Methods: Soluble ES and MMP-9 were measured in 68 patients with KD. 20 patients with febrile disease and 20 healthy children by using double antibody sandwich enzyme linked immunosorbent assay (ELISA). Patients with KD were separated into acute phase group, subacute phase group, recovery phase group.  Coronary artery lesion group (CAL), non-coronary artery lesion group (NCAL).  BVAS for GPA, FFS (1996) and FFS (2009) of patients with refractory disease (≥ 9.5) were the most frequently identified auto-antibodies (40%). Musculoskeletal manifestations (arthritis, and myalgia), mucocutaneous disorders (including vasculitic/necrotic lesions, mucosal ulcers, and purpura), neurological compromise (peripheral and central), and renal involvement (acute renal failure, glomerulonephritis, and lung–kidney syndrome) were the most frequently reported onset symptoms in 29%, 29%, 23%, and 21%, respectively. Interestingly, most of patients did not develop organic compromise other than the onset manifestation form.  Three percent of patients fulfilled polyautoimmunity criteria and 9% presented with multiple autoimmune syndrome.  ANCA-associated arteritis syndrome was the most common associated autoimmune disease described.  Cotricosteroids were the most common treatment used in 93% of patients, followed by azathioprine in 57%, cyclophosphamide, methotrexate, and rituximab in 29%, and antimarial in 21%.  No deaths occurred during follow-up.

Conclusions: Vasculitides are conditions with several subphenotypes, being ANCA-associated the most frequently reported.  Onset symptoms seem to be the main drivers of disease evolution.  Appropriate and prompt diagnosis is critical to enable timely intervention, aimed to prevent end organ damage and reduce morbidity in these patients.  Controlling disease activity and preventing progression is the milestone of treatment.  Characterization of Latin America population is pivotal to raise awareness of health-care workers, and policy makers.

AB0571 BIRMINGHAM VASCULITIS ACTIVITY SCORE MORE THAN 9.5 AT FOLLOW-UP IS AN INDEPENDENT PREDICTOR OF REFRACTORY DISEASE OF GRANULOMATOUS WITH POLYANGITIS

J. You, H.J. Kim, S.-W. Lee. Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea, Seoul, Korea, Republic Of

Background: Granulomatosis with polyangiitis (GPA), that is identical to what has been called Wegener's granulomatosis, is one of anti-neutrophil cytoplasmatic antibody (ANCA)-associated vasculitides (AAV). GPA is characterized by necrotising granulomatous inflammation usually affecting small to medium vessels, and it often involves the upper and lower respiratory tracts and commonly provokes necrotising glomerulonephritis.  It has been reported that the mortality rate in untreated patients increased up to 90% within 2 years after diagnosis, and the overall mortality rates were ranging from 12% to 44% within 4 to 10 years.  The major causes of death are known as cardiovascular disease, adverse events of immunosuppressive agents and major organ involvement of GPA.  If there might be predictors of relapse or refractory disease of GPA during the follow-up duration, they can help physicians to select the induction therapeutic regimens, decide the duration of the maintenance therapeutic regimens and adjust the follow-up interval in order to improve the disease course of GPA.

Objectives: We investigated whether clinical manifestations, anti-neutrophil cytoplasmatic antibodies (ANCAs), Birmingham vasculitis activity score (BVAS) for granulomatosis with polyangiitis (GPA) and five factor score (FFS) at diagnosis can predict relapse or refractory disease in 30 histology-proven GPA patients with the follow-up duration ≥12 weeks.

Methods: We reviewed the medical records of 30 GPA patients. We collected clinical data, ANCAs, BVAS for GPA, FFSs at diagnosis, and we compared variables between the two groups based on relapse or refractory disease. The optimal cut-offs were extrapolated. Multivariate logistic regression and Cox hazard model analyses were conducted to identify predictors of relapse or refractory disease.

Results: The mean age and follow-up duration of patients were 63.3 years old and 45.2 months. The mean initial BVAS for GPA, FFS (1996) and FFS (2009) were 5.4, 0.6 and 1.0. There were no significant predictors of relapse. The mean BVAS for GPA, FFS (1996) and FFS (2009) of patients with refractory disease were higher than those without (p<0.05 for all). Patients having BVAS for GPA ≥9.5, FFS (1996) ≥2 and FFS (2009) ≥2 exhibited significantly enhanced risk of refractory disease than those having not (RR 23.0, RR 11.0, and RR 55.0, respectively), and low cumulative refractory disease free survival rates. Multivariate Cox hazard model analysis proved BVAS for GPA ≥9.5 was an independent predictor of refractory disease during the follow-up duration ≥12 weeks.

