusted models, improvement in CDAI and the likelihood of achieving LDA were similar between the TCZ mono group and all TNFi + MTX groups (Table). Similar results were observed in the PS-matched cohorts.

Conclusions: TCZ mono was as effective as TNFi + MTX, regardless of MTX dose, for improving disease activity in patients with prior TNFi exposure. These data suggest that TCZ mono is an effective treatment option for patients with RA who cannot tolerate or prefer not to use MTX.

Results: The 330 pairs of propensity score-matched ABA and TNFi initiators had no substantial differences in baseline characteristics. Both treatment groups had similar mean change in CDAI at 6 months as well as achievement of LDA, remission and aMCR20/50/70 responses (Table). Among the 97 matched biologic-naïve pairs, there was no significant difference in change in CDAI for ABA initiators vs TNFi initiators (p=0.19). However, in the 233 matched biologic-experienced pairs, those initiating ABA had a greater improvement in mean change in CDAI (p=0.033) and were more likely to achieve an aMCR50 response (p=0.014).

Conclusions: Pts with RA who were CCP+ and received either ABA or TNFi had a substantial improvement in clinical disease activity. In the overall propensity score-matched sample, similar outcomes were observed for both treatment groups. However, analysis of the biologic-experienced cohort found that ABA initiators had a greater improvement in disease activity than TNFi initiators.

Comparative Effectiveness of Abatacept Versus TNFi in Patients with Rheumatoid Arthritis Who are CCP+ in the United States Corrona Registry

To compare the effectiveness of ABA vs a TNF inhibitor (TNFi) in pts with RA who are CCP+.

Methods: We included adult pts with RA from a large observational US cohort (1 Dec 2005–31 Aug 2016) who initiated ABA or a TNFi and who were CCP+ (≥20 U/mL) at or prior to initiation. Both groups had to have no prior exposure to other non-TNF biologics or targeted synthetic DMARDs. TNFi initiators were excluded if they had prior use of ABA. Using propensity score matching (1:1) stratified by prior TNFi use (0, 1 and 2+), effectiveness at 6 months after initiation was evaluated. Mean change in CDAI over 6 months following initiation was the primary outcome, with secondary outcomes being: achievement of remission (CDAI < 10), mACR20/50/70 responses and achievement of LDA/remission (CDAI < 10) in pts with moderate/high disease activity at initiation. A subset analysis was performed to consider separately pts who were biologic naïve and those who were biologic experienced at initiation.

Conclusions: Pts with RA who were CCP+ and received either ABA or TNFi had a substantial improvement in clinical disease activity. In the overall propensity score-matched sample, similar outcomes were observed for both treatment groups. However, analysis of the biologic-experienced cohort found that ABA initiators had a greater improvement in disease activity than TNFi initiators.

Corticosteroid-Sparing in Patients with Rheumatoid Arthritis on Tocilizumab: First Experience of BAB-EL-OUED HOSPITAL

Background: Tocilizumab (TCZ) is a monoclonal antibody directed against the IL-6 receptors. This treatment (TRT) allows for the cortisone weaning in preventing of its complications.

Objectives: The goal of this study is to evaluate the corticosteroid sparing in patients with RA treated with TCZ.

Methods: Prospective, descriptive study of patients hospitalized between 2012 and 2016, the diagnosis was made according to the ACR 1987 ACR/EULAR 2010 criteria. Included, are the patients treated with TCZ for at least 3 months associated with corticosteroids.

We have studied the following: the epidemiology, the associated DMARDs, the average DAS28VS, the average dosage of prednisone-equivalent and the percentage of patients with decreased or interrupted corticosteroids at M0, M3, M6 and M12.

Results: 28 patients (sex ratio: 0.7) treated with TCZ and corticosteroids, average age is 43.4 years (range 30–62). Average duration of the development of RA: 9.1±6.4 years. DMARDs was associated in 15 patient. At baseline. 46.2% of patients were on 10 mg/day of cortisone, the average dose of prednisone-equivalent was that 7.7±3.6 mg at M0, 5.3±3.2 mg at M3, 4.6±2.3 mg at M6, 2.6±2.6 mg at M12 with a statistically significant difference (p=0.000003). The average DAS28VS index was 5.6±0.9 at M0, 3.5±1.3 at M3, 3.0±1.2 at M6 and 2.6 ± M6 at M12 with a statistically significant difference (p=0.000001). Corticosteroid treatment was stopped in 12 patients after 1 year of treatment.

Conclusions: Through this study we note that the TRT using TCZ has enabled a significant reduction in the dose of corticosteroids. Stopping prednisone was possible in 50% of patients after 1 year of biotherapy.

THE INTERPLAY BETWEEN C3 AND C4 AND DISEASE ACTIVITY IN PATIENTS AFFECTED BY RHEUMATOID ARTHRITIS DURING TREATMENT WITH ANTI-IL6 RECEPTOR

P. Conigliaro1, P. Triggiani3, M.S. Chipeni1, I. Duca2, B. Kroegler1, R. Perricione1, 1Rheumatology, Allergology and Clinical Immunology, University of Rome Tor Vergata; 2Dipartimento di Medicina Interna e Specialità Mediche, Reumatologia, Sapienza Università di Roma, Rome, Italy

Background: The complement system (CS) is involved in the pathogenesis of rheumatoid arthritis (RA). Evidence reported that high C3 levels C4 in RA patients might reflect a pro-inflammatory status and represent a negative prognostic factor for TNF-inhibitors therapy.

Objectives: We evaluated CS in a cohort of RA patients treated with tocilizumab (TCZ) to explore whether there was any correlation between CS and both disease activity and response to therapy.

Methods: Consecutive outpatients affected by RA who started TCZ treatment i.v. at the Rheumatology Unit of "Policlinico Tor Vergata" in Rome (Italy) were enrolled (n=25) (Table I). We included 25 healthy subjects as controls. Disease activity was assessed by using DAS28 ESR-based while clinical response to therapy by EULAR response criteria. Peripheral blood samples were obtained from all patients at the time of each infusion. Laboratory assessment included ESR, CRP, RF, ACPA, C3, C4, CH50 assay. Clinical and laboratory data were registered at baseline (T0), after 1 (T1), 3 (T3), 6 (T6), 9 (T9), and 12 (T12) months from the beginning of the TCZ treatment.

Results: At baseline, both C3 and C4 were significantly higher in RA than in controls (Table I).

No difference in C3 and C4 resulted between ACPA positive and ACPA negative patients during the follow up. ESR, CRP and DAS28 levels were significantly reduced at T1, T3, T6, T9, and T12 with the respect to T0 (Figure 1-A-C). C3 levels were significantly reduced at T3, T6, T9 and T12 with the respect to T0 while C4 levels were significantly reduced at T3, T6, T9 and T12 with the respect to T0 (Figure 1D-E). The positive correlations resulted between DAS28 and both C3 and C4 at T1 and T3 (Figure 1F-I). C3 and C4 were directly related with ESR at T1 (C3: P < 0.002; C4: P < 0.005), T3 (C3: P < 0.04; C4: P < 0.03), and T6 (C3: P < 0.002; C4: P < 0.002) and with CRP at T1 (C3: P < 0.03; C4: P < 0.01) and T6 (C2: P < 0.001; C4: P < 0.03). When stratifying patients in accordance with the EULAR response to therapy, C3 decreased significantly with no-responders than in no-responders at T1; moreover, responders showed lower levels of both C3 and C4 at T1 and T3 with the respect to T0 (Figure 1L-O).

Conclusions: In RA patients, treatment with TCZ is able to reduce C3 and C4 levels in an early and sustained way. The disease activity is directly related with the reduction of C3 and C4 serum levels. RA patients with a good/moderate clinical response show significantly lower C3 and C4 levels than no-responders patients. Our preliminary data suggest that C3 and C4 can be a reliable marker of both the disease activity and the response to therapy in RA patients treated with TCZ.

COMPARISON OF TUBERCULIN SKIN TEST AND INTERFERON-GAMMA RELEASE ASSAY SCREENING IN PATIENTS WITH RHEUMATOID ARTHRITIS STARTING ANTI-TUMOR NECROSIS FACTOR FACTOR THERAPY

D.T. Archimandriti1, C. Ilou2, A.T. Tzallas2, E. Pelechas1, A.A. Drosos1, P.V. Voulgar1, 1Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina; 2Department of Computer Engineering, Technological Educational Institute of Epirus, Greece, School of Applied Technology, Ioannina, Greece

Background: Biologic agents provide clinical benefits in patients with Rheumatoid Arthritis (RA) but they are associated with an increased risk of tuberculosis (TB) infection.

Objectives: We investigated the accordance between the tuberculin skin test (TST) and the interferon-gamma (IFN-γ) release assay (IGRA) for the diagnosis of latent tuberculosis infection (LTBI) in patients with RA. The objective of our study was a direct comparison between the IGRAs and the TST regarding LTBI diagnosis in RA patients before starting anti-TNF agents and at least one year after the initiation of treatment.

Methods: Consecutive patients have been included in the study both before and after 1 year of the initiation of TNF-α antagonist therapy. A standard questionnaire was completed for each patient, including basic demographic data and concurrent immunosuppressive therapy (corticosteroids, disease-modifying anti-rheumatic drugs [DMARDs], synthetic and biologicals). The patients were screened for LTBI using IGRA and TST methods.

All analyses were performed with IBM-SPSS Statistics for Windows (version 21). The kappa coefficient (κ) was calculated to determine the concordance between the two tests: TST and IGRA. The strength of the agreement was considered "poor" for κ ≤ 0.20, "low-moderate" for 0.20 < κ < 0.40, moderate for 0.40 < κ < 0.60, "substantial" for 0.60 < κ < 0.80, and "optimal" for 0.80 < κ ≤ 1.

Results: 78 patients (67 female, 11 male) have been screened with TST and IGRA. The accordance between TST and IGRA was 98.7% (κ = 0.514, p = 0.001). A κ value of 0.514 represents a moderate accordance between the two tests. 6 female patients converted TST (4 became positive, and 2 became negative). No patient developed active tuberculosis.

Conclusions: A moderate accordance between the two methods (TST and IGRA) was obtained. In the absence of a diagnostic gold standard for LTBI, different issues should be taken into consideration regarding the two methods (cost, laboratory expertise and equipment etc). More studies are needed in the field in order to elucidate the cost-effectiveness but also the appropriateness of both methods.

LESS THAN 5% OF REAL-LIFE PATIENTS WHO SWITCH FROM IV TO SC ABATACEPT IN REAL-WORLD CLINICAL PRACTICE SIMULTANEOUSLY SUBSITUTE BACK TO THE IV FORMULATION

R. Alten1, H.-M. Lorenz2, X. Mariette3, H. Nüußlein4, M. Galeazzi5, F. Navarro6, M. Chartier7, J. Heitzmann8, C. Rauch9, M. Le Bars10, 1Schlosspark-Klinik University Medicine, Berlin, Germany; 2University Hospital, Heidelberg, Germany; 3Université Paris-Sud, Paris, France; 4University of Erlangen-Nuremberg, Nuremberg, Germany; 5University of Siena, Siena, Italy; 6Hospital Universitario Virgen Macarena, Sevilla, Spain; 7Bristol-Myers Squibb, Rueil-Malmaison; 8Excelya, Boulogne-Billancourt, France; 9Bristol-Myers Squibb, Munich, Germany

Background: Patients (pts) with RA may be able to switch from IV to SC abatacept without no loss of efficacy or safety concerns, but data are inconclusive.1, 4 In the ACTION [AbataceptIn Rheumatoid Arthritis clinical practice; NCT02109666] study, a 1-year interim analysis showed that switching had no adverse clinical effect.3

Objectives: To examine treatment patterns and explore abatacept formulation switching over 2 years in ACTION.

Methods: ACTION is a 2-year, prospective, observational study of pts with moderate-to-severe RA who initiated IV abatacept in Europe and Canada between May 2008 and December 2013. Assessments in biologic-naïve and biologic-failure pts were: baseline characteristics, rates of and reasons for switching (IV to SC), and re-switching to IV over 2 years. Descriptive data were generated: mean (SD) for continuous variables and n (%) for categorical variables. Rates of switching were estimated by Kaplan–Meier analysis. Cohorts were pooled to analyse further pts who switched owing to low numbers.

Results: In the ACTION cohort, 2350/2364 pts (99.4%) were evaluable for this analysis. 673 (28.6%) biologic naïve, 1677 [71.4%] biologic failure. A total of 729
(43.4%) biologic-failure pts had received 1, and 948 (56.6%) had received ≥ 2 previous biologics. Baseline characteristics in biologic-naïve and biologic-failure pts, respectively, were: mean (SD) age 59.9 (12.7) and 56.9 (12.5) years; RA duration 7.2 (8.22) and 12.1 (9.13 years); 496 (73.7%) and 1379 (82.2%) were women; 621 (92.3%) and 1592 (92.5%) had received prior MTX; and 533 (72.9%) and 1386 (82.6%) had received corticosteroids. Over 2 years, 195 pts switched from IV to SC abatacept (57 biologic naïve, 138 biologic failure; Fig.). Reasons for switching were available for 172 pts (51 biologic naïve, 121 biologic failure; some had > 1 reason): biologic naïve/biologic failure: pt wish 54.9%/82.0%, physician choice 31.4%/19.8%, safety 5.9%/9.9%, remission/major improvement 3.9%/5.0%, poor compliance 0%/4.1%, lack of efficacy 2.0%/3.3%, surgery 2.0%/0.8%, weight adjustment 2.0%/0.0%, other 49.0%/36.4%. Only eight pts (2.6%) re-switched to IV abatacept (2 biologic naïve, 6 biologic failure). Reasons for re-switching were: pt wish (n=4), lack of efficacy (n=4), safety issue (n=1) and other (n=2).

Figure. Patients Who Switched From IV to SC Abatacept Over 2 Years (Kaplan-Meier Analysis)

Conclusions: Less than 5% of pts who switched formulation from IV to SC abatacept in real-world clinical practice re-switched to the IV formulation, suggesting that switching has no clinical adverse impact. A change in formulation was mainly due to pt wish, reflecting their involvement in decision-making.

AB0413

INDUCTION AND PROGRESSION OF SUBCUTANEOUS NODULOSIS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOCILIZUMAB

R. Talotta, A. Batticciotto, M.C. Ditto, M.C. Gerardi, D. Ventura, P. Sarzi Puttini. Rheumatology Unit, University Hospital “Luigi Sacco”, Milan, Italy

Background: Tocilizumab (TCZ) is a monoclonal antibody (moAb) directed against the IL-6 receptor approved for moderate-to severe rheumatoid arthritis (RA) treatment. Some authors have reported a beneficial effect of TCZ in preventing lung and subcutaneous nodulosis in RA patients. On the contrary, to our knowledge no data concerning the acceleration of subcutaneous nodulosis that considerably worsened during the treatment with tocilizumab. Patients experimented the development of new subcutaneous nodules localized at the fingers, elbows or the inframammary fold, tending to ulceration. The management of this medical event included the tapering of MTX, the administration of steroids, the addition of HCQ, the use of antibiotics and surgery. However, neither pharmacological nor surgical treatment was completely effective, as nodules tended to recur and to increase in number and dimensions.

Results: To our knowledge this is the first report describing an accelerated subcutaneous nodulosis in a small cohort of RA patients treated with tocilizumab.

AB0414

THE USE OF RITUXIMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: IN WHICH INFUSION INTERVALS WERE GIVEN AND HOW DID THEY RESPOND? HUR-BIO REAL LIFE RESULTS

Background: Rituximab is one of the treatment options in rheumatoid arthritis (RA) patients and officially recommended as a maintenance treatment given every 6 months after the initial loading of first course.

Objectives: In this real life study, it was aimed to investigate the infusion frequency of rituximab maintenance treatment and possible effects on disease activity.

Methods: The HUR-BIO is a single-center biologic registry of Hacettepe University which is established in Ankara and in which patients have been prospectively recorded since 2012. This database has 1235 RA patient records as of August 2016. Rituximab was prescribed at least once in 273 (22.1%) patients. The residence address of 85 those patients was within the boundaries of center city (Ankara) and they were included in to the study. In our clinic, the dates and the DAS-28 scores at the time of rituximab courses were recorded. Rituximab infusion compliance was classified as: “regular” if there is less than one month delay, “slightly irregular” if less than 3 months delay and “irregular” if more than 3 months delay.

Results: The mean age of the 85 patients (80% female) was 59.1 (10.1), the mean disease duration was 12.9 (8.6) years and 74.1% of patients were seropositive. 39/85 (46%) patients previously used at least one biological agent (46 (54%) patients were biologic naïve before Rituximab therapy). Median rituximab course number was 3 (1–8). A total of 211 rituximab courses were given to 85 patients. Rituximab course number and percentage is shown in figure. The mean interval time between rituximab courses was 7.9 (2.8) months. Total of 102 (52.6%)
courses were admitted at normal times regularly, 60 (30.9%) were slightly irregular and 32 (16.5%) were irregular. There was no significant difference between the mean DAS-28 responses in the time of the courses and the rituximab infusion compliances [in regular group mean DAS-28 was 3.31 (1,19), in slightly irregular group mean DAS-28 was 3.26 (1.35) and irregular group mean DAS-28 was 3.57 (1.34), p = 0.05]. Before rituximab courses, 33.7% of patients had remission, 19.1% had low disease activity, 36.3% had moderate disease activity and 10.9% had high disease activity.

Conclusions: Rituximab administration was approximately 2 months delayed in RA patients who were living in center-city boundaries. The pre-treatment mean disease activity scores were similar, even if there was a delay in rituximab administration. In our center, about 85% of patients were taking RTX courses regular and/or slightly irregular and about half of the patients before treatment were in remission and/or low disease activity.

AB0415 TENDENCY TO CHOOSE FIRST BIOLOGIC AGENT THERAPY OF RHEUMATOID ARTHRITIS IN THE ELDERLY: RESULTS FROM JAPANESE MULTICENTER REGISTRY

T. Watanabe, T. Kojima, N. Takahashi, S. Asai, N. Asai, T. Matsumoto, Y. Sobe, N. Ishiguro. Orthopaedic Surgery and Rheumatology, Nagoya University Graduate School of Medicine Department of Orthopaedic Surgery; Nagoya, Japan

Background: Of the treatment of rheumatoid arthritis (RA), biologic agent therapies are chosen, if disease activity remains moderate or high despite csDMARDs therapy. In the elderly, with comorbidity and their less spare ability, safety is often concerned in the choice of biologic agent.

Objectives: We investigated the tendency to choose biologic agent and drug continuation rates in elderly in last decade.

Methods: Records of relevant patients with RA were collected from the Tsurumai Biologic Communication Registry, wherein the department of Nagoya University and 20 affiliated hospitals in Japan are enrolled. A total of 873 biologics-naïve and age 65 and older patients were recruited from January 2004 to December 2014. We studied the choice of the biologic agent year by year, and baseline disease activity and concomitant methotrexate (MTX) among TNF inhibitors, tocilizumab (TCZ) and abatacept (ABT) groups. Drug continuation rates were compared among TNF inhibitors, TCZ, and ABT groups.

Results: From 2005 to 2010, etanercept (ETN) was used the most (2007, 73.5%, 2009; 65.9%). After the advent of ABT, ABT was used the most (2011; 44.3%, 2014; 38.8%). Baseline disease activity slightly decreased as a whole (DAS28-CRP: 4.88 to 4.44). Despite baseline disease activity of TNF inhibitors group decreased (DAS28-CRP: 4.88 to 4.37), that of TCZ group increased (DAS28-CRP: 4.94 to 6.24).

In 2011–2014, baseline disease activity of TCZ group (5.85) was higher than that of TNF inhibitors group (5.11) (p<0.05). Concomitant MTX rate and dose were lower in ABT group (40.2%, 7.6mg) than that of TNF inhibitors group (79.0%, 8.8mg). 2 years drug continuation rate due to all unfavorable causes; ABT group was 82.4%, better than that of TNF inhibitors 77.1% and TCZ 69.2% (p<0.05). 2 years drug continuation rate due to adverse events; TCZ group was 80.8%, lower than that of TNF inhibitors 94.6% and ABT 96.2% (p<0.05).

Conclusions: ETN was used most before the advent of ABT. After the advent of ABT, ABT was used most and ETN decreased. This selection was made for speculation that ABT is lower risk than other biological agents. Baseline disease activity slightly decreased showing that tight control management became also popular among elderly. In 2011–2014, concomitant MTX rate and dose were lower in ABT group, but 2 years drug continuation rate was the highest.

AB0416 WHICH FACTORS PREDICT THE RESPONSIVENESS TO TOCILIZUMAB IN RHEUMATOID ARTHRITIS? THE DIFFERENCE BETWEEN THE USAGE AS THE FIRST BIOLOGIC AND AS THE SECOND BIOLOGIC

Y. Kunishita, R. Yoshimi, H. Naga, N. Hamada, Y. Soejima, Y. Sugiyama, N. Tsuchida, H. Nakano, D. Kishimoto, R. Kamiyama, Y. Asami, Y. Kinoda, H. Nakajima, Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan

Background: Although recent development of a variety of biologics has dramatically improved treatment for rheumatoid arthritis (RA), it is still unclear which biologics is better for use in each patient. Some previous studies have shown the predictive factors for good response (GR) to tocilizumab (TCZ), including low HAQ, high DAS28, low levels of serum soluble IL-6 receptor5), and low numbers of previous use of other biologics5). However, the consensus is not immediately available.

Objectives: To compare continuation rates (CR) of TCZ by the responsiveness to the therapy and to identify predictive factors for GR to TCZ in RA.

Methods: Patient with RA who newly started receiving TCZ after April 2008 in our hospital, were included in the study. We collected patient records, medication histories, laboratory data, and clinical parameters longitudinally after starting TCZ. Statistical analyses were performed using the chi-square test, binomial logistic regression analysis, Kaplan-Meier method, and the log-rank test.

Results: Ninety-two patients were included in the study. The mean age and disease duration at baseline were 60.0±13.5 years and 8.7±8.0 years, respectively. The seroprevalence of the anti-cyclic citrullinated peptide antibody and the rheumatoid factor were 95.4% and 95.7%, respectively. The rate of metotrexate and prednisolone at baseline were 45.7% and 64.1%, respectively. TCZ was administered as the first biologic in 42 patients, and as the second biologic in 33. DAS28 (ESR) and CDAI revealed high disease activity at baseline (5.2±1.5 and 25.4±14.1, respectively). The mean CR of all patients was 42.1±4.0 months. The CR was significantly higher in patients who achieved GR in EULAR response criteria at 6 months after starting TCZ than those who did not achieve GR (54.0±6.0 months vs 29.0±5.3 months, p<0.004). Multivariate statistical analysis revealed two predictive factors for achieving GR at 6 months after starting TCZ, the low number of previous use of other biologics and the low CDAI at baseline (p<0.018, odds ratio (OR) =0.386, and p=0.011, OR=0.944, respectively). We divided the patients into two groups, patients using TCZ as the first biologic and patients using it as the second biologic. Univariate statistical analyses revealed low usage rate and dose of prednisolone (PSL) and low serum creatinine level at baseline as the predictive factors for achieving GR in patients using TCZ as the first biologic, and low DAS28 (ESR), CDAI and HAQ-DI in the patients using TCZ as the second biologic. By multivariate statistical analysis, we identified the low CDAI as a predictive factor in the patients using TCZ as the second biologic.

Conclusions: RA patients who achieved GR at 6 months after starting TCZ showed higher CR than the others. This study also suggests that low number of biologics usage and low CDAI at baseline are the predictive factors for GR. The history of biologics usage may be important to identify the predictive factors for GR to TCZ.

Rheumatoid arthritis - non biologic treatment

AB0417 Efficacy and Safety of Methotrexate and Leflunomide as a combination therapy in Rheumatoid Arthritis Patients with High Disease Activity: Presenting at a tertiary care setting in Pakistan

B. Saimi, S. Samreen, A. Nasim, H. Gul, A. Masood, Rheumatology, Rawalpindi, Pakistan

Background: In the management of rheumatoid arthritis (RA), the goal is remission. However, it is not easy to attain this goal in all patients. It's not only the high disease activity, but rather other factors like availability and cost of biologics in developing countries. Therefore various combination therapies of conventional DMARDs are in vogue in such scenarios. Methotrexate (MTX) and Leflunomide (LEF) in combination is an effective option which can be fairly utilized in resource constraint settings to induce remission.

Objectives: To study the efficacy and safety profile of MTX+LEF combination in patients with active RA at 24 weeks.

Methods: This is a quasi-experimental study conducted at Rheumatology department, Fauji Foundation Hospital, Rawalpindi. 95 patients with active RA despite optimal dose (20–25 mg/week) of MTX. Leflunomide 20mg/day was added. Patients underwent clinical and laboratory review at 0, 4, 12 and 24 weeks to note down primary efficacy endpoints and adverse effects.

Results: Ninety five patients were enrolled with a mean age (years) ± SD of 51.7±8.9 and a mean duration of disease (years) of 8.6±7.1. Patients had active disease at baseline with a mean disease activity score (DAS28) of 5.99±0.6. At 24 weeks the mean change in tender joint count (TJC), swollen joint count (SJC), patients pain score on visual analogue scale (VAS) and DAS 28 were all statistically significant (p-value <0.000). The mean change in m HAQ was also statistically significant (p-value <0.000).

At 6 months the most frequent side effects (though mostly mild); were abdominal pain and nausea. 76 patients (79.1%) continued with the combination therapy. Only 3 patients stopped the treatment temporarily (due to raised ALT and vomiting), 14 patients discontinued treatment mainly due to diarrhea, severe oral ulcers and markedly raised ALT.

AB0418 COMPARISON OF ANTI-INFLAMMATORY DRUGS WITH GLUCOCORTICOIDS IN TREATMENT OF RHEUMATOID ARTHRITIS

B.N. Coskun1, F. Ullutas2, S. Ermurat1, E. Halilci1, 1 Rheumatology; 2Internal Medicine, Uludag University, Bursa, Turkey

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease that commonly presents with symmetrical polyarthritis of hands and feet. Pharmacological treatment options are non-steroid anti-inflammatory drugs (NSAIDs), glucocorticoids (GC) and disease modifying anti rheumatoid drugs (DMARDs) (csDMARDs) or (bsDMARDs or bDMARD).

Objectives: In this study we aimed to review the use of NSAID and GC in our patients.

Methods: The patients who diagnosed as RA at our office were included in the study. Patients were classified with EULAR 2010 RA criteria. The demographics and medications of the patients were recorded. All patients we examined pain with visual analog scale (VAS), global assessment of patient and doctor, number of tender and swollen joints (28 joints), health assessment questionnaire (HAQ), C- reactive protein (CRP), uric acid and Hb.

Conclusions: About 686 patients were enrolled in the study (156 female [48.5%], 106 male [51.5%]). Mean age was 53.2±12.21 and mean length of diagnosis was 10.74±17.09 months. The rate of rheumatoid factor (RF) and anti – CCP – WC was 17.9% and the deformity rate was 31.3%. In all patients, activity of disease was mild in 55%, moderate in 37.8% and severe in 7.3% with regard to DAS28. The score of disease activity was mild in 54.6%, moderate in 43.11% and severe in 2.3% in patients who were using only NSAIDs. These rates of disease activity was 57.2%, 40.7% and 2.1% in mild, moderate and severe disease respectively for the patients using only GC. In patients using both NSAIDs and GC, the disease activity was mild in 55%, moderate in 44% and severe in 1%. In comparison of the disease activity with medications revealed statistically significant difference in patients that using only GC and using both, but not in that using only steroid (respectively p: 0.022, p: 0.025, p: 0.46).

Conclusions: In our study we found that patients has mild activity of disease using high rates of NSAID and GC. It is important for providing remission using NSAIDs and GC along with DMARD. Our results demonstrate use of both GC and NSAIDs results in better outcomes.

AB0419 REAL WORLD USE OF TOFACITINIB IN RHEUMATOID ARTHRITIS: DATA FROM LATIN AMERICA

E.E. Schneeberger1, A. Salas2, L.F. Medina2, J.B. Zaccarías2, R.D. Mantilla3, J.C. Sarmiento-Monroy3, L.J. Elizondo4, B. Garro5, H. Madariaga6, L. Górriz7, R.D.N. Giorgi8, M. Pinheiro8, D. Ponce de Leon9,1. Servicio de Reumatología, Instituto de Rehabilitación Psicofísica; 2Servicio de Reumatología, HIGA San Martin de la Plata, Buenos Aires, Argentina; 3Servicio de Reumatología, Hospital Universitario del Valle, Cali, Colombia; 4Servicio de Reumatología, Hospital Italiano, Buenos Aires, Argentina; 5Epidemiología, Centro de Enfermedades de Calidad de la Región de Valparaíso, Chile; 6Reumatología, Unidad de Salud Publica, Hospital Italiano, Buenos Aires, Argentina; 7Reumatología, Gastroenterología, UCRH, Bogotá, Colombia; 8Reumatologo, Centro de Investigación Clinica de Ciudad Obregón, Sonora, Mexico; 9Reumatologo, Centro de Excelencia en Reumatología, Lima, Peru; 10Reumatologo, Clinica del Sur, Arequipa, Peru; 11Servicio de Reumatología, Hospital Santo Tomás, Panamá, Panama; 12Servicio de Reumatología, Hospital del Servidor Público Estadual, Brazil; 13Pfizer Inc, São Paulo, Brazil; 14Pfizer Inc, Lima, Peru

Background: Tofacitinib is an oral JAK inhibitor for the treatment of RA. Tofacitinib can be given as monotherapy or with csDMARDs. Published data on real world (RW) tofacitinib use in Latin America (LA) are limited. We characterise the patient (pt) population starting tofacitinib and gain insights into the safety profile in the RW LA setting.

Methods: Initial tofacitinib therapies in adult RA pts from 10 private/public centres in 6 countries (Argentina, Brazil, Colombia, México, Panamá, Peru) were considered. Data were retrospectively obtained via a standardised format, focusing on demographics, drug history, adverse events (AEs), safety events of special interest, latent tuberculosis (TB) screening, selected confirmed laboratory abnormalities and discontinuation rates. Tofacitinib use as monotherapy or with csDMARDs was at the rheumatologist's discretion.

Results: 280 pts with severe active RA were included; most were female (n=263; 91%), mean (SD) age was 51.3 (6.36) years (yrs) and mean (SD) disease duration was 10.4 (4.0) yrs. 89% of pts were RF+ or ACPA+. The max (range) follow-up period was 22 (10–34) months. Tofacitinib was given as 2nd-line therapy (post-csDMARD) in 44% of pts, after one biologic DMARD (bDMARD) in 18% of pts and after >3 bDMARDs in 38% of pts. Tofacitinib was given as monotherapy in 117/283 (41%) pts and with csDMARDs in 171/283 (59%) pts. Tofacitinib use corresponds to 13% of advanced therapies (JAK inhibitors, bDMARDs and biosimilars). Thirty-eight AEs were observed; upper respiratory infections (n=11), skin infection (n=5), herpes zoster (HZ; n=4) and urinary infections (n=4) were most common. Gastrointestinal intolerance was seen in 2 pts. Three (1%) pts had serious infection events (SIEs); no opportunistic infections (Nos), including TB, occurred. All HZ cases (n=4; 1.4%) were monomeric, non-serious and resolved without complication after antiviral therapy. Before starting tofacitinib, 5 pts (1.7%) were vaccinated against HZ and 5.6% were diagnosed with latent TB. No active
TB cases occurred with tofalenib treatment. One malignancy (thyroid cancer) was reported. Severe (≥3 ULN) elevation of liver enzymes or increases of CPK above normal were infrequent (<1%); no severe cytopenias were reported. Lipid increases occurred in 10% of pts. Tofalenib was withdrawn in 40 pts (13.9%) due to lack of efficacy (n=20; 7%), AEs (n=11; 3.8%) or other reasons (n=9; 3.1%), such as loss of follow-up, pregnancy, access issues or trials. Limitations include limited pt numbers and follow-up of exposure.

Conclusions: In the RW LA setting, tofaltenib was used mostly as 2nd-line therapy; no new safety signals emerged vs clinical trials. SIsEs and HZ were uncommon; no cases of TB/other OIs occurred, but were seen in the clinical programs.

groups compared to those of the control. 1,25(OH)2D3 had no significantly impact on the level of Th1, Th2, Treg and the ratio of Th1/Th2.

Conclusions: The present study demonstrated that 1,25(OH)2D3 inhibits the synthesis of Th1 cytokines IFN-γ, Th17 cytokines IL-17, IL-22, IL-6, TNF-α, and up-regulates Th2 cytokine IL-4, which indicated that the possible immunoregulatory role and bone-sparing effects of 1,25(OH)2D3 in RA through modulation of the Th1/Th17 and Th2 cytokine balance.

References:

Conclusions: 1,25(OH)2D3 inhibits the synthesis of Th1 cytokines IFN-γ, Th17 cytokines IL-17, IL-22, IL-6, TNF-α, and up-regulates Th2 cytokine IL-4, which indicated that the possible immunoregulatory role and bone-sparing effects of 1,25(OH)2D3 in RA through modulation of the Th1/Th17 and Th2 cytokine balance.

Methods: In the cross-sectional study, HR-pQCT of the second metacarpophalangeal joint (MC2) was performed in 124 patients with ERA at baseline, images were analysable in 117 patients. Erosions were visualized in 72 patients and parameters of bone erosions were assessed. In the prospective study, 63 ERA patients who had completed one year of follow-up with repeat HR-pQCT scan were also analysed. The number and volume of the erosions as well as bone mineral density (BMD) surrounding erosion were quantified. Data on demographic and disease-specific parameters including ESR, CRP, DAS 28, ACPAs and RF levels and treatment were recorded.

Results: At baseline, 90/117 patients were both ACPAs and RF positive (ACPAs+/RF+ group), 7/117 were only RF (RF+), 13/117 were only ACPAs (ACPAs+) and 7/117 were antibody negative (non-ACPAs+/RF+ group, n=27). Erosion depth and volume were increased in the ACPAs+/RF+ group compared with the non-ACPAs+/RF+ group (both P<0.05) (Table 1). Independent explanatory variables associated with a larger erosion volume included RF−E (P=0.012), older age (P=0.003) and a higher damage joint count (P=0.028). Images from 63 patients who completed 12 months follow-up were analysed. Erosion volume were significantly lower in patients who achieved simplified disease activity score (SDAI) remission at 12 months compared to those who did not (P=0.045). Linear regression analysis indicated that independent predictors for an increase in erosion volume included RF−E (P=0.032) and a higher damage joint count (P=0.009) at baseline and failure to achieve SDAI remission for an increase in erosion volume included RF−E (P=0.032) and a higher damage joint count (P=0.009) at baseline and failure to achieve SDAI remission at 12 months.

Conclusions: RF and ACPAs play an additive effect on erosion volume in ERA patients. Higher RF titre was associated with larger erosion volume at baseline and predicted progression of erosion volume after adjusting for baseline parameters and treatment response.

TREATMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS IN POLAND – ESTIMATE THE FREQUENCY OF USE OF METHOTREXATE DURING A RANDOM AUTHOR’S APPOINTMENT WITH A RHEUMATOLOGIST

K. Sikorska-Siudek1, M. Przygodzka1, R. Radomski2, S. Bojanowski2
1Mazovian Centre of Rheumatology and Osteoporosis; 2EHR.eu, Warsaw, Poland

Background: In accordance with the EULAR/ACR recommendations disease-modifying antirheumatic drugs (DMARDs), particulary methotrexate (Mtx) should be applied after diagnosis of rheumatoid arthritis (RA). The goal of the treatment is to get remission/low disease activity

Objectives: The aim of this study was evaluation of the RA treatment, the frequency of use of Mtx and its dose application during control visits to rheumatologist in all Rheumatology Centers in Poland. The disease activity was evaluated by using disease activity score 28 joint score (DAS-28).

Results: There were analysed 301 case records of patients diagnosed with RA on the basis of the ACR 1997 and/or ACR/EULAR 2010 criteria. Patients recently diagnosed were excluded from analysis. In the examined group were 226 women and 75 men, median age 58.0, disease duration 5.0. Patients were divided in groups depending on the type of applied therapy 215 (71%) patients were treated with Mtx monotherapy or combined with other DMARDs. 161 patients (53%) took glucocorticosteroids simultaneously. Average DAS28 – 5.0, disease duration 6.2 At 18 patients (6%) contraindications against the Mtx were stated. In addition, a Wilcoxon test was developed to determine differences between the pre-test score and the post-test score in the EVA of each patient. Statistically significant differences were found in the first session (Z=3.65, p<0.001), second session (Z=3.67, p=0.001) and third session (Z=3.56, p<0.001).

Conclusions: Hypnosis, as a behavioral technique, has shown efficacy in patients with chronic pain. In this research, a significant decrease in patients’ perception of pain has been demonstrated.

EFFECTIVITY OF THE COMBINATION THERAPY WITH METHOTREXATE, LEFLUNOMIDE AND MYPREDNISOLONE IN RHEUMATOID ARTHRITIS

L. Groppo1, E. Russo1, L. Chislan1, O. Bujor2
1Rheumatology and Nephrology, State University of Medicine and Pharmacy “Nicolae Testemitanu”; 2Arthrology, Republican Clinical Hospital, Chisinau, Moldova, Republic of

Background: The RA modern treatment approaches are based on “aggressive therapy”, which aims at suppressing autoimmune inflammation and prevent joint destruction at the early stages of the disease.

Objectives: To evaluate the effectiveness and tolerability of the triple combination therapy with methotrexate, leflunomide and methylprednisolone in patients with rheumatoid arthritis.

Methods: The study included 150 patients with rheumatoid arthritis. As a result of randomization, 50 patients received triple combination therapy (methotrexate +methylprednisolone +leflunomide), 50 patients with monotherapy with methotrexate, leflunomide 50 others. As a result all patients groups were comparable after all clinical and demographic indices.

Results: Our result showed that triple therapy is very effective in treating patients with RA. A significant improvement on the criteria of the AAR (ACR=50) at the end of the study was observed in most patients receiving methotrexate, leflunomide and methylprednisolone. This is confirmed statistically and clinically positive dynamics significantly in almost all indicators used of efficacy (pain, stiffness, number of tender and swollen joints, the activity of AR, the value VUSH index functional HAQ) In addition, the use of triple therapy decreased average dose simultaneous use of glucocorticosteroids daily (from 5.0 to 2.5 mg) and 76% of patients canceled anti-inflammatory non-steroid drugs.

Conclusions: After randomized trial data lasting 24 months based triple therapy (methotrexate, leflunomide and methylprednisolone) was highly effective in patients with high RA activity. A significant improvement according to the criteria of ACR (ACR=50) was obtained in 31 of 39 patients (79.4%), including the nine patients (23.0%) had developed clinical remission. Administration of the basic triple therapy was characterized by a significant clinical effect ACR stability of=50. It was maintained during not less than 15 months of research in 28 (90.32%) of patients who received this treatment and only 3 of 11 (27.27%) patients who received methotrexate alone group and 8 in 10 (80%) who administered LF (<0.039). Evidence recovery (ACR=50), as well as clinical remission was kept stable in all 28 patients that triple therapy was extended after the ending of basic research.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.6317
Background: Glucocorticoids (GCs) are frequently used in the treatment of Rheumatoid Arthritis (RA) but safety data was lacking. Org 214007–0, LGD-5552, Compounds 4 and 5 and PF-04171327 showed similar efficacy as a GC, but no safety data was provided.

Methods: To evaluate changes in serum bone turnover markers and Wnt inhibitors at 7- and 30-days after initiation of low dose GCs treatment of early RA.

Results: At baseline we observed a significant positive correlation between CRP and DKK1 serum levels (r=0.63; p<0.05) and between DKK1 and CTX serum levels (r=0.59; p<0.05). A significant decrease in serum levels of CRP, P1NP and Sclerostin was observed after 7 and 30 days of GC treatment (p<0.05). About DKK1, it has been detected a not significant tendency to decrease after starting GC. CTX serum levels showed no significant changes.

Conclusions: This study has shown that a low dose GC treatment might have complex and conflicting short-term effects on bone metabolism in early RA (a reduction of bone formation, without increase of bone resorption), different from those observed with higher dose, in other diseases or in healthy subjects. The observed decrease in P1NP and Sclerostin serum levels might mean that also low dose of GC could acutely suppress bone formation and induce loss of function and/or number of osteocytes.

LEFLUNOMIDE AS A SECOND LINE DMARD AFTER METHOTREXATE HAS LIMITED IMPACT ON RHEUMATOID ARTHRITIS IN REAL LIFE

G. Weigl, A. Erlen, M. Aringer. Medicine III, University Medical Center TU Dresden, Dresden, Germany

Background: If rheumatoid arthritis (RA) is not in remission or at least low disease under methotrexate (MTX), leflunomide is an approved conventional synthetic DMARD, which is commonly used in some countries. 

Objectives: To investigate in a real life situation whether patients with RA benefit from instituting leflunomide after methotrexate.

Methods: The clinical data of all RA patients who had at least once received leflunomide, and who agreed to the pseudonymized analysis of their data (approved by the local ethics committee), were analyzed from the time of leflunomide initiation on to the time of stopping leflunomide or the last visit in 2015, which ever came first.

Results: In total, 145 RA patients treated with leflunomide were identified. Of these, 87 received leflunomide after MTX had failed as a first line DMARD, and 8 received leflunomide as a first line DMARD. 50 patients had another first line therapy. Of the first line leflunomide patients 3 (38%) were still on leflunomide at the last visit, as compared to 7 of the 44 patients (16%) who were switched from MTX to leflunomide, and 0 of the 27 patients in whom leflunomide was added to MTX (p=0.01 vs 1st line leflunomide). For leflunomide monotherapy, 29% and 19% were still on the drug after 24 and 48 months, respectively, as compared to 14 and 0% under the combination with MTX. Of all patients who started leflunomide, remission (at least low disease activity) as per CDAI (>2.8 <10) was reached by 23% (57%) for 3 months, 20% (40%) for 6 months and 16% (34%) one year after initiating leflunomide monotherapy, with corresponding percentages of patients of 39% switched to other approaches at six months and 60% switched at one year. Under the combination of leflunomide and MTX, remission (at least low disease activity) was seen in 16% (53%) at 3 months, 20% (37%) at 6 months, and 8% (20%) at one year, and 55% and 71% had switched to other modes of action at six months and one year, respectively. Gastrointestinal and mucocutaneous adverse events and hypertension were common, and 4 of our patients experienced serious bacterial infections.

Conclusions: Leflunomide constitutes a longer term therapeutic option for a subgroup of RA patients with contraindications to MTX or after MTX failure. After one year, leflunomide had led to sustained acceptable disease control in approximately one third of the patients, but only in one in five under leflunomide combined with MTX. These results are supportive of the EULAR recommendations that patients should be switched to a second conventional DMARD in the absence of predictors of bad outcome only. If leflunomide is initiated, the patients need to be followed closely for potential secondary loss of efficacy.

SHORT-TERM EFFECTS OF LOW DOSE GLUCOCORTICOIDS ON BONE METABOLISM IN EARLY RHEUMATOID ARTHRITIS

M. Vitiello1, O. Viapiana1, N. Malavolta2, G. Saviola3, R. Bortolotti4, L. Idolazzi2, F. Bertoldo1, G. Orsolini1, M. Risoli1, D. Gatti1, M. Rossini1.

1Rheumatology Unit, University of Verona, Verona; 2Rheumatology Unit, AOU of Bologna, Bologna; 3Rheumatology and Rehabilitation Unit, Salvatore Maugeri Foundation IRCCS, Castel Goffredo, Mantua; 4Rheumatology Unit, Santa Chiara Hospital, Trento, Italy

Background: Glucocorticoids (GCs) are frequently used in the treatment of Rheumatoid Arthritis (RA). Studies in humans about the effects on bone turnover markers and modulators are poor, and results are discordant and controversial, probably because conducted with different doses and underlying diseases.

Objectives: To explore changes in serum bone turnover markers and Wnt inhibitors at 7- and 30-days after initiation of low dose GCs treatment of early RA.

Methods: 27 adult patients suffering from early RA were prospectively enrolled. Blood tests including C-Reactive Protein (CRP), amino-terminal propeptide of type 1 collagen (P1NP, marker of bone formation), carboxy-terminal telopeptide of type 1 collagen (CTX, marker of bone resorption), Sclerostin, and Dickkopf-related protein 1 (DKK1) were detected at baseline and 7 and 30 days after starting low dose of GC (methylprednisolone 4 mg/day).

Results: At baseline we observed a significant positive correlation between CRP and DKK1 serum levels (r=0.63; p<0.05) and between DKK1 and CTX serum levels (r=0.59; p<0.05). A significant decrease in serum levels of CRP, P1NP and Sclerostin was observed after 7 and 30 days of GC treatment (p<0.05). About DKK1, it has been detected a not significant tendency to decrease after starting GC. CTX serum levels showed no significant changes.

Conclusions: This study has shown that a low dose GC treatment might have complex and conflicting short-term effects on bone metabolism in early RA (a reduction of bone formation, without increase of bone resorption), different from those observed with higher dose, in other diseases or in healthy subjects. The observed decrease in P1NP and Sclerostin serum levels might mean that also low dose of GC could acutely suppress bone formation and induce loss of function and/or number of osteocytes.

Background: Tofacitinib is an oral JAK inhibitor for the treatment of rheumatoid arthritis (RA). Efficacy and safety of tofacitinib have been shown in RA patients in global Phase 2, Phase 3 (one study included Japanese patients) and long-term extension (LTE) studies and in two Phase 2 and one LTE study in Japanese patients.
ABT-494 has no effect on the QT interval at the doses being evaluated in rheumatoid arthritis phase 3 trials

M.-E.F. Mohamed, J. Zeng, P. Jiang, B. Hosmane, A.A. Othman. Clinical Pharmacology and Pharmacometrics, AbbVie, North Chicago, United States

Background: ABT-494 is a selective Janus Kinase 1 inhibitor currently being evaluated for treat Rheumatoid Arthritis (RA). The objective of this study was to assess the effect of ABT-494 on the QT interval at the clinical relevant doses from 1 mg to 48 mg single doses under fasting conditions and 3 mg to 24 mg twice daily under non-fasting conditions. Serial triplicate electrocardiograms and pharmacokinetic assessments were conducted. The relationship between change from baseline in Fridericia-corrected QT interval (QTcF) and ABT-494 plasma concentrations was characterized using linear mixed-effects modeling. To our knowledge, in patients with RA and secondary Raynaud’s syndrome, the change in QTcF from baseline to 2 hours post-dose was compared for subjects who received placebo under fasting and non-fasting conditions.

Methods: ABT-494 showed no potential for QT prolongation at the expected therapeutic and super-therapeutic plasma exposures for the doses being used in Phase 3 RA trials.

Correction of lipoprotein and endothelial dysfunction by using no donors (4.2% solution of arginine hydrochloride and l-arginine aspartate) in patient with rheumatoid arthritis in combination with the raynaud’s syndrome

O. Shetleri, R. Yatsyshyn. Internal Medicine #1, Ivanovo-Frankivsk National Medical University, Ivanovo-Frankivsk, Ukraine

Background: Lesion of the cardiovascular system is associated with uncontrolled inflammation and immune defects in patients with Rheumatoid Arthritis (RA). There is an evidence of the close pathogenetic connection between rheumatoid inflammation and accelerated development of atherosclerosis. The first sing of atherosclerosis is endothelial dysfunction (ED).

Objectives: Evaluate the effectiveness of NO donors (4.2% solution of arginine hydrochloride and L-arginine aspartate) in correction of lipopid and ED in patients with RA and secondary Raynaud’s syndrome.

Methods: 68 patients with RA were examined. All patients were divided into 2 groups: (37 people with RA in combination with secondary RS) received basic therapy of RA (methotrexate 10–15 mg/wk.), antiplatelet and vasodilatory drugs; II group (31 people – RA in combination with secondary RS) got similar therapy plus treatment with NO donors (4,2% solution of arginine hydrochloride and L-arginine aspartate).

Results: Levels of LC, LDL, AI and MI indexes were significantly higher than the norm in 2 compared groups before the treatment and 3 months after its start (p<0,05). There were significant decreases in levels of lipid profile, IA and MI index in II group 3 months after treatment in comparison to benchmarks (TC by 13,3%, LDL by 16,1%, TG by 14,7%, AI index by 13,8% MI index by 12,7% p<0,05) and they were significantly unchanged in I group (p>0,05). It was elucidated a direct reliable strong correlation in patients of II group between the level of FMD and endothelin-1 before treatment (=0,73, p<0,05) and after treatment (r=0,69, p<0,05). Symptoms of ED, levels of FMD, levels of endothelin-1 and NO donors were decreased in patients of both groups after the conducted therapy. It was established a proportionately reliable correction between CRP and LDL levels after treatment in II group of patient (r=0,63, p<0,05).

Conclusions: 1. There is a lack of flow-mediated vasodilation of brachial artery in patients with RA and secondary RS, which can indicate a dysregulation of endothelial function. 2. The level of CRP is increased in patients with RA and secondary RS and is associated with the risk of hyperlipemia and atherosclerosis. 3. The usage of NO donors (4,2% solution of arginine hydrochloride and L-arginine aspartate) in the treatment of RA with secondary RS significantly reduces the levels of IA and MI index, the level of atherosclerotic lipoprotein fractions (TC, LDL and TG) and decreases the severity of ED, which leads to minimizing the risk of atherogenesis and its complications.
**AB0434\ TOFACITINIB IN RHEUMATOID ARTHRITIS: REAL LIFE EXPERIENCE**

Background: Tofacitinib is a new small molecule, Janus kinase 1 and 3 inhibitor, interfering with the JAK-STAT signaling pathway. The JAK-STAT transmits the effects from the immune cell nucleus, influencing DNA transcription. Its efficacy and safety in Rheumatoid Arthritis (RA) has been demonstrated in different phase II, III and long-term clinical studies. It has been approved in Argentina for the treatment of patients with moderate to severe rheumatoid arthritis RA with failure to conventional DMARDs.

Objectives: To communicate real world safety data from patients with RA under treatment with Tofacitinib.

Methods: A retrospective, descriptive study from patients with RA (ACR/ EULAR2010) under treatment with Tofacitinib from September 2014 to December 2016 was conducted. Medical records from patients being treated with Tofacitinib were reviewed. Clinical data were recorded, concomitant treatments, and reported adverse effects were documented.

Results: 62 patients were treated with Tofacitinib. 53 were female and 9 were male, with a mean age of 57.91±14.72 years and average disease duration of 140.83±130.83 months. 18 patients (29%) had at least one comorbidity, the most frequent being hypertension (77%). Of the 62 patients studied, 54 (87%) had established RA (duration of illness greater than 24 months) and 8 patients (13%) with early RA (less than 24 months). In 54 patients Tofacitinib was indicated in combination with another DMARD (RMD), and in only patients, received treatment as monotherapy. The most commonly used DMARD in combination therapy was methotrexate (MTX) in 92.5%.

Treatments were indicated by failure to MTX or other conventional DMARDs. 12/62 treatments were indicated by failure to treatment with 1 biological DMARD and 13/62 treatments were indicated by failure to two or more biological DMARDs. The maximum exposure time was 21 months. During the time of exposure to Tofacitinib the following adverse events were observed: Herpes Zoster infection 2 cases (monomeric, no visceral involvement). We observed 80 patients with early RA, 50 patients of them were compared as a single “placebo” group. Baseline (BL) disease severity was classified as moderate or severe by Disease Activity Score in 28 joints with erythrocyte sedimentation rate (DAS28: moderate 3.2 to <5.1; severe ≥5.1) and Clinical Disease Activity Index (CDAI: moderate 10 to <22; severe ≥22). Results show CRP and ESR, the most frequently used parameters.

Conclusions: Most patients received combined treatment with DMARDs being the most commonly used Methotrexate. There were no cases of serious infections, opportunistic infections, cytopenias, dyslipidemia, or increased CPK. Patients discontinued Tofacitinib: one due to tachycardia, another case peripheral pain and another case due inefficacy. Most patients received combination treatment with DMARDs being the most commonly used Methotrexate. There were no cases of serious infections, opportunistic infections, cytopenias or dyslipidemia. The use of Tofacitinib in RA has a critical role in the development and progression of immune inflammation. The results of observation of patients for 6 months were showed that, of all indicators of patients in 2nd group was 33.4%. During the treatment was indicated improvement of laboratory parameters of disease activity of RA in both groups, features of activity of 1st group were decreased up to (DAS28 =2.9), signs of 2nd group were (DAS28 =3.6). However, there were 26% of cases of clinical remission of the disease in patients of 1st group than patients of 2nd group. Known side effects of combination therapy with MT and LF in most cases have not been severe, reversible and demanded the abolition of drugs in rare (11.2%) cases.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.3861

**AB0435\ COMBINATION THERAPY IN EARLY STAGE OF RHEUMATOID ARTHRITIS**

Background: To evaluate tofacitinib 5 and 10 mg twice daily (BID) efficacy in patients with moderate to severe rheumatoid arthritis (RA).

Methods: A randomized double-blind controlled study of 6–24 months’ duration, Tofacitinib was administered in 2 groups: 1st group consisted of 40 patients, 2nd group were (DAS28 ≤3.6). However, there were 26% of cases of clinical remission of the disease in patients of 1st group than patients of 2nd group. Known side effects of combination therapy with MT and LF in most cases have not been severe, reversible and demanded the abolition of drugs in rare (11.2%) cases.

Conclusions: Combined basic therapy of patients in the early stages of RA with methotrexate (MT) and Leflunomide (LF) has more efficiency than mono therapy.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.4770

**AB0436\ COMPARISON OF TOFACITINIB EFFICACY IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS: POOLED ANALYSIS OF PHASE 3 STUDIES**

Background: Tofacitinib is an oral JAK inhibitor for the treatment of RA. The maximum exposure time was 21 months. During the time of exposure to Tofacitinib the following adverse events were observed: Herpes Zoster infection 2 cases (monomeric, no visceral involvement). We observed 80 patients with early RA, 50 patients of them were compared as a single “placebo” group. Baseline (BL) disease severity was classified as moderate or severe by Disease Activity Score in 28 joints with erythrocyte sedimentation rate (DAS28: moderate 3.2 to <5.1; severe ≥5.1) and Clinical Disease Activity Index (CDAI: moderate 10 to <22; severe ≥22). Results show CRP and ESR, the most frequently used parameters.

Conclusions: Most patients received combined treatment with DMARDs being the most commonly used Methotrexate. There were no cases of serious infections, opportunistic infections, cytopenias or dyslipidemia. The use of Tofacitinib in RA has a critical role in the development and progression of immune inflammation. The results of observation of patients for 6 months were showed that, of all indicators of patients in 2nd group was 33.4%. During the treatment was indicated improvement of laboratory parameters of disease activity of RA in both groups, features of activity of 1st group were decreased up to (DAS28 =2.9), signs of 2nd group were (DAS28 =3.6). BL characteristics were balanced between treatment groups in each disease severity category. M3 efficacy was significantly greater with tofacoitinib 5 and 10 mg BID vs placebo, regardless of BL disease severity. As expected, larger proportions of tofacitinib-treated pts with moderate vs severe BL RA achieved LDA by either DAS28 (32.3–36.7% vs 13.8–19.1%) or CDAI (49.2–55.0% vs 28.0–31.2%). A greater proportion of pts achieved remission in the moderate vs severe BL groups by DAS28 (20.0–22.8% vs 6.2–9.0%) or CDAI (11.5–12.1% vs 5.1–6.7%). A greater proportion of pts achieved HAQ-DI <0.5 with moderate vs severe RA classified by DAS28 (45.0–60.6% vs 24.5–30.0%) or BL CDAI (40.8–52.4% vs 24.7–30.4%). Greater improvements from BL in disease activity were seen for pts with severe vs moderate RA classified by BL DAS28 (Table), and by BL CDAI (Tofacoitinib 5/10 mg BID ΔCDAI: -21.1/23.0 vs -8.1/-9.4; ΔHAQ-DI: -0.5/-0.6 vs -0.3/-0.4).

Conclusions: Tofacoitinib 5 and 10 mg BID demonstrated efficacy in treating pts with moderate and severe RA with >7 years’ mean disease duration. By M3, pts with severe vs moderate BL disease activity had greater improvements in disease activity and physical functioning; higher proportions of pts with moderate vs severe BL disease activity achieved remission, LDA or normal physical functioning. Interpretation of this post hoc analysis may be limited by the smaller sample size of the moderate disease group and the combining of mono- and combination-therapy results.

AB0437 EFFICACY AND SAFETY OF LONG-TERM ANALGESIC THERAPY WITH ETORICOXIB FOR PATIENTS WITH RHEUMATIC DISEASES

S. Lapshina, L. Myasoutova. Kazan State Medical University, Kazan, Russian Federation

Background: There are some data in literature on decompensation of arterial hypertension and other chronic diseases during the treatment with coxibs which in practice unfortunately limits their administration for patients with comorbidities.

Objectives: To evaluate the efficacy of analgesic effect of etoricoxib and frequency of comorbidities exacerbation on such treatment.

Methods: 58 patients with rheumatoid arthritis (34.4%), osteoarthritis (29.2%), anklyosing spondylitis (19%), gout (14%), psoriatic arthritis (3.4%) at the age of 25 to 75 years (the average age, 52.9±13.03 years) were included. They had 79.3% comorbidities (diseases of digestive system – 37.9%, arterial hypertension – 53.4% (including 3.2% with compensated hypertension), bronchial asthma – 1.7%). All the patients before the initiation of the study had taken NSAIDs (diclofenac, nimesulid, ketoprofen, meloxicam, aceclofenac, ibuprofen) with lack of effect or minimal effect (84.4%) or minimal effect (15.6%). Etoricoxib was administered in 100% cases. Patients were divided into 3 groups: 1) patients treated with other non-steroidal anti-inflammatory drugs (NSAIDs), 2) patients treated with etoricoxib alone, 3) patients treated with etoricoxib in combination with other drugs.

Results: By the second appointment 98.2% patients were taking etoricoxib regularly, and 97% of patients with moderate and severe RA with >7 years’ mean disease duration (more than 3 years). At the initiation of IGU were significant factors of clinical remission achievement (ΔCDAI: 40.8–52.4% vs 24.7–30.4%). Greater improvements from BL in disease activity were seen for pts with severe vs moderate RA classified by BL DAS28 (Table), and by BL CDAI (Tofacoitinib 5/10 mg BID ΔCDAI: -21.1/23.0 vs -8.1/-9.4; ΔHAQ-DI: -0.5/-0.6 vs -0.3/-0.4). A greater proportion of pts achieved HAQ-DI <0.5 with moderate vs severe RA classified by DAS28 (45.0–60.6% vs 24.5–30.0%) or BL CDAI (40.8–52.4% vs 24.7–30.4%). Greater improvements from BL in disease activity were seen for pts with severe vs moderate RA classified by BL DAS28 (Table), and by BL CDAI (Tofacoitinib 5/10 mg BID ΔCDAI: -21.1/23.0 vs -8.1/-9.4; ΔHAQ-DI: -0.5/-0.6 vs -0.3/-0.4).

Conclusions: Tofacoitinib 5 and 10 mg BID demonstrated efficacy in treating pts with moderate and severe RA with >7 years’ mean disease duration. By M3, pts with severe vs moderate BL disease activity had greater improvements in disease activity and physical functioning; higher proportions of pts with moderate vs severe BL disease activity achieved remission, LDA or normal physical functioning. Interpretation of this post hoc analysis may be limited by the smaller sample size of the moderate disease group and the combining of mono- and combination-therapy results.

AB0438 EFFICACY AT THREE YEARS OF DAILY CLINICAL USE OF IGURATIMOD IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Suto1, Y. Yonemoto1, K. Okamura1, M. Tachibana2, C. Okura1, M. Mutasaitiya3, K. Takeuchi2, K. Otsuka2, K. Ayate3, Y. Takano4, Y. Tamura4, M. Inoue5, H. Inoue6, H. Chikuda1. 1Department of Orthopaedic Surgery, Gunma University Graduate School of Medicine, Maebashi; 2Department of Orthopaedic Surgery, Iseaki Fukushima Hospital, Iseakashi; 3Department of Orthopaedic Surgery, Keiyu Hospital, Tatebayashishi; 4Department of Orthopaedic Surgery, Inoue Hospital, 5Department of Medicine, Inoue Hospital, Takekasi, Gunma, Japan

Background: Iguratimod (IGU) is a small-molecule antirheumatic drug that was developed in Japan and is currently only approved for treatment of rheumatoid arthritis (RA) in Japan and China. IGU suppresses tumor necrosis factor-alpha-induced production of interleukin (IL)-6, IL-8 and monocyte chemotactant protein 1 via the inhibition of nuclear factor-kappa B activation in cultured human synovial cells and human acute monocyctic leukemia cells. There are some reports about the efficacy and safety of IGU in patients with RA. However, the assessment about efficacy of the clinical use of IGU has mainly been restricted to short-term (within one year) outcome.

Objectives: The purpose of this study was to assess the efficacy of IGU in 3 years of daily clinical use.

Methods: Sixty-nine RA patients (14 males and 55 females, mean age of 63.9 years, mean disease duration of 14.9 years) were enrolled in this study. The clinical course of RA was evaluated during 3 years. The patients who discontinued the IGU therapy were analyzed by the last observation carried forward method.

Results: The survival rate at 3 years was 49.3%, and 8 patients discontinued the IGU therapies due to insufficient response, 12 patients due to adverse events such as exanthema, pneumonitis or hepatic disorder, and other patients based on their requests. The DAS28-CPR, DAS28-ESR, SDAI and CDAI significantly decreased at 6 months, 1, 2, 3 years compared with baseline. The low DAS28-CPR at 3 months and younger age were associated to the continuation of IGU. Furthermore, the IGU therapy were analyzed by the last observation carried forward method. The DAS28-CPR and the usage rate of prednisolone at baseline were significantly lower and patients’ age was younger. A logistic regression analysis revealed the low DAS28-CPR and low usage rate of prednisolone at baseline were significant factors contributing to the achievement of a clinical remission at 3 years.

Conclusions: We assessed middle-term outcome of the clinical use of iguratimod therapy in RA patients. The low DAS28-CPR and low usage rate of prednisolone at the initiation of IGU were significant factors of clinical remission achievement at 3 years.

AB0440 IMPACT OF VITAMIN D DEFICIENCY UPON DISEASE ACTIVITY AND IMMUNE DISORDER IN RHEUMATOID ARTHRITIS PATIENTS

Y. Liu, H.Y. Wen. Rheumatology, the Second Hospital of Shanshi Medical University, Taiyuan, China

Background: Emerging evidence suggests that vitamin D plays an important role in immune regulation.

Objectives: The objective of this work was to determine if patients with rheumatoid arthritis (RA) are at risk for vitamin D deficiency and whether vitamin D levels correlate with disease activity or immune disorders.

Methods: This study was a retrospective research. RA patients who had vitamin D levels and immune function indexes of each other were included. Patients receiving or have received vitamin D, corticosteroids, disease-modifying anti-rheumatic drugs or a tumor necrosis factor antagonist and those who had hepatic or renal insufficiency were excluded. Multivariate analysis was performed to examine correlations and control for confounding factors.

Results: As suggested threshold (<25 ng/ml), the overall prevalence of vitamin D insufficiency was 265 of 280 (94.6%). Mean serum vitamin D insufficiency levels of 11.15±4.74 ng/ml for RA patients were significantly lower compared to controls (31.62±6.46) (p<0.001). Among all the subjects, 208 (72.7%) were females. Vitamin D levels in high disease activity group were lower compared to vitamin D level in patients with low and moderate disease activity (DAS-28 score >5.1, 3.2–5.1, ≥3.2, respectively, p<0.001) and vitamin D levels had an inverse correlation with DAS28 score (r-coefficient-0.158, p=0.019, per 1 ng/ml). However, no significant relationship was found between vitamin D and these variables (T cell, B cell, NK cell, Treg, Th1, Th2, Th17/Treg) in patients.

Conclusions: Lower levels of vitamin D are associated with worse DAS28 and higher levels of Th17 with RA, especially in female patients. The levels of 1,25-dihydroxycholecalciferol (1,25(OH)2D3) could be a marker to monitor the disease activity in RA patients and vitamin D may be an alternative supplementary treatment for RA.

AB0441 USING OF SUBCUTANEOUS METHOTREXATE IN AGED PATIENTS WITH SEROPOSITIVE RA

Y. Muraviev, G. Gridneva, E. Luchikina, N. Demidova, V. Lebedeva, D. Karateev. V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

Background: Increasing life expectancy is a global prospect involving multiple nations, thus deeper insights into methotrexate (MTX) therapeutic potential in aged people is of paramount importance, as MTX still remains an anchor DMARD in RA management.

Objectives: To assess the results of 12-months therapy with subcutaneous MTX (SC MTX) injections in RA patients aged more than 60 years.

Methods: The 12 months’ study included pts receiving MTX (DAS28 >3.2), meeting ACR/EULAR (or ACR 1987) criteria, with RA lasting up to 3 years, and naïve to SC MTX. All pts were RF and/or ACPA-positive, 68% had increased BMI, 31% - obesity, 8% were smokers, 25% were taking oral GCS (<10 mg/day equivalent to prednisolone). All pts were administered SC MTX monotherapy (80 mg once a week as a DMARD, starting at 10–15 mg/week, with subsequent 5 mg up-titration each 1–2 weeks to max 30 mg/week) up to achieving the target (remission or minimum disease activity) or to emergence of an adverse drug reaction (ADR). Folic acid (min 5 mg/week) was administered at any day(s) except for the day of SC MTX injection for ADR prophylaxis. Disease activity was scored using DAS28. GEBAs were administered in pts with insufficient SC MTX clinical effect. Pts were monitored within universal institutional REMARKA program, envisaging physical examination, blood analysis and biochemistry panel (including liver enzymes and creatinine). STATISTICA 10 software was used for data processing.

Results: 32 RA pts (28 females, 4 males) were included (mean disease duration 12±10 months, mean age - 65.7±4.7 years, mean DAS28 score -5.6±2.0. Cumulative SCMT dose by the end of the study reached 264±180 mg). The therapeutic target (remission or minimum disease activity based on DAS28 score) was achieved in 20 pts receiving SCMT monotherapy, 12 pts received administration of GEBAs. Adverse drug reactions (ADRs) were documented in 10 pts, including cases of more than one ADR at a time: breast abscesses (1), alopecia (2), diarrhea (2), skin rash (1), a metallic aftertaste (1), local post-injection reactions (1), nausea (2), elevation of liver enzymes (3), leucopenia (1), pneumonia (1). There were 5 cases of SC MTX monotherapy discontinuation (2 - temporary, and 3 - permanent). The majority of pts (88%) could manage self-injection without additional training or assistance from medical staff.

Conclusions: 62.5% of aged RA pts participating in the study managed to achieve the therapeutic target after 12 months of SC MTX monotherapy, although 31% ADRs rate required temporary (2) or permanent (3) SCMT discontinuation.

AB0442 REAL-LIFE EXPERIENCE WITH BELIMUMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): CONTROL OF DISEASE ACTIVITY AND FLARES IN A MULTICENTER COHORT

A. Fanouliakis1, C. Adamichou2, S. Koutsoviti3, A. Klagou4, C. Tsilapaki2, K. Konsta5, D. Dimopoulou6, S. Ntal6, D. Vassilopoulos7, P. Konstantopoulou8, A. Elezoglou9, P. Sidopoulou9, A. Eridi9, G. Bertsa5, D. Boumpas10, 1Rheumatology and Clinical Immunology, “Attikon” University Hospital, Athens; 2Dept of Rheumatology, “Evangelismos” General Hospital, Athens; 3Dept of Radiology, “Attikon” University Hospital, Athens; 4Dept of Rheumatology, Clinical Immunology and Allergy, University Hospital of Heraklion, Heraklion; 5Dept of Rheumatology, “Asklepieion” General Hospital; 6Dept of Rheumatology, “G. Nennimatas” General Hospital; 72nd Dept of Internal Medicine, “Ippokratieon” General Hospital; 8Dept of Rheumatology, “G. Nennimatas” General Hospital; 9Dept of Rheumatology, “Ippokratieon” General Hospital; 10Private rheumatologist, Thessaloniki. 11Rheumatology, Hacettepe University, Faculty of Medicine, Ankara, Turkey

Background: Data on the efficacy of belimumab in SLE mainly originate from large randomized clinical trials, whereas reports from real-life clinical practice are lacking.

Objectives: To describe the clinical experience from the use of belimumab in Greece since the approval of the drug.

Methods: Multicentre observational study of patients receiving belimumab, with documentation of disease activity (SLEDAI-2K index), achievement of low disease activity
activity states (remission [SLEDAI-2K=0] and lupus low disease activity state [LL-DAS]), accrual of irreversible damage (SLICC damage index, SDI), number and severity of flares, and side-effects. Analyses were performed at quarterly intervals and only patients with at least 3 months of follow-up were included in the study. Results: A total of 56 patients were included [33 women (94.6%), mean (SD) age 44 (12.5)] at baseline, 25 females (44.6%) had positive ANA and 20 (35.7%) had positive anti-dsDNA) was evident in 30 patients (53.5%). Most frequent manifestations were arthritis (82.1%), inflammatory rash (73.2%), active hair loss (57.1%), mucosal ulcers (26.8%) and leukopenia (10.7%). Median (range) duration of follow-up was 9.1 (2.9 - 34.6) months. We observed a significant decrease in the SLEDAI-2K, physician global assessment (PGA) and daily prednisone dose over time, starting as early as 3 months after belimumab initiation (Table 1). This effect was significantly more pronounced in patients who were serologically active (SA) at baseline, even after exclusion of the serologic components. Table 1: Median (range) total number of flares for the 12 months before and after belimumab treatment. (1–24) at baseline vs. 2 (0–16) at 6 months and 0 (0–16) at 12 months, p < 0.0001 and p=0.013, respectively; for serologically inactive patients: 6 (2–23) at baseline vs. 6 (0–14) at 6 months and 5 (0–18) at 12 months, p=0.017 and p=0.024, respectively. For patients with ≥12 months of follow-up (n=20), belimumab treatment resulted in a significant decrease in flare rate (median [range] total number of flares for the 12 months before and after belimumab treatment, 3 (0–7) and 0 (0–2), respectively, p < 0.0001). 10 patients (17.8%) discontinued belimumab due to inefficacy after a median (range) 7.1 (5.5 - 20.4) months of therapy and 5 patients discontinued due to planned pregnancy. There were no drug discontinuations due to side-effects.

Conclusions: In real-life clinical settings, belimumab is efficacious in controlling disease activity of SLE and permitting tapering of glucocorticoid dose. Similar to data from RCTs, this effect seems to be more pronounced in serologically active patients.

AB0443 INFUSION REACTIONS TO RITUXIMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE ANALYSIS
A. Hennessey 1, J. Lukawaska 3, G. Cambridge 1, D. Isenberg 1, M. Leandro 1, 2
1Centre for Rheumatology and Bloomsbury Rheumatology Unit, University College London; 2Division of Rheumatology, Department of Medicine; 3Allergy Research Group, University of Newcastle; 4Newcastle University, Newcastle; 5Great Western Hospital, Swindon; 6Royal London Hospital, London; 7Basildon and Thruickor University Hospital, Basildon; 8University of Cambridge, Cambridge; 9Brighton and Sussex Medical School, Brighton; 10University Hospital Southampton, Southampton; 11University of Nottingham, Nottingham; 12University of Liverpool, Liverpool; 13BHRUT, Goodmayes; 14London School of Hygiene and Tropical Medicine, London, United Kingdom

Background: B lymphocytes are important in the pathogenesis of primary Sjögren’s syndrome (pSS), but two phase III trials (TEARS and TRACTISS) of the B cell depleting agent rituximab (RTX) failed to show an effect on their primary endpoints in pSS. Whilst RTX may lack efficacy in a non-stratified pSS population, other explanations for the infusional negative results include small size of the dataset, limited duration of follow-up and dose-limiting side-effects.

Objectives: To compare the effects of RTX versus placebo in pSS, in a multicentre, multivisoerstry substudy of TRACTISS.

Methods: Subjects consenting to SGUS were randomised to 1000mg RTX or placebo given at weeks 0, 2, 4 and 6, and scanned at baseline and weeks 16 and 48. RTX and placebo were administered as a 30-second intravenous infusion in a 300mg over 15 minutes for weeks 0 and 12. Total ultrasound scans included a 3.5-7.5MHz curvilinear transducer. The primary endpoint was presence/absence of disease activity (ACR criteria), with secondary endpoints of categorical response in the RTX arm (defined as a 1 point improvement) as a function of the baseline score, age category, disease duration and time point.

Results: 66 patients (49.6% of the total study population) consented to SGUS, and 52 (39.1%; n=26 RTX and n=26 placebo) completed the baseline and at least one follow-up visit. Estimated baseline-adjusted TUS at week 16 was 6.2 (95% CI 5.4–7.0) for placebo and 5.0 (95% CI 4.4–5.6) for RTX, and at week 48, 6.1 (95% CI 5.5–6.6) and 4.8 (95% CI 4.2–5.4) respectively. Estimated between group differences (RTX-placebo) in baseline adjusted TUS were -1.2 (95% CI -2.1 to -0.3; p=0.0099) and -1.2 (95% CI -2.0 to -0.5; p=0.0023) at weeks 16 and 48. Glandular definition was the only domain to show statistically significant improvement with an OR of 6.8 (95% CI 1.1–43.0; p=0.043) at week 16 and 10.3 (95% CI 1.0–105.9; p=0.050) at week 48. Improvement of ≥1 point in TUS was associated with improvement in oral dryness VAS at week 16 (diff=15.9; CI 1.5 to 30.3; p=0.030) but not week 48 in the RTX arm.
Conclusions: TUS differed between study arms, favouring RTX. This encourages further research into SGS5 as an imaging biomarker in PSS clinical trials.

Background: Given its immunomodulatory effects, hydroxychloroquine use is recommended in systemic lupus erythematosus (SLE). It is associated with a lower rate of appearance and of relapse of lupus nephritis (LN). LN is classically classified using ISN/RPS classification, but others indexes, such as the ones described by Austin and Hill, allow for the quantification of SLE activity in the kidney biopsy tissue.

Objectives: To analyze the association between the use of hydroxychloroquine and the activity of LN in the kidney biopsy.

Methods: Retrospective single center study of consecutive SLE and biopsy proven LN patients, diagnosed from 2010 to 2016. We evaluated the following outcomes: clinical remission, renal function and proteinuria at end of follow up (g/24h). Complete remission was defined as a reduction of proteinuria to <0.5g/24h, inactive urinary sediment and serum creatinine <115% of baseline; partial remission same parameters, except proteinuria <1g/24h if initial value <3g/24h, or reduction to <3g/24h if initial value >3g/24h. Kidney biopsies were evaluated by the INS/RPS LN classification and the morphological indexes described by Austin and Hill, obtained after histomorphological review of renal biopsies. The studied predictor was the use of hydroxychloroquine. Statistical analysis was performed with STATA software, using one-way ANOVA, Qui2 and Pearson/Sperman test were appropriate.

Results: During 6 years, there were 46 biopsy-proven LN cases, 84.8% (n=39) woman, median 35 years old (27–42.5) and 57.6% (n=19) caucasian. 39 patients were already known to have SLE, 7,44 (1,13–12.3) years previously. Of those 39 patients, 46% were under hydroxychloroquine and 77% under other immunosuppression.

The median follow-up was 31.9 (13.2–45.6) months. Based on biopsy findings, 35 patients were started on immunosuppression – induction in 50% of cases with MMF and in 50% with cyclophosphamide; maintenance in 81% with MMF; the rest with azathioprine. Complete remission was achieved in 58% of patients, 27% achieving partial remission. We observed 4 LN relapses. At the end of FUP, we saw a 96% (n=44) patient survival, with a median serum creatinine of 0.8 mg/dl (0.7–0.99), eGFR 98.9 m/1min (71.2–116.8) and proteinuria of 0.6/24h (0.2–1.6). From those 46 patients, 30 were under immunosuppressive therapy at the time of LN presentation, and 60% (n=18) were also under hydroxychloroquine. Table 1 summarizes the clinical findings:

With the use of hydroxychloroquine, we observed a lower histomorphological activity, as represented by a lower Hill biopsy index, and tendency towards lower Activity Index. We also saw a tendency towards lower proteinuria.

Conclusions: Our data reinforces the recommendations of using hydroxychloroquine for its adjunctive role in SLE patients, as we saw a lower histomorphological activity in kidney biopsy, and a trend towards lower proteinuria.

Background: T and B cell-driven immunity is critically involved in immunopathology of pSS. Recently we demonstrated synergistic T and B-cell activation upon T cell triggering and TLR7/9-driven B cell activation in pSS patients, accompanied by synergistic induction of immunoglobulins and IFN-γ and IL-17-producing T cells1.

In addition, TLR7/9-expressing activated pDCs associated with increased type I IFNs and IFN-inducible genes are increased in pSS patients. Several studies have shown that the DMARDs leflunomide and hydroxychloroquine inhibit immune activation in pSS but only show moderate efficacy. However, LEF and HCO target different pathways with overlapping, but also potentially additive mechanisms, where LEF primarily targets T and B cells and HCO TLR7/9-driven B cell and pDC activation.

Objectives: To assess the additive effects of LEF and HCO on CD4 T- and B-cell activation and production of interferons IFN-α and IFN-γ, TLR7-related cytokine CXCL13, as well as IgG and IgM in vitro employing SEB/TR79-triggered PBMC.

Methods: PBMCs of healthy individuals (n=9) and of pSS patients (n=8) were cultured with antigen (SEB), TLR9 and their combination, in presence or absence of LEF, HCO and their combination in clinical relevant concentrations. Proliferation of T and B cells and release of IFN-α, -γ, CXCL13, IgG and IgM were measured.

Results: In line with robust T and B cell activation, IFN-γ, IFNα, CXCL13, IgG and IgM production was achieved by a combination of SEB and TLR9 (at all least p<0.001). LEF dose dependently inhibited B and T cell proliferation, Interferon, CXCL13 and immunoglobulin production. HCO dose dependently inhibited B cell proliferation, IFN-α, CXCL13, and immunoglobulin production. T cell proliferation and IFN-γ production were inhibited by HCO only at higher concentrations. At several suboptimal concentrations LEF and HCO additively inhibited T cell proliferation both in healthy individuals and in pSS patients. (Figure 1). Significant additive effects were seen for all outcome measures except IFN-α. Since IFNα was already robustly inhibited by HCO alone (eg for pSS 90% at 3.3 μM, p<0.001), only trends towards additive effects were observed.

AB0447 ANTIMALARIALS IMPROVE SURVIVAL OF SYSTEMIC LUPUS ERYTHEMATOSUS ON CHOLESTEROL: RESULTS OF A FIFTEEN-YEAR CHINESE MULTICENTER RETROSPECTIVE STUDY IN JIANGSU PROVINCE

F. Wang1, W. Zhang1, S. Wang1, W. Pan2, L. Liu3, M. Wu4, X. Ding2, H. Wei2, Y. Zau1, X. Feng1, L. Sun1, 1Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing; 2Department of Rheumatology, HuaiAn First People’s Hospital, HuaiAn; 3Department of Rheumatology, Xuzhou Central Hospital, Xuzhou; 4Department of Rheumatology, Xuzhou Drum Tower Hospital of Nanjing University Medical School, Nanjing; 5Department of Rheumatology and Immunology, the Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing; 6Department of Rheumatology, Xuzhou Central Hospital, Xuzhou; 7Department of Rheumatology, Xuzhou Drum Tower Hospital of Nanjing University Medical School, Nanjing; 8Department of Rheumatology, Xuzhou Central Hospital, Xuzhou;
Background: Nowadays the importance of antimalarials, especially hydroxychloroquine (HCQ) and chloroquine (CQ), in treatment of systemic lupus erythematosus (SLE) has been demonstrated. However, few have examined the efficacy of HCQ and CQ on eastern Chinese SLE patients.

Methods: The analysis is based on 1372 patients who were enrolled in a retrospective study of 26 centers from January 1st, 1999 through December 31st, 2009, during which time is their first hospitalization. Baseline and follow-up clinical, laboratory and therapeutic data and survival status before April 30th, 2015 were recorded. Statistical analysis consisted of Chi-square test, t-test, Kaplan-Meier curves and logrank test.

Results: Compared with 562 patients without HCQ or CQ treatment, the hazard curves and logrank test. Compared with 562 patients without HCQ or CQ treatment, the hazard ratio (HR) of deaths in 810 patients taking those was reduced (HR 0.52, 95% CI 0.38–0.70, p<0.001). 376 of these 1372 patients experienced their second hospitalization, during which treatment group (165 of 376) showed lower blood level of total cholesterol (TG), compared to control group (4.47 (0.13) vs 5.03 (0.21), p=0.027), while no statistical difference of TG exists between the two groups, first hospitalization (p=0.05). Other metabolic data, such as systolic and diastolic blood pressure, fasting blood sugar, Triglyceride and uric acid were similar between the two groups in two times of hospitalization. On second inpatient visit, disease activity (SLEDAI, blood sedimentation rate, complement) and organ involvements (SLICC) of those who took antimalarials and no users have no significant differences.

Conclusions: Use of HCQ or CQ lower the risk of mortality and TG levels of eastern Chinese SLE patients.

AB0448 USE OF DENOSUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A REAL LIFE MULTICENTRIC EXPERIENCE

F. Crisafiulli1, M. Fredi2, A. Bortoluzzi3, I. Cavazzana2, F. Furini2, M. Govoni3, A. Tincani3, F. Franceschini3, 1Rheumatology Unit and University of Brescia; 2Rheumatology Unit, Brescia; 3Department of Medical Sciences, Rheumatology Unit and University of Ferrara, Ferrara, Italy

Background: The occurrence of osteoporosis (OP) and fragility fractures (FF) is a frequent comorbidity in patients with systemic lupus erythematosus (SLE), mainly due to the concomitant presence of many risks factors for secondary osteoporosis (drugs, gender, concomitant diseases). The use of corticosteroids (CS) increases the risk of osteoporosis induced by corticosteroid (GIOP) and FF [1]. Denosumab (DR) is a monoclonal antibody that binds to RANKL, inhibiting osteoclast formation and activation, used for both male and women OP to prevent FFx [2,3]. Previous RCT [2] reported a numerically higher serious adverse events of infections in the denosumab users. In particular severe skin infections were significantly more frequent [4]. The possible increase in infection risk might be a concern in subjects with concomitant conditions such as SLE. The use of denosumab in SLE with GIOP patients is recently reported in 17 cases within a RCT [5]. Anyway, no data regarding the tolerability and disease activity during therapy were reported.

Objectives: Our aim was to analyze the prevalence, the tolerability, and relevant changes in disease activity or damage in a cohort of SLE patients treated with denosumab.

Methods: among all SLE patients currently followed in two referral Center we selected the ones that received at least one dose of denosumab. Clinical, serological and demographic variables, concomitant diseases and therapies were collected from clinical charts. Damage index (SDI), activity index (SLEDAI-2K) were selected the ones that received at least one dose of denosumab. In particular severe skin infections were significantly more frequent [4]. The possible increase in infection risk might be a concern in subjects with concomitant conditions such as SLE. The use of denosumab in SLE with GIOP patients is recently reported in 17 cases within a RCT [5]. Anyway, no data regarding the tolerability and disease activity during therapy were reported.

Objectives: Our aim was to analyze the prevalence, the tolerability, and relevant changes in disease activity or damage in a cohort of SLE patients treated with denosumab. Among 793 patients in our cohorts, 21 (2.6%) were treated with denosumab.