Conclusions: BVAS for GPA ≥9.5 was an independent predictor of refractory disease during the follow-up duration ≥12 weeks.
Background: In Japan, rituximab (RTX) has become one of the dominant therapies for ANCA-associated vasculitides. The primary aim of RTX induction is remission induction followed by glucocorticoid discontinuation. In Japan, AAV, mostly MPO-ANCA-positive PMA, affects elderly patients at the age of over 70 years with severe MPA, with an acceptable safety profile and rapid glucocorticoid tapering. However, careful monitoring for infection is crucial in elderly patients.

Methods: Nineteen patients with AAV, including 14 newly diagnosed patients and 5 relapsed patients, had been treated with RTX. There were 10 males and 9 females. They were all MPO-ANCA positive; 16 were diagnosed with microscopic polyangiitis (MPA), 2 with granulomatosis with polyangiitis (GPA), and 1 with undifferentiated, according to the EMA classification of AAV. The median age of RTX induction was 71.3 years (range: 40–82 years). The efficacy was evaluated by the BVAS score at the time of first induction and after 6 month treatment. Adverse events were recorded during the 6-month treatment.

Results: The mean of BVAS decreased from 17.3 (range: 7–35) at the first induction to 1.2 (0–4) at 6 month of RTX treatment. Of the 10 patients who could be followed-up for over 6 months, 7 patients achieved remission (BVAS=0) (remission rate: 70.0%). The median of MPO-ANCA decreased from 136.1 IU/mL (range: 10.9–300 IU/mL) to 44.4 IU/mL (1.0–114.0 IU/mL) at 6 month. The dose of prednisolone decreased from 34.4mg/day (5–60mg/day) at baseline to 5.5mg/day (0–10 mg/day) at 6 month. The adverse events were as follows: 3 patients experienced reactivation of cytomegalovirus (CMV) with a CMV colitis, one patient with sepsis following urinary-tract infection, and one patient with bacterial pneumonia. One patient with PMA died of exacerbation of the disease itself. None of the patients had reported complications, 5 patients had no complications and 6 patients were missing data. All data was sourced from single case studies.

Conclusions: Out the indications, outcomes and complications of HSCT in a case series of 4 patients with BS managed at a single centre of excellence.

Methods: Case notes were reviewed for 4 patients from the Liverpool Behçet's Centre of Excellence (LBCE) who have undergone HSCT.

Results: The primary indication for 3 of the 4 patients who have undergone autologous HSCT at LBCE was refractory BS. Patient 1 underwent HSCT for multiple myeloma, but suffered from severe BS with neurological and venous involvement and is now in partial remission with occasional mild muco-cutaneous ulceration, not requiring systemic immunosuppression. Patient 2 underwent HSCT for severe refractory neuro-Behçet's. This patient is now in complete remission after commencing azathioprine for oral ulceration. The indications for HSCT in patients 3 and 4 were severe muco-cutaneous ulceration and dermatological involvement refractory to numerous biologic agents with high ongoing steroid dependency. Patient 3 also had previous thrombophlebitis and patient 4 had previous gastro-intestinal ulceration. They are both currently in complete remission but follow up time is limited. Patient 3 had a post-HSCT complication of pneumonia and mucositis which resolved without persistent morbidity, patient 4 had an upper limb deep vein thrombosis (DVT) as an inpatient.

Conclusions: HSCT is an effective treatment modality for severe refractory BS and can result in medication free remission. However, the associated risks should be considered and alternative treatment options deliberated or exhausted before opting for this treatment modality.

The most frequent vascular manifestation in BD. In this study, we looked at the pattern and outcome of venous events in BD.

Methods: Seventy-five patients, who fulfilled the criteria of the International Study Group for diagnosis of BD, were recruited. We studied the characteristics of patients with thrombotic venous events. Clinical data parameters were recorded, including age at onset, the vascular and extra-vascular manifestations of the disease.

Results: Twenty-six patients had vascular event. Twenty-three of these patients had a venous event. The mean age of the patients at the first venous event was 32 years. There were 22 males and 4 females. The first venous event occurred before BD diagnosis in one case (10.9%) and was the same time of onset of the disease in two cases. In the other cases, venous event occurred in patients followed for BD and the mean disease duration was 5, 82 years. The mean number of recurrence of venous events was 1.46. Deep vein thrombosis was the most frequent single vascular event (76, 92%). The most frequent localizations were in lower left leg (23 cases). Patients had cerebral vein thrombosis. A pulmonary venous involvement, a Budd-Chiari syndrome, an inferior and superior vena cava syndrome, and arm thrombosis were found in only one case each one. An arterial event was associated in 2 cases. An association with ocular manifestations was observed in 26, 9% patients and neurologic manifestations in 11, 53%.

Conclusions: Although there is no agreement on the frequency rate of the vascular lesions in the literature, most of the vascular lesions in the literature, most of the reported series indicate that the venous lesions are far more, by far more common than the arterial lesions. Kabba et al. reported 85% venous, 10% arterial and 5% miscellaneous with venous and arterial involvement which is similar to the reported frequency in our patients.

In conclusion, the frequency of vascular complications of BD in our patients is similar to those reported around the world.

AB0575 RETROSPECTIVE SURVEY OF CONCOMITANT AUTOIMMUNE DISEASES AND AUTOANTIBODIES IN A Cohort OF PATIENTS WITH ANCA-ASSOCIATED VASCULITIS (AAV)

M. Casal Mora, S. Prieto-González, O. Espigol-Frígola, M. Murcia, M. Alba, J. Hernández-Rodríguez, M. Cid, Division of Internal Medicine, Sant Joan de Déu Hospital; 2Department of Medicina, Porto Medical School, Porto, Portugal; 3Department of Autoimmune Diseases, Hospital Clinic, University of Barcelona. IDIBAPS, Vasculitis Research Unit, Barcelona, Spain; 4University Clinic for Visceral Surgery and Medicine, Bauchzentrum Bern, Bern, Switzerland

Background: Anti-neutrophil cytoplasmatic antibodies (ANCA) associated vasculitis (AAV) is a necrotizing vasculitits that predominantly affects small and medium arteries and has ANCA specificity for myeloperoxidase (MPO-AA) or proteinase 3 (PR3-ANCA). The major clinicopathologic variants of AAV include microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA) and eosinophilic granulomatosis with polyangiitis (EGPA). Recent studies have demonstrated the crucial role of complement activation in the pathogenesis of AAV. However, the clinical characteristics of AAV with hypocomplementemia (HC) still remain unclear.

Objectives: The aim of our study was to analyze the demographic, laboratory, treatment and clinical characteristics of AAV using medical records. To compare the AAV patients with and without HC.

Methods: Retrospective study of patients with AAV diagnosed and followed in a specific Systemic Autoimmune Diseases and Thrombosis Unit. We defined HC as the state in which at least one of the following was lower than the lower limit of the normal range: Complement C3 (C3), Complement C4 (C4). Demographic, clinical, treatment and evolution data were recorded and analyzed using SPSS 22.0.

Results: Thirty-six patients with AAV were included (94.4% MPO-ANCA, 5.6% PR3-ANCA). 8 patients were diagnosed of GPA, 21 of MPA and 3 of EGPA. 61% of the patients were males and the mean age at the onset of the disease was 63,1±14,38 years (30–85). 75% of patients had any vascular risk factors. Renal involvement occurred in 32 patients (88.9%); hematuria in 96.9%, proteinuria in 90.6% (>1 g/day), and gloomerular filtration decreased in 81,25%. Biopsy was performed in 22 patients and a focal and segmental necrotizing glomerulonephritis with extracapillary proliferation was the finding more common. Pulmonary disease (61,1%) included interstitial disease 40,9%, alveolar hemorrhage 22,7% and nodules 18,2%. Other clinical manifestations were constitutional syndrome 36,1% (the main symptom was asthenia); ear, nose, and throat manifestations 33.3%; neurologic involvement 27.8% (the main finding was polynyruropathy); articular manifestations 33.3% and skin lesions 16.7%. All the patients received prednisone in combination with cyclophosphamide (69.4%) or rituximab (13.9%). Azathioprine was used as glucocorticoid-sparing agent (41,7%). 83,3% of the patients needed hospital admission and 6 died (16,7%). Eleven patients (30.6%) had HC at their diagnosis of AAV. Compared to the AAV patients without HC (n=25), we found no significant differences in the frequency or severity of the manifestations (evaluated by Five factor score). The small sample size could in part explain these results.