Methods: Among all SLE patients currently followed in two referral Center we selected the ones that received at least one dose of denosumab. Clinical, serological manifestations, concomitant diseases and therapies were collected from clinical charts. Damage index (SDI), activity index (SLEDAI-2K) were calculated when denosumab was introduced (first cycle) and at the last evaluation (last cycle). For statistical analysis Chi-squared test or Fisher exact test was used.

Results: Among 793 patients in our cohorts, 21 (2.6%) were treated with denosumab. Demographic data reported a female prevalence (19 cases, 90%), mean age at onset of 36±10 years, mean duration of disease of 26±10 years and mean follow-up of 21±7.8 years; most frequent manifestations were arthritis (90%), cutaneous (67%) and neurological (67%). All patients were still treated with CS (mean duration of 25±6.8 years) with a daily dose of 8.5±3.5 mg/day. Other risk factors for OP were present in the majority of them: drugs (anticoagulants in 6pts, cyclosporin in 3 and antiplatelet in 2), chronic kidney disease (CKD) (4pts), hypovitaminosis D (15pts), anorexia, celiac disease and hemochromatosis (1pt, each). Indication for denosumab was OP with FFx in 17 cases: denosumab was used for a new FF during biphosphonates or after teriparatide. In the other 4 the indication was primary prevention with contraindications at the use of biphosphonates for concomitant severe CKD. Mean duration therapy was 4 cycles (range 1–8); data regarding disease activity, damage and adverse events are reported in table 1. No new FFx developed in any of the included patients at the last evaluation available.

Conclusions: In our cohorts denosumab is still used in few selected patients. However it could be considered as a valid option in GIOP patients because it was globally well tolerated and in our cohort it’s efficacy in the prevention of new fragility fractures was confirmed.

AB0449 OFF LABEL OF BIOLOGICS IN CONNECTIVE TISSUE DISEASES. A SINGLE CENTER EXPERIENCE

G. Orsolini1, C. Crowson2, O. Viapiana3, M. Rossini1, K.G. Moderr2
1Rheumatology, University of Verona, Verona, Italy; 2Rheumatology, Mayo Clinic, Rochester, United States

Background: Connective tissue diseases (CTDs) are a broad spectrum of autoimmune conditions including different entities such as systemic sclerosis (SSc), Sjogren syndrome (SSj), systemic lupus erythematosus (SLE) and autoimmune myositis. There are many patients that do not meet the classification or diagnostic criteria and they fall under the diagnosis of Undifferentiated connective tissue disease (UCTD). Treatment of refractory forms of these could be challenging and clinicians sometimes are forced to try off label drugs such as biologics on the basis of scarce literature support and the experience on different rheumatic disease.

Objectives: To evaluate duration of biologic drug administered off label for the treatment of CTD and investigate variables possibly associated to drug suspension.

Methods: We used ACE program to search among Mayo Clinic clinical records all the patients that had in their records the words “undifferentiated connective tissue disease” or “lupus” or “myositis” or “Sjogren” or “systemic sclerosis” or scleroderma*(and acronyms) AND “infliximab” or “etanercept” or “golimumab” or “certolizumab” or “tocilizumab” or “abatacept” or “adalimumab” (and their brand names).

All records were checked for definite diagnosis and patients with uncertain ones were excluded. Also medications were checked, patients without any information about treatments where excluded. All the records of the selected patients were used to collect information about the off label biologic treatment but also clinical, serological and demographic variables.

Results: We collected data on 122 patients with connective tissue diseases, some of them had other concomitant autoimmune diseases with indication for biologic treatment (e.g. rheumatoid arthritis, etc). We analyze the group with some CTD alone (n=72) considering SLE (n=18 – 25%), inflammatory myositis (n=22%). The other 27% tried also a second biologic and 4% a third. We consider for analysis the first treatment.

Mean treatment duration was 0.8 (±1.1) years. In our population 12.5% experienced a flare of CTD, 12.5% had infections, 18% had allergic reactions (of any type). The 44% experienced primary failure, 11% loss of efficacy, 31% had minor adverse events, 14% major ones (possible more than one reason for interruption).

Analysis showed no definite factors correlated with treatment duration or failure or adverse events, No difference due to type of CTD.

Conclusions: The study is retrospective and this limits the conclusions can be taken from it, however it is one of largest population of off label treatments in CTDs
so far. Due to retrospective data we choose as outcome only treatment duration and adverse events, direct outcomes of efficacy were impossible to evaluate. Our results indicates a poor treatment duration of biologics given off label in CTDs even if they still can be considered with caution in very selected cases after failure on the other label medications.

Disclosure of Interest: None declared

AB0450 THE DARK SIDE OF GLUCOCORTICOID THERAPY IN SYSTEMIC LUPUS ERYTHEMATOSUS: CAN WE DO SOMETHING ABOUT IT?

I. Saez-Comet,1 T. Guud,1 A. Neagu,2 D. Opris,1 A. Boranguí,1 S. Dalía-lliscus,1 D. Roseneau,1 A. Baláñescu,1 V. Bojinca,1 R. Ionescu.1 Internal Medicine and Rheumatology, UMF Carol Davila, St. Maria Hospital, Bucharest, Bucharest, Romania

Background: Corticosteroids are still one of the main treatment in Systemic Lupus Erythematosus (SLE). Beside the effect on controlling disease activity, they are also implicated in damage accrual. Both patients and physicians are some times not able to adopt a steroid free regimen when possible.

Objectives: To evaluate the knowledge and perception of patients with SLE upon glucocorticoids.

Methods: 84 patients with SLE were evaluated and data about demographic, clinical, serological characteristics or treatment were collected. Presence of steroids related side effects like hypertension, osteoporosis, cataracts or diabetes mellitus were also assessed. All patients completed a questionnaire in order to evaluate patient’s knowledge about steroids. They were asked if they had a discussion with the doctors about corticotherapy and side effects related to them, if they consider that this treatment could be stopped with specialist approval. Statistics was performed with SPSS program.

Results: All patients had treatment with corticosteroids during disease evolution. 57.14% of them experienced at least one steroids related side effect. This patients were significant older: mean age at evaluation 49.50 versus 36.47 (p<0.0001), a longer disease duration: mean SLE duration 9.27 versus 4.69 (p<0.016), a higher mean Prednisone equivalent dose: 8.86 versus 4.71 (p<0.031), a higher mean SLICC Damage Index: 1.53 versus 0.44 (p<0.0001) than patients without steroids related side effects. This complications were significantly more rare in patients that were on a steroid free regimen at the moment of evaluation versus those on a continuum steroid regimen (7.14% versus 50%, p<0.0001).

When patients were asked if they will stop steroids according to medical advice, almost 1/3 of patients - 28.57% - responded “no- to afraid to do that”. Patients willingness to adhere to a steroid free regimen in the future according to a physician recommendation was significant more frequent in younger patients (p=0.031, r=-0.235), in those with steroids initiated in less than 1 year (p=0.016, r=-0.297) and in those with less damage accrual (p=0.017, r=0.267). Flare at the moment of evaluation significantly reduced this possibility, at least from the patient perspective (p=0.041, r=0.224). The likelihood of a future steroid free regimen was increased by a previous discussion patient-doctor about steroids (p=0.002).

Conclusions: This study clearly shows that an open discussion with our SLE patients about corticosteroids is mandatory from the beginning. Patients should be informed about possibility of a steroid free regimen when disease status permits. This will increase patient’s willingness to get free of steroids when possible, helping physician to limit the continuum damage accrual of SLE patients.

AB0451 RIVAROXABAN VERSUS WARFARIN AS SECONDARY THROMBOPROPHYLAXIS IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME: A RANDOMIZED, MULTICENTER, OPEN-LABEL, CLINICAL TRIAL

Objectives: To investigate the efficacy and safety of rivaroxaban in preventing recurrent thrombosis in patients with APS compared with warfarin. Methods: This is a phase 3 randomized, multicenter, non-inferiority open-label RCT. Eligible APS patients will be stratified for venous/arterial thrombotic history receiving warfarin will be stratified according the presence of SLE and venous/arterial thrombotic history and randomized (1:1) either to continue warfarin (standard of care, normalized ratio (INR) 2–3 or 2.5 to 3.5 in those with recurrent thrombotic events) or to switch to rivaroxaban (20 mg /day) . The primary efficacy outcome is the development of any thrombotic event during the study period. Secondary efficacy outcomes include time to thrombosis, type of thrombosis (arterial or venous), overall causes of death, evaluation of a prognostic biomarker panel of recurrent thrombosis. The primary safety outcome will be major bleeding. Secondary safety outcomes include any adverse event and minor bleeding.

The study has 3 years follow-up. First patient was included in March 2013 (EUDRA-CT:2010–019764–36).

Conclusions: If the study demonstrates a non-inferior anticoagulant effect compared with warfarin, this would provide sufficient supporting evidence to make rivaroxaban a standard of care for the treatment of patients with APS with previous thrombotic history.

AB0452 CASE REPORT OF ALLOGENEIC UNRELATED-DONOR MESENCHYAL STEM CELLS (MSC) INFUSION IN SJOGREN SYNDROME (SS) WITH REFRACTORY THROMBOCYTOPENIA

J. Qi, M. Qiu, J. Gu. Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University; Guangzhou, China

Background: Intravenous MSC infusion has been reported occasionally in SS treatment and Immune Thrombocytopenia, although the effect of this therapy is still to be confirmed. This is a report of the possible role of MSC in the therapy of SS refractory thrombocytopenia. Methods: We report a case of SS with refractory thrombocytopenia in a 45-year-old female who was admitted to our hospital due to a persistent thrombocytopenia (PLT 8.0*10E9/L) after an episode of bacterial pneumonia. The patient had a history of SS for 10 years and had received multiple courses of corticoids, mycophenolate mofetil, rituximab, and plasma exchange, but the thrombocytopenia did not improve.

Conclusions: This case is consistent with the hypothesis that MSC infusion may be an option to be considered in refractory SS. Further studies are needed to evaluate the role of MSC in refractory SS.

AB0453 OFF-LABEL USE OF MYCOPHENOLATE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOUSIS IN A RHEUMATOLOGY CENTER IN COLOMBIA

K. Mendoza,1 D. Buitrago-Garcia2, P. Santos-Moreno3, J. Urrego2

Objectives: Our objective is to report our experience with the use of Mycophenolate in patients with Systemic Lupus Erythematosus (SLE) in a rheumatology center in Colombia. Methods: This is a retrospective observational study of medical records of patients with SLE followed in the rheumatology department of the Center in Colombia between January 2015 and December 2017. Results: We analyzed 123 patients with SLE. Mycophenolate was used in 117 (95%) patients, in 79 (64%) patients in combination with other drugs. The most frequent indication for use was induction (64%) followed by maintenance (21%) of therapy. The most common side effects were gastrointestinal (11%) and infections (10%). Conclusions: Mycophenolate is an effective and safe drug in the treatment of Systemic Lupus Erythematosus (SLE) in a rheumatology center in Colombia. Further studies are needed to evaluate the long-term efficacy and safety of Mycophenolate in this population.
prevention of the rejection of some transplants. Mycophenolate mofetil was found to be associated with a lower risk of toxic adverse events such as ovarian failure, alopecia and leucopenia, compared with cyclophosphamide (1).

Objectives: To describe the population of patients with SLE receiving mycophenolate during a five year period.

Methods: We conducted a retrospective observational study, extracting information from a database in our rheumatic diseases center; we reviewed the clinical record of each patient with diagnosis of SLE and receiving mycophenolate. Descriptive epidemiology was performed for each variable presented.

Results: 1989 patients were diagnosed with Systemic Lupus Erythematosus (SLE) during 2011 and 2016 and 297 were receiving mycophenolate. Regarding demographic characteristics 94% were woman and 6% men, mean age was 49 years ± 15. 41% of patients were employed, 40% were housekeepers, 11% students and 8% retired. The indication for mycophenolate was mainly for lupus nephritis 62%, SLE with systemic sclerosis 30% and only for SLE in 8% of cases. 36% of patients received a daily dose of 2000 mg; 30% 1500 mg, 20% 1000 mg, 8% 3000 mg, 1.5% 6000 mg and 1% 500mg. The mean value for 24 hour urine protein was 792 mg/dl ± 140 and for creatinine was 0.84 mg/dl ± 0.36. In our population patients were taking mycophenolate during a median of 24 months with a minimum of 6 and a maximum of 132.

In combination with mycophenolate 28% of the patients were taking corticoids, 21% hydroxychloroquine, 20% chloroquine, 17% antihypertensive drugs, 7% other medications and only 4% were taking the mycophenolate alone.

Conclusions: Despite of the absence of a license for mycophenolate for the management of Systemic Lupus Erythematosus, the use-off-label of this drug continues to be frequently as an alternative and effective treatment in patients with lupus nephritis and other conditions associated to SLE.

AB0454  CLINICAL AND IMMUNOLOGICAL ACTIVITY IN POLISH COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS TREATED WITH GLUCOCORTICOIDS

K. Pawlak-Bus, P. Leszcynski. Department of Rheumatology and Rehabilitation, University of Medical Sciences, Poznan, Poland

Background: Nowadays the lupus treatment strategy is based on background therapy, immunosuppressive drugs and glucocorticoids (GC). Using minimal effective dose of GC only in flares is a recomandation for preventing complications which increase mortality.

Objectives: To evaluate SLE clinical and immunological activity in lupus patients during the standard clinical care and analyze GC treatment

Methods: We observed Polish cohort of patients with SLE 127 patients (118 female and 9 male) with average age 43±6 years, average disease duration 7,8±5,6 years. All of them were treated with oral and pulse GC and standard immunosuppressive therapies (CTX, MMF, AZT,MTX, CsA). As a background therapy 77% of these patients were on chloroquine or hydroxychloroquine. All patients were assessed according to Systemic Lupus Erythematosus Disease Activity Index assessed by SLEDAI (version 2000) and divided into 5 groups: no GC, low dose, medium dose, high dose and puls GC group. Immunological activity was assessed by anti-dsDNA and C3 and C4 complements levels.

Results: In analyzed group 28 of patients without GC the average SLEDAI score was 7 and 50% of this pts not revealed any immunological activity. Low dose of GC was used in 50 pts with average SLEDAI score 13 and in 24 pts of this group anti-dsDNA and C3 or C4 levels upper limit were not observed. Medium dose of GC was used in 20 pts with average SLEDAI score 19 and it was contained with high immunological activity in 55% (n=11) of pts. In 27 of pts, high doses of GC including puls therapy were needed, the average SLEDAI score was very high 30 and most of pts from this group 70% were immunologically active.

Conclusions: In this Polish cohort lupus patients GC doses depended on lupus activity. Minimazing glucocorticoid exposure is an important part of appropriate management of lupus patients. Proper assessment of clinical and immunological lupus activity is critically for treatment decisions, especially for long-term GC use.

AB0455  SURVIVAL OF PREDNISONE-FREE REMISSION IN SLE PATIENTS WITH SEROLOGICALLY ACTIVE CLINICAL QUIESCENT DISEASE

L. Naiotto, F. Ormetto, M. Zen, L. Iaccarino, M. Gatto, M. Larossa, A. Doria. Department of Medicine, Rheumatology Unit, University of Padova (Italy); Padova, Italy

Objectives: To evaluate survival of prednison (PDM) – free remission in systemic lupus erythematosus (SLE) patients and to investigate the potential predictors of disease flares.

Methods: Inclusion criteria were: (1) Diagnosis of SLE according to American College of Rheumatology (ACR) Classification Criteria of SLE; (2) Caucasian ethnicity; (3) Clinical remission (clinical SLEDAI-2K=0) at the time of PDM-withdrawal; (4) Stop of PDM treatment between 2010 and 2016; (5) At least two visits per year between January 2010 and April 2016.

Disease activity was assessed according to SLE Disease Activity Index-2000 (SLEDAI-2K). Damage was measured by the SLICC/ACR Disease Damage Index (SDI) – score >3, positive anti-dsDNA antibodies (abs) and-or low C3/C4, type of SLE-involvement and concomitant immunosuppressive treatment could be predictors of flare. Multivariate logistic regression analysis was run to investigate the predictors of flare. Covariates included in the analysis were all variables reaching p<0.20 in the univariate analyses.

Results: Among 400 patients evaluated, 104 (26%) fulfilled inclusion criteria. Baseline characteristics are reported in table 1. Twenty-two (21.2%) patients flared. Mean time to flare was 19.9±13.14 months. Types of flare were 7 renal, 7 articular, 4 cutaneous, 2 haematological, 1 serositis and 1 neurological. Variables included in the multivariate logistic regression analysis were: positive anti-dsDNA abs and-or low C3/C4, skin, articular and haematological involvement. Skin involvement resulted predictive of flare (OR 3.07, 95% CI 1.11-8.53, P 0.031) as reported in table 2.

AB0456  SAFETY AND RETENTION RATE OF BELIMUMAB: DATA FROM A MULTICENTRIC ITALIAN STUDY

L. Iaccarino1, M. Larossa1, L. Andreoli2, E. Bartoloni-Bocci3, A. Bortoluzzi4, F. Ceccarelli5, F. Conti5, R. De Angelis6, G. De Marchi7, S. De Vita7, A. Doria1.

1University of Padova, PADOVA; 2University of Brescia, BRESCIA; 3University of Perugia, PERUIGA; 4University of Ferrara, FERRARA; 5University la Sapienza, ROMA; 6University of Ancona, ANCONA; 7University of Udine, UDINE; 8University of Firenze, Firenze; 9University of Milano, MILANO; 10University of Pisa, PISA; 11University of Reggio Emilia, Reggio Emilia, Italy

Background: Belimumab is used in the treatment of systemic lupus erethmatosus (SLE), but few data on its safety in daily clinical practice are available to date.

Objectives: To investigate safety, retention rate (RR), reasons and predictors of belimumab discontinuation in a prospective multicentric Italian study.

Methods: A total of 186 active SLE patients refractory to standard therapy were treated with belimumab as add-on-therapy in 11 Italian centers. Adverse events (AEs) were defined as “any untoward medical occurrence in a patient
treated with a pharmaceutical product which does not necessarily have a causal relationship with this treatment. AEs were subdivided into non-infectious, infectious, infusion and hypersensitivity reactions. Infusion and hypersensitivity reactions were defined as transient AEs related to belimumab occurring within 6 hours and 6–48 hours after drug administration, respectively. AEs were defined as severe (SAE) in case of hospitalization and/or death and/or life-threatening manifestations. Infections were considered severe in case of hospitalization and/or intravenous antibiotic use and/or death. Infusion and hypersensitivity reactions were considered severe when intensive care unit support was required. As baseline predictors of discontinuation the following variables were analyzed: gender, age, age at SLE onset, disease duration, disease activity pattern (relapsing remitting or chronic active), SLEDAI-2K ≥7.5 mg/day, concomitant immunosuppressant, antimalarial drug use, number and type of comorbidities, number of previous organ involvement, type of major involvement and number of flares in the 12 months before belimumab initiation. Data were analyzed using the SPSS (version 23.0, Chicago, IL) software.

**Results:** A total of 453 EAs were recorded in 132 patients after a mean follow-up period of 17.5±10.6 months (range 3–36): 443 (97.8%) were non severe and 10 (2.2%) SAEs (Table 1). No deaths and severe infusion/hypersensitivity reactions occurred. Belimumab discontinuation was observed in 58 patients (30.8%) after 10.4±7.5 months of follow-up (Table 2). RR was 91.5% at 6 months, 81.4% at 12 months, 72.9% at 18 months, 72.4% at 24 months, 69.7% at 30 months and 69.2% at 36 months. No associations were found between baseline variables and drug discontinuation.

**Table 1.** AEs observed in 132 patients with refractory SLE treated with belimumab

**AB0457**

LONG-TERM EFFECTIVENESS OF TREATMENTS FOR NEUROPSYCHIATRIC MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS

L.D. Fajardo Hermosillo, Rheumatology, IMSS, Guadalajara, Mexico

**Background:** Neuropsychiatric involvement of systemic lupus erythematosus (NPSLE) is one of the most deleterious complications of the disease, leading to great decrease of quality of life and poor prognosis [1]. Factors such as activity of disease have been associated NPSLE [1,2]. The current treatment of NPSLE remains mostly empiric, requiring high-dose corticosteroids and extensive immunosuppressive therapy [3,4]. Short-term efficacy of treatments in NPSLE have been evaluated by several studies, however few studies have been performed to evaluate long-term efficacy of these drugs [4].

**Objective:** To compare the long-term effectiveness among drugs and associated factors in the treatment of NPSLE.

**Methods:** 209 patients (>14 years) from a Mexican cohort from 2011 to 2017 were examined. SLE and NPSLE cases fulfilled 1997 ACR and 1999 ACR criteria respectively. Demographic factors, comorbidities and pharmacologic treatments were reviewed for patients with NPSLE. Variables were studied by bivariate, multivariate and survival analyses.

**Results:** Of 209 SLE patients, 37 (17.7%) had NPSLE; of them 32 were women. The mean age [standard deviation (SD)] was 38.8 (14.6) years. The mean of time at onset of SLE [SD] was 6.2 (5.4) years. SLEDAI and SLICC mean [SD] were 22.1 (10.2) and 1.83 (1.2) separately. Diffuse and focal manifestations of NPSLE were presented in 20 and 17 cases. Central and peripheral nervous system events of NPSLE were described in 34 and 3 of patients. The NPSLE manifestations more prevalent were cerebrovascular disease (n=15), psychosis (n=8) and seizure disorders (n=5). A total of 112 cycles of treatments were analyzed [prednisone (PDN) n=30, intravenous (iv) methylprednisolone (MTP) n=23, iv cyclophosphamide (CYC) n=13, azathioprine (AZA) n=12, mycophenolate mofetil (MMF) n=11, rituximab (RTX) n=10, hydroxychloroquine (HCQ) n=9, plasmapheresis (PPH) n=2 and iv immunoglobulin (IVIg) n=2]. Cognitive dysfunction was more associated to higher SLE activity, damage and mortality. Also, psychosis was more associated to receive higher doses of oral PDN or iv MTP to employ iv CYC and to be linked with renal SLE disease activity. On the other hand, central vascular disease was more associated to receive HCQ and to have antiphospholipid antibodies. The main cause to therapy discontinuation was inefficacy and was more common in patients treated with iv CYC. Corticosteroids survival in months was higher in-group PDN <15 mgid (97.89±16.4; IC95% 65.8–130). AZA survival in months (90±30.8; IC95% 29.6–150) was higher than others treatments for NPSLE and was more associated to use (IV Ig OR 10.8, 95% CI 1.04–111, p=0.04). When the first therapy was failed, the drug as second therapy used with higher survival in months was MMF (100±56.5; IC95% 1.6–218).

**Conclusions:** This study suggests that patients with diffuse manifestations and central nervous system involvement in NPSLE presented more activity, damage and mortality and therefore used more PDN, MTP and CYC. Among the treatments as first therapy for NPSLE with the better long-term efficacy was AZA and when it failed, MMF remained as better second therapy.

B CELLS DEPLETION FOR THE TREATMENT OF SYSTEMIC AUTOIMMUNE DISEASES

M.L. Velloso Feijoo, S. Rodriguez Montero, N. Plaza Aulestia, J.L. Marenco de la Fuente. Rheumatology Unit, Valme University Hospital, Seville, Spain

**Background:** Systemic autoimmune diseases (SAD) have traditionally been treated with steroids and immunosuppressants, but not all patients respond to these measures. Rituximab (RTX) has been used in several SAD with favorable results, but there are only a few reports of isolated clinical experiences, with a very small number of patients. Data about use of this drug under conditions of daily clinical practice may be relevant.

**Objective:** To describe the characteristics of patients with SAD who are candidates for treatment with RTX.

**Methods:** Demographic data, SAD disease, treatment and response variables were included. We use the EULAR definitions of partial response (improvement of at least 50% of the main manifestations of the disease) and complete response ( disappearance of the manifestations of the disease), because of the heterogeneity of the SAD and their multiple manifestations.

**Results:** We included 53 patients, 90.6% were women. The mean age at diagnosis was 31.42±14.33 years; and the median duration of disease at the onset of RTX 1.99 (0–7.5) years. Patients received a median of 2 cycles (1–3 min
Conclusions: In our study, patients treated with RTX achieved response in 88.7%, similar to some experiences of RTX off-label use. Remission of the disease occurs in 50% of the patients. The best results are observed in SLE, especially in lupus nephritis, and Sjögren disease. The results in SS are promising due to the limited therapeutic resources for this disease.

AB0459 TREATMENT OF SYSTEMIC AUTOIMMUNE DISEASES WITH RITUXIMAB: SAFETY DATA
M.L. Velloso Feijoo, N. Plaza Auletia, S. Rodríguez Montero, J.L. Mareno de la Fuente. Rheumatology Unit, Valme University Hospital, Seville, Spain
Background: Systemic autoimmune diseases (SAD) have traditionally been treated with steroids and immunosuppressants, but not all patients respond to this strategy. Rituximab (RTX) has been used in several SAD with favorable efficacy and safety results; there are only reports of isolated clinical experiences of small series of patients. The description of this drug safety data in daily clinical practice may be relevant.

Objectives: To describe the adverse events and the hospital admissions during the treatment of a series of patients with SAD with RTX.

Methods: Demographic data, related to disease and treatment, response and safety variables were included. We use the EULAR definitions of partial response (improvement of at least 50% of the main manifestations) and complete response (disappearance of the manifestations), because of the heterogeneity of the SAD.

Results: We included 53 patients, 90.6% were women; the mean age at diagnosis was 31.42±14.33 years, and the median duration of disease at the onset of RTX 1.99 (0–7.5) years. Patients received a median of 2 cycles (1–3; min -1, max 12); and the median interval between cycles was 14.81 months (6–15.75; min 6, max 120).

The SAD were SLE with 23 cases (43.4%), systemic sclerosis with 7 cases (13.2%), Sjögren’s syndrome with 6 cases (11.3%), vasculitis with 5 cases (9.4%), Still disease with 3 cases (5.7%), autoimmune cytopanies with 3 cases (5.7%), dermatomyositis with 2 cases (3.8%), Behcet’s disease with 2 cases (3.8%) IgG4 disease with 1 (1.9%) case and sarcoidosis with 1 case (1.9%).

A partial response was observed in 27 patients (50.9%) and complete in 20 patients (37.7%). There was no response in 6 of the 53 patients (11.3%). The response by disease groups is detailed in Table 1.

</tbody>
</table>

Conclusions: The most frequent adverse event were the infectious, mainly respiratory tract infections followed by an infusion reaction. No patient developed opportunistic diseases. This findings are similar than observed in other studies on patients with SAD treated with RTX. Infusion reactions are becoming less frequent, due in part to premedication.

We are dealing with a large number of patients with refractory EAS treated with RTX, so the data obtained from this study show an acceptable safety profile.

AB0460 USE OF INTRAVENOUS IMMUNOGLOBULIN (IVIG) IN AUTOIMMUNE RHEUMATIC DISEASES: EXPERIENCE IN A THIRD LEVEL MEDICAL CENTER
M. Pérez Crisóstom1,2, R. Ríchar Rocha1, G. Horta Baas1, L. Barile Fabris1, M. Portela Hernández1,2, Rheumatology;1 Iimss, Mexico City, Mexico
Background: IVIG therapy in rheumatology has been used as an alternative treatment for patients with refractory, severe disease, or with contraindication to the use of conventional immunosuppressive therapy as serious infections. It has recently been increased its use to treat multiple autoimmune diseases, however with a limited number of precise indications as there are not enough studies to increase the level of evidence for the administration of IVIG

Objectives: To describe the experience gained with the use of IVIG in autoimmune rheumatic diseases in a third level medical center

Methods: This is an observational, descriptive and retrospective study. We report the use of IVIG in our clinical practice, efficacy and adverse effects. We included consecutive patients with autoimmune rheumatic diseases that received IVIG between 2012 and 2015. The information was extracted from clinical records.

Results: We included 35 patients: 19 women, 16 men, 18 with systemic lupus erythematosus (SLE), 15 with autoimmune inflammatory myopathy, 1 with primary Sjögren’s syndrome (SSp) and 1 with polyarteritis nodosa (PAN).

The most common indication was active disease associated with severe infection that contraindicated the use of immunosuppressants in 24 patients and in 11 patients refractory activity disease to conventional therapy. The most frequent indications in patients with SLE were: 6 thrombocytopenias, 5 lupus nephritis, 4 pulmonary hemorrhage and 3 neuropathies; of the group of inflammatory myopathy the indications were: 6 dysphagia, 5 respiratory insufficiency and 4 refractory myopathy. In patients with SSS and PAN the indication was peripheral neuropathy. The mean number of IVIG applications was 3.3 (range 1–15). Activity scales were decreased in all patients with IVIG: mean SLEDAI at baseline 15.6 and in the follow up 4.5; in inflammatory myopathies remission was reached in 86% of the cases. The steroid dose was significantly reduced in most patients in the follow up. Four patients had adverse effects associated with IVIG: 2 with tachycardia and hypertension, one with acute pulmonary edema and one with hemolytic anemia.

Conclusions: In our experience, IVIG administration was effective in controlling the activity of the autoimmune rheumatic disease, mainly in patients with concomitant infection, and with a good safety profile.

Discussion: IVIG was an effective alternative treatment in patients with contraindication of conventional treatment or in refractory disease, however it is a high cost treatment and should be used in well selected cases.

AB0461 BENEFITS OF VITAMIN D IN SLE DEPEND ON THE ORGAN SYSTEM
M. Petri1, L.S. Magder2, 1Johns Hopkins University School of Medicine; 2Biostatistics, University of Maryland, Baltimore, United States
Background: Low 25-OH Vitamin D is associated with SLE. Both a randomized clinical trial and a longitudinal cohort study proved that supplementation reduced SLE disease activity.

Objectives: We examined whether Vitamin D benefits in SLE are dependent on the organ system.

Methods: Vitamin D and SLEDAI components were measured at each cohort visit starting in 2010 and 16,519 visits of 1,345 different patients were included. The patients were 92% female, 50% Caucasian, 41% African American. Organ-specific disease activity was defined as a set of binary variables based on SLEDAI. If the patient received any score for any component, then the patient was defined as having that type of activity.

Interestingly, after adjustment for repeated measures and covariates, the relationship between vitamin D and immunologic disease activity totally disappeared.
Vitamin D supplementation significantly reduces therapeutic plasma exchange (TPE) for refractory SLE. Vitamin D supplementation (in those whose level is below 40 ng/mL) has a significant benefit on total cholesterol that is independent of age, sex, ethnicity, Plaquenil, prednisone and body mass index. Vitamin D supplementation - as it also helps systolic blood pressure - is both important for SLE activity and for reduction of cardiovascular disease.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.1647

AB0463 THERAPEUTIC PLASMA EXCHANGE (TPE) FOR REFRACTORY SLE: A COMPARISON OF OUTCOMES BETWEEN DIFFERENT SUB-PHENOTYPES?

A. Soyouz1, Q. Karadas2, L. Kilic3, T. Karagaç Akyol2, S. Aparas Bilgen4, O.I. Ozcebe5, 1Department of Internal Medicine; 2Department of Internal Medicine, Division of Rheumatology, Hacettepe University Faculty of Medicine; 3Blood and Apheresis Unit, Hacettepe University Hospitals; 4Department of Internal Medicine, Division of Haematology, Hacettepe University Faculty of Medicine, Ankara, Turkey.

Background: Therapeutic plasma exchange (TPE) offers an alternative therapeutic modality for patients with systemic lupus erythematosus (SLE) and primary antiphospholipid syndrome (APS). However, there is conflicting evidence regarding its efficacy in different sub-phenotypes.

Objectives: This study aims to investigate the main clinical characteristics and outcomes of patients with different phenotypes of SLE and APS treated with TPE at a tertiary care centre.

Methods: Database of Blood and Apheresis Unit between 2001–2013 was screened for patients with SLE and primary APS. SLE disease activity index (SELENA-SLEDAI), the indications for treatment, complications and outcomes were obtained from review of medical records and phone calls. A total of 24 patients (SLE: 20, APS: 4) were recruited for the study.

Results:

- Mean ages of SLE (M/F: 1/19) and primary APS (M/F: 2/2) were 32.4±12.89 and 52.0±10.7, respectively. The main indications for TPE were haematologic, neurologic, pulmonary involvement and APS-related. TPE was preferred in 8 patients because of leucopenia, and co-infection. SLEDAI was significantly decreased after TPE (16.7±8.3 vs. 8.8±3.1; \(p=0.001\)). Both primary APS and SLE related CAPS patients had completely responded to TPE. Success rate of TPE in patients with thrombotic complications were lower than those with haemolytic anaemia. Median (IQR 25%-75%) TPE sessions were 6.5 (5.10-6).

Conclusions: This study suggests catastrophic antiphospholipid syndrome (CAPS) and other APS related problems respond well to the TPE treatment. TPE should be kept in mind for the treatment of patients with other features of SLE, especially those resistant to other agents and in the presence of leucopenia and psychosis

AB0462 VITAMIN D SUPPLEMENTATION SIGNIFICANTLY REDUCES CHOLESTEROL IN SLE

M. Petri1, L.S. Magder2, 1Johns Hopkins University School of Medicine; 2University of Maryland, Baltimore, United States

Background: The benefit of vitamin D on SLE global and renal activity have now been proven by both cohort studies and a clinical trial. The benefits on cardiovascular risk factors, however, are less well understood.

Objectives: We present the first longitudinal study on hyperlipidemia.

Methods: A within-person analysis assessed the question is: "When a person has a vitamin D level lower than his/her average, are they more likely to have renal disease activity?" Note, this analysis implicitly adjusts for race, sex, and all variables (measured and unmeasured) that are invariant within a person. The results are shown in Table 2.

Table 2. Within-person analysis of the relationship between vitamin D levels and renal activity adjusting for prednisone use, plaquenil use, and implicitly for all time-invariant characteristics

<table>
<thead>
<tr>
<th>Vitamin D Level (ng/mL)</th>
<th>Immunologic Disease</th>

<td>0.080</td>
<td></td>
</tr>
</tbody>
</table>

For Renal, it appears (based on the within-person analysis), that increasing vitamin D results in a reduction in renal activity. Based on other analyses, it is clear this drop was mostly among those in the vitamin D deficiency range.

Conclusions: Low vitamin D is associated with cutaneous and renal SLE activity, vitamin D results in a reduction in renal activity. Based on other analyses, it is shown in Table 2.

Table 1. Difference in Cholesterol at each visit per 10 ng/mL difference in between the patient's average cholesterol as a function of differences in a patient's vitamin D at that visit and the patient's average vitamin D.

<table>
<thead>
<tr>
<th>Vitamin D Level (ng/mL)</th>
<th>Odds Ratio</th>
<th>P-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 ng/mL or more than personal average</td>
<td>1.5 (1.3, 1.8)</td>
<td>&lt;0.0001</td>

</tr>
</tbody>
</table>

This means that at a particular clinic visit, if a person's vitamin D is higher than the person's mean vitamin D by 10 ng/mL and the person has vitamin D below 40 ng/mL, then the expected cholesterol will decrease by 3.4 mg/dL. There is no significant effect of higher vitamin D among those whose mean vitamin D exceeds 50.

Conclusions: Vitamin D supplementation (in those whose level is below 40 ng/mL) has a significant benefit on total cholesterol that is independent of age, sex, ethnicity, Plaquenil, prednisone and body mass index. Vitamin D supplementation - as it also helps systolic blood pressure - is both important for SLE activity and for reduction of cardiovascular disease.

AB0464 AZATHIOPRINE METABOLITES IN CONNECTIVE TISSUE DISEASE

P. Pentony, T.Y.E. Tsai. Rheumatology, the Canberra Hospital, Canberra, Australia

Background: Azathioprine (AZA) is a common treatment for connective tissue diseases (CTD). AZA is a pro-drug which is metabolised to active moieties of
ASSOCIATION BETWEEN SAFETY, EFFICACY AND 6-thioguanine (6-TGN) and 6-methylmercaptopurine (6-MMP). These metabolites, rather than the absolute dose of AZA, are associated with clinical efficacy and toxicity. An idiosyncratic skewed metabolism towards 6-MMP in some patients ("shunters") increases the risk of hepatotoxicity and treatment failure. Allopurinol can correct such shunts.1 Therapeutic protocols using metabolite concentrations have been shown to be more effective, improve efficacy, and decrease treatment morbidity in IBD.1 Only one small study estimated a therapeutic 6-TGN level for SLE patients.2 There are scant data on AZA shunters in connective tissue disease.3

**Objectives:** Explore the proportion of AZA therapeutic failure, toxicity, and shunters in CTD patient populations.

**Methods:** Retrospective, multicentre audit of AZA metabolite levels in CTD patients from 2012–2016. Patient demographics, treatments, disease activity and drug toxicity were also extracted.

**Results:** 61 testing episodes occurred in 34 patients whose mean age was 55 (32–79) years; predominantly female (N=26, 77%), with SLE (N=19, 56%). Active disease was present in 15/61 (25%) episodes. 20/34 (60%) patients were on HCQ + AZA. 25/34 (76%) of patients were either on no or minimal AZA dose. 6-MMP shunters had significantly lower median 6-TGN levels compared with appropriate and overdosed (17% and 31%) disease (44% & 31%), compared with appropriate and overdosed (17% and 19% p<0.24). Surprisingly, patients who were overdosed by 6TGN levels had the lowest mean AZA dose. AZA metabolites can identify the multiple causes for therapeutic failure (underdosing, shunting, or true non-response), and enable early detection of shunters to avoid liver toxicity.

**AB0465 ASSOCIATION BETWEEN SAFETY, EFFICACY AND HYDROXYCHLOROQUINE DOSAGE IN THE TREATMENT OF CUTANEOUS LUPUS ERYTHEMATOSUS AND SYSTEMIC LUPUS ERYTHEMATOSUS**

R. Wakya, T. Kameda, M. Izumikawa, S. Nakashima, H. Shimada, H. Ozaki, A. Kondo, N. Kadowaki, H. Dobashi. Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Kagawa University, Kagawa, Japan

**Background:** Hydroxychloroquine (HCQ) are considered to be effective against cutaneous lupus erythematosus (CLE) and symptoms associated with systemic lupus erythematosus (SLE) such as rashes, joint pain, and fatigue. In a randomized, controlled trial in stable active patients with SLE on HCQ treatment, those who achieved blood HCQ levels greater than or equal to 1000ng/ml had a tendency for reduced SLE flares during a 7 month period [1]. To prevent ocular toxicity, HCQ should be maintained at a dose of 6.5mg/kg or less for ideal body weight [2], however, optimal HCQ dosage is unclear.

**Objectives:** To extract the problem of the dosage based on ideal body weight and identify safer and more effective HCQ dosage.

**Methods:** We enrolled patients who took HCQ for SLE or CLE more than 3 months in our institute and 2 related facilities from September 2015. We used Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI) to evaluate cutaneous symptoms and evaluated effect at start of administration and 3 months of that. The attending doctors assessed the adverse events (AEs). We investigated the change of serum biomarker, such as the value of serum complement and anti-ds-DNA body, the number of white blood cells, lymphocytes and platelets.

**Results:** We enrolled the 30 patients with administration of HCQ more than 3 months and in CLE were 2 cases, in SLE were 28 cases. In 21 cases HCQ dosage were based on ideal weight. The AEs were in 13/30 cases (43.3%). The AEs were the new cutaneous symptoms in 5 cases, eye manifestation in 3 cases (abnormal visual field in 2 cases, color anomaly in 1 case), diarrhea in 2 cases, fever in 2 cases, feeling of fatigue in 2 cases, renal dysfunction in 1 case, muscular pain in 1 case, and pericarditis in 1 case. The eye manifestation in the 3 cases disappeared for a few days by stopping or reducing HCC dosage. Although we needed glucocorticoid treatment for pericarditis, the other AEs improved by reducing HCC dosage or stopping. The AEs of taking HCC 200mg/day were in 6 cases, 200mg and 400mg alternatively on every other day in 6 cases, and 400mg/day in 1 case. The AEs of taking HCQ based on ideal body weight were in 10/21 cases (47.6%) and by minimal dosage in 3/9 cases (33.3%). 22/28 cases (78.6%) significant improved cutaneous symptoms (amount of mean change of CLASI -4.57, p=0.024). There is no difference in the efficacy of cutaneous symptoms between group received HCC based on ideal body weight (80.0%) and the others (92.3%). 5/21 cases of HCQ based on ideal body weight were made to reduce HCC dosage due to AEs, but all 5 cases improved cutaneous symptoms. 53.3% (16/30) cases increased complement, but other biomarkers didn’t change.

**Conclusions:** HCQ was effective for the treatment of CLE even when HCC dosage was reduced due to AEs. These findings suggest that low-dose HCC is also effective and safe, and HCQ initial dosage wasn’t the need to adjust for ideal body weight.

**AB0466 THE EFFECT OF OMEGA-3 FATTY ACIDS ON DISEASE ACTIVITY, ENDOTHELIAL FUNCTION, INFLAMMATORY MARKERS, AND LIPID PROFILE IN SYSTEMIC LUPUS ERYTHEMATOSUS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED, CONTROLLED TRIALS**

R. Castillo1, P.P. Uy1, D.M. Francisco1, S. Lakshminarayanan2. 1Internal Medicine, 2Rheumatology, University of Connecticut, Farmington, United States

**Background:** Omega-3 fatty acids have been shown to have potentially beneficial immunomodulatory activity in autoimmune conditions such as rheumatoid arthritis and Sjogren’s syndrome. Whether this extends to systemic lupus erythematosus (SLE) remains unclear.

**Objectives:** We undertook this study to summarize the body of evidence available from published clinical trials on the effectiveness of omega-3 fatty acids on clinical and/or laboratory outcomes in SLE.

**Methods:** Two independent reviewers systematically searched PubMed, MEDLINE, Scopus, and the reference lists of related articles for studies published from inception to November 2016 using relevant keywords. Randomized, controlled trials (RCTs) on SLE patients comparing omega-3 fatty acids with placebo were included in the analysis. The quality of the included RCTs was assessed in accordance with the Cochrane Handbook. A random effects model was used to pool extracted data. Heterogeneity was evaluated with Chi2 test and I2, with p-values <0.05 considered significant. Data presented in median and interquartile range were converted to mean and standard deviation using the method described by Wan et al.

**Results:** A total of seven clinical trials consisting of 303 subjects with a duration of treatment ranging from 12 to 52 weeks were included. In studies using SLAM-R as the measurement of disease activity (n=82), there was a statistically significant mean score reduction in the omega-3 fatty acid group vs. the placebo group at 24 weeks. However, in studies that used mean change in SELENA-SLEDAI (n=117, WMD -0.87, 95% CI: -1.16, 0.24, I 2=85%, p=0.20) scores, there was no significant effect of omega-3 fatty acids on disease activity. In studies using PGA (n=117, WMD -0.46, 95% CI: -1.16, 0.24, I 2=85%, p=0.20) scores, there was no significant effect of omega-3 fatty acids on disease activity. In studies using PGA (n=117, WMD -0.46, 95% CI: -1.16, 0.24, I 2=85%, p=0.20) scores, there was no significant effect of omega-3 fatty acids on disease activity. In studies using PGA (n=117, WMD -0.46, 95% CI: -1.16, 0.24, I 2=85%, p=0.20) scores, there was no significant effect of omega-3 fatty acids on disease activity.
any difference between the two groups (n=141, WMD: -0.01, 95% CI: -0.03, 0.01, I²=0%, p=0.26). The data on percent increase in flow-mediated dilation was conflicting. In terms of inflammatory markers, there were likewise no clear associations, with some studies reporting significant changes in ESR, CRP, IL-12, and IL-13 levels which were not observed in others. With regards to lipid profile, treatment with omega-3 fatty acids has been associated with a non-significant trend toward increase in all lipid profile parameters at 12 weeks including HDL (WMD 6.83, 95% CI: -0.38, 17.33, I²=0%, p=0.06).

Conclusions: The limited data on the use of omega-3 fatty acids has not shown clear benefit in improving disease activity, endothelial function, inflammatory markers, or lipid profile in patients with SLE. Larger studies for longer durations using standardized scales for measuring outcomes are needed.

AB0467 Efficacy and safety of assisted reproductive technologies (ART) in rheumatic patients: a multicenter study

P. Reggia 1, H. Sebbar 1, L. Andreoli 1, A. Hoxha 2, M. Larosa 3, F. Ceccarelli 4

1Rheumatology and Clinical Immunology, ASST Spedali Civili di Brescia, Brescia, Italy; 2Rheumatology Unit, Department of Medicine - DIMED, University of Padua, Padova, Italy; 3Internal Medicine and Medical Specialties Department, Policlinico Umberto I, "La Sapienza" University of Rome, Rome; 4Allergology and Clinical Immunology, U.O. Internal medicine, Ospedale San Raffaele, Milan; Italy

Background: Always more frequently rheumatic patients (pts) ask for Assisted Reproductive Technologies (ART) for infertility problems. The main concern is determined by the ovarian stimulation, associated with an increased risk of disease flare and thrombosis.

Objectives: To describe a case series of ART cycles in pts affected by rheumatic diseases, analyzing pregnancy rate and outcome, fetal-maternal complications and disease flares.

Methods: We included all the consecutive pts evaluated in the Pregnancy Clinic of 5 Italian Rheumatology Units after having performed ≥1 ART cycle from 1997 to 2016.

Results: We included 60 pts: infertility was primary (no previous spontaneous conception) in 68% of cases, idiopathic in 76.5%, of male origin in 8.3%, of female origin in 15%, mixed in 0.2%. One hundred and eleven ART cycles were performed: 135IUI, 44FIVET (Sertoli cell), 51GnRH, 131IORT (Sertoli cell), 45GnRH-Antagonist, 2GnRH-Agonist, 4gonadotropins only. Patients were divided in two groups according disease activity: with low disease activity, after spontaneous therapy discontinuation, No cases of thrombosis were reported. During puerperium: 1 (2.5%) post-partum hemorrage (no LMWH ongoing), 1 arterial flare (2.5%). Additional informations are available in Table 1.

Conclusions: We didn't found any good reasons to discourage ART performance in rheumatic pts: the safety seems to be high and the complications rate is in line with that reported in general population. An adequate prophylaxis during stimulation, pregnancy and puerperium seems to provide a good protection from thrombotic complications.

AB0468 Possible effects of belimumab therapy on T- and B-cell phenotype in a cohort of patients with systemic lupus erythematosus (SLE)

S. Piantoni 1, F. Reggia 1, M. Stresi 2, F. Dall’Ara 1, L. Andreoli 1, A. Tincan 1, P. Airò 1

1Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Brescia, Italy; 2Internal Medicine Unit, University of Brescia, Brescia; Italy

Background: B- and T-cell activation are one of the pathogenic mechanisms of systemic lupus erythematosus (SLE). After repeated antigen stimulation, T-cells undergo different modifications, leading to the differentiation into effector memory T-cells (CR7-CD45RA-) and highly experienced memory T-cells (CR7-CD45RA+). Similarly, down-modulation of CD28 may lead to the expansion of the CD28neg T-cells, a subpopulation with peculiar effector activities (1).

Methods: Phenotypic analysis of peripheral blood B and T lymphocytes was determined by the ovarian stimulation, associated with an increased risk of disease flare and thrombosis.

Objectives: To describe a case series of ART cycles in pts affected by rheumatic diseases, analyzing pregnancy rate and outcome, fetal-maternal complications and disease flares.

Methods: We included all the consecutive pts evaluated in the Pregnancy Clinic of 5 Italian Rheumatology Units after having performed ≥1 ART cycle from 1997 to 2016.

Results: We included 60 pts: infertility was primary (no previous spontaneous conception) in 68% of cases, idiopathic in 76.5%, of male origin in 8.3%, of female origin in 15%, mixed in 0.2%. One hundred and eleven ART cycles were performed: 135IUI, 44FIVET (Sertoli cell), 51GnRH, 131IORT (Sertoli cell), 45GnRH-Antagonist, 2GnRH-Agonist, 4gonadotropins only. Patients were divided in two groups according disease activity: with low disease activity, after spontaneous therapy discontinuation, No cases of thrombosis were reported. During puerperium: 1 (2.5%) post-partum hemorrage (no LMWH ongoing), 1 arterial flare (2.5%). Additional informations are available in Table 1.

Conclusions: We didn't found any good reasons to discourage ART performance in rheumatic pts: the safety seems to be high and the complications rate is in line with that reported in general population. An adequate prophylaxis during stimulation, pregnancy and puerperium seems to provide a good protection from thrombotic complications.

EVALUATION OF PILOCARPINE TREATMENT IN XEROSTOMIA BY PULSED Doppler COLOR ULTRASONOGRAPHY: ECHOPILO STUDY

T. Depino 1, A. Saraux 1, S. Boisrame 2, D. Cornec 1, J.O. Pers 3, T. Marhadour 1, D. Guellec 1, V. Devauchelle-Pensec 1, S. Jousse-Joulin 1, 1 Rheumatology, Cavale Blanche Hospital; 2 Odontology Department; 3 Immunology Department, Morvan Hospital, Brest, France

Background: The ultrasonography of salivary glands (USSG) has proved its utility in diagnosing and following primary Sjogren’s patient’s (pSS) (1,2). The evaluation of disease activity is still of interest and can be studied by assessing the inflammatory status of SG using US Doppler.

Objectives: To evaluate the vascularization of salivary glands, and particularly the parotid gland (PG) using Pulsed Doppler color ultrasonography (USSGPD) in patients complaining of xerostomia before and after treatment by pilocarpine.

Methods: We prospectively included patients with objective dry mouth syndrome (using salivary flow rate) at Brest University Hospital (DiapSS cohort). The vascularization was assessed by the resistive index (RI) at the left parotid. Only patients with pathological RI (r>0.8) were included in order to observe evolution after pilocarpine. USSGPD was carried out by the same operator. A dental consultation with measure of salivary flows before and after stimulation was performed. These examinations were performed at baseline and after 3 months of treatment with pilocarpine at 4 mg 3 times daily.

Results: Among the 19 patients included, 11 received pilocarpine treatment for the whole 3 months period, 6 of the 8 remaining patients stopped the pilocarpine due to side effects. Among the 11 patients with a follow-up evaluation at 3 months, 5 had pSS according to AECG criteria. The differences of RI before and after lemon stimulation were on average of -0.04 at baseline and -0.04 at M3. The sum of the four glands’ grades average of the four glands was 3.47 at M0 and 4.18 at M3. The non-stimulated salivary flow was on average of 1.96 mL/min at M0 and 5.81 mL/min at M3. None of these observed differences were statistically significant before and after 3 months of treatment by Pilocarpine. RI before and after lemon stimulation (p=0.953), the sum of the four glands’ grades (p=0.858), the non-stimulated (p=0.26) and stimulated salivary flow (p=0.139). Concerning the 3 patients with Sjogren’s syndrome, there were no differences using RI before and after treatment but the RI was lower in this subgroup compared to the xerostomia patients. The study was marked by a large number of pilocarpine’s discontinuation (31%) due to adverse effects.

Conclusions: Preliminary results showed no significant differences between the 4 gland’s grade, ultrasound’s RI and salivary non and stimulated flow before and after three months of pilocarpine’s treatment. The vascularisation of salivary glands in patients who continued to follow our treated patient with Sjogren’s syndrome or with xerostomia but more studies are needed to prove the interest of this procedure.

RESPONSIVENESS OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS AFTER RITUXIMAB TREATMENT: A SINGLE CENTER EXPERIENCE

Y.P. Tsao, C.Y. Tsai. Medicine, Taipei Veterans General Hospital, Division of Allergy, Immunology, Rheumatology (Air), Taipei, Taiwan, Province of China

Background: Systemic lupus erythematosus (SLE) is a complex disease with multi-organ presentations. Lupus nephritis, which results from autoantibody deposition at glomerulus, induces inflammation and damage. Lupus nephritis is also the leading cause of morbidity in SLE patient and associated with poor prognosis.

Objectives: To evaluate the treatment responsiveness of rituximab in patients with SLE.

Methods: Patients should fulfill the criteria of 1997 American College of Rheumatology classification criteria for SLE. Patients underwent chemotherapy, with severe lupus nephritis, under hemodialysis or after kidney transplantation were excluded. Total 37 patients were evaluated receiving rituximab infusion from 2009 to 2013. Clinical parameters were measured before and after rituximab usage.

Results: Among the 37 patients, the female patient was 89.2%. Mean age was 38.9±3.9 years old. The mean creatinine level remained during the 26 months of follow-up. In the beginning of the treatment, the mean creatinine level was 1.40mg/dl (SD 0.84). After 12, 24, 36 months of follow-up, the mean creatinine levels were 1.73mg/dl, 2.16mg/dl, and 2.40mg/dl, respectively (p=0.431, 0.148, 0.328). The mean proteinuria level was 3.51g/day initially (SD 2.52), but it rapidly decreased to 1.60g/dl after 6 months of follow-up (p<0.001), and further decreased to 1.40g/day, 1.12g/day, and 0.90g/day after 12, 24, 36 months of follow-up (p<0.001, 0.002, 0.012). The mean ds-DNA level was 216IU/ml in the starting of the treatment, and it decreased to 97.04IU/ml, 88.28IU/ml, 94.61IU/ml after 12, 24, 36 months of follow-up (p<0.002, 0.003, 0.05). The C3 level revealed elevation after 96 months of follow-up. The mean C3 level was 70.63mg/dl initially, and increased to 88.60mg/dl, 90.65mg/dl, and 96.20mg/dl after 12, 24, 36 months of follow-up (p<0.001, 0.002, 0.011). The platelet level remained similar from the beginning of the study to 36 months of follow-up (269.97K/cumm to 253.5K/cumm, p=0.929). The improvement of proteinuria was significant and could be detected in 6 months, which had significant correlations with the reduction level in 24 months (p<0.001). This suggested that early improvement of proteinuria may predict the further responsiveness.

Conclusions: Although the role of rituximab still remained controversial in the treatment systemic lupus erythematosus, it showed positive responses in our single center’s experience. Early response to rituximab was an important predictor of further sustained responsiveness and reduction of proteinuria and other clinical parameters.

SLE, Sjögren’s and APS - clinical aspects (other than treatment)

AB0471 WIDE HETEROGENEITY IN TREATMENT PROTOCOLS AND INAPPROPRIATE USE OF PREDNISOLONE FOR ANTI-RO/LA ASSOCIATED-CONGENITAL-HEART-BLOCK: A SYSTEMATIC REVIEW OF 492 CASES

A. Erden 1, L. Killic 1, E. Bilgin 1, A. Fanourakis 3, S. Ceylan 2, B. Hymabaccus 2, T. Z. Serfen 1, F. Gurler 1, A. Sari 1, B. Armanan 1, O. Karadag 1, S. Kiraz 1, D. Boumpas 3, U. Kalyoncu 1. 1 Department of Rheumatology; 2 Department of Internal Medicine, Hacettepe University Faculty of Medicine, Ankara, Turkey; 3 Rheumatology and Clinical Immunology, 4th Department of Internal Medicine, Attikon University Hospital, Athens, Greece

Background: Congenital heart block (CHB) risk is 1–2% in case of maternal anti SSA/Ro and/or anti SSB/La antibody positivity. CHB have significant mortality (20–30%) and available therapeutic options’ efficacy is contradictory.

Objectives: To systematically review and assess the treatment protocols and inappropriate use of prednisolone for antiphospholipid syndrome (APS) patients with associated congenital heart block (CHB) from a decade-period (2008–2018).

Methods: A comprehensive systematic review was performed using Medline, Embase, and Cochrane Library databases. A query of the literature was conducted using the keywords (antiphospholipid syndrome AND congenital heart block) AND (treatment OR management OR inappropriate use OR side effects OR mortality).

Results: A total of 492 cases of APS with CHB aged between 3 and 10 years were included. The majority of cases were female (68%). The most common CHB type was complete atrioventricular block (78%). The prevalence of anti-SSA/Ro/La antibodies was 84%. A total of 161 cases (32.8%) of CHB were found to have APS. The most frequent antiphospholipid antibody found was anti-SSA/Ro (87.7%). The treatment regimens varied widely across the included studies. The most common treatment approach was the combination of aspirin and warfarin (51%). Prednisolone was used in 66.3% of cases with a median cumulative dose of 656mg (range 12.5–10,000mg). The use of prednisolone was inappropriate in 22% of cases as it was used for antiphospholipid syndrome other than CHB. Moreover, 32 cases (6.5%) had side effects associated with prednisolone use. The mortality rate was 7.8% (38 cases).

Conclusions: The treatment of APS patients with CHB varies widely across the included studies. Prednisolone use was inappropriate in 22% of cases as it was used for APS other than CHB. The use of prednisolone was associated with side effects in 6.5% of cases. The mortality rate was 7.8% (38 cases).

AB0472 IMPACT OF DISEASE ON FAMILY AND SOCIAL LIFE IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

H. Babagül1, Ö. Varan2, S.C. Guven2, D. Teker2, H. Küçükg1, A. Tufan2, S. Haznedaroglu1, M.A. Öztürk1, B. Goker1.

Background: Systemic lupus erythematosus (SLE) is a chronic connective tissue disease with involvement of various organ systems and characteristically has a higher incidence in women than men. The disease, as well as its treatment, could have significant effects on the quality of life of lupus patients.

Objectives: Here, we aimed to investigate the impact of SLE on quality of the social and family life of women.

Methods: One hundred and twenty women diagnosed with SLE were included in the study. A questionnaire including questions about family and social relations were applied and demographic information, educational status, marital status, organizational involvement and treatment data were obtained. The results of this study are preliminary and the study is still ongoing.

Results: One hundred and twenty patients were studied. The average age was 37 (±10). 77 patients were married, 29 patients were single, 12 patients were divorced and 2 patients were widows. 29% of the patients were employed. 10.8% of the patients declared having difficulty in accepting their illnesses. 94.8% of the married patients had nuclear families. Relationship with partners and family problems, social activities, age and educational level.

Conclusions: There is no consensus in the treatment of CHB. Drug selection and dosing regimens have wide heterogeneity. More than half cases received no treatment. Of note, prednisolone has often been used, despite its inability to cross the placenta.

AB0474 THYROID DYSFUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS: ITS IMPACT AS A CARDIOVASCULAR RISK FACTOR

A. Mabrook1, M.I. Ab Elkareem2, M.M. Rayan, Rheumatology, Alazhr University, Assuit, Egypt

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease caused by immune system-mediated tissue damage. Thyroid function abnormalities and thyroid autoantibodies have been frequently described in patients with rheumatologic autoimmune diseases, such as SLE.

Objectives: The aim of this study was to assess thyroid function and anti-thyroid antibodies in SLE patients and evaluate the effects of the thyroid dysfunction on the clinical parameters, disease activity and assess its impact as a cardiovascular risk factor.

Methods: A total number of fifty SLE female patients were selected. Triglycerides (TG), total cholesterol (TC), LDL and high density lipoprotein (HDL), Thyroid Stimulating Hormone (TSH), serum free3T3 (FT3), freeT4 (FT4), Serum thyroid peroxidase antibodies (TPOab) and serum thyroglobulin antibodies (Tgab) were measured. Disease activity was evaluated by SLEDAI score.

Results: In our study, anti CCP antibodies were found in 8 (11.4%) of SLE patients and 4 (13.3%) SSc patients, while anti MCV antibodies were found in 14 (20%) SLE patients and 8 (26.7%) SSc patients. There is a significant association between presence of anti CCP Abs and anti MCV Abs and a clinically evident arthritis in both SLE and SSc. Strong relationship between high CRP level and a severe arthritis and joint erosions was noticed in SLE patients.

Conclusions: A significant radiological evidence in the form of synovial hypertrophy and bony erosions were found using ultrasonography and plain X-ray with seropositive anti CCP and anti MCV Abs in both SLE and SSc patients. In this study, anti CCP antibodies were found in 2 SLE patients and SSc disease activity score (Medsger score) for SSc patients.

AB0473 ANTI CCP AND ANTI MCV ANTIBODIES ARE MARKER OF ARTHRITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS & SCLERODERMA

A.M. Elsaeed1, S.A. ElBakry1, N.O. El-Azizi2, S.I. Ibrahim1, A. Abdelzaher1, N.M. Loffy3, F.M. Badr1, 3. Internal Medicine & Rheumatology: Clinical pathology, Facility of Medicine- Ain Shams University, Cairo, Egypt

Background: Anti-citrullinated protein antibodies (ACPA) have been reported as more specific serological markers of rheumatoid arthritis (RA). They provide a superior alternative to the rheumatoid factor (RF) test in laboratory diagnostics of RA. Different studies suggest that the enzymatic citrullination and the production of ACPAs may also be associated with other inflammatory arthritis-associated autoimmune diseases [2].

Objectives: To detect the presence of anti CCP and anti CMV antibodies in SLE & SSc and its correlation to radiological findings and disease activity.

Methods: Our study was included 70 SLE patients and 30 systemic sclerosis (SSc) patients diagnosed according to ACR classification criteria. After informed consent, all patients were subjected to detailed history taking, full clinical examination, including rheumatological examination, laboratory investigations: Included CBC, ESR, CRP with titur, urine analysis, renal & liver function, serum uric acid. Anti CCP antibodies & Anti MCV antibodies by ELISA. X-ray and US on both hands and knees and disease activity score using SLEDAI score for SLE patients and SSc disease activity score (Medsger score) for SSc patients.

Results: In our study, anti CCP antibodies were found in 8 (11.4%) of SLE patients and 4 (13.3%) SSc patients, while anti MCV antibodies were found in 14 (20%) SLE patients and 8 (26.7%) SSc patients. There is a significant association between presence of anti CCP Abs and anti MCV Abs and a clinically evident arthritis either in both SLE and SSc. Strong relationship between high CRP level and a severe arthritis and joint erosions was noticed in SLE patients.

Conclusions: Thyroid disorder is more common in lupus patients especially those in exacerbation and +ve for antithyroid Ab and those with thyroid dysfunction had increased cardiovascular risk. These patients should be investigated for Lipid profile echocardiography and neck US for detection of early atherosclerosis and other CVD those with thyroid dysfunction had increased cardiovascular risk.

Changes in heart rate variability reflect changes in clinical status and patient reported outcomes in systemic lupus erythematosus: a longitudinal analysis

A. Thanou1, S. Stavrakis2, J.C. Reynolds2, S. Kamp1, P. Kamp1, J.A. James1,2, J.T. Merrill1.

Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation; 2University of Oklahoma Health Sciences Center, Oklahoma City, United States

Background: We previously observed an association between systemic lupus erythematosus (SLE) disease activity and heart rate variability (HRV) with a preliminary observation of consistency between these two measures when disease activity changed between two timepoints (1).

Objectives: To prospectively test the hypothesis that HRV reflect longitudinal changes in clinical status and patient reported outcomes.

Methods: The current project evaluated HRV measurements using a 5 min ECG recording following a minimum of 2 visits in an ongoing clinical trial. HRV parameters were calculated in the time domain (RMSSD and pNN50) and the frequency domain [high frequency (HF) as well as low frequency to high frequency (LF/HF) ratio]. A mixed effects linear model, with generalized estimating equations to account for clustering of visits for each patient, was used to compare changes in HRV between paired visits and to examine linear associations between HRV parameters and clinical scores. All models were adjusted for baseline values of each HRV parameter.

Results: Forty nine patients (age 44.9±11.7, 46 female), followed in a total of 413 paired visits (median time between visits 1 month), were included. Global BILAG score was inversely associated with RMSSD (regression coefficient β=−1.39±0.01; p<0.0001). BILAG, SLEDAI and PGA were directly associated with the LF/HF ratio (β=−0.96±0.02; p<0.0001, 0.42±0.10; p<0.0001 and 0.83±0.09; p<0.0001, respectively). Changes in BILAG were inversely associated with changes in RMSSD and pNN50 (β=−7.0±1.9; p=0.003 and −1.6±0.04; p=0.001, respectively). BILAG changes were also directly associated with changes in the LF/HF ratio (β=0.78±0.05; p=0.001). Categorical improvement, defined as ≤1 letter grade improvement in BILAG and no new BILAG A or B scores, occurred in 77 (19%) visit pairs (group 1) and either no improvement or worsening in 335 (81%) group 2. RMSSD and HF increased in group 1 compared to group 2 (group difference=−33.3±10.1; p=0.001 and −39.9±4.1; p<0.0001, respectively), and the LF/HF ratio decreased in group 1 compared to group 2 (group difference=3.1±0.8; p<0.002). Changes in Physical Component Summary (PCS) of SF36v2 were inversely related to changes in SLEDAI and PGA (β=−0.39±0.14; p=0.006 and −0.19±0.02; p=0.001, respectively). Changes in Mental Component Summary (MCS) were inversely related to changes in BILAG, SLEDAI and PGA (β=−0.23±0.07; p=0.0001, −0.31±0.10; p=0.002 and −0.08±0.03; p=0.008, respectively). PCS was related to HF (β=0.67±0.02; p=0.001), whereas MCS was inversely related to the LF/HF ratio (β=−0.11±0.03; p=0.001). Changes in PCS were related to changes in pNN50 (β=−0.21±0.05; p<0.0001) and changes in MCS were related to changes in HF (β=1.57±0.18; p<0.0001).

Conclusions: Changes in HRV reflect changes in clinical status and patient reported outcomes in patients with SLE. These data suggest that HRV may be a simple non-invasive tool used to gauge or predict clinical improvement in SLE. Further studies are warranted.

AB0476 INNER EAR INVOLVEMENT IN SYSTEMIC RHEUMATIC DISEASES

G. Tsireves1, P.V. Vougir2, D. Archimandriti3, E. Pelechas2, D. Asimakopoulos1, A.A. Drossos1.

Ototorhinolaryngology Clinic; "Rheumatology Clinic, Department of Internal Medicine, "University of Ioannina, Ioannina, Greece

Background: Patients with systemic rheumatic diseases have increased prevalence of sensorineural hearing loss (SNHL). Detection of cochlin specific antibodies has been reported in patients with idiopathic sensorineural hearing loss. Interestingly, cochlin has been shown a stronger link to autoimmune hearing loss. In the present study, we evaluated the presence of antibody specific for cochlin in patients with systemic rheumatic diseases and to detect human cochlin antibodies in their sera.

Methods: This was a prospective study. Patients older than 18 year old who gave informed consent and fulfilled the criteria of American College of Rheumatology for rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), Sjogren's syndrome (SS) and systemic sclerosis (SSc) were included. Complete head and neck clinical examination was performed, including otoscopy, nasendoscopy and hearing examination with pure tone audiometry (250Hz -8000Hz). All medical treatments as well as Disease activity score (DAS) 28 for RA and SLE disease activity index (SLEDAI) for SLE were documented. An average tone loss was calculated, taking as a starting point the loss in dB at various frequencies according the American Committee on Hearing and Equilibrium Guidelines for Meniere's disease and also recommendation 02/1 of “Bureau International d'Audiophonologie” (BIAP). Blood samples of the patients were tested for the presence of IgG anti-cochline antibodies (COCH-IgG). The results were compared with disease of sex and age matched healthy subjects.

Results: We studied 133 patients (60 with RA, 41 with SLE, 24 with SS and 8 with SSc) and 133 healthy subjects.61.4% of patients reported vertigo, 41% hyperacusis, 39% hearing loss, 38% tinnitus, 37.9% headache and 2.1% tinnitus and hyperacusis. The prevalence of patients with unremarkable otoscopy was inversely associated in patients affected by RA, SLE, SS and SSc in comparison to healthy controls (66.6%, 31.71%, 54.17% and 75% respectively). The average hearing thresholds (AHT) calculated using BIAPI recommendation 02/1 were significantly increased in RA compared to SLE. AHT were also increased in patients with RA and secondary SS but without statistical significance compared to RA patients. There was a statistically significant correlation between AHT and DAS28 in RA. No correlation observed between AHT and SLEDAI. COCH-IgG were detected in two samples (one patient with RA and one with RA and SS).

Conclusions: Cochlin has been shown to have a stronger link to autoimmune hearing loss, but our study concerned correlation of hearing loss with human cochlin IgG (COCH). Additional prospective studies are needed to elucidate its pathogenesis.

AB0477 VITAMIN D STATUS, SYSTEMIC LUPUS ERYTHEMATOSUS ACTIVITY AND ENDOTHELIAL DYSFUNCTION

A. Caraba, V. Crisan.

Internal Medicine-Rheumatology, University of Medicine and Pharmacy “Victor Babes” Timisoara, Romania, Timisoara, Romania

Background: Systemic lupus erythematosus (SLE) is an autoimmune inflammatory disease, in which cardiovascular complications due to premature and accelerated athero-sclerosis represent a serious problem. Endothelial dysfunction is the first step in the atherosclerosis development. Low levels of vitamin D have a high prevalence in lupus patients, correlating with high prevalence of cardiovascular diseases in these patients.

Objectives: The aim of this study was represented by the assessment of endothelial dysfunction in patients with active systemic lupus erythematosus, and correlations of this with SLE activity and vitamin D status.

Methods: The study was performed on a group of 35 female patients with active systemic lupus erythematosus. In all the patients were assessed: SLE activity using SLEDAI (SLE Disease Activity Index), vitamin D status and endothelial dysfunction of patients with active disease.

Results: The mean age ± standard deviation was 33.8±8.55 years, and the average duration of SLE was 8.9±1±5.29 years. The assessed parameters had the following values: SLEDAI 9.02±4.51, vitamin D 12.79±2.45 ng/ml, FMD 9.26±2.34%, and 9 patients (25.71%) had vitamin D deficiency, and 31 patients had vitamin D insufficiency, and FMD 9.26±2.34%. There were significant correlations between vitamin D levels and FMD (r=0.4517, p=0.0003), and between vitamin D levels and SLEDAI (r = 0.6297, p=0.00025).

Conclusions: Low values of vitamin D levels were present in all the studied patients, correlating with the systemic lupus erythematosus activity, and endothelial dysfunction.

AB0478 COMPARATIVE STUDY BETWEEN PATIENTS WITH NORMAL AND OVERWEIGHT IN A COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS FROM ARGENTINA

Background: Systemic lupus erythematosus (SLE) have an increase cardiovascular risk, worsened by overweight and obesity. Increased BMI is associated with other severe complications and comorbidities as lupus nephritis, hypertension, insulin resistance and dyslipidemia. Body weight is a modifiable risk factor.

Objectives: To determine the frequency of overweight and obesity in patients with SLE and their impact on this disease

References:
OBJECTIVES: The aim of the research was to study the processes of formation of antibodies to the enzyme purine metabolism (PM) - xanthine oxidase (XO) and adenosine deaminase (ADA) - in patients with systemic lupus erythematosus (SLE) with laboratory indicators of secondary antiphospholipid syndrome (APS).

METHODS: 30 healthy people and 60 SLE patients with different clinical manifestations were included in this research. Antibodies to the investigated enzymes were determined in the procedure of an indirect ELISA-test using immobilized form of the corresponding enzyme as antigen array (We have developed this technique). The results of the detection of antibodies to the XO (anti-XO) and ADA were recorded on a spectrophotometer at a wavelength of 450 nm. b2-glycoprotein-I-dependent (b2GP-I) activity was assessed in patients with APS. The results of the detection of antibodies to ADA were classified as positive (OR: 0.78, IC 95%: 0.63–0.98) (p=0.03).

RESULTS: Antibodies to the enzyme PM may be a factor in the development and maintenance of vascular disorders in patients with SLE, and their detection can be used as an additional test in the complex diagnosis of SLE with symptoms of APS.

DISCLOSURE OF INTEREST: None declared.

AB0470 A FUNCTIONAL MAGNETIC RESONANCE IMAGING STUDY ON THE PSYCHOPATHOLOGY OF PATIENTS WITH PRIMARY SJOGREN'S SYNDROME AND ANXIETY DISORDER

B. Cui, Y. Liu. West China Hospital, Chengdu, China

BACKGROUND: Sjogren syndrome (SS) is a chronic systemic autoimmune disease characterized by exocrine gland inflammation and symptoms of oral and ocular dryness. Anxiety affects as many as 50–70% of persons living with SS. While anxiety is commonly experienced, very little is known concerning the mechanisms of cognitive dysfunction in SS.

OBJECTIVES: To reveal the psychopathology of patients with Sjogren's syndrome and anxiety disorder.

METHODS: 12 patients with pSS and anxiety disorder (SAS≥50), 11 patients with pSS, and 10 healthy controls were recruited. (1) Self-rating Anxiety Scale (SAS) was used to assess anxiety level of participations. All the subjects went through functional magnetic resonance imaging (fMRI) while listening actively to neutral words, negative words and negative words alternating with neutral ones.

RESULTS: When subjects listened to neutral words alternating with no words, perfrorental cortex and BA21 were active in patients with pSS and anxiety disorder. When subjects listened to negative words alternating with no words, patients showed increased activity in prefrontal cortex, BA21, anterior cingulate and fusiform. Furthermore, when subjects listen to negative words alternating with neutral words, patients with pSS and anxiety disorder showed more increased activity and accrual damage including chronic renal disease.

DISCLOSURE OF INTEREST: None declared.

DOI: 10.1136/annrheumdis-2017-eular.2766

AB0479 THE ROLE OF ANTIBODIES TO XANTHINE OXIDASE AND ADENOSINE DEAMINASE IN THE DEVELOPMENT OF ANTI-PHOSPHOLIPID SYNDROME IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

OBJECTIVES: The results of the detection of antibodies to the XO (anti-XO) and ADA were recorded on a spectrophotometer at a wavelength of 450 nm. b2-glycoprotein-I-dependent (b2GP-I) to the phospholipid antibodies (aPL) class IgM and IgG were determined by using a commercial test kit "Anti-Phospholipid Screen IgG/IgM" (O:tergentec). The levels of IgG aPL/IgM did not exceed 10 GPL/MPL-U/ml in the group of healthy individuals. The results of the detection of antibodies to ADA (anti-ADA) and antibodies to the ADC (anti-ADC) were recorded on a spectrophotometer at a wavelength of 450 nm. Determination of antibodies to the enzyme PM - xanthine oxidase (XO) and adenosine deaminase (ADA) in patients with systemic lupus erythematosus (SLE) with laboratory indicators of secondary antiphospholipid syndrome (APS).

RESULTS: Antibodies to the enzyme PM may be a factor in the development and maintenance of vascular disorders in patients with SLE, and their detection can be used as an additional test in the complex diagnosis of SLE with symptoms of APS.
activity in prefrontal cortex, anterior cingulate, and caudate nucleus than that of SLE patients with positive aPL were found to have MRI abnormalities, while MRI abnormalities were found in only 8 SLE patients with negative aPL (100% vs. 44.4%) (p=0.001). There was a statistically significant correlation between SLE disease activity and both NP manifestations and aPL antibodies also had a significant correlation with NP manifestations. MRI abnormalities included discrete white matter lesions (60%), cortical atrophy (25%) and gross infarctions (15%). MRA revealed atherosclerotic changes of one or more of the large intracranial vessels in (27.2%) of NPSL patients.

Conclusions: Elevation of PCSK9 was observed in patients with SLE and correlated with CRP but not atherogenic lipids, particularly in female patients. The result was indicative of pathogenic role of PCSK9 in the low-grade inflammation which promotes the atherogenic process in SLE patients.

AB0483 RESPONSIVENESS OF LUPUS IMPACT TRACKER AMONG CHINESE PATIENTS WITH LUPUS

C.C. Mok 1, J. Block 2, M. Jolly 2.
1Medicine, Tuen Mun Hospital, HK, Hong Kong; 2Medicine and Behavioral Sciences, Rush University Medical Center, Chicago, United States

Background: Lupus Impact Tracker (LIT), a 10 item, patient reported outcome tool for patients with systemic lupus erythematosus (SLE) has undergone psychometric validation and responsiveness studies in the US and Europe.

Objectives: To report results on responsiveness of Lupus Impact Tracker among Chinese patients with SLE.

Methods: 430 patients with SLE meeting the ACR classification criteria were recruited in Hong Kong, China at a single center. LIT scores from two visits one year apart were analyzed for responsiveness and Minimal Clinically Important

AB0482 ELEVATION OF SERUM PROPROTEIN CONVERTASE SUBTILISIN/KEXIN TYPE 9 (PCSK9) CONCENTRATIONS AND ITS CORRELATION WITH C-REACTIVE PROTEIN, BUT NOT AHEROTGENIC LIPIDS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Fang 1, L. Huang 2, T. Luo 2, X. Chen 2, L. Lin 1
1Rheumatology Department; 2Nuclear Medicine Department; 3Ultrasonic Cardiogram Department, Second affiliated hospital of Fujian Medical University, Quanzhou, China

Background: Patients with systemic lupus erythematosus (SLE) have a tendency of accelerated atherosclerosis with controversial benefits from statin. This phenomenon can only partly be explained by traditional risk factors for cardiovascular disease. Proprotein convertase subtilisin/kexin type 9 (PCSK9) is a serine protease associated with cardiovascular risk that not only regulates cholesterol metabolism, but acts as a critical regulator of inflammatory reaction. PCSK9 inhibitors were also highly promising drugs bringing added cardiovascular benefit when administered with statin [1] [2].

Objectives: The present study firstly aimed to compare serum PCSK9 levels in SLE patients and healthy controls. The association between PCSK9 concentrations with atherogenic lipids and C-reactive protein (CRP) in SLE patients was also analyzed.

Methods: 77 individuals encompassed; 47 patients with SLE and 30 age- and sex-matched controls. Serum PCSK9, lipoproteins concentrations and CRP levels were assessed in patients and controls. Individuals with history of smoking, diabetes, infection and statin and stool use were excluded.

Results: Serum PCSK9 levels were significantly elevated in patients with SLE, compared with healthy controls (p=0.034). PCSK9 positively correlated with serum levels of CRP (r=0.351, p=0.018); The tendency seemed more significant in female patients (r=0.487, p=0.001); No correlation with statistical significance between PCSK9 levels with disease activity (SLEDAI) or sipr fus parameters was found (p>0.05, all) (Table 1).

Table 1. Characteristics of patients and controls and correlational analysis of PCSK9 levels and disease parameters in SLE patients. Data are shown as number or median (interquartile range), respectively

Difference (MCID) against patient report and physician assessed anchors of changes in health. Two patient reported anchors were used (Global change in health and item 2 of Short Form 36 form). Physician assessed anchors of change in health were disease activity (Physician global assessment-PGA, SELENA-SLEDAI) and damage (SLICC-SDI/ACR). Change in PGA of ≥0.3 and SELENA-SLEDAI of ≥4 in either direction was used to define worsening in disease activity. Analysis of variance was used to compare changes in LIT score against the anchors.

Results: Mean (SD) age of participants was 42 (14) years. Ninety five percent (n=42) of patients have live birth with mean weight at birth of 2.558 g and 73% of patients according to gestational age.

AB0484 LUPUS NEHRITIS AND PREGNANCY: MATERNAL AND FETAL OUTCOME

PB. Alba1, C. Otaduy1, C.A. Gobbi1, A. Alvarez2, A. Albiero3, E.H. Albiero1, M.L. Propato2, M.A. Yorio1, 1Rheumatology, Córdoba State University; 2Rheumatology, Hospital Materno Neonatal; 3Rheumatology, Hospital Córdoba, Córdoba, Argentina

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease that primarily affects women during their reproductive years. The presence of Lupus nephritis (LN) may result in an increased risk of disease flare and adverse maternal and fetal outcomes, such as preeclampsia, fetal loss, and preterm delivery.

Objectives: The purpose of this work is to evaluate pregnancy outcome in SLE patients with previous diagnosis of LN.

Methods: We retrospectively studied SLE patients according to previous diagnosis of LN by renal biopsy who attended to Materno Neonatal Hospital during the last 5 years. We evaluated demographic, clinical, and laboratory and obstetric data. Renal biopsies were classified according ISN/RNP 2004. Lupus activity was evaluated by modified pregnancy SELENA SLEDAI score at the conception and during pregnancy. Maternal complications were evaluated: Preeclampsia, HELLP, Gestational Diabetes, Premature rupture of fetal membranes, arterial and venous thrombosis, mortality, the way of end of pregnancy, and others. Fetal outcome was evaluated as live birth, gestational age and weight at birth.

Results: 44 pregnancies in 32 patients were included. Maternal mean age was 30.75 years old, 84% were from Córdoba city, 70.5% did not have health insurance, and they have mean previous pregnancies of 4 with 1 live birth. Maternal complications were: Pre eclampsia in 12 patients (12.5%), Preterm delivery in 6 patients (6.25%), Premature rupture of fetal membranes in 9 (8.33%), Gestational Diabetes in 7 (7.29%), Arterial Thrombosis in 2 (2.08%), Venous thrombosis in 3 (3.12%), 33.69% have normal labour and 66.33% cesarean section. 86% of patients have live birth with mean gestational age of 36 weeks with mean weight at birth of 2.558 g and 73% of patients according to gestational age.

INCIDENCE OF VERTEBRAL FRACTURES: 8 YEARS FOLLOW-UP STUDY IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Mendoza Pinto 1,2, M.D.L.L. Leon Vazquez 3, A. Montiel Jarguin 4, H. Sandoval-Cruz 2, M.A. Buendia-Luca 1, M. Garcia-Carrasco 1,6, 1 Medicine School, BUAP; 2 Systemic Autoimmune Diseases Research, Hgr36-Cibior, IMSS; 3 Systemic Autoimmune Diseases Research, Hgr-36 Imss; 4 Hospital de Traumatología y Ortopedia, IMSS; 5 Radiology Unit, Hgr-36 Imss; 6 Systemic Autoimmune Disease Research Unit, Hgr36-Cibior, IMSS, Puebla, Mexico

Background: Vertebral fractures (VF) are the hallmark of bone fragility. Patients with systemic lupus erythematosus (SLE) are at high risk of developing prevalent VF. Although several risk factors for VF in patients with SLE have been suggested, there is limited longitudinal supporting data in the literature.

Objectives: The aims of this study are to determine the incidence of VF and to evaluate possible associations between potential risk factors and the occurrence of VF in women with SLE.

Methods: Consecutive patients with SLE were enrolled in a prospective, observational study from 2006 to 2015. Information on potential risk factors, including demographics, clinical data and bone mineral density (BMD) at the lumbar spine and hip on dual-energy X-ray absorptiometry was collected at baseline and follow-up. Semi-quantitative analysis was used to determine incident VF on lateral thoracic and lumbar radiographs, defined as any vertebral body graded normal at baseline and at least mildly deformed (20–25% reduction or more in any vertebral height) during follow-up. Differences in baseline characteristics were assessed in patients with and without radiographic VF.

Statistical analysis: The Chi-square or Fisher's exact test, independent samples t-test, and Mann-Whitney U-test were used as appropriate to compare baseline characteristics of patients with and without prevalent or incident VF. Possible risk factors for incident VF were assessed by multivariate logistic regression analysis.

Results: Of 110 SLE patients included, with a median follow-up of 8 (IQR 8–9) years, 22 (20%) had radiographic VF at baseline; 35 (32%) patients had a new VF. The annual incidence rate of new morphometric VF was 3.5 (95% CI 2.4–4.9) per 100 patient-years. Most fractures were located in the mid-thoracic and thoracolumbar region of the spine. Table 1 shows sociodemographic and clinical differences between patients with and without VF. In the multivariable analysis, VF were significantly associated with baseline BMD at the total hip and longer disease duration. Cumulative glucocorticoid dose, postmenopausal status and previous prevalent VF were not associated with VF.

Conclusions: In this SLE cohort in daily clinical practice, radiographic VF were frequently present in SLE patients, especially those with longer disease duration and low hip BMD.

NEUROLOGIC MANIFESTATIONS AND THEIR IMPACT ON CHRONIC DAMAGE IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME: RESULT FROM A MONOCENTRIC COHORT

M. Mazuil,1, D. Potarrieux2, I. Saulescu3, A. Borangi4, L. Groseau1, C. Constantinescu4, V. Vlad5, F. Berghera1, V. Bojncja1, D. Opris-Belinski1, A. Balanesca1, D. Predeteanu4, R. Ionescu1,2,1. “Stanta Maria” Clinical Hospital, Carol Davila University of Medicine, Bucharest, Romania; 2 “Stanta Maria” Clinical Hospital, Bucharest, Romania

Background: Antiphospholipid syndrome (APS) is an autoimmune disease with wide clinical features and cumulative damage. The nervous system involvement is very broad and severe.