Conclusions: Our patients with HC at diagnosis of AAV did not have different characteristics than those without HC. More studies are needed to determinate if HC is a predictor of poor prognosis in AAV patients.

AB0577 SYSTEMIC AUTOIMMUNE VASCULITIS IN RHEUMATOID ARTHRITIS – A POSTMORTEM CLINICOPTHLOGIC STUDY OF 161 PATIENTS

M. Bély, 1 A. Apáthy 2 1Department of Pathology, Policlinic of the Order of the Brothers of Saint John of God; 2Department of Rheumatology, St. Margaret Clinic Budapest, Budapest, Hungary

Background: Systemic vasculitis of autoimmune origin (A-SV) may be regarded as a basic histological manifestation of rheumatoid arthritis (RA) [1,2]. The aim of our study was to characterize the severity of systemic autoimmune vasculitis at death in RA patients.

Methods: A randomized autopsy population of 161 in-patients with RA was studied.

A-SV was confirmed clinically according to the criteria of the ACR [4]. The severity of vasculitis was evaluated by semi-quantitative, visual estimation on a 0 to 3 plus scale in 12 organs (heart, lung, liver, spleen, kidney, pancreas, gastrointestinal tract, adrenal gland, skeletal muscle, peripheral nerve, skin and brain) at death) [1]. 0*: no vasculitis; **: sporadically (scattered) located gender (OR 2.710,95% CI 1.034–7.099,p=0.043), MPA syndrome (OR 3.578, 95% CI 1.334–9.523,p=0.011) and MPO carriers (OR 3.346, 95% CI 1.166–9.601,p=0.025).

Conclusions: A substantial percentage of AAV patients, particularly MPA and anti MPO carriers, have associated autoimmune diseases and autoantibodies. The high frequency of our study (retrospective assessment and lack of comparator) do not allow accurate estimation of prevalence. The severity of AAV and difficulties in management, may lead to overdiagnosis of associated autoimmune diseases which appear to be frequent. Associated autoimmune disease may contribute to additional burden in AAV patients. (Supported by SAF 2014 57708-R).

Disclosure of Interest: None declared

vasculitis, “2”: less than five, “3”: five or more involved blood vessels/microscopic
field with a x20 objective.

The age at death, and the onset and duration of RA with mild (<0.2/patient), or
severe (0.2A-SV, were compared by Student (Welch) t-probe.

Results: 16 (50.0%) of 32 patients had a “mild” degree of A-SV (females 11, avg
age of 70.91 years, range 68 – 90, onset of RA: 62.55, avg disease duration: 8.39
years at death; males 5, avg age of 71.6 years, range 83 – 58, onset of RA: 57.2, avg
disease duration: 14.4 years).

16 (50.0%) of 32 patients had “severe A-SV” (females 8, age of 60.88 years,
range 62–32, onset of RA: 52.67, avg disease duration: 13.5 years at death; males
8, avg age of 65.0 years, range 78–53, onset of RA: 53.25, avg disease duration:
11.75 years).

Four (12.5%) of 32 patients had “extremely severe A-SV” (with an average
cumulative value of severity/RA patient with SV >0.630) (females 1, age of 82.0
years, onset of RA: 62.0, average disease duration: 20.0 years at death; males 3,
average age of 69.7 years, range 78 – 59, onset of RA: 60.7, average disease duration:
duration: 9.0 years).

Severity of SV in 32 RA patients with A-SV – according to increasing average values
of vasculitis/patient – is summarized in Figure.

Conclusions: A-SV is caused by circulating immune complexes in RA. Immune
complexes spread via the bloodstream and provoke vasculitis throughout the
body.

We found no differences in the linear and basically parallel development of A-SV
between patient groups with mild and severe vasculitis.

The progression of vasculitis was the same in both patient groups suggesting
differences in production of circulating immune complexes.

Quantitative differences in the production of circulating immune complexes may
be related to a “benign” or “aggressive” clinical course of RA, which may be due
to genetical and other factors.

In 4 of 32 RA patients the severity of vasculitis showed a “step-wise” growth
with “extreme severe” A-SV (0.630 or <) according to increasing average values
of vasculitis/patient (Figure 1). There was no gradual transition between the
“extremely severe” and “severe” degrees A-SV. This profile of “step-wise”
general severity in patients with vasculitis may represent a subgroup of patients
with a different genetic-immunologic background.

AB0578 ARTERIAL ANEURYSMS MOROCCAN EXPERIENCE STUDY OF 37 CASES.

M. Moudatir1, M. Moudatir2. Internal medicine; 2 rue la saone, Polo,
University hospital Ibn rochd, Casablanca, Morocco

Background: Behcet’s disease is a systemic vasculitis with a tropism for the
venous system. Arterial involvement is uncommon (1%) and mainly represented
by aneurysms that can be life-threatening.

Objectives: This retrospective study was conducted in the internal medicine
department of the University Hospital Ibn Roch of Casablanca, over a period
of thirty-five years between 1980 and 2016. Where included all the cases of
Behcet’s disease diagnosed in our service (1618 case).

Methods: We aimed to determine the epidemiological profile, the different
possible clinical manifestations and to discuss both prognosis and treatment
in such cases.

Results: 37 patients – 32 men and 5 women – presented arterial involvement
in type of arterial aneurysm, which represents a rate of 2.35%.

Mean age at diagnosis was 32 years old (ranges 17–54). This complication was
the revealing event for Behcet's disease in 2 cases, concomitant in 3 cases and
occurring after an average of 6-year-period evolution of the disease in 32 cases.

The aneurysm affected: the pulmonary artery (22 cases), the abdominal aorta
(5 cases), the femoral artery (5 cases), the internal carotid artery (2 cases), the
iliac artery (2 cases) and the middle cerebral artery (1 case). The aneurysm was
associated with venous disease (18 cases), pulmonary embolism (2 cases) and
intracardiac thrombus (1 case).

The management treatment has relying on anticoagulants (6 cases), anti-aggregating
agents (9 cases), corticosteroids (36 cases), immunosuppressive drugs –
cyclophosphamide (23 cases) and azathiope (12 cases), while 7 patients
underwent surgical intervention.

Evolution was favorable in 23 patients and with negative outcome in 14 patients
(9 relapses and 5 deaths).

Conclusions: Arterial aneurysms are the most common arterial complications in
the context of Behcet’s disease, while the prognosis remains poor in the absence of
early and appropriate management (anticoagulants, immunosuppressive agents,
surgery).

AB0579 IMMUNE RELATED DIFFUSE ALVEOLAR HAEMORRHAGE: SINGLE CENTER EXPERIENCE AND LONG TERM OUTCOME – RHEUMATOLOGICAL PERSPECTIVE.

Rheumatology and Clinical Immunology, Medanat the Medicity, gurgaon, India

Background: Diffuse alveolar haemorrhage (DAH) is a feature of several immune
and nonimmune disorders. Failure to diagnose and treat DAH syndromes in their
early stages may lead to acute respiratory failure, CKD and death. Prognosis is poor
with in-hospital mortality ranging from 20% to 100%. Immune related DAH
is monophasic and if treated early and achieved remission, long term outcome is
good.

Objectives: To evaluate the therapeutic response and long term outcome in
patients with Immune related (AAV & SLE) DAH.

Methods: A retrospective review of medical records of patients admitted under
Rheumatology and Clinical immunology department with Immune related DAH
was made with regards to their presentation, treatment & response, mortality,
 morbidity and long term outcome. Study was performed after approval and ethical
clearance from IRB.