Objectives: The aim of this study is to analyze the impact of neurologic manifestations on Damage Index in Patients with APS (DIAPS).

Methods: All consecutive patients known with APS were included in our monocentric cohort. Data on medical history, clinical manifestations, aPL profile and medication were collected. DIAPS score was used to measure damage in each patient.

Results: Seventy six patients with APS were included: 11 patients with primary APS and 66 patients with secondary APS, with mean disease duration of 9.59±7.39 years. Overall, 35 patients (46.1%) had neurologic manifestations. Their mean disease duration was 9.2±5.76 years. Seven patients had primary APS and 28 patients had secondary APS. Six patients were on chronic oral anticoagulant therapy and low dose aspirin, 12 patients on oral anticoagulant alone and 15 patients on low dose aspirin. Transient ischemic attack was the first manifestation of APS in 4 patients (11.42%) at mean age of 29.5±10.96 years. Their mean DIAPS value was 7.75±4.19. Ischemic stroke was the first manifestation of APS in 12 patients (34.29%) at mean age of 40.06±13.61 years, with DIAPS mean value of 7.41±3.67. All of these patients had neurologic sequelae. The DIAPS value was higher in patients with neurologic manifestations (3±2.9 vs 5.71±3.62, p<0.001) and DIAPS value correlated significantly to neurologic manifestations (R=0.416, p<0.000) reflecting its impact on cumulative damage in APS patients.

Conclusions: Neurologic manifestations in APS patients have a great impact on cumulative damage especially in patients presenting with ischemic stroke or transient ischemic attack as the first manifestation of APS.

CAPILLAROSCOPY FINDINGS IN CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS, A DUTCH EXPERIENCE OF 20 CHILDREN AND ADOLESCENTS

D. Schonenberg-Meinema 1, M. vd Berg 1, A. Nassar-Sheikh-Shaladi 1, G. de Bree 1, L. Hak 1, M. van Onna 1, K. Melsens 1, M. Cutolo 2, T. Kuijpers 1, 1 Department of Pediatric Hematology, Immunology, Rheumatology and Infectious Diseases; 2 Department of Clinical Immunology and Rheumatology, AMC Amsterdam, Amsterdam, Netherlands; 4 Department of Rheumatology; 5 Department of Internal Medicine, Ghent University Hospital, Ghent, Belgium; 6 Research Laboratory and Academic Unit of Clinical Rheumatology, University of Genova, Genova, Italy.

Background: Capillaroscopy findings can be qualitatively described as: normal, microangiopathy (non-specific abnormalities) or scleroderma pattern (1). Capillary abnormalities, described in varying prevalence in patients with systemic lupus erythematosus (SLE), are mainly described as microangiopathy (2–4)

Objectives: To describe capillary characteristics in a cross-sectional cohort of patients with childhood-onset SLE (cSLE) by quantitative and qualitative assessment

Methods: Nailfold videocapillaroscopy (NVC) was performed in cSLE-patients (onset ≤18 years) with a x200 magnification lens (Optika). The following capillaroscopic characteristics were evaluated per millimeter: density (compared to mean density known for age, sex and ethnicity) (5), number of abnormal shapes (as defined by the EULAR study group on microcirculation in Rheumatic Diseases (6)), giant capillaries (defined as apical diameter >50 mcm), maximum apical diameter (dilatations defined as apical diameter ≥50–500 mcm) and microbleedings large hemorrhages and small multiple point-shaped hemorrhages surrounding the capillary loop [image].

Results: 4063 capillaries from 20 patients with cSLE were analyzed. All patients showed capillary abnormalities, 15% (n=3) showed a scleroderma-pattern. A lower mean density (mean 6.7, range 1.9–9.5) was seen in 55% (n=11), multiple
The SLE-key® Rule-Out test performs well as an aid in the analysis of common gram-negative bacteria and hyperuricemia in premenopausal women with systemic lupus erythematosus and development of nephritis.

Conclusions: The diagnosis of patients referred in the clinical rheumatology setting remains an ongoing challenge. The SLE-key® RuleOut test provides a laboratory aid to improve the diagnostic and dispositional efficiency saving undue concern, time and resources both to the patient and to the healthcare system. A retrospective analysis of our practices prior to the introduction of SLE-key® is warranted.

The SLE-key® Rule-Out test performs well as an aid in clinical practice.

D. Massenburg, J. Oldenberg, A. Sei, T. Krause, A.F. Wells. Rheumatology and Immunotherapy Center, Franklin, WI, United States

Background: The SLE-key® test was developed by ImmunArray and was validated to rule out SLE with 94% sensitivity, 75% specificity and a negative predictive value (NPV) of 93%.1 We reported earlier that the SLE-key® RuleOut test could aid in the diagnosis and disposition of a cohort of 55 patients in our clinical practice.2

Objectives: We have now expanded this cohort and report here the usefulness of the SLE-key® test in adding the management of a cohort of challenging and suspected SLE patients in a large clinical practice.

Methods: In patients referred to the Rheumatology and Immunotherapy Center, Franklin, WI, results from the SLE-key® RuleOut test were included as part of the clinical evaluation. Serum samples were collected from individual subjects with informed consent and tested at VERACIS (Richmond, VA), using the SLE-key® (iChip®).

Results: We reviewed the diagnoses and clinical disposition of patients both before and after SLE-key® testing. In particular, we looked at the ability of the SLE-key® test to enhance our ability to reach a definitive diagnosis across the full cohort of patients, at the disposition of patients who were referred with a suspicion of SLE as part of the differential diagnosis, at the impact of SLE-key® testing on the diagnosis of the subset of patients who presented with minimal symptoms, and at the group of patients who had been referred following an ANA test. Results are summarized in Table 1. In the cases where SLE was ruled out, patients were treated for a variety of disorders including fibromyalgia, joint pain, MCTD, Sjogren’s disease and others.

AB0480 ANALYSIS OF COMMON GRAM-NEGATIVE BACTERIA AND THEIR DRUG RESISTANCE IN HOSPITALIZED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

D. Chen, Z. Zhan. Rheumatology, The first affiliated hospital of SUN YAT-SEN UNIVERSITY, Guangzhou, China

Background: Infection is an important cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE). The spectrum of infectious agents in SLE patients varies significantly among different ethnic groups. The national surveillance study from the China showed that Gram-negative bacteria (GNB) was the most common bacterial infection in China, while Gram-positive bacteria (GPB) was predominant in European countries.

Objectives: To identify the spectrum and drug resistant pattern of infection caused by GNB in patients hospitalized with SLE.

Methods: The clinical and microbiological data from hospitalized SLE patients with bacterial infection between June 2005 and June 2015 was collected and then analyzed retrospectively.

Results: Two hundred and sixty-eight episodes of bacteria had been identified from 3815 hospitalized patients. In terms of isolated microorganisms, gram-negative bacteria (GNB) were predominant over gram-positive bacteria (GPB) as 178 isolates vs. 90 isolates). In the GNB, Escherichia coli (66/178, 37.1%) was the most common isolate, followed by Acinetobacter baumannii (36/178, 20.2%), Klebsiella pneumoniae (24/178, 13.5%), Pseudomonas aeruginosa (20/178, 11.2%), Haemophilus influenzae (10/178, 5.6%), Salmonella sp. (7/178, 3.9%), Enterobacter aerogenes (5/178, 2.8%), Stenotrophomonas maltophilia (5/178, 2.8%), Citrobacter freundii (3/178, 1.7%), Proteus mirabilis (3/178, 1.7%).

Resistant isolates (53/178, 30.0%) were more common documented in GNB, mostly extended-spectrum beta-lactamase (ESBL) producing Escherichia coli (30/66, 45.5%) and Klebsiella pneumonia (6/24, 25%), and multi-drug resistant acinetobacter baumannii (39.1%). Susceptibility tests showed that the ESBL-producing strains were highly sensitive to carbapenems, β-lactamase inhibitor compound families, and certain cefalosporin (Cefepime and Cefazidime) in vitro. (the resistance rate ~20%), whereas it was highly resistant to ampicillin and Gentamicin. Besides carbapenems and Cefoperazone/sultabactam, Acinetobacter baumannii was resistant to most antibiotics.

Conclusions: GNB was predominant in Chinese hospitalized patients with SLE. The drug resistance of GNB has increased significantly. It was necessary to rational use of antibiotics in patients with SLE.

AB0481 THE ASSOCIATION OF BASELINE HYPERURICEMIA IN PREMENOPAUSAL WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND DEVELOPMENT OF NEPHRITIS

D.H. Lim1, S. Hong2, J.S. Oh3, Y-G. Kim2, C-K. Lee2, S.W. Choi1, B. Yoo2.

1Division of rheumatology, Department of Internal Medicine, Ulsan university hospital, Ulsan; 2Division of rheumatology, Department of Internal Medicine, Asan Medical Center; 3Division of rheumatology, Department of Internal Medicine, National Medical Center, Seoul, Korea, Republic Of

Background: Renal involvement is a common and serious manifestation of SLE. Hyperuricemia may be associated with lupus nephritis as a result of renal
Oxidative damage to nucleic acids has been found to be associated with etiopathogenesis and disease activity of inflammatory disorders. Oxidised guanine species have been recognized as a biomarker of oxidative DNA and RNA damage by endogenously generated oxygen radicals. Sjögren’s syndrome (SS) is an autoimmune disorder and associated with overexpression of proinflammatory cytokines. Related to excess expression of proinflammatory cytokines, a prooxidant state could be postulated in SS.

**Objectives:** We aimed to evaluate levels of nucleic acids oxidative stress products in patients with SS.

**Methods:** 11 patients with SS diagnosed according to 2012 American College of Rheumatology (ACR) Classification Criteria for Sjögren’s Syndrome. 19 patients with psoriatic arthritis (PsA), diagnosed according to Classification Criteria for Psoriatic Arthritis (PsARC), 9 patients with rheumatoid arthritis (RA), diagnosed according to 2010 Rheumatoid Arthritis Classification Criteria, and 12 healthy controls were included. All SS patients were on hydroxychloroquine sulphate 400mg/day. All PsA and RA patients were on methotrexate 15–20mg/week and folate acid 5mg/week. The serum samples were collected from patients and stored at -30°C until assayed. Three oxidised guanine species, 8-hydroxy-2'-deoxyguanosine as a DNA oxidation marker, 8-hydroxyguanosine as a RNA oxidation marker, and 8-hydroxyadenosine as a DNA and RNA oxidation marker, were measured using DNA/RNA Oxidative Damage ELISA Kit (Cayman Chemicals, USA).

**Statistics:** All data are presented as mean and standard deviation (SD). Differences between groups were examined using Kruskal-Wallis tests. The Mann-Whitney U test was performed to test the significance of pairwise differences using Bonferroni correction to adjust for multiple comparisons. A p-value less than 0.05 were considered as statistically significant. Statistical analysis of correlation was performed by using the Spearman rank test.

**Results:** There was no statistically significant difference between the groups in terms of age and gender. The average level of serum oxidised guanine species in the PsA, RA, SS and healthy control groups were 2871.7±2336.20, 2672.0±292.04, 3375.57±344.21, 2777.55±237.05 pg/mL, respectively. Oxidised guanine species levels were significantly higher in patients with SS and positively correlated with CRP levels (p<0.011, r=0.726) (table 2).

**Conclusions:** A marked increase in DNA damage leading to oxidative stress may contribute to tissue damage in SS.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.3286
**Results:** Two hundred forty-two SLE patients were evaluated; 94.4% of them were female. Mean values were as follows: at age diagnosis 33.9±13.5 years, disease duration 15.8±10.5 years, SLEDAI 5.91±10.56, SLICC score 1.06±1.42, BLSy levels 1.81±1.757 ng/mL. The 22.5% of patients displayed increased BLSy levels. The 29.6% of total patients exhibit SLEDAI values up to 6, and only the 7% of the values up to 10. Higher BLSy levels were significantly correlated to the ANAs positivity (p=0.0006) and lymphopenia (p>0.01) but showed no correlation with hypercomplementemia neither anti-dsDNA. The statistical analysis did not yield differences in the clinical activity or accumulated damage between patients with lower and higher BLSy levels.

**Conclusions:** In our series we observed a 22.5% of patients with high levels of BLSy, and the 7% of cases had BLSy high levels and SLEDAI ≥6. BLSy upregulation is related to ANAs positivity and lymphopenia. We have found no statistical evidences on the relationship of BLSy levels and clinical activity in our series of patients.

**AB0494 INCREASED LEVELS OF INTERFERON ALPHA AND INTERLEUKIN-10 AS CLINICAL ACTIVITY BIOMARKERS IN SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS**

E. Grau García1, M. Fernandez Matilla2, C.M. Feced Olmos1, E. Labrador Sánchez2, C. Nájera Herranz1, F. Vicen Bernabé1, J.E. Oller Rodriguez1, J.A. Castellano Cuesta2, F. Forner Ferrer4, D. Herráiz Marín4, J.A. Román Ibarra1, E. Grau Garcia3, 3Medical School, UCV, 4Biostatistics Unit, IIS la Fe, Valencia, Spain

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by immune system disruption, including deregulation of cytokine production. Interferon alpha (INF1A) is considered a key molecule in SLE etiopathogenesis, being responsible of the differentiation of dendritic cells from monocytes, and indirectly of interleukin 10 (IL10) upregulation. The B lymphocyte stimulating factor (BLyS) is involved in autoantibodies production and clinical activity, and is regulated by other cytokines as IL10 and INF1A.

Our objective was to evaluate INF1A, IL10 and BLyS levels and clinical activity in SLE.

**Methods:** A cross-sectional, observational study of 142 patients diagnosed of SLE according to SLICC 2012 criteria and 34 healthy controls was performed. A complete blood-test was made, and clinical data by personal interview was collected. We analyzed serum concentration of IL10, BLSy and INF1A by colorimetric methods. Patients were dichotomized as high and low levels for each cytokine based on the cytokine level above 2 SD of the mean in healthy controls. Biostatistical analysis with R (3.3.2.) was performed.

**Results:** In our SLE patients we observed higher values of IL10, BLSy and INF1A than controls (P<0.001, P=0.005 and P=0.004 respectively), showing an average values in patients of 13.39±27.73 pg/mL IL10, 1811.31±1757.81 pg/mL BLSy. The mean clinical activity measured by SLEDAI was 5.91±5.06. Statistical analysis indicate that INF1A levels are correlated to IL10 levels (P<0.001), and to a lesser extent with increased IL10-INF1A-BLSy levels. Patients with high INF1A>IL10-BLSy showed a significant rise in C3-C4 consumption (P<0.001 and P=0.001 respectively) and high anti-dsDNA (P=0.001 and P=0.002 respectively). Patients with increased INF1A-BLSy showed high anti-dsDNA (P=0.004) and ENA positivity (P=0.001) and ANAs positivity (P>0.01). In addition, patients with increased IL10-INF1A-BLSy showed ANAs (P<0.001) and antiphospholipid autoantibody positivity (P=0.004).

**Conclusions:** The 69% of our SLE patients displayed almost one cytokine increased, being the INF1A the cytokine that mainly is increased. However, increased IL10 levels, irrespective of whether there is also increased levels of BLSy and/or INF1A, is the cytokine which best fits to clinical activity in SLE.

**Disclosure of Interest:** None declared

**AB0495 ASSESSMENT OF FRACTURE RISK IN A COHORT OF EGYPTIAN FEMALE SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS**

E.A. Hafez1, S.A. El Bakry1, S. Ibrahim1, C.S. Morad1, S.A. Hamza2, D.M. Abd El-Khalil1, 1Internal medicine and Rheumatology; 2Genetic Medicine, Faculty of Medicine, Ain Shams University, Cairo, Egypt

**Background:** Survival of systemic lupus erythematosus (SLE) patients has improved dramatically due to improved treatment, and the morbidity pattern has shifted towards long-term complications as osteoporosis. SLE occurs in women during child-bearing years and the disease often persists to the postmenopausal period1. Assessment of fracture risk in SLE patients is important as fractures may occur while bone mineral density (BMD) is above the osteoporotic threshold or at or above the osteopenia threshold2. Osteoporosis diagnosis measurement helps to assess fracture risk and select patients for treatment.

**Objectives:** To assess the fracture risk in a cohort of Egyptian female SLE patients by using BMD and osteocalcin level with correlation to disease activity, damage index and drugs in use.

**Methods:** 70 females with SLE ≥40 years old satisfying the SLICC classification criteria were enrolled with detailed history taking including disease duration, drugs in use, traditional risk factors, regular exercise, history of previous fractures and menstrual history. Assessment of disease activity using Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and disease damage using the Systemic Lupus International Collaborative Clinics/ American College of Rheumatology Damage Index (SLICC/ACR DI). Serum calcium, phosphorus and alkaline phosphatase were measured. BMD measured by dual energy X-ray absorptiometry (DEXA) scans at lumbar spine (LS) (L2-L4) and femoral neck (FN), serum osteocalcin level and World Health Organization fracture risk assessment tool (FRAX®).

**Results:** 14/70 (20%) patients had LS osteoporosis, 25/70 (35.7%) had LS osteopenia and 6/70 (8.6%) had FN osteoporosis, 30/70 (42.9%) had FN osteopenia. FRAX-Majer 0.2% was observed in 10% of patients, FRAX-HIP ≥3% was seen in 27.1% of patients. Serum osteocalcin level was significantly decreased in SLE patients with lower BMD than those with normal BMD, and significantly decreased in patients with osteoporosis than with those osteopenic. A significant negative correlation was found between osteocalcin level and age of patients, disease duration, SLEDAI and SLICC scores, current, IV pulse and cumulative steroids, immunosuppressants, anticoagulants, but there was a positive correlation with antimalarials and calcium supplements.

**Conclusions:** SLE patients are at greater risk for developing osteoporosis and osteopenia. Ten-year risk of major and hip fractures was higher in SLE patients with high levels of INF1A and/or BLyS, and SLEDAI were associated with a higher 10-year probability of major osteoporotic fracture. FRAX predicted incident hip and major osteoporotic fractures among SLE patients with normal and low bone mass not just those with frank osteoporosis. Physicians should be alerted to the higher risk of future fractures in SLE patients for periodic monitoring.

**AB0496 VENOUS THROMBOSIS IS MORE PREVALENT IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME (APS) ACCOMPANYING SYSTEMIC LUPUS ERYTHEMATOSUS, WHILE LIVEDO RETICULITIS IN PRIMARY APS**

E. N. Haladji, A. Wieczorek, M. Olesińska. Connective Tissue Diseases, Institute of Geriatrics, Rheumatology and Rehabilitation, WARSAW, POLAND, Warsaw, Poland

**Background:** APS may overlap with other systemic autoimmune diseases like systemic lupus erythematosus (SLE) or rheumatoid arthritis (RA) than occur as a distinct disease. Our purpose was to evaluate what are the differences between patients with primary APS and APS accompanying SLE.

**Objectives:** The objective of this study was to compare patients with primary APS with SLE patients without APS and APS accompanying SLE.

**Methods:** 112 patients with APS were included to the study, 57 of them with primary APS and 55 with coexisting SLE. These patients were followed at the Department of Connective Tissue Diseases, NiGRF, Warsaw, Poland. At inclusion a full medical history and physical examination data were recorded.

**Results:** Both groups were similar in age, gender and duration of disease. Among all the clinical manifestations of APS, venous thrombosis was more frequent in patients with concomitant SLE. Skin involvement was significantly more prevalent in primary APS and it was caused mainly by livedo reticulitis. APS patients with vascular manifestations of APS/SLE showed more frequent arterial and venous thrombosis than APS patients. APS. Although epilepsy occurrence is comparable in APS and APS/SLE, higher frequency of EEG changes in APS/SLE group suggests that the mechanisms...
SIX CASES OF MACROPHAGE ACTIVATION SYNDROME AS TOTAL BODY WATER AND ITS CORRELATION WITH SICCA

F. Dall’ara1, I. Cavazzana2, M. Frassi2, M. Taraborelli2, M. Fredi2, F. Franceschi2, L. Andreoli1, A. Tincani1, P. Airò2.

1Immunology, University of Brescia - Dscs; 2Rheumatology and Clinical Immunology, University of Brescia - Dscs; 2Rheumatology and Clinical Immunology, Spedali Civili di Brescia, Brescia, Italy

Background: Macrophage Activation Syndrome (MAS) is a life-threatening syndrome characterized by excessive immune activation. It can be triggered by conditions affecting immune homeostasis, such as infections, malignancies and rheumatic disorders, including Systemic Lupus Erythematosus (SLE). In previous studies, prevalence of MAS among SLE patients ranged from 0.9% to 4.6%. Objectives: To describe the presentation and treatment of both MAS and SLE in patients with both syndromes. Methods: Monocentric retrospective evaluation: patients with MAS according to HLH classification criteria were identified in our cohort of SLE patients (classified according to ACR and SLICC criteria) followed for at least 1 year between 1972 and 2014. Results: Among 511 patients with SLE (mean age at diagnosis: 31 years ± 2), 6 patients (1.2%) with MAS were identified (all female). Their main clinical and laboratory features are reported in Table 1. Median HLH score was 22 (IQR 18–26), with a probability of having MAS of 96%. In all cases, MAS happened simultaneously to the onset of SLE. Median age at diagnosis was 31.5 years, median SLEDAI was 12. All patients had fever above 38°C. Lymphopenia, lymphadenopathy, and high titer ANA positivity. Workup for infections and malignancies was negative in all cases. All patients were treated with corticosteroids, and cases in which fever persisted or temperature was persistently above 38°C in the absence of signs and symptoms of infection were treated with immunosuppressive drugs and cytotoxic agents such as etoposide were used only in one case.

**TOTAL BODY WATER AND ITS CORRELATION WITH SICCA SYMPTOMS IN PRIMARY SJÖGREN’S SYNDROME**

1Rheumatology; 2Laboratory of Immunology, Fundación Valle del Lili, Cali, Colombia

Background: Differentiation of Systemic Lupus Erythematosus (SLE) activity and infection in a febrile SLE patient become difficult, since initial clinical presentation may be similar. Several biological markers (including procalcitonin and CRP) have been evaluated, with discordant results. Soluble CD14 (sCD14), also called receptor for lipopolysaccharide (LPS)-binding protein (LPS-LBP) complexes, CD14 could activate a series of signal transduction pathways and inflammatory cascades, and lead to systemic inflammatory responses.

Objectives: To evaluate the utility of sCD14 as a novel biomarker to discriminate infection vs. activity in SLE patients admitted with systemic inflammatory response syndrome (SIRS).

Methods: We included 11 patients with SLE (ACR criteria 1997) and SIRS (International conference 2001) admitted to the ER and/or ICU. The measurement of sCD14 in plasma by enzymatic immunoassay of chemiluminescence in vitro was performed to differentiate active SLE vs. infection. Infection was considered if a positive culture/PCR was obtained. Mann-Whitney test was used to evaluate the association of variables with infection.

Results: All patients were female; mean age 37.9 years. An infectious disease was confirmed in 5 cases (3 bacterial including urinary tract infection, pneumonia and bacteremia; 1 viral infection by Chikungunya virus and 1 fungal by histoplasma capsulatum). sCD14 was elevated in the infected SLE patients (median: 1005 pg/ml–R: 533–1415) vs patients with lupus flare (median: 431.5 pg/ml–R: 369–579) (p = 0.04).

Conclusions: High values of sCD14 levels seem to be useful to differentiate infections from activity in SLE patients with SIRS. More patients and further analysis are necessary to define the clinical use of this biomarker.

**TOTAL BODY WATER AND ITS CORRELATION WITH SICCA SYMPTOMS IN PRIMARY SJÖGREN’S SYNDROME**

1Rheumatology; 2Laboratory of Immunology, Fundación Valle del Lili, Cali, Colombia

Background: Patients with primary Sjögren’s syndrome (PSS) suffer from severe alterations in both the quality and quantity of saliva and tears. Body water represents around 50–55% of the body weight. Tears contain 98% of water and saliva 99.5%.

Objectives: To evaluate the percentage of total body water (TBW) among patients with PSS and to assess its correlation with sicca symptoms.

Methods: We included 85 patients with PSS and 85 historical non diabetic controls and to assess its correlation with sicca symptoms.

Objectives: To evaluate the percentage of total body water (TBW) among patients with PSS and to assess its correlation with sicca symptoms.

Methods: We included 85 patients with PSS and 85 historical non diabetic controls and to assess its correlation with sicca symptoms.

Objectives: To evaluate the percentage of total body water (TBW) among patients with PSS and to assess its correlation with sicca symptoms.

Methods: We included 85 patients with PSS and 85 historical non diabetic controls and to assess its correlation with sicca symptoms.
TBW negatively correlated with age (ρ=−0.25, p<0.02), disease duration (ρ=−0.30, p<0.005), BMI (ρ=−0.78, p<0.001) and the ocular component of the ESSPRI (ρ=−0.28, p<0.01), but not with the NSWSF or the ESSPRI oral component. When we compared the patients in the 25% percentile (group with the lowest % of water) vs. the remaining patients, the former group was older (56.8±6.1 vs. 54±14.2, p=0.02), with longer disease duration (12.4±5.9 vs. 10.8±7.12, p<0.03), lower scores at the Schirmer test (1 (range 0–8) vs. 2 (range 0–9), p=0.01), higher BMI (31.1±15.1 vs. 23.7±2.9, p<0.001) as well as with higher ESSPRI ocular domain scores (8.3±1.4 vs. 6.7±2.5, p<0.007). With the linear regression analysis, the variables that remained associated with the TBW were disease duration (p=0.002, p=0.005), BMI (p=0.057, p=0.001) and the ocular domain of the ESSPRI (p=0.015, p<0.001).

Conclusions: Patients with PSS had similar TBW percentage than controls. However among patients with PSS, the TBW had a negative correlation with the involvement of ocular symptoms independently of disease duration, age and BMI.

AB0500 TOLERABILITY, EFFICACY AND IMMUNOGENICITY OF 23-VALENT PNEUMOCOCCAL VACCINE IN SLE PATIENTS

Background: Consequent infections turn out to be the second leading cause of death in systemic lupus erythematosus (SLE) pts after SLE se. Immunization of SLE pts with pneumococcal vaccine is an important prophylactic approach to prevent severe lower respiratory tract (LRT) infections in SLE pts.

Objectives: To study the tolerability of 23-valent pneumococcal vaccine for immunization of patients with SLE.

Methods: The study included 30 SLE pts, 27 females, 3 males, aged 19 - 62 y. Duration of follow up (FUP) was 12 months in 24 pts, and 7–10 months – in 6 pts. High disease activity at the time of immunization was documented in 1 patient, low activity – in 20 pts, moderate – in 4 pts, and remission – in 5. 29 pts were treated with glucocorticosteroids (GCs), mycophenolate mofetil, and rituximab, no GCs. Among them 7 pts were treated with GCs, mycophenolate mofetil, and rituximab, no GCs. Among them 7 pts were treated with glucocorticosteroids (GCs), mycophenolate mofetil, and rituximab, no GCs. Among them 7 pts.

Results: To study the relevance of 23-valent pneumococcal vaccine for immunization of patients with SLE.

Methods: The study included 30 SLE pts, 27 females, 3 males, aged 19 - 62 y. Duration of follow up (FUP) was 12 months in 24 pts, and 7–10 months – in 6 pts. High disease activity at the time of immunization was documented in 1 patient, low activity – in 20 pts, moderate – in 4 pts, and remission – in 5. 29 pts were treated with glucocorticosteroids (GCs), 23 – with hydroxychloroquine, 14 pts – with cytostatic (CS) agents. Twelve pts were on biological disease-modifying antirheumatic drugs (bDMARDs). One dose (0.5 ml) of 23-valent polysaccharide vaccine was administered subcutaneously. The duration of FUP was 7–12 months. Control visits were scheduled as follows: at baseline (Visit 1), at 1st, 3rd, and 12th months (Visit 4) after immunization. Standard clinical examination and lab tests, including blood immunology, were performed at each visit. Vaccine immunogenicity was evaluated based on the level of serum antibodies (AT) to Streptococcus pneumoniae capsular polysaccharide (VaccZymeTM PCP Ig 2 panels (The Binding Site Ltd, Birmingham, UK)) – 4 times during year.

Results: Non-post-inmunization complications were seen in 11 (36.7%) pts, local reactions of varying intensity lasting from 2 to 7 days were documented in 18 (60%) pts. One patient (3.3%) developed the local type III hypersensitivity reaction known as Arthus phenomenon. All symptoms subsided within 7 days after the whole FUP.

Conclusions: Obtained results are indicative of good tolerability, safety and immunogenicity of 23-valent pneumococcal vaccine in SLE pts. Further studies are necessary for more comprehensive evaluation of vaccine clinical efficacy.

AB0501 THE ASSOCIATION BETWEEN GLUCOCORTICOIDS AND DAMAGE ACCRUAL IN PATIENTS WITH SLE USING GLUCOCORTICOID FOR LONG-TERM

G. Wang, X. Li, Z. Dou, W. Wang, R. Liu. Rheumatology and Immunology, Anhui Provincial Hospital Affiliated to Anhui Medical University, Hefei, China

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease characterized by a relapsing-remitting course. Long-term prognosis of SLE patients remains poor [1]. Due to the effect of potent anti-inflammatory and immunosuppressive, glucocorticoids (GCs) remain the cornerstone of SLE treatment. However, GCs produce several adverse reactions, most are time and dose dependent, limiting their clinical usefulness. Increased longevity with prolonged exposure to GCs and inflammatory insults might contribute to organ damage accrual, which retards further improvement of survival in these patients. The objective of this study is to evaluate organ damage caused by SLE has been considered an important part of the assessment of prognosis. The Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index (SDI) is a validated instrument designed to measure irreversible damage resulting from SLE disease activity and its treatment. The study of damage accrual in patients with SLE caused by the long-term treatment of GCs is still not clear. In a large SLE cohort, followed prospectively, we determined to investigate the association between damage accrual with GCs, both cumulative prednisone dose and high-dose prednisone. The results of our study could shed more light on the risk/benefit ratio of GCs in long-term maintenance treatment with SLE patients.

Objectives: To evaluate the association between long-term glucocorticoids use and damage accrual in patients with systemic lupus erythematosus.

Methods: Medical records of 535 SLE patients from Department of Rheumatology and Immunology of Anhui Provincial Hospital were retrospectively reviewed. Exclusion criteria: (1) patients with missing or incomplete medical records; (2) patients with inadequate medical data for SDI calculation; (3) patients without previous treatment with corticosteroids; (4) patients with active SLE. A total of 192 patients (35.9%) had been treated with high dose of prednisone. In addition, 86.9% of patients had been treated with hydroxychloroquine. The highest organ damage came from musculoskeletal (n=79, 14.8%), followed by skin damage (n=35, 6.5%) and renal (n=28, 5.2%). Ninety patients were diagnosed with hypertension. Cumulative prednisone dose was associated with osteoporosis, osteonecrosis and hypertension; exposure to high-dose prednisone was associated with osteonecrosis, lupus nephritis and hypertension.

Conclusions: Long-term taking prednisone predicted damage accrual. The most common damage was osteoporosis, osteonecrosis and hypertension.

AB0502 STRONG REDUCTION OF ANTI-MÜLLERIAN HORMONE IN SYSTEMIC LUPUS ERYTHEMATOSUS WOMAN OF REPRODUCTIVE AGE

C. Li, J. Xie, X. Wang, X. Liu, G. Chen. Division of Rheumatology and Clinical Immunology, the First Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China

Background: Systemic lupus erythematosus (SLE) is a clinically autoimmune disease characterized by production of autoantibodies and immune complex deposition. That induces multiple organ damages such as nephritis, pneumonitis and central nervous system (CNS) lupus et al. Moreover, SLE which mainly occurs in reproductive woman could threaten ovarian function. In recent years, ovarian reserve dysfunction in SLE are attracting increasing attentions. Especially cyclophosphamide (CYC) therapy was already well known as a higher risk to ovarian reserve dysfunction in SLE patients. In addition, 86.9% of patients had been treated with hydroxychloroquine. The highest organ damage came from musculoskeletal (n=79, 14.8%), followed by skin damage (n=35, 6.5%) and renal (n=28, 5.2%). Ninety patients were diagnosed with hypertension. Cumulative prednisone dose was associated with osteoporosis, osteonecrosis and hypertension; exposure to high-dose prednisone was associated with osteonecrosis, lupus nephritis and hypertension.

Objectives: To study the relationship between anti-Müllerian hormone (AMH) and damage accrual in systemic lupus erythematosus (SLE) women of reproductive age.

Methods: SLE women during reproductive ages 18–40 years were recruited compared with age-matched healthy controls (HC). AMH Levels and its relationship to clinical parameters and disease activity were investigated.
Background: Pregnancy outcome is one of the major concerns to manage systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) since they often affect women in reproductive ages. However, the predictive factors of poor pregnancy outcome and disease flare during pregnancy have not fully investigated.

Objectives: To elucidate the factors affecting the pregnancy outcome in patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA).

Methods: Patients with SLE and RA in our university pediatric cohort 2012 and 2016 who experienced pregnancy were retrospectively reviewed. Medical information was collected from their chart.

Results: Thirty six pregnancies in 26 SLE patients and 26 pregnancies in 21 RA patients were identified. Among SLE pregnancies, the mean age, disease duration and prednisolone dose were 32.7±4.6, 8.9±7.7 years and 5.6±4.1 mg/day, respectively. The disease activity was well controlled (the mean SLEDAI, 2.4±2.1). Live birth pregnancies were 31 (86.1%) and fetal loss occurred in 5 pregnancies (3 spontaneous abortions, 1 ectopic gestation and 1 hydatidiform mole). The mean dose of prednisolone was significantly lower in the pregnancies with live birth than those with fetal loss (4.9±3.4 vs 11.3±3.3mg/day, p=0.02), while proteinuria, SLEDAI, history of lupus nephritis, positivity of antiphospholipid antibodies and anti-SSA/ Ro antibodies were not significantly different between the two groups. Maternal lupus flare occurred in 8 (16.7%) during pregnancy or after the delivery and was significantly associated with proteinuria at the time of conception (p=0.02). Low body birth occurred in 9 (29.0%) and was also significantly associated with proteinuria at the time of conception (p=0.002). Among RA patients, the mean age and disease duration were 33.5±5.6 and 9.9±7.4 years. The mean DAS28-ESR, CDAI and HAQ were 2.18±0.88, 3.07±4.10 and 0.30±0.50, respectively and 14 achieved DAS28-ESR remission (≤2.6). Seven (26.9%) discontinued biological agents before conception while 8 (34.8%) continued to use biological agents. Although 5 (19.2%) experienced the disease flare during pregnancy, all 26 pregnancies were live birth. The patients who discontinued biological agents more frequently experienced the disease flare than those who continued, during pregnancy or postpartum within 1 year after delivery (85.7% vs 25%, p=0.04).

Conclusions: High live birth rates were observed in both SLE and RA pregnancies on the condition of well-controlled disease activity. In SLE pregnancies, less prednisolone dose at the time of conception may be associated with live birth. SLE pregnancies with proteinuria and RA pregnancies with discontinuation of biological agents are associated with disease flare and should be cautiously monitored.

DOES VITAMIN D DEFICIENCY CONTRIBUTE TO COGNITIVE Dysfunction in Patients with Systemic Lupus Erythematosus?

H.A. Hussein¹, N.A. Fouad², L. Daken³, A. Elmar³, S.R. Mohamad⁴, I. Internal Medicine, Fayoum University, Cairo; ²Rheumatology; ³Neurology; ⁴Medical Biochemistry, Fayoum University, Fayoum, Egypt

Background: Neurocognitive impairment is one of the most common SLE manifestations. However, its pathophysiology remains poorly understood [1]. Vitamin D deficiency is a potential risk factor for cognitive impairment [2,3].

Objectives: Our aim is to evaluate the relationship between 25(OH)D3 level and cognitive performance in patients with SLE.

Methods: Thirty Egyptian patients diagnosed as systemic lupus erythematosus and their age and sex matched controls were subjected to a battery of neuropsychological evaluation by California Verbal Learning Test (CVLT-II), Controlled Oral Word Association Test (COWAT) and Trail making test and evaluation of depression by using Beck Depression Inventory (BDI). Serum level of 25(OH)D3 was measured in cases and controls.

Results: Patients with SLE had a worse performance than controls in verbal memory total recall, executive function and phonemic verbal fluency as there was a statistically significant difference in CVLT-II total recall, Trail making test and phonemic-COWAT respectively. There was no significant difference between the patients and controls in Beck Depression Inventory (BDI). There was a significant positive correlation between the vitamin D level and executive function assessed by trail making test (r =0.399, p=0.03).

Conclusions: Vitamin D deficiency in patients with SLE could have a significant impact on their cognitive performance.

COBALAMIN (VITAMIN B12) STATUS IN PATIENTS WITH ANTI PHOSPHOLIPID SYNDROME (APS), ITS ASSOCIATION WITH ATHEROSCLEROTIC VASCULAR LESIONS

I. Segeda 1, S. Shevchuk 1, I. Kuvkova 2, O. Shevchuk 2, I. Segeda 2, S. Shevchuk 2, I. Kuvkova 3, O. Shevchuk 2, 1Rheumatology, Institute of Invalid Rehabilitation; 2Rheumatology, Vinnytsya National Medical University, Vinnytsya, Ukraine; 3Internal Medicine, Institute of Invalid Rehabilitation, Vinnytsya, Ukraine. *Affiliation not provided

Background: Cobalamin (vitamin B12) insufficiency is associated with the development of many diseases. It is known that the growth of clinical and subclinical manifestations of atherosclerotic vascular lesions are often associated with low cobalamin level. Cobalamin status is unknown in patients with antiphospholipid syndrome (APS). There are no data about the role of folate in the development of atherosclerotic vascular lesions in patients with APS.

Objectives: To evaluate vitamin B12 status in patients with APS and to explore its relationship with atherosclerotic vascular lesion.

Methods: We observed 82 patients with APS and 37 healthy individuals. Content of cobalamin (vitamin B12) in serum were determined by immunochromatographic detection (ECLA). Cobalamin level above 200 pg/ml was considered as normal within 200–300 pg/ml - both extremely low, below 200 pg/ml - insufficiency. All patients were underwent detection of endothelial dysfunction - dilatation of brachial artery endothelium, investigation of “intima-media” thickness of common carotid artery (IMT) and the presence of atherosclerotic plaques (AP).

Results: In patients with APS we recorded a significant reduction of cobalamin in the serum (351±14.3 pg/ml (95% CI: 148–562 pg/ml) compared to control group (445±18.1 pg/ml (95% CI: 272–622 pg/ml). Indicators of cobalamin status in patients with secondary APS were significantly worse than those with primary APS. Thus, in patients with secondary APS cobalamin content was on 28.7% lower (95% CI: 140–559 pg/ml) than in the control group. In patients with primary APS cobalamin content was on 13.0% lower (95% CI: 202–586 pg/ml) than in controls, but 18.7% higher than in patients with secondary APS. Cobalamin deficiency (vitamin B12) insufficiency is associated with significant thickening of the walls of the common carotid artery. Thus, in patients with cobalamin deficiency IMT was on 17% higher than that in patients with optimal levels of the vitamin. Cobalamin deficiency is also associated with endothelial dysfunction. Thus, in patients with vitamin deficiency dilatation of brachial artery was significantly, by 48.6% less than in people with normal vitamin B12 status. The share of people with the presence of atherosclerotic plaques, transient ischemic attack (TIA), stroke, myocardial infarction (MI) and angiina in patients with cobalamin deficiency was also higher.

Conclusions: Thus, in patients with APS low cobalamin status is associated with subclinical manifestations of atherosclerotic vascular lesions.

PREGNANCY OUTCOMES IN WOMEN WITH RHEUMATIC DISEASES: A SINGLE CENTER-STUDY

Background: Systemic Lupus Erythematosus (SLE), Antiphospholipid Syndrome (APS) and Thrombophilia are associated with considerable pregnancy-related morbidity. Multidisciplinary teams allows the application of an experienced protocol to monitor and treat them during pregnancy in order to reduce adverse pregnancy outcomes and this way improve the prognosis of the pregnancy.

Objectives: To investigate pregnancy outcomes in women with rheumatic diseases and thrombophilia from a Spanish cohort.

Methods: A population of 93 patients diagnosed with SLE, APS and Thrombophilia attended in a specialized multidisciplinary unit of Rheumatic Diseases and pregnancy from the Complejo Hospitalario Universitario de Granada, Spain from January 2012 to December 2016. The following variables were collected: age, presence of antiphospholipid antibodies and anti Ro, thrombotic episodes and prior abortions, treatment during pregnancy, obstetric outcomes births/abortion and pregnancy length. The statistical analysis was done using the McNemar Test.

Results: 93 pregnant women were included in the study. 26 were diagnosed with SLE, 32 with APS and 35 with Thrombophilia (mostly, Heterozygotes for MTHFR gene). 80% of them were younger than 35 years and 52.7% were from the reproductive age. 66.7% had one or more prior abortions, meaning a total record of 159 abortions and an average of 1.7±1.76 abortions per patient. The treatment received by the patients is specified in Table 1. 9 patients (3 APS and 6 thrombophilia) received a treatment with intravenous gammaglobulin with doses of 400 mg/kg, apart from Low-Molecular-Weight Heparin (LMWH) and Acetylsalicylic Acid (ASA), two days in a row at the beginning and then every three weeks during the whole pregnancy. 90 (96.8%) pregnancies were developed. 6 of them were preterm pregnancies and 84 were term pregnancies. Only 3 abortions (3.2%) occurred in the patients monitored. In the case of the number of abortions was statistically significant (p=0.001). Regarding those 3 registered abortions, 2 were patients diagnosed with SLE, with no record of previous abortions and they occurred during the second trimester of pregnancy. 1 was diagnosed with APS and she had record of 2 previous abortions and occurred during the first trimester of pregnancy. Those patients who received treatment with gammaglobulin iv showed an improvement of 4.8±1.85 previous abortions per patient and all had a term delivery (100%).