Results: From June 2012 to August 2016, 18 patients (15 were AAV related &
3 as SLE related) were admitted. Amongst AAV patients, PR3 positive were
11 & MPO positive were 4. Fourteen patients were females and 4 males, age
 ranged from 14 – 68 yrs (median=54.5 yrs). Mean duration of disease before
onset of DAH was 3 months. Nine (50%) patients had associated kidney and
musculoskeletal involvement. Eleven (61.11%) patients were admitted under
ICU care requiring artificial ventilation. Pulse methylprednisolone injections were
given in 15 (83.33%), Cyclophosphamide in 13 (72.22%), IVig in 2 (11.11%),
plasmapheresis in 7 (38.88%) patients. Time from first consultation to pulse
methylprednisolone was in range from 1 to 5 days. Out of 18, 11 patients
achieved remission. In hospital mortality was seen in 5 (27.77%) patients, all
were AAV (MPO>3, PR3<2), all were complicated with sepsis with MODS
before death. Out of 7 who received plasmapheresis, 2 patients (28.4%) died, 2
patients developed CKD ( dialysis independent). Duration of ICU care
ranged from 3 to 28 days & 2 to 40 days respectively. Mean follow
up was 16 months (range 11–42 months) Two had relapse on follow up (1 nephritis, 1 persistant cavities with episcleritis) who were given
Rituximab. Total 5 (38.46%) received Rituximab out of which 2 were refractory
achieved remission. In hospital mortality was seen in 5 (27.77%) patients, all
were AAV (MPO>3, PR3<2), all were complicated with sepsis with MODS
before death. Out of 7 who received plasmapheresis, 2 patients (28.4%) died, 2
patients developed CKD ( dialysis independent). Duration of ICU care
ranged from 3 to 28 days & 2 to 40 days respectively. Mean follow
up was 16 months (range 11–42 months) Two had relapse on follow up (1 nephritis, 1 persistant cavities with episcleritis) who were given
Rituximab. Total 5 (38.46%) received Rituximab out of which 2 were refractory
achieved remission.

Conclusions: High index of suspicion with early diagnosis and treatment results
in low mortality and better long term outcome. All mortality was because of delay
in diagnosis. Rituximab is effective in achieving remission in refractory as well as
relapsed cases.

and clinical outcome: results from affiliated hospitals of Catholic University of
Feb;30(1 Suppl 70):S77–S9.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.7012
Background: Behçet's disease is a kind of systemic vasculitis affecting multiple systems. Although symptomatic cardiac involvement in Behçet's disease is uncommon, the mortality rate may reach up to 29%. Conduction disturbances might lead to poor outcome and often need permanent pacemaker implanted. The clinical characteristics of conduction disturbances in Behçet's disease were rarely reported before.

Objectives: To investigate the clinical characteristics of Behçet's patients with conduction disturbances and explore the underlying risk factors.

Methods: We reviewed 57 medical records of Behçet's disease with cardiovascular lesions in Anzhen Hospital, Capital Medical University between January 2002 and July 2015, and analyzed the clinical characteristics.

Results: (1) There were 13 patients with conduction disturbances out of a total of 57 Behçet's disease cases (22.8%) in our research: three patients with first-degree atrioventricular block; one patient with Mobitz type I second-degree atrioventricular block; four patients with third-degree atrioventricular block; one patient with the left anterior branch block; one patient with complete right bundle branch block; three patients with first-degree atrioventricular block combined with the left anterior branch block or complete right bundle branch block. One patient (7.7%) died from infectious endocarditis and aortic root abscess during hospital stay.

(2) Hemoglobin level was significantly lower in cases than controls (111.23±23.06 vs. 127.16±19.66 g/L, P<0.017); the median of albumin level in cases was higher than controls (34.5 (14.2) vs. 27.6 (20.7) mg/L, P=0.024) (Table 1). C reactive protein level was higher in cases than controls [26.12 (21.3) vs. 6.7 (16.4) mg/L, P=0.045] (Table 1).

(3) The aortic valvular insufficiency presented more frequently in patients in the case group than the control group (92.3% vs. 47.7%, respectively; P=0.004). Heart reconstruction can be seen in Behçet's patients with cardiac involvement. The echocardiography showed the following parameters were significantly different between two groups: left ventricular end-diastolic diameter (64.85±10.96 vs. 52.5±10.13 mm, P=0.011); left ventricular end-contraction diameter (48 [15] vs. 31 [13] mm, P=0.001); left atrial diameter [50 [17] vs. 35.85 (13) mm, P=0.003]; outflow tract of right ventricle [26 (7) vs. 27 (6) mm, P=0.045] (Table 1).

(4) Aortic valvular insufficiency was an independent risk factor for Behçet's disease with conduction disturbances (OR =1.157, 95% CI 1.034, 1.293, P=0.011).

Conclusions: Behçet’s disease is one of the unusual etiologies of atrioventricular block. The evaluation of conduction disturbance should be kept in mind when diagnosing BD’s patient.