Table 1. The treatment received by the patients

Conclusions: Our results demonstrate a decrease in the number of abortions and a larger number of term pregnancies since the inclusion of patients with high risk pregnancies in our unit. Prophylactic treatment is effective for the prevention of abortions, reaching higher rate live birth pregnancies. The multidisciplinary evaluation is essential to prevent complications in women diagnosed with rheumatic diseases with high obstetric risk.

EFFECT OF ALCOHOL CONSUMPTION AND SMOKING ON NEUROPSYCHIATRIC MANIFESTATIONS AND DISEASE ACTIVITY IN POLISH COHORT OF SYSTEMIC LUPUS ERTHYMATEOUSOS

J.N. Kim, S.-K. Kim, J.-Y. Choe, C.I. Lee. Division of Rheumatology, Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, Korea, Republic Of

Objectives: We assessed correlations of smoking habits and alcohol consumption with disease activity or damage in patients with systemic lupus erythematosus (SLE).

Methods: A total of 505 patients with SLE were enrolled in the KORean lupus Network (KORNET) SLE registry from January 2014 to January 2016. Disease activity and organ damage were measured by the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) and the Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) damage index, respectively. Multivariate logistic regression analysis was used to analyze associations with cutaneous lesions.

Results: There are no differences in SLEDAI-2K and SLICC/ACR damage indexes according to either smoking status or alcohol consumption. More frequent cutaneous damage was observed in current alcohol drinkers compared to non-current alcohol drinkers (p=0.020). Cutaneous involvement was associated with alcohol consumption [Odds ratio (OR) 4.048, 95% confidence interval (CI) 1.251 – 13.102, p=0.020]. Both low (<5 glasses/week) and high (>6 glasses/week) amounts of alcohol consumption had a significant impact on cutaneous damage compared to the absence of current alcohol consumption (p=0.033 and p=0.027, respectively). Pairwise comparison of alcohol consumption and smoking status with cutaneous damage showed that only alcohol consumption was significantly associated with the presence of cutaneous damage, compared to non-current alcohol consumption and non-current smoking (OR 3.513, 95% CI 1.190 – 10.920, p=0.030).

Conclusions: Current alcohol consumption, but not smoking, might influence the development of cutaneous damage in patients with SLE.

IDENTIFICATION OF NOVEL BIOMARKERS ASSOCIATED WITH DISEASE ACTIVITY OF PRIMARY SJÖGREN’S SYNDROME AND CLINICAL RESPONSE TO VAY736

J. Doucet1, R. Kazama1, M. Cabanski1, E. Kamphausen1, P. Maguire1, A. Arraam-es2, M.-A. Valentin1, Y. Li2, A. Auger-Sarrazin1, S. Kaiser1, P. Follet1, S. Oliver3, A. Vitaliti1. 1Translational Medicine/Biomedical Development, Novartis Institutes for Biomedical Research; 2Global Development NPH, Novartis AG; 3Translational Medicine, Novartis Institutes for Biomedical Research, Basel, Switzerland

Background: Overexpression of B cell activating factor (BAFF) contributes to the pathogenesis of primary Sjögren’s syndrome (pSS) [1]. Treatment of pSS patients with VAY736, an anti-human BAFF receptor mAb, appears promising and was associated with a positive therapeutic effect [2]. Given the complexity and heterogeneity of pSS, there is a need to further identify molecular mechanisms involved in pSS and to propose new biomarkers for diagnostic and monitoring purposes.

Objectives: To address this question, we assessed a panel of biomarkers in 27 patients from a clinical trial and tested their associations with pSS activity and treatment response.

Methods: This study comprised 27 pSS patients treated with a single intravenous dose of VAY736 at 10 mg/kg (n=12), 3 mg/kg (n=6), or placebo (n=9). The disease activity scores included EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) and Patient Reported Index (ESSPRI), patient’s and physician’s inflammation, and damage indexes according to either smoking status or alcohol consumption. More frequent cutaneous damage was observed in current alcohol drinkers compared to non-current alcohol drinkers (p=0.020). Cutaneous involvement was associated with alcohol consumption [Odds ratio (OR) 4.048, 95% confidence interval (CI) 1.251 – 13.102, p=0.020]. Both low (<5 glasses/week) and high (>6 glasses/week) amounts of alcohol consumption had a significant impact on cutaneous damage compared to the absence of current alcohol consumption (p=0.033 and p=0.027, respectively). Pairwise comparison of alcohol consumption and smoking status with cutaneous damage showed that only alcohol consumption was significantly associated with the presence of cutaneous damage, compared to non-current alcohol consumption and non-current smoking (OR 3.513, 95% CI 1.190 – 10.920, p=0.030).

Conclusions: Current alcohol consumption, but not smoking, might influence the development of cutaneous damage in patients with SLE.

NEUROPSYCHIATRIC MANIFESTATIONS AND DISEASE ACTIVITY IN POLISH COHORT OF SYSTEMIC LUPUS ERTHYMATEOUSOS PATIENTS

K. Pawlik-Bus, M. Spalek, P. Leszczynska. Department of Rheumatology and Rehabilitation, University of Medical Sciences, Poznan, Poland

Background: Neuropsychiatric systemic lupus erythematosus (NPSLE) is defined as a wide range of neurological and psychiatric symptoms due to inflammation and ischemic processes. It is difficult to recognize primary NPSLE because of multiple central and peripheral symptoms.

Objectives: The aim of the study was to identify and classified the group of NPSLE patients with evaluation of disease activity.

Methods: We observed chronic neuropsychiatric (NP) manifestations in the cohort of 128 Polish patients with SLE. All patients with suspicion of NP symptoms had neuropsychological and imaging examinations. Symptoms of NPSLE were observed in 38 (30%) patients (34 female and 4 male) with average age 38±6 years (range 18-61 yrs), average disease duration 6.6±5.6 years (range 1.0-18.0 yrs). Patients were treated with oral and pulse glucocorticoids (GC) and 89% of them standard immunosuppressive drugs (CYC, MMF, AZA,MTX, CsA). As a background therapy 82% of these patients were on chloroquine or hydroxychloroquine (CQ/HQ). All patients were assessed according to Systemic Lupus Erythematosus Disease Activity Index by SLEDAI (version 2000), Physical Global Assessment (PGA) and damage index (SDI).

Results: Central and peripheral NPSLE symptoms were recognized and categorized (Tab 1). All NPSLE patients had symptoms from central nervous system, but only 16% (n=4) of them had peripheral lupus manifestations. Mean SLEDAI score at NP event was very high 29±6.6, but mean SLEDAI score without NP symptoms was 15±8.3 and was connected with musculoskeletal, mucocutaneous, renal and hematological domains respectively n=29, 76%; n=23, 60%; n=11, 29%; n=8, 21%. Low disease activity was estimated at 3% of patients examined Most of patients (n=37, 97%) had moderate or high disease activity regardless of NP symptoms. In our study group lupus patients during NPSLE symptoms were immunologically active with increased anti-dsDNA antibodies (n=30, 78%) and/or lower complements C3 and/or C4 levels (n=21, 55%).

Conclusions: In Polish lupus cohort we observed more frequently lupus-related primary neuropsychiatric symptoms from central nervous system, especially cognitive dysfunctions, mood disorders, cerebrovascular events. Clinical activity of NPSLE patients was rather high and definitely most of patients were immunologically active despite aggressive immunosuppressive treatment and with standard background therapy.

VITAMIN D: POTENTIAL ROLE IN ANTIPHOSPHOLIPID SYNDROME

L. Riancho-Zarrabeitia1, M. Cuberína1, S. García-Canal2, G. Daroca2, M. García-Usunzua3, J.L. Hernández4, M. López-Hoyos5, P. Muñoz2, M. Agudo1, V. Martínez-Taboada1. 1Rheumatology; 2Hospital Universitario Marqués de Valdecilla, Santander, Spain; 3Biochemistry; 4Internal Medicine, Hospital Universitario Marqués de Valdecilla, Santander, Spain

Background: Vitamin D due to its immunoregulatory properties, has been implicated in the pathogenesis of autoimmune diseases, such as antiphospholipid syndrome (APS).

Objectives: A) To determine vitamin D levels in patients with primary APS and to compare them with patients with positive antiphospholipid antibodies (aPL), not fulfilling clinical criteria for APS, and with healthy controls. B) To analyze the association of the vitamin D levels with both the clinical manifestations and the immunological profile of patients with primary APS.

Methods: We conducted a retrospective study including patients attended at the rheumatology clinic from a tertiary facility in Northern Spain. We included 74
patients with primary APS, 54 patients with positive aPL serology not meeting clinical criteria for APS and 326 healthy controls adjusted by the month of vitamin D analysis. We considered 30 ng/ml and 10 ng/ml as the thresholds for vitamin D insufficiency and deficiency, respectively.

Results: Median levels of vitamin D were similar in the three groups; (21 range 5–60) in primary APS, 25 (4–50) in the aPL-positive group, and 21 (4–100) in controls. Overall, 53.9% of measurements were performed during the sunny season (April to September). Ten percent of patients with primary APS were males, versus 16% in the aPL serology group and 26% among healthy controls (p=0.007). Mean age was 46±15 in primary APS, 49±17 in the aPL-positive group and 53±10 in the controls (p=0.001). Regarding vitamin D insufficiency, 82% of APS patients had levels of vitamin D (<30 ng/ml) versus 70% and 72% of patients with aPL serology and controls, respectively (p=0.168). When analyzing the prevalence of vitamin D deficiency (<10 ng/ml), we found significant differences across the three groups: 62% in patients with primary APS, 11.1% in patients with positive serology and only 4.9% in healthy controls (p=0.002). There was no significant association between insufficient levels of vitamin D and the presence of thrombotic or obstetric events. Nevertheless, we found a trend for the presence of more thrombotic events in patients with vitamin D deficiency (p=0.097). Regarding the immunological profile, we found no association between vitamin D and either the number of positive antibodies or their serological evolution. However, we found an association between insufficient levels of vitamin D and the presence of lupus anticoagulant (54.7% vs 18.2%, p=0.047).

Conclusions: More than 80% of patients with primary APS have insufficient levels of vitamin D and they have very low levels of vitamin D. Primary APS patients show a higher frequency of vitamin D deficiency than healthy controls. Patients with vitamin D insufficiency have more commonly positive lupus anticoagulant.

AB0512 EPIDEMIOLOGICAL, CLINICAL AND IMMUNOLOGICAL CHARACTERISTICS OF ANTIPHOSPHOLIPID SYNDROME: STUDY OF 170 PATIENTS

Background: Antiphospholipid syndrome (APS) is an autoimmune disease defined by the presence of antiphospholipid antibodies (aPL) and thrombosis and/or pregnancy morbidity. Although thrombotic and obstetric APS are considered the same disorder, there are pathogenetic and clinical differences between them.

Objectives: To describe the epidemiological, clinical and immunological characteristics of a cohort of APS patients from a defined population and to study the differences between thrombotic, obstetric and mixed APS.

Methods: Retrospective study including patients attending the rheumatology and the obstetric clinics of a tertiary facility in Northern Spain. All patients met APS classification criteria.

Results: We included 184 patients with thrombotic APS, 76 with obstetric APS and 10 with mixed APS. Main demographical characteristics are showed in table. There were differences in the age of discovery a positive serology (46±15 in thrombotic APS, 36±8 yr in obstetric, and 36±14 in mixed APS). Moreover, the prevalence of systemic lupus erythematosus (SLE) was higher in patients with thrombotic and mixed APS (26% and 30% vs 5% in obstetric APS, p=0.001). Anticardiolipin antibodies were overall, the most frequently positive. Lupus anticoagulant was significantly more common in patients with thrombotic and mixed APS (70% and 71% vs 30% in obstetric APS, p=0.002). We found no differences in the load of antibodies between the three groups. Regarding traditional cardiovascular risk factors (CVRF), tobacco use was the most common, followed by hypertension and dyslipidemia. The last two factors were more frequent in patients with thrombotic and mixed APS than in those with obstetric APS (p<0.001). As expected, treatment with heparin was more frequent in obstetric and mixed APS, while oral anticoagulants were more frequently used in thrombotic APS. Antimalarial drugs were less frequently used in obstetric APS (17% vs 37% and 30%, p=0.020), probably due to a lower prevalence of lupus in this group.

Conclusions: In our cohort, patients with thrombotic or mixed APS have a higher frequency of SLE than patients with obstetric APS. Positivity for lupus anticoagulants was more commonly observed in thrombotic APS. Regarding traditional CVRF, hypertension and dyslipidemia are more common in patients with thrombotic or mixed APS.

AB0513 FATigue IN CHINESE PATIENTS WITH PRIMary SJÖgren’s SYNDROME: A CROSS sectional STUDY

L. Li1, Y. Cui1, S. Chen1, Q. Zhao1, L. Li2, Z. Gu1, 1Department of Rheumatology, Affiliated Hospital of Nantong University; 2School of Nursing and sleep disturbance, Nantong, China

Background: Primary Sjögren’s syndrome (pSS) is the second most common systemic autoimmune disease, with a female-male ratio of 9:1, and characterized by sicca symptoms of the eyes and mouth, including joint pains and multi-system involvement. pSS affects patients’ health-related quality of life (QoL), mental status and relationships with family. In pSS patients, symptoms such as fatigue, depression, and anxiety, as well as decreased quality of life, general well-being and loss of well-being are commonly reported. Among them, fatigue is the most common problem that includes physical and mental fatigue, it can be as disabling as pain, which is difficult to manage and has a notable impact on QoL. Fatigue is a tiredness which may be mental, physical, or both, and that results in an inability to function at normal performance levels. However, the underlying pathophysiological mechanisms of fatigue remain unclear. A number of studies have reported the association of fatigue with Primary Sjögren’s syndrome (pSS), whereas, because of the small sample size of pSS patients, we still lack large sample studies to find the relationship between pSS and fatigue.

Objectives: To investigate the relationship of fatigue severity to other clinical features in primary Sjögren’s syndrome (pSS) and to identify factors contributing to the physical and mental aspects of fatigue in Chinese patients.

Methods: Thirty-seven consecutive patients with pSS according to the American-European Consensus group (AEGG) criteria were included. Demographic, clinical and biological characteristics for all patients were collected. The Fatigue Severity Scale (FSS), Profile of Fatigue (ProF), Visual analogue scale, Hospital Anxiety and Depression Scale (HADS), OHIP-14 Scale, MDADI Scale and PSQI Scale were adopted to assess fatigue, depression, anxiety, xerostomia, xerophthalmia and sleep disturbances. Associations with fatigue were compared using multivariate regression.

Results: 94% of our patients were women. The mean age of patients was 51.13±13.23 years, and the mean disease duration was 4.12±4.49 years. The mean oral dryness was 51.13±13.23 years, and the mean oral dryness was 33.56±26.3. Anticoagulant therapy, defined as the FSS score >4, was present in 64% of the patients. Dry symptoms, low educational level, Pain and depression had a negative impact on fatigue scores. The regression models explained that Pain and depression were the strongest predictors of fatigue according to the FSS.

Conclusions: Fatigue is a tiredness which may be mental, physical, or both, and that results in an inability to function at normal performance levels. However, the underlying pathophysiological mechanisms of fatigue remain unclear. From our study, we found that psychosocial variables are determinants of fatigue, and fatigue is associated with depression, but depression is not the primary cause of fatigue in primary SS. Therefore, the investigation of the pathophysiological correlates of physical and mental aspects of fatigue is needed to guide the development of more effective interventions.

AB0514 THE RELATIONSHIP BETWEEN SERUM LEVEL OF C-TERMINAL TEOLOPEPTIDE OF TYPE I COLLAGEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: EPIDEMIOLOGICAL STUDY

S. Shevchuk, L. Denyschych, L. Marynych. National Prograg Medical University, Vinnytsya, Ukraine, Vinnytsya, Ukraine

Background: It is well known, that the incidence of osteoporosis in patients with systemic lupus erythematosus (SLE) is higher compared to the population level. Its severity in patients with SLE is associated with a number of factors: female gender, disease activity, damage index, glucocorticoid therapy etc. One of metabolic factors indicating the reducing bone mineral density (BMD) is the level
of C-terminal telopeptide of type I collagen (CTX). Its place in the formation of osteoporosis in SLE patients is poorly understood, as well as its relationship with the course of the disease.

Objectives: The aim of study was to determine serum level of CTX in the SLE patients and its relationship with structural and functional state of bone tissue, considering frequently occurred skin lesions.

Methods: The study involved 58 SLE women (study group) and 29 healthy individuals (control group) representative by age and gender. The mean age of patients was 45.1±1.03 years. For every patient data were recorded on age, body mass index (BMI), chronic SLE damage (SLICC/ACR DI) and disease activity score (SLEDAI), cumulative glucocorticoid dose, serum concentrations of interleukin-6 (IL-6) and C-reactive protein (CRP), bone resorption marker (CTX). Serum concentration of CTX was determined using ELISA test system “Nordic Bioscience Diagnostics A/S”. Changes in BMD of the lumbar spine and proximal hip were determined by Dual-energy X-ray absorptiometry.

Results: It was established, that in patients with SLE serum level of C-terminal telopeptide of type I collagen was 1.23±0.04 ng/ml (higher than 23% compared with the control group), increased CTX practically had no correlation with age, duration of the disease, smoking and BMI. At the same time the serum CTX was associated with chronic SLE damage index (r =0.51), SLEDAI disease activity (r =0.41), concentration of IL-6 (r =0.45) and CRP (r =0.44).

Conclusions: Alterations of bone metabolism were found in 19% female SLE patients in the form of increased serum CTX and closely associated with the severity and activity of the disease, high levels of CRP and IL-6 and did not depend on the age, disease duration, smoking and body mass index.

ABO515 SKIN MANIFESTATIONS AS INDEPENDENT PREDICTORS AND THE INITIAL RISK FACTORS FOR SYSTEMIC ANTIPHOSPHOLIPID EVENTS

L. Stojanovich 1, A. Djokovic, N. Stanisavljevic, M. Zdravkovic. Internal Medicine Department, University Hospital Center Banja Luka, Bosnia and Herzegovina

Background: Antiphospholipid syndrome (APS) patients express skin manifestations with the presence of various levels of antiphospholipid antibodies (aPL). Several studies have shown the frequency of dermatological manifestations with APS [1,2,3], including livedo reticularis, cutaneous ulcers, acrocyanosis, and others.

Objectives: Dermatological manifestations can be the initial clue in the diagnosis of this disease.

Methods: Our study includes a total of 508 APS patients; 360 were APS patients (283 female and 77 male, mean age 44.0±12.9 years), 148 had APS associated with SLE/SAPS (133 female and 15 male, mean age 47.7±14.8 years). aPL antibodies included anti-β2GPI, anti-β2GPI, anti-β2GPI, and anti-β2GPI. In all patients we considered data frequently occurred skin lesions.

Results: Our results showed prevalence of skin manifestations in SAPS group of patients regressing to PAPS (Table 1). Patients with skin manifestations overall had higher prevalence of thrombosis (Table 2).

Conclusions: Dermatological manifestations can be very often the initial symptoms of severe manifestations of APS. Our study showed that patients with secondary APS had higher prevalence of skin lesions, and that some aPL types were risk factors for thrombotic manifestations in APS patients.

ABO516 INCIDENCE OF CANCER IN A COHORT OF PATIENTS WITH PRIMARY SJÖGREN SYNDROME

M. Bron, S. Mojanov, M. Scolnik, L. E. Pompermajer, I. J. Gandino, E. R. Soriano. Rheumatology Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina

Background: The most severe complication of Sjögren Syndrome is the development of lymphoproliferative processes. Several neoplasia have been associated with the disease, being non-Hodgkin lymphoma the most frequent one.

Objectives: Our objective was to evaluate incidence of cancer in a cohort of patients with primary Sjögren Syndrome.

Methods: A retrospective descriptive study was performed in a university hospital with its own insurance system and captive population. Using electronic medical records and laboratory database we review the entries performed between 01/01/2000 and 12/31/2015. We analyzed those patients of Sjögren Syndrome, complain of dry mouth/eyes, or positive antibodies anti- Ro/SSA and anti-La/SSB.

Among these patients, we included those fulfilling either ACR 2012 or EULAR 2002 Sjögren criteria, or those who were diagnosed as Primary Sjögren Syndrome by the treating rheumatologist even if they did not fulfill criteria.

We then proceeded to register and analyze demographic, clinical and histopathologic information available on their clinical records.

Results: One hundred fifty-seven patients with Primary Sjögren Syndrome were identified. Female accounted for 95.5% of the cohort; mean age at diagnosis was 49.4 years (SD 19). Median follow-up time was 7.7 years (IQR 8). The development rate and type of neoplasia was the following:

- Lymphomas: Three (Two MALT lymphomas of the parotid and one disseminated non-Hodgkin lymphoma), Density of Incidence 260/100,000 person/year (CI 95%: 50 – 750/100,000 person/year)
- Multiple Myeloma: One
- Skin (non-melanoma) neoplasia: Four
- Solid organ Neoplasia: Seven (Four breast cancer, one lung cancer, one uterine cancer, one tongue cancer), Density of Incidence 600/100,000 person/year (CI 95%: 240 – 1240/100,000 person/year)

Univariate analysis showed association between lymphoma and cryoglobulinemia (p=0.01; OR=5.8), low C4 fraction of complement (p=0.01; OR=5.1), anemia (p=0.02; OR=1.96) and leukopenia (p=0.03; OR=1.67).

Conclusions: Development of cancer is a known complication of Primary Sjögren Syndrome. The association between lymphoma and cryoglobulinemia, low C4 fraction of complement, anemia and leukopenia enhances the importance of periodic screening for neoplasms among this subgroup of patients with Primary Sjögren Syndrome.

ABO517 PREDICTIVE FACTORS FOR INFECTION IN SYSTEMIC LUPUS ERYTHEMATOSUS

M. Kechida 1, N. Lorenzo 2, R. Klii 1, S. Hammami 1, I. Khochtali 1, 1Internal Medicine and Endocrinology Department, Fattouma Bourguiba Hospital, Monastir, Tunisia; 2Internal Medicine and cancerology Department, Saint-Cyr Hospital, Lyon, France

Background: it’s known that infection could complicate the course of systemic lupus erythematosus (SLE) because of the immune status or the long term use of steroids and immunosuppressors.

Objectives: This study was aiming at determining the prevalence of infectious complications during SLE and their predictive factors.

Methods: A retrospective bi-centric analyzes of 289 patients diagnosed as SLE between January 2004 and December 2016 according to the ARA criteria of 1997 was conducted. A descriptive analysis of infectious complications was first made, then a comparative study between patients with (group 1) and without (group 2) infectious complications was performed to detect predictive factors.

Results: Mean age was 84.6±13 years (14–72 years) with a sex ratio F/M=6.
Cardiac involvement and lupus nephritis (LN) were developed in 20% of patients. About 13.75% of patients had neurological manifestations, 26.5% articular complications, 16% vascular involvement and 10% of them developed infected complications. Eight percent of these infections were diagnosed concomitantly with the diagnosis of SLE and 92% of them after the diagnosis of lupus with an interval of at least 52.9% of the patients developed more than 2 episodes of infection. The spectrum of infectious complications was: pulmonary in 33.3%, urinary in 22.2% and cutaneous in 13.9%. Tuberculosis was the most frequent infection 12.5%. Lupus flare complicated the infection in 28.6% of patients with mean SLEDAI score at 10. Comparative study between group 1 and group 2 revealed that LN, corticosteroids and immunosuppressors were associated with a high risk of infection (p=0.002, p=0.017 and p=0.034 respectively). In multivariate analysis only LN was an independent predictive factor (OR=3.5, 95% CI=1.06-12.87, p=0.049).

Conclusion: Infections that complicate the course of SLE with flares presenting in 1/3 of cases. Half of the patients had more than 2 episodes of infection during their follow up. The presence of LN represents a predictive factor of such complication.

AB0518  NEW 2016 ACR/EULAR CLASSIFICATION CRITERIA FOR SJÖGREN'S SYNDROME: USEFULNESS AND APPLICABILITY IN CLINICAL PRACTICE

M. Returto Guerrero1, L. Sierra Herranz2, C. Moriano Morales1, C. Iñiguez Ubiaga1, M. Garjo Buitó1, A. Crespo Golmar1, C. Álvarez Castro1, D. Díez Álvarez2, A. López Robles1, M. Martín Martínez1, T. Perez Sandoval1, E. Díez R. Complex of León, Leon, Spain

Background: The Sjögren syndrome (SS) is an autoimmune disease where the cellular and humoral mechanisms affect the exocrine glands. In 2016, new classification criteria validated by ACR and EULAR were established.

Objectives: To compare the new criteria with those used so far in our hospital, as well as to assess the need for changes in the current diagnostic strategy.

Methods: Retrospective observational study in which 65 patients diagnosed with SS at the Hospital of León were randomly included. We reviewed the diagnostic tests performed and the fulfillment of the different classification criteria developed since 1993. Other variables studied were: sex; age at the time of diagnosis and the months from the onset of symptoms; xerostomia and xerophthalmia; extrav glandular involvement, ESSDAI; immunosuppression; Raynaud; lymphoma development; and analytical alterations.

Results: The mean age at the time of diagnosis was 54.9 years ±14 [23–82], with an average of months from the onset of symptoms to the diagnosis of 10.2±9.5 [0–36]. 90.8% were women. 87.7% presented xerostomia; and 91% showed xerophthalmia, being severe in 43.1%. 64.6% had extrav glandular manifestations; being the most prevalent the joint manifestation (60%) and the cutaneous one (18.4%). Over the past year, 37% developed haematological abnormalities in the form of cytopenias, and 73% biological alterations. At the time of the study, 32.8% presented low activity, 38.5% moderate activity and 9.2% high activity; meanwhile ESSDAI and EULAR higher in almost all included. We reviewed the diagnostic tests performed and the fulfillment of the different classification criteria developed since 1993.

Conclusion: In our study, the mean age at the time of diagnosis was 54.9 years ±14 [23–82], with an average of months from the onset of symptoms to the diagnosis of 10.2±9.5 [0–36]. 90.8% were women. 87.7% presented xerostomia; and 91% showed xerophthalmia, being severe in 43.1%. 64.6% had extrav glandular manifestations; being the most prevalent the joint manifestation (60%) and the cutaneous one (18.4%). Over the past year, 37% developed haematological abnormalities in the form of cytopenias, and 73% biological alterations. At the time of the study, 32.8% presented low activity, 38.5% moderate activity and 9.2% high activity; meanwhile ESSDAI and EULAR higher in almost all included. We reviewed the diagnostic tests performed and the fulfillment of the different classification criteria developed since 1993.

AB0519 LABORATORY ABNORMALITIES IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

M. Fernandez Castro1, J.L. Andreu2, C. Sanchez-Piedra3, V. Martinez Taboada4, A. Olive5, J. Rosas6 on behalf of SJOGRENSER group, part of the Spanish Society of Rheumatology Systemic Autoimmune Diseases Study Group (EASSER), 1 Rheumatology, Hospital Infanta Sofia; 2Rheumatology, Hospital Puerta de Hierro Majadahonda; 3 Research unit, Spanish Society of Rheumatology; 4 Rheumatology, Hospital Marqués de Valdecilla, Madrid; 5 Rheumatology, Hospital Hospital Germans Trias i Pujol, Barcelona; 6 Rheumatology, Hospital Hospital Marina Baixa, Alicante, Spain

Background: Primary Sjögren’s syndrome (pSS) is a chronic systemic autoimmune disease often accompanied by analytical abnormalities. Altered levels in serum protein concentration, blood cell count and autoantibodies contribute to the broad spectrum of biological manifestations that characterize this disease.

Objectives: The objective of this study is to evaluate the prevalence of laboratory abnormalities in patients with pSS from the SjogrenSER registry.

Methods: We conducted a multicentre transversal study of a cohort of pSS patients fulfilling 2002 European/American criteria, from 33 Spanish rheumatology departments. Every patient was interviewed for data collection and signed an informed consent. Data were also collected by reviewing medical records. Local ethics committees approved the study. Variables were analysed by descriptive statistical methods, using means, medians and rates. Chi-square was used to evaluate the statistical associations. A p < 0.05 was considered significant.

Results: Four hundred and thirty-seven patients were included. Fifty-six percent of the patients had hematological involvement; 29% of the patients had dermatological manifestations, 14% had hipocomplementemia. More than half of the patients had abnormalities, more than 35% had leukopenia, 30% had anemia, 25% had lymphopenia, 9% had thrombocytopenia. The median ESR was 25 mm. Age at diagnosis and age at onset of symptoms were significantly lower in patients presenting RF+ vs RF- (48.71 vs 53.73, p < 0.001 and 44.76 vs 49.53, p < 0.001, respectively), decreased C3 vs normal C3 (45.66 vs 51.18, p < 0.004 and 42.2 vs 48.99, p < 0.018, respectively), decreased C4 vs normal C4 (47.02 vs 50.89, p = 0.042, for age at diagnosis) and HGG (47.59 vs 54, p < 0.001, and 43.44 vs 50.16, p < 0.001, respectively). ESR was significantly higher in patients with hematological involvement (35.94 vs 26.24, p < 0.001), RF+ (36.39 vs 22.91, p < 0.001), decreased C3 vs normal C3 (37.8 vs 30.53, p < 0.002) and C4 (38.71 vs 30.42, p < 0.041), HGG (36.21 vs 26.03, p < 0.001) and increased ß2microglobulin (38.80 vs 27.91, p = 0.009). ESSDAI (Eular Sjögren Syndrome Disease Activity Index) was significantly higher in patients with haematological involvement (5.38 vs 3.69, p < 0.001), RF+ (5.40 vs 3.53, p < 0.001) and HGG (5.31 vs 3.93, p < 0.001).

AB0520 THE ROLE OF LEPTIN IN SJÖGREN'S DISEASE

M. Erdogʌn1, M.E. Tezcan2, K. Başkʌş2. 1 Internal medicine division of Rheumatology, Cerrahpaşa Medical Faculty; 2 Internal medicine division of Rheumatology, 3 Pathology, Dr. Lütfi Kirdar Kartal Training and Research Hospital, Istanbul, Turkey

Background: Sjögren's disease (SD) is a multisystemic disease mostly manifest with sicca symptoms. Lymphocytic infiltration of the glandular and extra glandular organs is the dominant pathologic feature of the disease. Multiple stimulators were accused in the pathogenesis of SD. Leptin, an endogenous peptide, involves in various metabolic processes as well as immune system (1). Increased serum leptin level is observed in patients with autoimmune diseases such as SD, systemic lupus erythematosus and rheumatoid arthritis when compared to healthy controls (2).

Objectives: Even if serum leptin level increases in the patient with SD, there is no clear data about its effect on extraglandular manifestations.

Methods: We studied leptin density in acinar and ductal structures of the salivary glands by immunohistochemistry in patients with SD. The relationship between intensity of lymphocytic infiltration and density of leptin in the salivary gland of SD patients with control group. Furthermore we evaluated the relation between intensity of lymphocytic infiltration and density of leptin in the salivary glands of SD patients.

Results: We applied leptin immunostain to minor salivary glands samples of 24 SD patients, who were fulfilled American College Rheumatology Sjögren’s Disease Classification Criteria (ACR-SDCC) and 19 patients who undergo minor salivary gland biopsy due to clinically on suspicion of SD but not fullfilling the ACR-SDCC and had no lymphocytic focus on biopsy. Herein, leptin density in acinar and ductal structures of the salivary glands were evaluated in both groups.

Moreover,
minor salivary gland samples of SD patients were also assessed for relationship between focus score, disease progression (evaluated with SSDAI) and leptin immunostaining.

**Results:** Demographic features of both group were similar. Furthermore, there were no difference in leptin staining features of both group. Additionally, we found that higher focus score (≥2) was associated with more diffuse leptin staining and higher SSDAI scores related with diffuse acinar staining.

**Conclusions:** Different leptin staining features in higher focus score and higher disease activity might indicate the role of leptin especially in more significant disease. Leptin may locally stimulate chemotaxis and activate infiltration of glands with inflammatory cells. We suggested further studies aimed to understand autocrine effect of leptin and evaluate its role in SD pathogenesis.

**AB0521 ANTIPHOSPHOLIPID SYNDROME - ATHEROSCLEROSIS AND CLINICAL-INMUNOLOGICAL CORRELATIONS**

N. Stoilov1, V. Boyadzhieva2, R. Rashkov1. 1Clinic of Rheumatology; 2Clinic of Rheumatology, UMAB “Sv. Ivan Rilski”, Sofia, Bulgaria

**Background:** Antiphospholipid syndrome (APS) is an autoimmune, multisystem disease characterized by thrombocytopenia, venous and/or arterial thrombosis, pathological course of pregnancy in women (preeclampsia, eclampsia, miscarriage) and the presence of a heterogeneous group of antibodies - antiphospholipid antibodies. Recent studies show that in the pathogenesis of atherosclerotic process, relevant inflammatory component of the immune response, as well as elements of autoimmunity (autoantibodies and autoantigens autoreactive lymphocytes) may play a role. A number of autoimmune rheumatic diseases, including RA, SLE and APS are characterized by accelerated atherosclerosis and therefore an increased risk of cardiovascular morbidity and mortality.

**Objectives:** The aim of the study was to investigate the incidence of cardiovascular events and atherosclerosis in patients with primary and secondary antiphospholipid syndrome, spaymo healthy subjects and patients with systemic lupus erythematosus without antiphospholipid antibodies.

**Objectives of the study:**
- To compare the damage to aa. Carotid in patients with APS compared to healthy subjects and patients with SLE without antifosfolipidi antibodies.
- To compare Are score in patients with APS compared to healthy individuals without antifosfolipidi antibodies.
- To compare atherosclerosis of aorta in patients with APS compared to healthy subjects and patients with SLE without antifosfolipidi antibodies.
- To compare cutaneous vascular lesions (Raynaud, Livedo reticularis, periungual vasculitis, son palp gangrene, asphyxia, vasculitis lesions) on the limbs and body in patients with aPL spaymo healthy subjects and patients with SLE without antifosfolipidi antibodies.

**Methods:** For the purpose of this study examined 127 patients, 18 men (14%) and 109 women (86%), positive antiphospholipid antibodies. Patients were selected from the Department of Rheumatology, University Hospital “St. Ivan Rilski” – Sofia. All the patients were tested for: ANA, aPL, standard laboratory tests.

**Instrumental methods:**
- Calcium score of a. coronaria sinister, a. anterior descendens sinister, a. circumflexa sinistra, a. coronaria dexter, Aorta, Valva aortae.
- Ultrasonographic examination of aa. Carotid to measure the Intima-media thickness.

**Results:** It was proved strong, statistically significant correlation between aCL antibodies and the presence of plaques in the left common carotid artery (p=0.041). Absent the dependence between the antibody titers and incidence of carotid plaques. The presence of positive aCL antibodies in the group with APS, 33.3% (14) establishes a positive calcium score of coronary aeri, 11.9% (5) plozhitefnite for aorta. Aortic valve Absent deposits. In the control group positive calcium score is when one person (5.88%).

**Conclusions:** We found that patients with antiphospholipid syndrome suffer from early development of atherosclerosis. In the process of atherosclerosis involving inflammatory component of immune response. Atherosclerosis can be viewed as an inflammatory autoimmune disease. It is proved strong, statistically significant correlation between aCL antibodies and the presence of plaques in the left common carotid artery (p=0.041).

**AB0522 CLINICAL FINDINGS AND THEIR RELATIONSHIP WITH THE PROFILE OF ANTIPHOSPHOLIPID ANTIBODIES IN DOMINICAN PATIENTS**

R. Vasquez-Colon1, P. Gottschalk1, C. Tino1, P. Lopez1, R. Tejeda1, E. Loyo1. 1Reumatología, Hospital Regional Universitario Jose Maria Cabral y Baez; 2Investigaciones Clinicas, Pontificia Universidad Catolica Madre y Maestra, Santiago, Dominican Republic

**Background:** There is an increased risk of thrombotic events and obstetric morbidities in individuals with antiphospholipid antibodies (APAs) compared with the general population. The risk of complications is further increased in those patients who have a rheumatic diseases and antibody positivity.

**Objectives:** The purpose of this study is to determine the clinical findings and their relationship with the profile of antiphospholipid antibodies in patients with rheumatic disease, of the Division of Rheumatology of the Hospital Regional Universitario José M. Cabral y Baez, Dominican Republic.

**Methods:** Patients with 18 years of age and above, with a confirmed rheumatic disease was eligible for enrollment; those with positive titers for APAs, that met the inclusion and exclusion criteria, were included in our study. The institutional review board approved the protocol. This is a transverse study, with retro-prospective data gathering from patients and their medical records. Demographic information at the time of APA measurement and medical information regarding the rheumatic disease and clinical course were collected from the patient’s medical record, with a follow-up of 10 years.

**Results:** 40 patients were included in this study. The male to female ratio was 19:11; mean age was 36±10 years. A large number of patients (13 patients, 32.5%) were asymptomatic for antiphospholipid syndrome (APS) at the time of this study; eight patients (20%) were carriers without defining manifestations. Ten patients (25%) were categorized as vascular APS and five patients (12.5%) as obstetric APS: three patients (7.5%) had vascular and obstetric APS. One patient presented with catastrophic APS. In evaluating such specific profile of antiphospholipid antibodies, aCL was observed that corresponded to the antibody most frequently identified with IgG isotypes (52.5%) and IgM 47.5%. The lupus anticoagulant (LA) corresponded to the second most common (37.5%). The isotypes of the anti-B2GPI-I were identified in less proportion. We report 89 pregnancies during the follow, with 29 abortions and 60 live births, of which 12 were premature and 11 born with intrauterine growth restrictions.

**Conclusions:** The most frequent clinical manifestations were livedo reticularis, vascular thrombosis in lower extremities, Raynaud’s phenomenon, migraine, cerebrovascular disease, thrombocytopenia, leukopenia, and alteration of urine sediment.

AN ANALYSIS OF THE FACTORS INFLUENCING THE BODY IMAGE DISTURBANCE WITH SYSTEMIC LUPUS ERYTHEMATOSUS LIVING IN CHINA

Q. Zhao, Y. Cui, L. Li, S. Chen, C. Zhou, Z. Gu. Department of Rheumatology, Affiliated Hospital of Nantong University, Nantong, China

Background: Systemic Lupus Erythematosus (SLE) is a chronic, autoimmune rheumatic disease that can affect multiple systems/organs in the body and is characterized by relapses and remission, usually affects women in the reproductive age group. SLE may cause inflammation activity and damage in any of the organs, often leading to decreased physical, emotional and social abilities, depression, pain, fatigue, visible or invisible changes in appearance. Recent studies have indicated that body image disturbance (BID) can lead to a variety of cognitive, emotional and behavioral changes. BID will cause the individual having a negative perception of the body, negative emotional experience and the corresponding behavior disorders.

Objectives: To explore the relationship between social and economic status, disease activity, mental state, self-esteem, quality of life and the essential BID with Systemic Lupus Erythematosus Living in China.

Methods: The investigation is from in October 2015 to December 2016 at the Affiliated Hospital of Nantong University. There are 109 cases of hospitalized patients, including 8 cases of male, female 101 cases, mean age is 35.3±12.2. Scale including body image disorder scale (BID), respectively. Body image was assessed using the Body Image Disturbance Questionnaire (BIDQ) with a total of 45 items. The BIDQ includes seven scaled items scored from 0 (not affected) to 8 (extremely affected) pertaining to appearance-related concerns (BIDQ1); mental preoccupation (BIDQ2); emotional distress (BIDQ3); social, occupational, or functional impairment (BIDQ4); social life interference (BIDQ5) and educational, occupa- tional health (BIDQ6); body image (BIDQ7). Systemic lupus erythematosus disease activity index (SLEDAI); the hospital anxiety and Depression Scale (HADS) in systemic lupus erythematosus; disease-specific HRQOL measure for adults with SLE (Lupus QOL), including health (PH), pain (PN), planning (PL), intimate relationship (IR), a burden to others (BV), emotional Health (EH), body image (BI), fatigue (F). Spearman’s coefficient for nonparametric and Pearson’s coefficient for parametric data were computed. Variables that were significant in univariate analysis were included in a multivariate linear regression model. All p-values less than 0.05 were considered statistically significant.

Results: SLE patients were most concerned about their body size (33.38%) and skin (32.23%), 55.34% SLE patients were more concerned about the change of body shape caused by disease. There was significant correlation between BID and disease status, psychological status, and quality of life in patients with SLE. Physical health is correlated with BID1, Pain is correlated with BID1, BID4–7, Planning is correlated with BID2, BID7–7. Intimate relationships is correlated with BID4–7, Burden to others is correlated with BID3–7, Emotional health, fatigue are associated with BID3–7. Anxiety and depression also affect BID, anxiety is an important predictor of BIDQ1, BIDQ3–6, depression is a predictor of BIDQ2, BIDO 3–6.

Conclusions: Patients with Systemic Lupus Erythematosus Living in China are much easier bear with BID, anxiety, depression, less quality of life will lead to BID, in view of the body image perspective, this study will help explore the influence factors of BID in patients with SLE.

TRANSLATION AND VALIDATION OF THE FATIGUE SEVERITY SCALE, THE PITTSBURGH SLEEP QUALITY INDEX AND THE MODIFIED HEALTH ASSESSMENT QUESTIONNAIRE INTO THE MALTESE LANGUAGE, IN A COHORT OF MALTESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

R. Mangi 1, A.A. Borg 1, L. Camilleri 2, 1 Rheumatology, Mater Dei Hospital; 2 Statistics and Operations Research Department, University of Malta, Msida, Malta

Background: The Fatigue Severity Scale (FSS), Pittsburgh Sleep Quality Index (PSQI) and Modified Health Assessment Questionnaire (mHAQ) are validated questionnaires that measure fatigue, sleep quality and function respectively. Research in the Maltese population, on systemic lupus erythematosus (SLE) requiring the use of these questionnaires, necessitates their translation and validation into the Maltese language.

Objective: The aim of the study is to translate, validate and perform cross-cultural adaptation of the FSS, PSQI and mHAQ into the Maltese language, according to the recommended methodology.

Methods: The original instruments were translated into Maltese by two translators whose mother language is Maltese. One of the translators had a medical background and was knowledgeable on the concepts being examined in the questionnaires; while the other did not. The two translated versions of the instruments were then compared and the discrepancies were resolved by reaching a consensus on the best Maltese version that reflects the underlying meaning of the original English version. The preliminary Maltese translations were then given to two other translators for back translation into English. English was the native language of these translators and they were totally blind to the original versions. The back translated English versions were then compared to the original English questionnaires and any discrepancies were highlighted. The equivalent statements in the Maltese translations were discussed and changes made as required to reflect the exact wording of the English versions. The Maltese translations were produced and pilot tested in a sample of 20 bilingual SLE patients to evaluate the clarity of the questionnaires. These 20 patients were also asked to fill in the original English version of the FSS, PSQI and mHAQ, seven days after filling in the Maltese versions. Psychometric testing was carried out to assess the reliability of the translation, internal consistency and validity.

Results: Reliability of the translation of the FSS, PSQI and mHAQ into Maltese was analysed by using Kendall’s tau test for statements having an ordinal scale and Pearson’s correlation test for variables having a metric scale. The p value for the statement in the FSS, PSQI and mHAQ was <0.001, which means that the reliability of the translated versions was satisfactory. Internal consistency of the Maltese translations was demonstrated using Cronbach’s alpha. This was calculated to be 0.877 for the FSS, 0.859 for the PSQI, and 0.897 for the mHAQ. Validity of the Maltese translation of the FSS was assessed by its correlation with the visual analogue scale for fatigue using Pearson’s Correlation test. Pearson’s R value was 0.809 and the p value was <0.001 confirming a positive significant correlation.

Conclusions: This study has confirmed the reliability and internal consistency of the translated English versions of the FSS, PSQI and mHAQ and in Maltese. Moreover, a back translation of the FSS has been shown. The Maltese translations can be finalised and used for research purposes.

B1 CD5+ Lymphocytes in Systemic Lupus Erythematosus Patients: Relation to Disease Activity

S.I. Nasef1, H.H. Omar2, H.H. Omar3, M.S. Ghaly1. 1 Physical Medicine, Rheumatology and Rehabilitation; 2 Internal Medicine, Faculty of Medicine, Suez Canal University, Ismailia, Egypt

Background: B cells are essential players in the pathogenesis of Systemic lupus erythematosus (SLE). Membrane CD5 elevates the threshold of B cell receptor mediated responses, and thus prevents the release of antibodies. So, misguided signalling through CD5 could lead to autoimmunity. Hence, CD5+ B cells were considered to play a paradoxical role in preventing rather than inducing autoimmunity. This challenging view differs from the old interpretation that elevated levels of B1 CD5+ cells in SLE patients represent a direct source of autoantibodies responsible for organ damage.

The clinical implications of this new concept for the role of B1 CD5+ cells in SLE have not been fully addressed yet and there is no consensus agreement about the proportions of B1 CD5+ cells in SLE patients. Moreover, the relation of B1 CD5+ cells to disease activity and organ damage is not sufficiently studied.

Objectives: To assess the expression of B1 CD5+ cells in SLE patients and to evaluate their relationship with disease activity and organ damage.

Methods: We recruited 100 SLE patients and 100 healthy control subjects. Based on SLE disease activity index (SLEDAI), patients were divided into two groups; active SLE (n=50) and inactive SLE (n=50). SLE was active when SLEDAI was ≥4. The expression of (CD5+CD20+) B1 cells was evaluated using flow cytometry. Lymphocytes were gated depending on both side and forward scatter. From the gated lymphocytes, B1a cells were identified double positive cells for CD20 and CD5. Percentage and absolute numbers of CD20+CD5+ (B1a cells) and their mean fluorescence intensity (MFI) were measured. The histogram of CD5 expression was used to assess its expression on CD20 cells (figure 1).

Results: Mean age of patients was 31.3±8.8 years. Females constituted 94% (n=94). Mean disease duration was 5.2±4.8 years. Mean SLEDAI was 10.28±5.16. The proportions of (CD5+CD20+) B1 cells were significantly lower in SLE patients versus controls (5.9±4.4% vs 20.2±4%, p<0.001). Similarly, the absolute numbers of (CD5+CD20+) B1 cells (cell/mm²) were significantly lower in SLE patients versus controls (100.2±103.4 vs 557.6±163.3, p<0.001). The expression of (CD5+CD20+) B1 cells was decreased in active SLE patients (4.5±3.8%) in comparison to inactive patients (7.3±4.7%) (p=0.027). B1 (CD5+CD20+) absolute cell number (cell/mm²) was significantly lower in active SLE patients (71.4±82.9) compared to inactive ones (129.0±115.1) (P=0.047).

MFI of CD5+CD20+ was significantly decreased in SLE patients compared to healthy control (146.9±109 vs 196±48, P=0.033). B1 cells (CD5+CD20+) correlated positively with C3 (r=0.322, p=0.022) and C4 (r=0.307, p=0.030). No correlation was found between (CD5+CD20+) B1 cells and disease duration, autoantibodies or any specific system or organ damage.

Conclusions: Expression of B1 CD5+ cells was significantly decreased in SLE patients. Decreased B1 CD5+ cells expression was associated with higher disease activity. B1 CD5+ cells correlated positively with complement levels. These findings denote that CD5 expression on B cells may play a regulatory role in SLE pathogenesis and decrease occurrence of flares.

Progranulin and Insulin-Like Growth Factor-2 as Biomarkers for Disease Activity and Pathological Changes in Lupus Nephritis

S. Goma, M. Abdelaziz, E. El-Hakeim, M. El Zohri, S. Sayed. Assiut University, Assiut, Egypt

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune inflammatory disease (1), characterized by the production of autoantibodies, and formation of immune complexes due to the polyclonal activation of T and B lymphocytes that result in tissue and organ damage (2). During inflammation, neutrophils and macrophages release serum proteases to cleave progranulin (PGRN) into granulin (GRN), which exert their pro-inflammatory effects that counteract the anti-inflammatory effects of intact PGRN (3). Insulin-like growth factor-2 (IGF-2) binds to insulin-like growth factors (IGFs) with high affinity (4). Although reports suggest that IGFBP-2 is a reliable biomarker of renal deterioration, it is still needed to confirm that it has high sensitivity and specificity in discriminating kidney disease caused by SLE from other origins.

Objectives: The aim of this study was to explore whether PGRN and IGF-2 can be used as useful markers not only for accurate diagnosis of patients with active lupus nephritis (LN) but also for prediction of the disease activity in these patients.

Methods: Twenty-five patients with systemic lupus erythematosus, twenty-five patients with chronic renal failure and twenty-five age- and sex-matched healthy volunteers were enrolled in the study. Routine laboratory investigations and measurement of serum PGRN and IGFBP-2 levels were done.

Results: Our results showed that the mean age of SLE, CRF and control groups 31.12±12.4, 38.7±9.4 and 32.96±13.66 respectively with no significant difference between the three groups. There was female predominance in the three groups. Disease duration was 4.76±4.26 in SLE patients. The mean of SLEDAI score was 15.04±7.54. All renal biopsy results were class 2, 3, and 5 with a percentage of 32%, 24%, and 44% respectively.

PATIENT ACTIVATION AND THE FACTORS AFFECTING IT IN PRIMARY SJÖGREN’S SYNDROME

S.T. Souter 1, B. Hargreaves 2, K.L. Hackett 2, W.-F. Ng 1. 1 New University; 2 Institute of Cellular Medicine & NIHR Newcastle Biomedical Research Centre, Newcastle upon Tyne, United Kingdom

Background: Increased patient activation has been associated with reduced costs of treatment1 and improved patient outcomes2. The effect of primary Sjögren’s syndrome (pSS) on patient activation however has not been established.

Objectives: This study aims to identify how activated patients with pSS are, and to ascertain whether markers such as ESSPRI score, EQ5D dryness score and self-reported quality of life influence this.

Methods: Patient activation in 170 pSS patients was assessed using the 13-item Patient Activation Measure (PAM-13). A PAM-13 score from 0–100 was obtained using the PAM-13 Scoring Spreadsheet, which also gave a corresponding activation level ranging from 1–4. Descriptive statistics of the PAM-13 scores was performed, and frequency analysis of the corresponding activation level. Demographic, clinical and self-reported measures such as age, gender, ESSPRI score and EQ5D-3L score were linked to each patients’ PAM-13 scores. Spearman’s correlation analysis was performed to assess the relationship between the continuous variables and PAM-13 score. Fisher’s chi-square test was used to assess the relationship between activation level and the categorical variables.

Results: The mean PAM-13 score of the 170 patients studied was 59.5 (SD 13.9): 17.6% of patients were in level 1 of activation, 28.5% in level 2, 40.0% in level 3, and 15.9% in level 4. The mean age of the sample was 59.6 (SD 13.1), and 83.5% were female. EQ5D-3L score had the strongest correlation with increased PAM score (r = 0.40, p = 0.000). Increasing self-reported pain in the ESSPRI questionnaire was correlated with a decreasing PAM score (r = -0.35, p = 0.000), as was increasing EQ5D-3L score (r = -0.37, p = 0.000). Increasing abnormal fatigue (r = -0.19, p = 0.016) and EULAR dryness (r = -0.19, p = 0.013) score were also weakly correlated with a decrease in PAM-13 score. Decreases in patients self-reported mobility (p = 0.000), self-care (p = 0.002), and ability to perform daily activities (p = 0.018) were also associated with differences in activation score.

Conclusions: Factors such as a patients self-reported health and pain have a moderate correlation with activation in pSS patients, while dryness and fatigue are only weakly correlated with changes in activation. This should be considered in the future when devising treatment plans and clinical trials.

BACKGROUND: The prevalence of anti-centromere antibodies (ACA) among patients with primary Sjögren’s syndrome (pSS) varies from 3.7% till 10.9% [1]. They have special course of the disease: 1) with some features of systemic sclerosis (SSc), but rarely evolve to it, 2) higher prevalence of hepatitis and possible biliary cholangitis - PBC. Objectives: to describe the peculiarities of this subgroup; to evaluate it’s importance long-term morbidity.

RESULTS: In our study 2/3 (64%) ACA+pts with pSS didn’t fulfill ACR2012 criteria, because of the lack of aRo or aLa or combination of RF+ANA. According to the criteria, 2014 [4] also just 60–68% pts will have ≥4scores for diagnosing pSS. SSc (limited form) due to new criteria [5] might be revealed in 11/50 (22%) cases. MALT lymphoma of salivary glands arised in 5/6 pts with visible enlargement of parotid glands.

Conclusions: pSS with positive ACA is challenging for diagnostics with comprehensive classification criteria (32-64% doesn’t meet it [3,4]). These patients overlaps SSc, some PBC, PBC is not rare among, but biliary tract lesions (AMA= rarely absent, 2% in our study) with slightly elevated liver enzymes, especially GT, and stage 1 typical to PBC without progression) are more common.

AB0532 VITAMIN D IN A MALAYSIAN LUPUS COHORT AND ITS CORRELATIONS WITH CLINICAL AND IMMUNOLOGICAL PARAMETERS

S.G. Ong, H.J. Ding, Medicine, Kuala Lumpur Hospital, Kuala Lumpur, Malaysia

Background: Numerous studies have demonstrated that inadequate vitamin D levels are common in systemic lupus erythematosus (SLE) patients and they correlate inversely with disease activity. To date, there is paucity of data on the prevalence of vitamin D status, as well as its clinical and immunological associations in Malaysian SLE patients. Objectives: Our study aimed to determine the prevalence of vitamin D deficiency and insufficiency in SLE patients, and to examine the association between vitamin D status with gender, ethnic groups, clinical manifestations of SLE, Schirmer’s test, cardiovascular risk factors, bone mineral density and autoantibodies. Methods: This retrospective study included 216 SLE patients who attended the Rheumatology Clinic of Kuala Lumpur Hospital between January 2013 and December 2015. All patients had medical records. All patients fulfilled the 1997 American College of Rheumatology revised classification criteria for SLE. Serum 25(OH)D concentrations were measured by electrochemiluminescence immunoassay. Results: A total of 216 SLE patients were included in this study. Eleven (5.1%) were males and 205 (94.9%) were females. There were 141 (65.3%) Malay, 53 (24.5%) Chinese, 19 (8.8%) Indian and 3 (1.4%) of other ethnic group. This corresponded with the pattern of ethnic distribution in the Malaysian population. Their ages ranged from 14 to 75 years, with a mean age of 35.9±7.1 years. Mean duration of SLE at the time of 25(OH)D analysis was 6.9 years (range from 0 to 39 years), and mean age was 35.1±6.4 years (range from 14 to 75 years). Mean 25(OH)D concentration was 51.3±14.8 nmol/L (range from 7.5 to 156.1 nmol/L). Fifty (23.1%) patients had vitamin D deficiency, 120 (55.6%) had vitamin D insufficiency, while 46 (21.3%) had adequate vitamin D levels. Our study showed statistically significant association between vitamin D status and ethnic group (p<0.001). The Chinese ethnic group had the lowest proportion of patients with vitamin D deficiency and insufficiency (60.4%), while Malay had the highest proportion at 86.5%. Mean levels of serum 25(OH)D in Chinese, Indian and Malay SLE patients were 66.3±36.7 nmol/L, 54.9±36.4 nmol/L, and 45.0±27.5 nmol/L, respectively. Among the clinical manifestations of SLE, only lupus nephritis showed a statistically significant association with vitamin D status (p<0.001). In terms of cardiovascular risk factors, hypertension demonstrated significant correlation with vitamin D status (p=0.032). No significant association was found between vitamin D status and gender. Nonetheless, male SLE patients had higher mean 25(OH)D concentrations at 69.4±36.9 nmol/L, compared to female at 50.2±31.6 nmol/L. There were no significant correlations between vitamin D status and clinical features of lupus such as cutaneous lesions, arthritis and NPSLE; positive Schirmer’s test; cardiovascular risk factors, that are, dyslipidemia and diabetes mellitus; osteoporosis; and autoantibodies which included anti-dsDNA antibody, anti-Ro antibody, anticardiolipin antibody and rheumatoid factor.

Conclusions: Sub-optimal vitamin D levels are prevalent among SLE patients in a tropical country and are associated with ethnic group, lupus nephritis and hypertension. It is essential to include vitamin D supplementation in the management of SLE patients.

AB0533 JUVENILE AND JUVENILE-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: CLINICAL CHARACTERISTICS, DISEASE ACTIVITY AND DAMAGE

T.A. Gheita1, R.E. Gheith1, H.S. El-Fishawy2, D.M.R. Bahgat3, A.M. Nour El-Din4, T. Rheumatology and Clinical Immunology; 5Internal Medicine; 6Clinical and Chemical Pathology; Faculty of Medicine - Kasr Al-Ainy School of Medicine - Cairo University, Cairo; 7Peditrics, National Research Centre (NRC), Giza, Egypt

Background: The diagnosis of systemic lupus erythematosus (SLE) in children is challenging as the heterogeneous manifestations and disease impact on the child’s growth highlighted the importance of timely diagnosis and management. Objectives: The aim of the present study was to assess and compare the clinical characteristics, disease activity and damage between juvenile (JSLE) and juvenile-onset (JO-SLE) Egyptian patients. Methods: Seventy-eight SLE patients (26 JSLE and 52 JO-SLE) were included in this study. Disease activity was assessed using the SLE Disease Activity Index (SLEDAI) and organ damage using the Systemic Lupus International Collaborating Clinics (SLICC) index. Results: The mean age of the JSLE children was 13.2±2.09 years and 23.17±4.26 years for JO-SLE cases. JO-SLE cases were older at disease onset with a higher female-to-male ratio. There were no noticeable gender differences. There was a significantly higher frequency of serositis, nephritis and hematological involvement in the JO-SLE cases (57.7%, 76.9% and 73.1%) compared to the JSLE cases (15.4%, 30.8% and 30.8%) (p<0.001 for all). The erythrocyte sedimentation rate, creatinine and proteinuria were significantly increased in JO-SLE while alkaline phosphatase was higher in JSLE cases. In JO-SLE cases, sedimentation rate, creatinine and proteinuria were significantly increased in JO-SLE while alkaline phosphatase was higher in JSLE cases. In JO-SLE cases, the mean SLEDAI was higher (6.6±1.8 vs 3.1±1.97; p=0.003) and the SLICC tended to increase compared to the JSLE children. More JO-SLE cases received hydroxychloroquine and azathioprine.

Conclusions: The existence of differences in clinical phenotype has been confirmed, between JSLE and JO-SLE especially as regards serositis, nephritis and hematological affection. The disease damage was comparable which denotes that the maximum organ involvement occurs in childhood with an almost stationary course. Rheumatologists caring for children with SLE must be aware of the greater risk of major haematological and renal involvement as well as important long-term morbidity.

AB0534 THROMBOTIC MICROANGIOPATHY IN PREGNANT WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: CHARACTERISTICS AND OUTCOMES
T. Kirsanova1, M. Vinogradova1, A. Kolyvanova2, N. Klimchenko1, 1 Federal State Budget Institution “Research Center for Obstetrics, Gynecology and Perinatology” MoH, Russian Federation; 2 Moscow State University, Moscow, Russian Federation

Objectives: to evaluate the impact of thrombotic microangiopathy (TMA) on perinatal and maternal outcomes in patients with systemic lupus erythematosus (SLE).

Methods: This study included 21 SLE patients with pregnancy, who developed TMA signs during pregnancy. Patients underwent general survey, clinical and laboratory assessment for disease activity and APL-antibodies. All of them had low SLE-activity indices.

Results:

TMA signs were found in 7/21 SLE patients (33%). Patients with TMA had significantly higher systolic and diastolic blood pressure (P<0.05), higher serum creatinine and lower estimated glomerular filtration rate (P>0.05) than that of those without TMA lesions (tab.1). APLA positivity was significantly more frequent in patients with TMA (3/7 vs 0/14). TMA onset in 2 patients occurred before 20 gestational weeks, 5/7 have developed PE signs (23–38 weeks), only 3/7 had classical HELLP syndrome. There was no PE in patients without TMA. There was a significant association between the detection of TMA and adverse perinatal outcomes (tab.2).

Patient with TMA and SLE had a poor outcome and most severe course: 5/7 had a PE (3/7 developed HELLP), 3/7 had antenatal fetal death, 3/7 had signs of heart damage. 5/7 a variety of neurological manifestations. Despite of PE signs in 5/7 with TMA the blood sFlt/PlGF levels were slightly above normal (average sFlt/PlGF levels in preeclampsia without SLE in our another study is 404.47).

Conclusions: TMA is not an uncommon disorder in pregnant patients with SLE. It is associated with APLA positivity only in 1/3 cases. TMA was significantly associated with renal impairment, systemic hypertension and adverse perinatal outcomes. Less increased ratio of sFlt-1/PlGF in TMA patients than “pure” PE may confirm that PE in patients with TMA is not a condition due to angiogenic factors imbalance. Circulating concentrations of angiogenic factors appear not to be suitable markers to assess the severity of PE and adverse outcomes in SLE patients. Thus, TMA may be an important cause of renal injury and renal dysfunction in a subset of pregnant patients with SLE and associated with worse renal and perinatal prognosis. Complement over-activation via both classical (SLE+APS) and alternative pathways might play an important role in the pathogenesis of TMA in SLE.

AB0535 FATIGUE IS ASSOCIATED WITH HS-CRP IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS
T. Aung1, L. Sahakian, B. Skaggs, J. Grossman, M. McMahon. Rheumatology, UCLA, Los Angeles, California, United States

Background: Fatigue is highly prevalent and has a negative impact on quality of life in patients with Systemic Lupus Erythematosus.1 The 9-item Fatigue Severity Scale (FSS) is one of the commonly used self-report questionnaires to measure fatigue in patients with chronic disease.2 Although fatigue is one of the most commonly reported symptoms in SLE, previous studies have not consistently found any clear association between disease activity (as measured by the SLEDAI)3 or with laboratory measures of disease activity.2

Objectives: To determine whether fatigue is associated with any laboratory measures of disease activity or inflammation in patients with SLE.

Methods: SLE patients and age-matched controls participating in our longitudinal “Biomarkers of Cardiovascular Disease in SLE” completed FSS questionnaires at study entry. Laboratory measures of cardiovascular risk assessment and lupus disease activity assessments were performed in plasma, including high sensitivity C-reactive protein (hs-CRP), myeloperoxidase (MPO), homocysteine, fasting lipid panels, erythrocyte sedimentation rate (ESR), C3, C4, dsDNA, and urine protein/creatinine ratio (UPCR).

Results: 54 patients and 37 control individuals participated. FSS scores were higher in patients with SLE (4.79±1.63 mean ± SD) compared to healthy subjects (3.17±1.83, P<0.001). There were no significant correlations between FSS and age, gender, or SLE disease duration. In SLE patients, there was significant correlation between FSS scores and hs-CRP (r=0.56, p=0.004), and an inverse correlation with myeloperoxidase (-0.37, p=0.045). No associations between FSS and C3, C4, dsDNA, ESR, UPCR, fasting lipid panels, or homocysteine were seen in the SLE group. No associations between FSS and laboratory measures of cardiovascular risk assessment were seen in the control group.

Conclusions: Although fatigue is not correlated with traditional laboratory measures of disease activity in SLE patients, we did find significant associations between fatigue, hs-CRP, and myeloperoxidase in our cohort. Future longitudinal studies are underway to determine whether these associations also reflect the risk for progression of cardiovascular disease in patients with high fatigue.

AB0536 ANTICARDIOLIPIN ANTIBODIES IN SYSTEMIC LUPUS ERYTHEMATOSUS
T. Ben Salem, I. Naceur, M. Tougouri, M. Lamloum, I. Ben Ghorbel, M.H. Houman. Internal Medicine, Rabta university hospital, Tunis, Tunisia

Background: Anticardiolipin (ACL) antibodies have been independently associated with high incidence of thrombotic diseases and pregnancy associated disorders in patients with systemic lupus erythematosus (SLE).

Objectives: This study aims to assess influence of ACL antibodies in SLE and their association with clinical, biological and immunological features.

Methods: A retrospective study of 246 patients with systemic lupus erythematosus (revised ACR criteria) conducted in an internal medicine department over a period of time of 14 years. Two groups were compared according to the positivity of ACL antibodies (group1: positive ACL/ group2: negative ACL).

Results: ACL antibodies were positive in 48.8% of SLE patients (screened in 168 patients). This prevalence was similar in female and male. Poor general state at diagnosis was more frequent in the ACL positive group (55.7% vs 38.6%; p=0.02). The following data were comparable in the two groups: joint involvement (91.8% vs 90.8%; p=0.7), pericarditis (33.8% vs 37.8%; p=0.6) and pleural effusion (24.1% vs 29.5%; p=0.44). Alopecia (38.6% vs 27.9%; p=0.2), central nervous system involvement (12.5% vs 18.8%; p=) and peripheral neuropathy (6.4% vs 11.1%; p=) were more frequent in the group 2 without significant difference. Prevalence of lupus nephritis was more important in the group 1 (52.8% vs 38.8%; p=0.07). Thromboembolic complications: deep venous thrombosis (13.8% vs 11.9%; p=0.72) and pulmonary embolism (10.8% vs 7.1%; p=0.51) were more frequent in patients with ACL antibodies without significant difference. Obstetrical complications were more frequent in group 1 but differences were not statistically significant; spontaneous abortions (29.5% vs 20.4%; p=0.29), intra-uterin death (13.6% vs 9.3%; p=0.5), premature birth (6.8% vs 1.9%; p=0.3). There were no associations between hematologic disorders and ACL antibodies; leucopenia (51.3% vs 39.5%; p=0.13) and, lymphopenia (81% vs 80.2%; p=0.9), anemia (77.2% vs 74.4%; p=0.6) and thrombopenia (22.8% vs 23.5%; p=0.9) were comparable in the two groups. Frequencies of anti-ds DNA antibody and of antibodies to extractable nuclear antigens were similar in the two groups. Only anti-B2GPI1 antibodies were significantly associated to ACL antibodies (5.1% vs 17.2%; p=0.001).

Conclusions: ACL antibodies were found in 30–40% of patients with SLE, this is comparable to our group.

No significant associations of ACL antibodies to thrombotic events or obstetrical complications were found in our patients.

ACUTE ALCALCULOUS CHOLECYSTITIS: A RARE MANIFESTATION OF SYSTEMIC LUPUS ERYTHEMATOSUS

Background: Acute acalculous cholecystitis (AAC) is a rare complication of systemic lupus erythematosus (SLE) but should be recognized

Objectives: The aim was to describe clinical, biological and radiological features of AAC in SLE patients.

Methods: We report four cases of AAC complicating SLE among 246 patients. Results: Case 1: A 39-year-old woman with one year history of arthralgia and Raynaud’s phenomenon was admitted for fever, cutaneous lesions, nausea and abdominal pain. The right upper quadrant of the abdomen was tender and we noted oral ulcerations and wrist synovitis. Laboratory data showed lymphopenia, hemolytic anemia and anergy. After treatment of an acute respiratory episode, there was no cholecystitis or cytology. Antinuclear antibodies (ANA), anti-nucleosome, anti-Sm and anti-ribosome antibodies were positive. Abdominal sonography revealed ascites and gallbladder wall thick was thin and irregular. The diagnosis of AAC complicating a SLE was made and patient was treated with antibiotics and corticosteroids. Two weeks later, she was asymptomatic and abdominal sonography was normal. Case 2: A 32-year-old woman had SLE with arthralgia, cutaneous manifestations, hematological involvements and pulmonary hypertension; she was treated with corticosteroids and cyclophosphamide. Six month later, at time of the second pulse of cyclophosphamide, she presented with jaundice and tender hepatomegaly where nontender abdominal pain. Liver enzymes rates were normal except bilirubin which was high at 47 UI. Her abdominal sonography showed gallbladder wall thickness without bile ducts enlargement or gallstones. Patient was continued on steroids and cyclophosphamide but she died because of heart failure. Case 3: A 45-year-old patient with 12-year-history of SLE was admitted for fever and dyspnea. On physical examination, there was tenderness on right upper quadrant of her abdomen. Cholestasis and cytology were found. Abdominal sonography showed a striated and thick gallbladder wall (17 mm). Computer tomography confirmed the gallbladder wall thickness and noted pericholecystic edema. Biological data showed anemia, thrombopenia and cholestasis. ANA, anti-DNA and anti-Sm were positive. Abdominal sonography showed gallbladder wall thickness and pericholecystic edema. SLE diagnosis with peripheral neuropathy, lupus nephritis, hematological manifestations and ACC was made. Patient was given corticosteroids and cyclophosphamide with good outcome.

Conclusions: Only few cases of AAC complicating SLE are reported. Cholecystitis can be an initial manifestation of SLE and reveal the disease or can occur at any time of the disease course. ACC is always associated to other disease manifestations. Patients present with abdominal pain, vomiting and fever. Ultrasonography and computed tomography confirm the diagnosis. The outcome is good with steroids. Sometimes patients are given antibiotics and/or underwent cholecystectomy because of infectious cholecystitis suspicion. None of our patients required surgery.

DOES ERYTHROCYTE SEDIMENTATION RATE REFLECT DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS? CORRELATION WITH ACUTE PHASE REACTANTS, IMMUNOLOGICAL PARAMETERS AND PROTEINURIA

V.S. Schläfer, K. Weiß, A. Krause, W.A. Schmidt. Medical Center for Rheumatology and Clinical Immunology Berlin-Buch, Immunlalus Krankenhaus Berlin, Berlin, Germany

Background: Patients with active systemic lupus erythematosus (SLE) are considered to have increased erythrocyte sedimentation rate (ESR) rather than raised C-reactive protein (CRP). Yet published evidence is low for this statement. ESR is used as a marker of disease activity and in the absence of the disease. Secondly, to determine if these parameters are associated with disease flare or infections.

Objectives: Firstly, to assess how ESR correlates with above mentioned laboratory parameters: in general, in the presence of clinical activity and/or infection or in the absence of both. Secondly, to determine if these parameters are associated with disease flare or infections. Methods: A retrospective analysis of patients of a tertiary referral centre with SLE under treatment between 2006 and 2015. Data on laboratory parameters, infection and disease flare, judged by the treating physician, were extracted. Patients were divided in four SLE groups: flare only (n=147), infection only (n=48), both (n=23), and neither infection nor flare (n=153). ESR was correlated to CRP, ferritin, proteinuria, C3-reduction and raised dsDNA-antibodies for the whole cohort and within each SLE group. Further, the association between all laboratory parameters and a) disease activity with and without infection, b) the presence of infection with and without disease activity, was tested.

Results: We identified 203 SLE patients, 26 males, with a total of 371 visits. Mean age was 45.6 years (SD: 16.5 years). Table 1 (top part) shows the correlation
coefficients of ESR with the other laboratory parameters. ESR correlated moderately with CRP amongst all groups (r=0.47–0.58); weakly with ferritin in the general and the flare group (r=0.26); and very weakly with C3-reduction and raised dsDNA-antibodies (r=0.02) in each group. Concerning proteinuria, the correlation was weak for all, for flaring and for silent patients (r=0.22–0.35), moderate for the mean value of proteinuria and activity (r=0.58). There was no correlation in infected patients (r=0.06). Table 1 (bottom part) displays the p-values for the association of parameters with disease activity or infection, respectively. ESR, reduction of C3, proteinuria and raised dsDNA-antibodies were all associated with disease activity in the whole cohort and in the non-infected group; CRP only in non-infected patients. In the infected group, raised dsDNA-antibodies and proteinuria were the only parameters showing significant relation to disease activity. ESR and CRP were significantly associated with infections when looking at all or at inactive patients, but not in active patients.

Table 1: Correlation of laboratory parameters to ESR and association with disease flare and infection

Conclusions: Both, ESR and CRP are elevated in patients with SLE flare and are weakly correlated with other laboratory activity parameters. Thus, while normal CRP argues against infection elevation of ESR and CRP is not sufficient to distinguish between SLE flare and infection.

AB0540 ORGAN DAMAGE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

V. Zivkovic 1, B. Mitic 2, B. Stamenkovic 1, S. Milenkovic 1, J. Jovancevic 1, I. Alekos 1 1Institute for Treatment and Rehabilitation “Niška Banja”, Niš, Serbia

Background: Organ damage in patients with systemic lupus erythematosus (SLE) occurs as the consequence of the disease itself, administered therapy, primarily corticosteroid and cytostatic, as well as the accompanying diseases and complications.

Objectives: Our aim in this paper was to examine the degree of irreversible organ changes in SLE patients using the SLICC/ACR Damage Index (SDI) and to establish the correlation of organ damage with disease activity, quality of life, and severity of fatigue, as well as with the immunological parameters – anti-dsDNA antibodies, anti-nucleosome, anti-C1q antibodies, and MCP1 in the serum and urine.

Methods: The study involved 83 SLE patients (77 women and 6 men), aged 45.8±9.2 years on the average, with average disease duration of 10.6±7.9 years, hospitalized at the Clinic of Rheumatology of the “Niška Banja” Institute, in whom the diagnosis was made based on the revised 1997 ACR criteria. The disease activity was evaluated using the Systemic Lupus Erythematosus Disease Activity Index (SLDAI) and a physician’s global assessment. The degree of organ damage was evaluated using the SDI. The quality of life was assessed based on the Medical Outcome Survey Short Form 36 (SF-36), and the severity of fatigue was measured using the Fatigue Severity Scale (FSS). The level of antibodies was determined using the ELISA test, and serum and urine MCP1 with the sandwich enzyme immunosorbent assay method according to the manufacturer’s instructions (R&D Systems, Inc. Minneapolis, USA).

Results: The mean organ damage index in all SLE patients was 1.8±2.0 (median 1, min 0, max 9). Twenty-five (30.1%) patients did not have any organ damage (SDI=0); 21 (25.3%) had SDI=1; SDI=2 or 3 was found in 20 patients (24.1%), and 17 patients (20.5%) had SDI=4. Neuropsychic and musculoskeletal changes were the most common organ damage manifestations, present in 23 (27.7%) of patients. In 21 patients (25.3%), cardiovascular changes were seen, and ocular lesions in 14 patients (16.9%). Renal and pulmonary changes were found in 13 patients (15.7%), cutaneous changes in 3 patients (3.6%), and gastrointestinal changes in 2 patients (2.4%). In 5 cases (6.0%) malignancies were detected, and diabetes mellitus in 2 patients (2.4%). A statistically significant positive correlation was established with age, disease duration (r=0.412, p<0.001), SLEDAI (r=0.359, p<0.001), global physician’s assessment (r=0.357, p<0.001) and fatigue (r=0.296, p<0.007), and a negative correlation with quality of life (r=−0.386, p<0.001). There were no correlations of SDI with the level of anti-dsDNA, anti-nucleosome, anti-C1q antibodies, nor with serum levels of MCP1.

Conclusions: Musculoskeletal, neuropsychic, and cardiovascular changes were the ones most commonly seen. Organ damage positively correlated with age and disease duration, a higher disease activity, poorer quality of life, and more severe fatigue.

AB0541 CO-MORBIDITY STATUS IN SYSTEM LUPUS ERYTHEMATOSUS PATIENTS

V. Dostankov 1, V. Yagur 2, N. Dostankov 2, K. Chizh 2, 1Inomed; 22-d Department of Internal Medicine, BSMMU, Minsk, Belarus

Background: The improved survival of patients with Systemic Lupus Erythematosus (SLE) over the past decades highlighted the problem of co-morbidity (several different chronic pathologies presence) in SLE patients because many of them reach the age when the burden of concomitant diseases could increase and become ordinary.

Objectives: To evaluate the frequency of concomitant diseases and to estimate the total co-morbidity status in SLE patients.

Methods: The retrospective study of co-morbidity in SLE patients was conducted on the database of Byelorussian Republican Rheumatologic Center. It included 212 patients: 192 women and 20 men at the age of 16.1 to 68.3 (mean ± SD: 33.1±12.3 years) at the baseline (first visit). The diagnosis of SLE was in conformance with 1997 ACR modified classification criteria for SLE [1]. The comprehensive assessment patient co-morbidities was performed by Kaplan-Feinstein co-morbidity index (KFI) [2] which includes twelve pathology categories: arterial hypertension (HT), heart disease (HD), presence, nervous system (ND) involvement, respiratory system (RD) pathology, vascular (VD), kidney (KD), liver (LD) gastrointestinal (GID) and musculoskeletal (MSD) diseases, other pathology (OD), malignancies and alcoholism. A co-morbidity score of 1 indicates low level of co-morbidity, 2 - moderate and 3 - high level of co-morbidity for corresponding pathology. The possible grade of co-morbidity is calculated as a sum score for all categories and varies from 0 to 36 points.

Results: KFI in SLE patients at the first visit varied from 0 to 7 points (Me: 2; 25–75% range: 0–3) and had minor differences in age and sex groups (NS, Fisher’s exact test). One-third of patients (n=68) had no co-morbidities. One of the most common pathology was HT which was diagnosed in 39 patients (18.4%, 95% CI 5.6–26.7%); 34 women and 5 men (p=0.591, NS, Fisher’s exact test). Over the 13-year follow-up period the frequency of HT dramatically increased to 52.9% (95% CI 47.0–68.0%) i.e. 2.9 times vs baseline (p<0.001). Prognostic odds ratios (OR) of HT were 7.6 (95% CI 3.1–18.2) and 3.2 (1.4–7.6) for lupus nephritis presence and signs of glucocorticoid disease (“cushingoid”), correspondingly.

Other common co-morbidities were GID and HD. Coronary HD and congestive heart failure were revealed in 43 (20.3%) patients. GID were registered in 44 (20.8%) patients, among them 9 (4.2%) patients had gastric/gastrointestinal ulcer. VD, ND and RD were revealed in 7 (3.3%) patients for each category, KD and LD frequency was 6 (2.8%) for both pathology. MSD were registered in 8 (3.8%) and OD, including different infections, anemia, diabetes etc. were registered in 39 (18.4%) patients. There were no cases of malignancies or alcoholism in our patients.

Conclusions: Total co-morbidity status revealed in SLE patients at baseline varied up to the 20 percent of the maximal possible level for all age and sex groups. Arterial hypertension was one of the most common pathology which demonstrated significant and predictable growth over the 13-year follow-up period.

**AB0542** PRESENTATION AND OUTCOME OF LUPUS NEPHRITIS IN THE MULTICULTURAL SOCIETY OF WESTERN AUSTRALIA – A SINGLE CENTRE EXPERIENCE

W.D. Raymond1, K. Minas1, L. Tyack2, B. Wong2, A. Douglas2, A. Kang3, D. Wong3, A. Chakera1,2, J. Nossent1,4, 1School of Medicine & Pharmacology, University of Western Australia; 2Renal Medicine; 3Pathology; 4Rheumatology, Sir Charles Gardner Hospital, Perth, Australia

**Background:** Lupus Nephritis (LN) is one of the most severe complications that can occur in patients with Systemic Lupus Erythematosus (SLE) as it increases the risk of morbidity and mortality. As with SLE, there is a significant impact of ethnicity on LN severity and outcome.

**Objectives:** To investigate the impact of ethnicity of LN presentation and health outcomes in a multicultural referral centre in Western Australia.

Methods: A retrospective cohort study of 104 patients with biopsy confirmed lupus nephritis (LN) collating clinical characteristics, renal histopathology, serology, medication use, disease activity (Systemic Lupus Erythematosus Disease Activity Index - 2k (SLEDAI-2k)), organ damage (SLICC-Damage Index (SDI)), and clinical outcomes from index biopsy event to the last visit. Outcomes included the high serum creatinine (≥150umol/L), low eGFR (<50%), the need for renal replacement therapy (RRT), and death. Outcomes were assessed across ethnicity with comparative statistics, Chi-square, and survival analysis.

**Results:** Asian (n=17, 16.3%), Caucasian (n=79, 76.0%) and Indigenous (n=8, 7.7%) patients were similar for age (p=0.164), gender (p=0.399) and SLEDAI (8.5 vs 9.0 vs 13.0, p=0.897), non-renal SLICC-2k (10.5 vs 2.5 vs 1.0, p=0.528). Time to biopsy from the initial SLE diagnosis was shorter in Asian and Indigenous patients (p=0.055). At the index biopsy, ethnic groups were similar for WHO Class distribution (predominantly Classes 3 and 4, p=0.345) and clinical signs of renal dysfunction (p=0.12). Asian and Indigenous patients had lower SLEDAI-2k scores (16.0 vs 26.5 vs 520.0, p=0.81), albeit non-significantly (due to low numbers).

**Conclusions:** There was no significant differences in disease activity or organ damage between the different ethnic groups.

**AB0544** LEVELS OF VITAMIN D IN A COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS. RELATIONSHIP WITH DISEASE ACTIVITY AND BONE MASS

**Background:** Vitamin D (vit D) is an immunoregulatory hormone which seems to mediate immune tolerance. Several studies have suggested that vit D deficiency may be related to increased disease activity in patients with systemic lupus erythematosus (SLE).

**Objectives:** To analyze 25-hydroxyvitamin D (25-OHD) levels in a cohort of patients with SLE and to investigate their relationship with clinical, analytical, immunological and densitometric parameters.

**Methods:** Prospective study including patients with SLE (according to SLICC criteria 2013) performed in an Academic Hospital with a referral area of 800,000 inhabitants. 152 patients with SLE were included (138 women [46 postmenopausal] 14 men) with a mean age of 46±12 years (range: 20–75). Clinical parameters (including risk factors for osteoporosis, presence of skeletal fractures, treatment with glucocorticoids (GCC) as well as SLE involvement including haematologic, renal, neurological and skin), biochemical determinations (including 25-OHD, parathormone (PTH)), immunological (ANA, DNA and complement) and SLE activity and severity (assessed by SLEDAI and SLICC index) were assessed in all patients. Bone mineral density was performed by DXA (at lumbar spine and proximal femur).

**Results:** Vit D deficiency was defined as 25-OHD values under 20 ng/mL. Low bone mass was considered as T or Z score <-1 SD; and osteoporosis as T <-2.5 SD [age =50 years] or Z <-2 SD [age <50 years]. The study was approved by the Clinical Research Ethics Committee and all patients provided informed consent to participate. Statistical analysis was performed by SPSS 20.

**Results:** The mean values of 25-OHD were 19.8±11.4 (range, 4.2–66.6); 87.5% of patients had 25-OHD levels below 30 ng/mL, 61.2% below 20 ng/mL and 15.1% below 10 ng/mL. The lowest levels were in vitamin and depression (80%) and in patients with GCC treatment (98%). 42.8% of patients received vitamin D supplements. 56.5% of patients had low bone mass (T or Z score <-1 SD), and 15.8% had osteoporosis. Levels of 25-OHD showed no correlation with SLE disease activity (complement, AC antibodies, SLICC/SLEDAI) neither with bone mass by DXA. Patients with low bone mass (T or Z <-1 SD scale) were older (at the time of inclusion and age of SLE diagnosis), had higher SLICC and lower complement levels whereas no differences were observed in SLEDAI and 25-OHD values. 37.5% of the patients were treated with GCC. Patients without GCC treatment had higher prevalence of vit D deficiency (73.9% vs. 55.6%, p=0.034) compared to patients with GCC treatment.

**Conclusions:** 61.2% of patients with SLE have 25-OHD deficiency, which is more frequent in winter and spring, and mostly in those patients without GCC treatment. 25-OHD values showed no correlation with the disease activity and the few patients with low bone mass had higher SLICC and hypocomplementemia. Thus, our results suggest the need to perform clinical guidelines to assess bone mass and bone metabolism in this clinical condition. Additionally, we recommend quantifying vit D levels in winter/spring and don’t forget to assess those patients without GCC treatment.