References:
factors, i.e. smoking history (6.3% vs 38.4%), hypertension (10.4% vs 30.5%) and diabetes (12.5% vs 17.9%). Instead these patients had more upper respiratory inflammations (chronic sinusitis, chronic otitis media and allergic rhinitis, 33.3% vs 6.6%) before the disease onset.

Conclusions: We found that MPA had more atherosclerotic risk factors, and MPO-GPA had more upper respiratory inflammations. These factors may determine MPA or GPA phenotypes in MPO-ANCA positive AAV.

AB0583 DIFFERENCES BETWEEN ISOLATED AORTITIS AND NON-INFECTIOUS AORTITIS SECONDARY TO OTHER ENTITIES. STUDY OF 93 PATIENTS FROM A SINGLE CENTER

N. Vegas-Revenga, I. Lorica1, D. Prieto-Peña1, J.L. Hernández2, I. Martínez-Rodríguez2, J.I. Banzo2, M. Calderón-Goercke1, V. Calvo-Río1, L.C. Domínguez-Casas1, C. González-Vela1, P. Fuentevilla1, M.A. González-Gay1, R. Blanco1, J. Rheumatology; 2Internal Medicine; 3Nuclear Medicine; 4Internal Medicine, Hospital Universitario Marqués de Valdecilla. IDIVAL, Santander, Spain

Background: Non-infectious aortitis is an inflammation of aortic wall which may be isolated or associated with a cluster of diseases.

Objectives: Our aim was to compare the clinical and laboratory findings of patients with isolated aortitis and patients with aortitis secondary to other underlying conditions.

Methods: Retrospective study of 93 patients with non-infectious aortitis diagnosed by PET/CT scan from a referral center from January 2010 to December 2016. We have considered two groups: group a) isolated aortitis; and group b) secondary aortitis. Distributions of categorical variables were compared by the Pearson Chi2 or Fisher exact test. Quantitative variables were analyzing using the Student t test or Mann-Whitney U test as appropriate.

Results: Ninety-three patients were diagnosed with non-infectious aortitis. One patient was excluded due to missing data. Group a) was composed by 54 patients (34 women/20 men) with a mean age of 67±11 years; group b) comprised 38 patients (28 women/10 men) with a mean age of 68±11 years. In this group, the underlying conditions we found were: giant cell arteritis (n=24), Takayasu arteritis (n=3), spondiloarthropathy (n=3), Sjögren’s syndrome (n=3), ulcerative colitis (n=2), sarcoidosis (n=1), rheumatoid arthritis (n=1), polyarteritis nodosa (n=1). The comparative study between both groups is shown in the TABLE. Only inflammatory low back pain and polymyalgic syndrome yielded statistical significance.

Conclusions: In this study, we observed that the presence of inflammatory low back pain and polymyalgic syndrome might have clinical relevance in the clinical suspicion of primary aortitis. However, larger studies are needed to corroborate these findings.

AB0584 UTILITY OF PET/CT SCAN FOR THE DIAGNOSIS OF AORTITIS. A STUDY OF 170 PATIENTS FROM A SINGLE CENTER IN A 6-YEAR PERIOD

N. Vegas-Revenga1, J.L. Lorica1, D. Prieto-Peña1, I. Martínez-Rodríguez2, J.I. Banzo2, M. Calderón-Goercke1, V. Calvo-Río1, C. González-Vela1, J. González-Vela1, M.A. González-Gay1, J.L. Hernández2, R. Blanco1, J. Rheumatology; 2Internal Medicine; 3Nuclear Medicine; 4Internal Medicine, Hospital Universitario Marqués de Valdecilla. IDIVAL, Santander, Spain

Background: Aortitis is the inflammation of the aortic wall. This entity is often under-recognised due to its frequent presentation with non-specific symptoms. PET/CT scan represent a major breakthrough to establish an early diagnosis, but this is an expensive technique.

Objectives: Our aim was to compare the baseline characteristics of patients with a suspicion of aortitis and positive results on PET/CT scan, and those with a negative result, in order to search for predictive factors, that improve the clinical probability of diagnosis aortitis by this imaging technique.

Methods: Retrospective study on 170 patients and PET/CT scans ordered by suspicion of aortitis from a referral center from January 2010 to December 2016. According to a pre-specified protocol, baseline epidemiological and clinical variables of patients with positive and negative PET/CT scans results for aortitis were reviewed. Distributions of categorical variables were compared by the Pearson Chi2 or Fisher exact test. Quantitative variables were analyzing using the Student t test or Mann-Whitney U test as appropriate.