**AB0543** ANXIETY AND DEPRESSION IN CHINESE PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

Y. Cui1, L. Li1, Q. Zhao1, S. Chen1, L. Li2, Z. Gu1, 1Department of Rheumatology, Affiliated Hospital of Nantong University; 2School of Nursing, nantong University, Nantong, China

**Background:** Primary Sjögren’s syndrome (pSS) is a multisystem autoimmune disorder characterised by lymphocytic infiltration and exocrine failure of salivary and lacrimal glands, resulting in the classical symptoms of the disease including xerostomia (dry mouth) and keratoconjuctivitis sicca (dry eyes). pSS has the potential to impair both psychological state and the health-related quality of life (HR-QOL). A common mental health problem among adults with pSS is anxiety and depression. In addition, depression is more common in pSS than in the general population and has been associated with enhanced fatigue, reduced health-related quality of life, increased levels of lymphocytes and increased health care costs. Besides, depressed pSS patients have poorer long-term outcomes, including more complications. Anxiety was more common than depression in pSS. The most affected domains were vitality in the SF-36 and general/physical fatigue in the MPFI. Extangulard systemic involvement was not a major determinant of QOL alteration in patients with pSS.

**Objectives:** Prevalence of anxiety and depression are high in women with Primary Sjögren’s syndrome (pSS). Our aim was to compare anxiety and depression in pSS patients and healthy controls and evaluate its relationship with the disease activity, sleep and quality of life; as well as to analyze potential determinants of anxiety and depression.

**Methods:** Sixty-seven patients fulfilling the American-European Consensus Group criteria for pSS (mean age 52.67 years (s.d. 13.16)) and 42 age-matched healthy controls were included. Participants completed self-administered questionnaires, namely Hospital Anxiety and Depression Scale (HADS), Depression Symptom Scale (DSS), Short Form 36 (SF-36) scores and the Pittsburgh Sleep Quality Index (PSQI). In addition, the European League Against Rheumatism Sjögren’s Syndrome Disease Activity Index (ESSDAI); Patient Reported Index (ESSPRI) and systemic inflammation (erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) level) were recorded in patients. Independent samples t-tests, χ2 analyses and logistic regression modeling were used to analyze the data.

**Results:** pSS patients experienced greater anxiety and depression than controls (HADS-A scores: mean: SD 6.5±3.4 for pSS versus 3.8±3.4 for controls; P <0.002. HADS-D scores: mean: SD 7.6±4.1 for pSS versus 4.2±3.5 for controls; P <0.002). And there were significant correlations among fatigue, pain, disease activity, dryness, sleep, quality of life and anxiety/depression. Meanwhile, logistic regression analysis revealed that poor quality of life and ESSPRI were significantly associated with anxiety/depression in pSS patients. **Conclusions:** The study suggests that optimal care of pSS patients may include the assessment and management of anxiety and depression. Early recognition and appropriate intervention is therefore essential to reduce the negative impact of anxiety and depression on the patient’s quality of life and outcome of their disease.

**AB0545** EFFECT OF EMPATHY NURSING ON THE LIFE QUALITY OF THEPATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Y. Wen1, L. Yan1, L. Linlin2, 1Department of Rheumatology; 2Nursing department, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

**Background:** The patients with Systemic Lupus Erythematosus always had sub-healthy status in psychology and been troubled by the chronicity of the disease. Empathy nursing is an effective treatment for chronic disease such as cancer or terminal patients.
CLINICOPATHOLOGICAL CHARACTERISTICS OF SJÖGREN’S SYNDROME IN THE PRESENCE OR ABSENCE OF OBJECTIVE SICCA SYMPTOMS

Y. Suzuki 1,2, H. Fuji 1, K. Yamada 1, M. Kawano 1, Division of Rheumatology, Department of Internal Medicine, Kanazawa University Graduate School of Medicine, 2Division of Nephrology and Rheumatology, Department of Internal Medicine, Ishikawa Prefectural Central Hospital, Kanazawa, Japan

Background: Sjögren’s syndrome (SS) is generally diagnosed on the basis of objective criteria, including xerophthalmia, xerostomia, autoantibodies, and labial salivary gland biopsy. Patients without objective sicca symptoms (non-sicca SS) require a biopsy. For such patients, we should evaluate pretest probability using parameters other than sicca symptoms before performing an invasive biopsy. To assess pretest probability, data on clinicopathological characteristics of non-sicca SS are needed.

Objectives: This study aimed to analyze the clinicopathological features of non-sicca SS. Epidemiological data, antibody profiles, organ involvement, and labial salivary gland biopsy results in non-sicca SS patients were compared with those in SS patients with objective sicca symptoms (sicca SS).

Methods: We selected 103 patients with primary SS who met Japanese or American College of Rheumatology criteria; those whose results exceeded the focus score by 1 underwent salivary gland biopsy. Objective xerophthalmia was evaluated with the Schirmer’s test, and objective xerostomia with the Saxon’s test. Seventeen patients were excluded because neither test was performed. Sicca SS was defined as a positive Schirmer’s and/or Saxon’s test result. Clinical and laboratory data were compared in 70 sicca SS and 16 non-sicca SS patients.

Results: Non-sicca SS patients were younger at diagnosis (45.9±14.8 vs. 61.4±15.1 years, p<0.001), had a shorter disease duration (1.1±1.5 vs. 6.9±8.9 years, p<0.001), and had a higher rate of positive anti-SS-A/Ro antibody (100 vs. 40%, p<0.001). In the lower rate of positive lymphocytic antibody (6.3 vs. 44.3%, p<0.005). Subjective xerophthalmia and xerostomia rates were similar between the groups, but fewer non-sicca SS patients had sicca symptoms as chief complaints (18.8 vs. 58.6%, p<0.004). There were no significant differences in focus score, leukocyte and lymphocyte counts, serum IgG levels, and positive rheumatoid factor and antinuclear antibody levels. The maximum European League Against Rheumatism Sjögren’s Syndrome Disease Activity Index (ESSDAI) score during follow-up showed no significant difference (3.3±4.27 in non-sicca SS vs. 3.8±3.68 in sicca SS, p=0.30). However, more non-sicca SS patients had ESSDAI scores ≥ 1 (100 vs. 71.4%, p<0.015), a lower correlation with the biological domain of the ESSDAI (87.5 vs. 58.6%, p<0.003) in sicca SS.

Disclosures: This study was supported by a research grant from the Ministry of Education, Culture, Sports, Science, and Technology of Japan.

CIRCULATING PROLACTIN LEVEL IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: EXPLORATORY RESEARCH

Y. Mura 1, M. Saito 2, K.-E. Sada 1, N. Yasima 1, Division of Rheumatology, Department of Internal Medicine, Showa University School of Medicine, Shinagawa-ku, Tokyo, 2Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama City, Japan

Background: Hypertension (HT) and dyslipidemia (DL) are the risk factors for all-cause mortality, cardiovascular and cerebrovascular disease, and end-stage renal disease in SLE patients. Neither disease activity nor chronic damage were associated with the metabolic syndrome in SLE patients and there were few reports about the risk factors of HT and DL in Japanese SLE patients.

Objectives: We aimed to describe a prevalence of HT and DL and to identify the risk factor of HT and DL in Japanese SLE patients.

Methods: All SLE patients visited at Showa University Hospital and Okayama University Hospital from January 2016 to September 2016, were enrolled in a cross-sectional study. SLE patients who satisfied American College of Rheumatology (ACR) criteria were included. HT was defined as usage of anti-HT drugs and DL was defined as usage of anti-DL drugs. We performed descriptive statistics and binary logistic regression analysis to identify the risk factors of HT and DL. Variables considered possible risk factors were BMI, drinking status, smoking status (current smoking), current daily dose of glucocorticoids, past maximum dose of glucocorticoids, lupus nephritis, Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K), and Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SLICC/ACR-DI).

Results: In total, 244 participants were enrolled. The mean age was 46.2±15.3 years, and 222 (91%) were female. The mean current daily dosage of glucocorticoids was 6.7±5.9 mg, and the mean SLEDAI-2K was 5.0±5.2 and the mean SLICC/ACR-DI was 1.3±1.7. The prevalence of HT and DL were 29.1% (71/244) and 22.1% (54/244). Both HT and DL were confirmed in 11.9% (29/244) patients.

On binomial logistic regression analysis, BMI (regression coefficients (β)= -0.039; 95% CI =0.000 to 0.879), past maximum dosage of glucocorticoids (β= -0.036; 95% CI =0.036 to -0.004) and lupus nephritis (β= -0.727; 95% CI =0.230 to 1.241) were identified as the significant independent risk factors of HT. On the other hand, only age (β< -0.030; 95% CI = -0.055 to 0.008) was identified as the independent risk factor of DL. There was no independent risk factor of having both HT and DL.

Conclusions: Our results could help to identify patients at higher risk of HT and DL.

CIRCULATING PROLACTIN LEVEL IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS CORRELATION WITH DISEASE ACTIVITY: A META-ANALYSIS

Y.H. Lee, Y.H. Seo. Rheumatology, Korea University Medical Center, Seoul, Korea, Republic Of

Background: Prolactin has an immune stimulatory effect and may promote autoimmunity by encouraging the development of antigen presenting cells expressing MHC class II and co-stimulatory molecules and modulating IFN-γ secretion.

Objectives: This study aimed to evaluate the relationship between circulating prolactin level and systemic lupus erythematosus (SLE), and to establish a correlation between plasma/serum prolactin levels and SLE activity.

Methods: We performed a literature search for studies that examined prolactin status in SLE patients and controls, and the relationship between circulating (serum or plasma) prolactin levels and SLE using PUBMED, EMBASE, and Cochrane databases. We conducted a meta-analysis comparing the plasma/serum prolactin level in patients with SLE and healthy controls, and calculated correlation coefficients between circulating prolactin level and SLE disease activity.

Results: Twenty-five studies with a total of 1,056 SLE patients and 426 controls were included. Prolactin levels were significantly higher overall in the SLE group than in the control group (SMD =0.987, 95% CI =0.512 – 1.463, p=4.7x10^-5).

Conclusion: This study provided evidence that circulating prolactin levels were significantly higher in patients with SLE than in healthy controls. There was considerable heterogeneity between studies, and this may be due to differences in the studied populations and the measurement methods of prolactin. Further studies are needed to clarify the relationship between circulating prolactin level and SLE disease activity.
a significantly positive correlation between circulating prolatin level and SLE activity (Correlation coefficient -0.379, 95% CI -0.028-0.487, p=4.0x10^-7).

Conclusions: Our meta-analysis demonstrated that circulating prolatin levels are higher in patients with SLE and that a significantly positive correlation exists between prolatin levels and SLE activity.

Vasculitides

**AB0549 DEMOGRAPHIC FEATURES AND CLINICAL ASPECTS OF BEHÇET’S DISEASE IN OMANI PATIENTS**

A.S. Al Ghafri, H. Al Wahshi. Rheumatology, Royal Hospital, Muscat, Oman

Background: Behcet’s disease (BD) is a chronic, relapsing, multi-system vasculitides of unknown aetiology. Few reports support the hypothesis that BD has a primarily hereditary basis. It complicated diversified clinical features predominantly involving oral and genital ulcers, ocular and cutaneous lesions. The clinical features of this disease have been described to be different according to geographical areas and gender.

Objectives: The objective of the study is to explore the demographic features and clinical aspects of BD in Omani patients.

Methods: 56 BD patients were recruited and clinical data parameters were recorded including age, sex, age at diagnosis, duration of symptoms till diagnosis, disease characteristics such as oral and genital ulcers, ocular manifestations, the presence of arthritis and cutaneous lesions such as papulopustular lesions and erythema nodosum. Furthermore, other systemic involvement was studied including gastrointestinal, neurological & vascular manifestations. Laboratory tests of BD and treatment used were recorded in each patient.

Results: The onset was between 6–74 years with a male predominance. Oral ulcers were the most common manifestation, followed by genital ulcers, ocular lesions and arthritis. Vascular lesions and GI manifestations were less common. Cutaneous manifestations were rare in patients with BD. The frequency of neurological involvement was significantly high. There were no reported cardiac or urogenital manifestations.

Conclusions: There are quite significant clinical geographical and gender differences among BD patients in which genetic and immunological factors might participate in its aetopathogenesis.

**AB0550 AN AUDIT OF BEHÇET’S SYNDROME RESEARCH: RECENT 6 YEARS**

A. Murt1, A. Ercaliskan1, H. Yaziç2, 1Internal Medicine, Cerrahpasa Medical Faculty; 2Rheumatology, Academic Hospital, Istanbul, Turkey

Background: A previous audit by our group of Behçet’s syndrome (BS) research, published in 2011 (1) had revealed a list of problems related to research methodology. They were mainly the relative lack of prospective studies, proper use of control groups, a marked under utilization of power calculations where needed and a paucity of studies reporting negative results.

Objectives: We have reassessed the same items as in the previous survey in articles about BS since published. An additional item looked at was self criticism in manuscript preparation (2).

Methods: Original articles from 15 highest impact factor journals of internal medicine, rheumatology and ophthalmology between January 2010 and February 2016 were analyzed by two observers. Study designs, presence of necessary control groups, power calculations and reporting of negative outcomes were tabulated. Presence of self-criticism was assessed both by reading and specific word scanning. Discrepancies between the observers was reconciled in a joint session of all 3 authors.

Results: A total of 188 articles, 149 (79%) clinical and 39 (21%) basic, were analyzed. Of 94 studies in which a time-element classification was appropriate; 53/94 studies (56%) were prospective. 28 patients (23.1%) were aPL-Abs negative. Clinical characteristics of this disease and finally 1/3 with positive TAB (33,3) were ordered by the NC with 31.9% in the former surveys. Similarly, an optimistic note might be that inclusion of diseased controls in genetic association studies, 26% in the current survey showed basic research in BS included more self-criticism (41–51%) as compared to what was noted among the general rheumatology manuscripts (15–20%) (2).

**AB0551 THE IMPACT OF TEMPORAL ARTERY BIOPSY ON DIAGNOSIS OF GIANT CELL ARTERITIS IN CLINICAL PRACTICE**

E. Kaltonoudis 1, D. Kirochristos 2, A. Bai-Papoudou3, P. Voulgari 3, A.A. Drosos 3. 1Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina; 2Department of Surgery, University Hospital of Ioannina, Department of Surgery; 3Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece

Background: Temporal artery biopsy (TAB) is the current gold standard for diagnosis of giant cell arteritis (GCA). Clinical manifestations of GCA include cranial symptoms, features of polymyalgia rheumatica (PMR), fever of unknown origin (FOU) and large vessel involvement, following by elevation of C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR). In these patients TAB confirms the diagnosis.

Objectives: In the current study the impact of TAB on diagnosis of GCA in a large number of patients is presented.

Methods: 245 patients who had undergo TAB were evaluated. All patients were more than 50 years old and were admitted in a tertiary University Hospital during the period 2006–2016. More specifically 164 were admitted in the division of internal medicine (DIM), 53 in the rheumatology clinic (RC), 6 in the eye clinic (EC) and 3 in the neurology clinic (NC). All the clinical and laboratory data were recorded and analyzed appropriately.

Results: The mean age of the patients was 68.6±5.6 year and 61.5% were women. 49/245 patients had positive TAB (21.17%). More specifically 5/6 positive TAB (83.3%) were ordered by the EC with signs of visual disturbances, mainly visual loss, diplopia and headache. 12/56 positive TAB (22.6%) were ordered by the RC with clinical features of headache and PMR. 31/164 (18.9%) with positive TAB were ordered by DIM with clinical signs of PMR, FOU and anemia of chronic disease and finally 1/3 with positive TAB (33,3) were ordered by the NC with clinical features of severe headache. All patients with positive TAB had elevated levels of CRP and ESR.

Conclusions: In elderly patients with cranial symptoms, visual disturbances, PMR, FOU and raised acute phase reactants, the possibility of GCA is very high and TAB is necessary to confirm diagnosis.

**AB0552 ANTIPHOSPHOLIPID ANTIBODIES IN GIANT CELL ARTERITIS**

A. Hocevar, R. Jese, Z. Rotar, P. Zigon, S. Cucnik, M. Tomsic. Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia

Objectives: The aim of our prospective study was to evaluate the role of antiphospholipid antibodies (aPL) on the clinical presentation of giant cell arteritis (GCA).

Methods: GCA patients diagnosed for the first time between 1. September 2011 and 31. December 2016 at our secondary/tertiary rheumatology center and in whom aPL-Abs were determined at presentation were included. We studied four types of aPL-Abs in patient sera: lupus anticoagulants (LA), IgG and IgM isotype of anticardiolipin antibodies (aCL), of antibodies to β2-glycoprotein 1 (aβ2GPI) and of antibodies to phosphatidylserine-prothrombin complex (aPS/PT). LA activity was determined only in patients not receiving anticoagulant therapy. A dilute Russell viper venom test was used and a ratio above 1.2 was considered positive. aCL, aβ2GPI and aPS/PT were measured using an in-house ELISA. A value above the 99th percentile of healthy control population was taken as positive.

Results: During the 64-month observation period we performed all aPL-Abs tests in 121 GCA patients (81 females (66.9%); median (IQR) age 73.8 (66.4; 78.7) years). We found LA, aCL and aβ2GPI in 59 (48.8%), 55 (45.5%), 15 (12.4%) and 18 (14.9%) cases, respectively. Fifty-four patients (44.6%) were single, 25 (20.7%) double, 13 (10.7%) triple and 1 (0.8%) quadruple aPL-Abs positive. 28 patients (23.1%) were aPL-Abs negative. Clinical characteristics of individual aPL-Ab type groups are presented in Table 1. There was one case of

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.1078
The presence of aCL was associated with extracranial large vessel vasculitis (RR 1.9 (95% CI 1.1–3.2)) in patients with active disease. The presence of aPL was associated with retinal vasculitis (RR 2.1 (95% CI 1.1–4.3) for permanent or transient visual loss in cases of double or triple aPL positivity vs. LA, aCL and a2GPI negative cases). At least 1 year follow-up data (median (IQR) of 103 (54; 105) weeks) were available for 73 patients. 32 patients (43.8%) relapsed, most frequently those with positive a2GPI (62.5%).

Conclusions: Our results indicate that aCL could identify GCA patients with extracranial large vessel disease. The double- or triple-posibility for any combination of LA and/or aCL and/or a2GPI seems to be a marker of severe visual manifestation.

RELATIONSHIP BETWEEN DISEASE ACTIVITY AND NEUTROPHIL-LYMPHOCYTE RATIO, PLATELET-LYMPHOCYTE RATIO AND MEAN PLATELET VOLUME IN BEHÇET’S DISEASE

I.E. Okatan, M. Turgutalp, A. Ataev, E. Uslu Yurteri, M.E. Yaya, A.B. Keleşoğlu Dincer, T.M. Turgay, G. Kinikli, Department of Internal Medicine, Division of Rheumatology, Ankara University Faculty of Medicine, Ankara, Turkey

Objectives: Behçet’s syndrome (BS) is an autoimmune disease characterized by chronic inflammation and endothelial dysfunction. There are only a few studies examining the relationship between neutrophil-lymphocyte ratio (NLR), mean platelet volume (MPV), platelet-lymphocyte ratio (PLR) and Behçet’s disease activity.

The aim of this study was to determine NLR, PLR and MPV levels and their association with disease activation in BS patients with mucocutaneous, ocular and vascular involvement.

Methods: The study included 259 patients with BS and 41 healthy individuals. We compared the MPV, NLR and PLR values of patients with active and inactive disease. NLR and PLR were significantly higher while MPV was lower in the active group than the inactive and control groups (Table 1). Statistically significant higher PLR and NLR were found in the active MC and vascular groups, significantly lower MPV was seen only in vascular active group. This significance was not seen in active ocular group (Table 2).

We also evaluated the same patient’s active and inactive periods of the disease, lower MPV, higher NLR and PLR values were seen MC and vascular groups (for all p < 0.05). When the active 3 groups were compared within themselves, the MPV value was significantly lower and NLR and PLR values were significantly higher in vascular group than active ocular and active mucocutaneous groups (p < 0.033, < 0.001, 0.01 respectively).

Conclusions: The low MPV and the high NLR and PLR are found in the active disease group which is also significant in vascular and mucocutaneous disease. In the light of our findings, NLR and PLR were associated with the activity of BS especially with vascular involvement. The low MPV and the high NLR and PLR. The low MPV and the high NLR and PLR may be useful disease activity markers in Behçet’s disease.
ANCA VASCULITIS AND CLASSIC CARDIOVASCULAR RISK FACTORS: COINCIDENCE OR CAUSALITY? C. Buqua, J.J. Rios, Á. Robles, A. Noblejas, E. Martínez, C. Soto, I. Vives, J.A. Troncoso, L. Bailón, F. Arnálich. Internal Medicine, la Paz Hospital, Madrid, Spain

Background: Unlike other autoimmune diseases (rheumatoid arthritis or systemic lupus erythematosus), the mechanisms involved and the association between ANCA vasculitis with cardiovascular risk factors (CVRF) or cardiovascular events (CVE) are unknown. There may be a phenomenon of “early” atherosclerosis that contributes to the increased cardiovascular risk. This process would not be explained only by the co-existence of the classic CVRF.

Objectives: We reviewed the prevalence of classical CVRF and CVE in a cohort of patients diagnosed with ANCA vasculitis. We analyzed whether the appearance of these factors was prior to or subsequent to the diagnosis of the disease or during its evolution.

Methods: A descriptive cross-sectional analysis of the classic CVRF and CVE was analyzed in a cohort of patients with ANCA positive vasculitis in follow-up in the Autoimmune Diseases Division of a Spanish hospital. The main demographic characteristics, type of vasculitis and the presence of arterial hypertension, type 2 diabetes mellitus (T2DM), dyslipidaemia, smoking and obesity were reviewed. Likewise we analyzed CVE (heart failure-HF-, acute coronary syndrome-ACS-, stroke or transient ischemic attack-TIA- and peripheral arteriopathy -PA-) and if each factor was presented at the diagnosis of the disease or they appeared during the evolution after starting immunosuppressive treatment.

Results: A total of 35 patients were studied: 21 women (60%) and the average age was 53 years old. A number of 15 were microscopic polyangiitis, 9 granulomatosis with polyangiitis and 11 allergic granulomatous angiitis. Twenty one patients presented hypertension, 9 of them (42.9%) developed it after the diagnosis of vasculitis. From 7 patients with diabetes mellitus, 5 of them were before diagnosis with vasculitis. Nineteen presented dyslipemia and 9 of them (47.4%) presented lipid alteration during the evolution of vasculitis. Overweight/obesity was evident in 4 of the 11 cases after the diagnosis of vasculitis. Only 5 patients did not have a cardiovascular event. ACS was observed in 3 patients, HF in 2 and PA in 1 patient. There were no cases of TIA or ischemic stroke. Four of them had dyslipidemia (3 after diagnosis of vasculitis (p<0.18) and 3 had hypertension (2 after diagnosis of vasculitis, p=0.66). Three patients were overweight or obese (p=0.3) and two had T2DM (p=0.2), both of them appeared after the diagnosis. Previous history of smoking was observed in 4 of the 5 patients (p=0.06). In 3 patients (71.4%) the cardiovascular event was recorded prior to vasculitis diagnosis and only in 2 cases it occurred during the evolution.

Conclusions: This study shows that a high percentage of patients with ANCA vasculitis also presents some type of classic CVRF despite of CVE were not elevated. The diagnosis and treatment of ANCA-positive vasculitis did not statically correlate with a greater number of CVE, therefore it would be necessary to carry out studies with a larger number of patients in order to establish conclusions. It is not well defined that weight may have these factors in the prognosis of patients with ANCA vasculitis. These data suggest the need to maintain a close monitoring and therapeutic approach of classic CVRF in this relatively young group of patients.

INCIDENCE AND RISK FACTORS OF INFECTIONS IN SYSTEMIC NECROTIZING VASCULITIS C.E. Pena, M. Pera, C. Costi, G. Lucila, P. Castellani, Y. Nuccetti, M. Garcia. HIGA San Martin la Plata, la Plata, Argentina

Background: Infections in patients with systemic vasculitis represent one of the main causes of mortality. Risk factors of infection such as corticosteroid use, intensity of immunosuppressive therapy, age, presence of leucopenia, lymphopenia, hypogammaglobulinemia, associated organic involvement, and dialysis dependence have been identified.

Objectives: a) To determine the incidence of infection in patients diagnosed with Polyangiitis with Granulomatosis (PAM), Eosinophilic Polyangiitis with Granulomatosis (EGPA),Microscopic Polyangiitis (PAM) and Panarteritis Nodosa (PAN) in patients with clinical characteristics and associated risks factors. Methods: Analytical, observational, retrospective study. Data source: clinical records of patients diagnosed with ANCA associated vasculitis and Panarteritis Nodosa, evaluated in a center of rheumatology (2000–2016). Variables: Demographic data, clinical manifestations, laboratory data, infectious events such as pneumonia, urinary infection, prolongation of hospitalization or prolonged treatment, re-occurrences of herpes zoster virus or opportunistic infections), sites of infection, isolated microorganisms, mortality related to the infected event.

Results: 80 patients, 61.25% women. Mean age at diagnosis: 49.2 years (range 18–77). Types of vasculitis: 41.2% GPA, 18.7% EGPA, 26.25% PAM, 3.73% PAN not associated with HBV and 10% ANCA-associated vasculitis that did not met classification criteria. Systemic involvement (88%), pulmonary (59%), renal (58%) and otorhinolaryngology (43.6%) were the most frequent. 36 infectious events were recorded in 28 patients. Follow-up time: Median 22 m (IQR6–64). Incidence of infection: 38.4%, with a median of 3 m (IQR 1–18 m) from diagnosis of vasculitis. Low respiratory infections (40.7%), sepsis (39.3%), and urinary tract infections (15%) were the most common. 25% of these patients presented a second infectious event, being low respiratory tract the most frequent site (47%). Two patients had a 3rd event (soft tissue infection, septic shock).

Bacterial etiologie was the most prevalent (45%). Mortality at the 1st event was 14.3% (n: 4). 71.4% of patients were in the induction phase of treatment. Immunosuppressants used prior to infectious event: cyclophosphamide (48.1%), azathioprine (11.1%), methotrexate (7.4%), mofetil mycophenolate (3.7%), none (22.2%). Corticosteroids ≤30 mg/d were observed in 35.7% patients, ranging from 7.5–30 mg/d (10.7%), and ≤7.5 mg/d in 35.7%. Presence of leuocopenia (26%), lymphopenia (44%), hypoalbuninemia (24%), renal insufficiency (63%) and dialysis dependency (37%) were identified in patients with infectious events. Renal infection (p=0.01) and dialysis dependence (p=0.001) were significantly associated with infection.

Conclusions: The incidence of infection was 38.4%. Lower airway infections, septicaemia and urinary tract infections are the most commonly implicated sites. Most infections occurred in the induction phases of the disease. Dialysis dependence and presence of renal involvement were significantly associated with the presence of infection.

AB0558  BIOSIMILAR INFILXIMAB FOR BEHÇET'S SYNDROME
E. Dinçsoy1, S.N. Esatoğlu1, E. Seyahi1, M. Melikoğlu1, I. Fresko1, G. Hatemi1.
Background: The efficacy and safety of biosimilar infliximab has been studied in several inflammatory conditions and biosimilar was approved for all indications of the reference product in several countries. However, to the best of our knowledge, there was no published reports on its use in Behçet’s syndrome (BS).
Objectives: We aimed to report our experience with biosimilar infliximab for the treatment of 3 different types of organ involvements in BS.
Methods: We reviewed the charts of all BS patients who were prescribed infliximab in our multidisciplinary BS clinic. Among the 88 patients who were prescribed infliximab, 4 had used biosimilar infliximab (5 mg/kg) due to refractory disease despite conventional immunosuppressives.
Results: Case 1: The first patient was a 28-year-old man who had received azathioprine (AZA), cyclosporine-A and methotrexate for 6 years for ocular involvement. Six months after the immunosuppressives were stopped due to sustained remission he had a stroke with right hemiparesis. Cerebral MRI revealed venous infarct extending from posterior limb of left internal capsule to pons and mesencephalon, involving corpus callosum. Cervical MRI revealed a hyperintense lesion between C3-C8 segments. His cranial MR venography excluded sinus thrombosis. He received intravenous pulse corticosteroid followed by biosimilar infliximab. He achieved clinical remission and his MRI at month 3 showed complete regression of the lesions. He is still in remission at 7th month of therapy.
Case 2: The second patient was a 24-year-old man using AZA 2.5 mg/kg/day for refractory skin lesions when he developed bilateral external iliac vein and right common iliac vein thrombosis. He received intravenous pulse corticosteroid followed by biosimilar infliximab. After one year treatment was switched to etanercept 50 mg/week and is attack-free for the last 7 months. Case 4: The fourth patient was a 26-year-old man who had prescribed infliximab for panuveitis refractory to AZA, ciclosporin-A and interferon-alpha. The first infusion was biosimilar infliximab, but the following infusions were reference infliximab due to reimbursement policy of the hospital. There were no adverse events after switching to reference infliximab and the patient is doing well at 8 months of therapy.
Conclusions: Our limited experience showed that biosimilar infliximab may be effective for BS patients refractory to conventional immunosuppressives.

AB0559  IMPROVING THE MANAGEMENT OF GIANT CELL ARTERITIS: A REVIEW OF CARE PATHWAY FOR PATIENTS WITH SUSPECTED GIANT CELL ARTERITIS IN A DISTRICT GENERAL HOSPITAL
1Rheumatology Department, Brighton and Sussex University Hospitals NHS Trust; Brighton, 2Rheumatology Department, East Surrey Hospital, Redhill, United Kingdom.
Background: Giant cell arteritis (GCA) requires prompt diagnosis and treatment to prevent irreversible neuro-ophtalmic complications. Conversely, misdiagnosis leads to unnecessary treatment with high dose glucocorticosteroids (GC) and their associated complications. The British Society of Rheumatologists (BSR) guideline emphasises early recognition of symptoms and prompt treatment when index of clinical suspicion is high.
Methods: Case notes of patients seen in ESH with suspected GCA between March 2015 and December 2016 were reviewed retrospectively. Cases were identified through keyword search on hospital discharge letters and Rheumatology clinic letters.
Results: Case notes of 67 patients (21M, 46F) were analysed. Of those presenting with suspected GCA, 31% fulfilled ACR classification criteria. 28% had documented visual symptoms at presentation.
Conclusions: This study aims to audit the management of patients with suspected GCA against BSR guidelines. It also aims to evaluate patients’ journey, to identify inefficiencies within the management pathway, in order to initiate improvements in clinical practice.

AB0560  STUDY ON STREPTOCOCCAL INFECTION RELATIONSHIP WITH HENOCCH SCHONLEIN PURPURA IN CHILDREN
F. Li1*, H. Zang2. 1Department of Pediatric Allergy, Immunology and Rheumatology; 2Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children’s Medical Center, Guangzhou, China
Objectives: To study hemolytic Streptococcus infection relationship with Henoch-Schonlein Purpura in children.
Methods: 42 cases in children with Henoch-Schonlein Purpura (Observer Group) and healthy children in 40 cases of physical examination (the control group) for blood antistreptolysin O (ASO) detection, observation group at the same time to blood ASO detection positive 2 cases, accounted for 5%, both comparison differences has not significance (χ²=9.35, p<0.01).
Conclusions: Streptococcal infections may be an important factor related to Henoch-Schonlein Purpura in children. Purpura and Purpura of abdominal type children with 23 cases, blood ASO detection positive 17 cases, accounted for 73.9%; non-abdominal type Purpura children with 19 cases, blood ASO detection positive 2 cases, accounted for 5%, both comparison differences has not significance (χ²=22.22, p<0.01); abdominal type Purpura children with 23 cases, blood ASO detection positive 17 cases, accounted for 73.9%; non-abdominal type Purpura children with 19 cases, blood ASO detection positive 2 cases, accounted for 5%, both comparison differences has not significance (χ²=9.95, p<0.01); 14 cases in children with recurrent Henoch-Schonlein Purpura, ASO blood test positive in 12 cases, 85.7%; non-recurrent attacks of 28 cases of children with Henoch-Schonlein Purpura, ASO blood test positive in 10 cases, 35.7%, comparing the two differences are significant (χ²=9.35, p<0.01).
Conclusions: Streptococcal infections may be an important factor related to Henoch-Schonlein Purpura in children. Purpura and Purpura of abdominal type recurrence is related with streptococcal infection, which is the great value to observation and treatment.

Background: Rituximab (Rtx), a novel biological, having B cell depletive mechanism is an anti-CD 20 antibody and is found to be useful in patients of ANCA associated vasculitis. In AAV the disease activity correlates with increased circulating B cells. Rituximab has been found to be useful in depleting these B cells. Accordingly, in our RVE study, Rituximab was shown to be non-inferior to Cyclophosphamide in induction remission. It also shows that the regimen (Rtx) may be superior to the standard regimen of Cyclophosphamide and glucocorticoids for remission induction in severe relapsing ANCA-associated vasculitis. In our study, B cell therapy was given in those patients only who had persisting disease activity or relapse.

Objectives: To assess response of Rtx in relapsed/refractory cases of AAV and show that it is a good therapeutic strategy in such cases.

Methods: In our cohort there were 49 patients of ANCA associated vasculitis, diagnosed by clinical and serological criteria, (by both ELISA and IFA) classified according to ACR criteria and supported, wherever possible, by biopsy. In this prospective study, patients were seen during January 2012 to January 2017. A total of 15 patients received Rituximab for various reasons. Rituximab (Rtx) was given intravenously on day 1 and day 15 as induction therapy and subsequently 6 monthly maintenance doses of 500 mg were administered. No other immunosuppression other than steroids were given.

Results: Median follow up was 22 months. All patients had received Cyclophosphamide (median of 6 grams) and 1mg/kg glucocorticoids at onset. Among the patients who received Rituximab, all had anti PR3 positivity and all were GPA clinically. 14 patients (93.33%) had lung involvement, renal involvement was seen in 7 (46.6%) patients, 13 (86.6%) patients had upper respiratory tract involvement, 6 (40%) had ophthalmic involvement. Nervous system involvement was seen in 1 (6.6%) and myocarditis was seen in 3 (20%) each. 3 (20%) patients had gangrene.

Indications for receiving Rtx were heterogenous. It was given for involvement of more than two-thirds of patients. Increasing evidence supports a role of circulating B cells. Rituximab has been found to be useful in depleting these circulating B cells. Rituximab was shown to be non-inferior to Cyclophosphamide in induction remission. It also shows that the regimen (Rtx) may be superior to the standard regimen of Cyclophosphamide and glucocorticoids for remission induction in severe relapsing ANCA-associated vasculitis.

Conclusion: Our study shows that Rituximab is an effective therapeutic strategy for refractory/refractory especially PR3+ AAV also it can be used as a maintenance regimen for long term.

Results: 15 patients, 6 males and 9 females (mean age 71.6 ± 7 years – duration symptoms at onset 1.7 ± 1.3 months – mean ESR 60 mm/h 52 – mean CRP 8 mg/dl ± 5.2) entered the study. US halo sign was bilateral in 10/15 (66.7%). The mean halo thickness was 0.53 mm ± 0.12. Five patients had USG +1, six patients +2 and four patients +3. The histological inflammatory grade 1 was present in seven pts, grade 2 in four and grade 3 in four pts. No significant correlation were found between USG and histological inflammatory grade, nor with the presence of giant cells, calcifications, lamina necrosis and intima-media thickness.

Conclusions: No correlation has been found between the size of the halo sign and the histological inflammatory grading.

The long term health related quality of life (HRQOL) impact on giant cell arthritis (GCA) patient

**AB0567**

**THE LONG TERM HEALTH RELATED QUALITY OF LIFE (HRQOL) IMPACT ON GIANT CELL ARTHRITIS (GCA) PATIENT**

H. Horiuchi, General Medicine, Kurashiki Central Hospital, Okayama, Japan

**Background:** Health related quality of life (HRQOL) of Giant cell arthritis (GCA) patients is important because it adds depth to our understanding of how a disease and its treatments affect them. Though only one previous study has addressed the short term impact of GCA on HRQOL, the long term impact has not fully been investigated.

**Objectives:** The aim of our study is to assess the long term HRQOL outcomes of GCA patients using the Japanese version of EuroQol 5 Dimension (EQ-5D).

**Methods:** 40 GCA patients who admitted to our hospital from November 2004 to June 2014 were enrolled. All patients were received prednisolone over 2 years. Patients who had lost their eyesight were excluded because vision concern for HRQOL nor it is difficult to measure by using EQ-5D. This is a retrospective study and data were collected by telephone interview. Patients evaluated their health status using five dimensions. The EQ-5D score were calculated based on the Japanese version of the value set. Primary outcome is the mortality rate and the norm of EQ-5D score. As a secondary analysis, we classified the patients as follows and compare the mortality rate and EQ-5D score between two groups.

**Results:** One study focused on GCA patients with prednisolone therapy over 2 years. It showed that EQ-5D was decreased compared with the Japanese norm but it didn’t clearly decrease after 2 years of treatment. These findings suggest the value of measuring health status by EQ-5D at least at first 2 years of treatment, because it would allow comprehensive evaluation of the patient’s health condition and add another dimension to the subjective symptoms and laboratory data.

**APPLICATION OF OZONATED WATER IN ORAL ULCER PATIENTS WITH BEHCET’S DISEASE**

H. Miao, L. Zhang, G. Zhang, K. Xu. Rheumatology, Shanxi Dayi Hospital, Taiyuan, China

**Background:** Behcet’s disease is a systemic vasculitis disease of unknown etiology. Oral ulcer is the most common symptoms, the ulcer is various, the swelling and pain is obvious, and it is easy to recur, these symptoms affected the patient’s diet and life seriously. Therefore, it is important to care the patients with Behcet’s disease of oral ulcer. The ozonated water had many functions such as immune activation and immune regulation, it can induce the production of many cytokines,promote the repairment of oral epithelium.At the same time, the ozonated water had a direct effect on the nerve endings, it played a better analgesic effect, it was widely used in oral mucositis which induced by chemotherapy. But there were few studies about application ozonated water in the patients with Behcet’s disease of oral ulcer, it was not widely used in clinical practice.

**Objectives:** Apply the ozonated water in patients with Behcet’s disease, observe the effectiveness in patients with Behcet’s disease of oral ulcer.

**Methods:** From June 2014 to June 2016,82 cases of hospitalized patients with Behcet’s disease were randomly divided into study group and control group (n=41), the control group used nursing method of gentamycin sulfate solution and the number of giant cells in the present case were not remarkably high. A systematic literature review identified 4 cases of 18F-FDG-PET positive temporal arteries in GCA, a systematic literature review was performed identifying 83 cases of 18F-FDG-PET positive temporal arteries in GCA. In our case, the number of giant cells in the present case was not remarkably high. A microscopic neutrophilic abscess. When compared with 2 other cases of temporal arteritis with a negative 18F-FDG uptake, the severity of inflammation and the number of giant cells in the present case were not remarkably high.

**Conclusions:** This was a retrospective chart review of 3 patients with giant cell arteritis who underwent all of 18F-FDG-PET, MRA, CT angiogram, ultrasound and histopathologic evaluation of temporal arteries. To investigate the cases of GCA-PET positive temporal arteries in GCA, a systematic literature review was done in Pubmed using 18F-FDG-PET AND (“temporal arteritis” OR “giant cell arteritis”).

**Results:** The mortality rate was 56.0% (14 patients) in Group1 and 6.6% (1 patient) in Group2. It was significantly higher in Group 1 (P<0.05). The median EQ-SD score was 0.764 (95% confidence interval [CI] 0.597–0.870) in Group1 versus 0.768 (95% CI 0.621–0.915) in Group2. There was no statistically significant difference between them (P=0.813).

**Conclusions:** This study focused on GCA patients with prednisolone therapy over 2 years. It showed that EQ-SD was decreased compared with the Japanese norm but it didn’t clearly decrease after 2 years of treatment. These findings suggest the value of measuring health status by EQ-5D at least at first 2 years of treatment, because it would allow comprehensive evaluation of the patient’s health condition and add another dimension to the subjective symptoms and laboratory data.

**CHANGE IN SERUM LEVEL OF SOLUBLE E-SELECTIN AND MMP-9 IN CHILDREN WITH KAWASAKI DISEASE**

H. Zeng, Department of Pediatric Allergy, Immunology and Rheumatology, GuangZhou Women and Children’s Medical Center, Guangzhou, China

**Objectives:** Kawasaki disease (KD) is a kind of febrile disease without definite etiology. Coronary artery aneurysms are the major complication of Kawasaki disease. With 111R-pimonidazole imaging of the vascular damage of GCA of remains unknown. This study WIIF conducted to explore the pathophysiological role of E-selectin (ES), CAMstrx metalloproteinase 9 (MMP-9) in KD, and to look for the evidence of direct relationship between the plasma levels of ES,MMP-9 and the incidence of the coronary artery lesion (CAL).

**Results:** There were 16 male (40%) and 24 female (60%). The median age was 83.5 (95% CI 79.24–87.76). The mortality rate was 37.5% (15 patients). Kaplan-Meier curve is shown in Figure1. The median EQ-SD score was 0.746 (95% confidence interval [CI] 0.852–0.640) and it is lower than Japanese norm (0.853 in male and 0.808 in female). In the secondary analysis, the mortality rate was 56.0% (14 patients) in Group1 and 6.6% (1 patient) in Group2. It was significantly higher in Group 1 (P<0.05). The median EQ-SD score was 0.764 (95% CI 0.579–0.870) in Group1 versus 0.768 (95% CI 0.621–0.915) in Group2. There was no statistically significant difference between them (P=0.813).

**Conclusions:** This study focused on GCA patients with prednisolone therapy over 2 years. It showed that EQ-SD was decreased compared with the Japanese norm but it didn’t clearly decrease after 2 years of treatment. These findings suggest the value of measuring health status by EQ-5D at least at first 2 years of treatment, because it would allow comprehensive evaluation of the patient’s health condition and add another dimension to the subjective symptoms and laboratory data.