Results: In 170 patients, PET/CT scans were performed due to clinical suspicion of aortitis, and were positive in 93 (54.7%) cases. Patients (113 women/57 men) had a mean age of 67.7±13.1 years (range, 20–90 years). One patient was excluded because missing clinical or laboratory data. The underlying diseases at the moment of ordering the PET/CT scan were: giant cell arteritis (GCA) (n=28), spondiloarthropathies (n=7), connectivopaties (n=6), Takayasu arteritis (n=3), ulcerative colitis (n=3), other condition (n=11). The remaining 111 patients did not have any underlying condition suggestive of aortitis. Two out of 170 patients suspected an infectious aortitis (Brucella and Salmonella); however, PET/CT was negative in both cases.

Characteristics of patients with positive and negative PET/CT scans were summarized in the Table. Patients with GCA had a higher percentage of positive PET/CT scans, whereas they were negative more frequently in patients who did not have any condition suggestive of underlying aortitis. Only inflammatory low back pain and polymyalgic syndrome were significantly more frequent in patients with positive PET/CT scans. The remaining clinical and laboratory variables did not show differences between both groups.

Conclusions: In this study, we have found that the presence of inflammatory low back pain and polymyalgic syndrome, especially in GCA patients, may have clinical relevance in ordering a PET/CT scan when aortitis was suspected.

AB0585 VASCULITIS DAMAGE INDEX IN LIMITED AND SYSTEMIC GRANULOMATOSIS WITH POLIANGIITIS IN MEXICAN PATIENTS

O. Vera-Lasstra, A.G. Angulo-González, J. Sepúlveda-Delgado. Internal Medicine, Hospital Especialidades CMN la Raza. Instituto Mexicano Seguro Social, Mexico City, Mexico

Background: Granulomatosis with polyangiitis (GPA) has been transformed
from life-threatening conditions to chronic relapsing long-term diseases as a result of significant advances in immunosuppressive therapy. Structured clinical assessment using Vasculitis Damage Index (VDI) should form the basis of a treatment plan and be used to document progress.

Objectives: To investigate the Vasculitis Damage Index and clinical manifestations in localized and systemic polyangiitis in Mexican patients.

Methods: We enrolled 61 patients with GPA according to The American College of Rheumatology (ACR) criteria at a referral hospital during the period from 2005 to 2015. Clinical and laboratory data, organ involvement and the Vasculitis Damage Index (VDI) were recorded at baseline. Patients were divide into systemic and localized forms of vasculitis.

Results: There were 61 GPA patients (34 men and 27 women) mean age 42 years old at diagnosis. Systemic form was observed in 53% and localized form 47%. Chronic sinusalitis was the most frequent manifestation in 33% followed by oteological in 26%. Subglottic stenosis (n=3) (52,6%) involvement of peripheral muscle or bire nal hemorrhage 1.0%. Of the patients with the systemic form 22 presented focal and segmental glomerulonephritis and 10 patients (32%) rapidly progressive glomerulonephritis. Distal-symmetrical polyneuropathy and cranial neuropathy were present in 24%; scleritis 24.5% and propiosis in 16%, palpable purpura 26.2% and ulcers in 9 patients (14.8%). The VDI score in the systemic form was 3.8 and in the localized 2.6. p< NS. The disease related damage was pronounced in kidneys and upper airways. The majority of patients in the induction to remission phase received steroids plus cyclophosphamide, 7 patients also received plasmapheresis and in maintenance phase they were treated with methotrexate or azathioprine.

Conclusions: In the cohort of patients with GPA, a high chronic damage was found which was similar in both systemic and localized forms of this vasculitis. The VDI was more prominent in kidneys and upper airways in GPA patients.

AB0586 EVALUATION OF ASSOCIATION BETWEEN ANTIPHOSPHOLIPID ANTIBODIES OR LUPUS ANTICOAGULANT POSITIVITY AND SEVERITY OF VASCULAR INVOLVEMENT IN TAKAYASU ARTERITIS PATIENTS

E. Firt1, A. Erden1, A. Sarı2, B. Armagan3, L. Kılıço, O. Karadag4, A. Akdoğan1, 2

1Internal Medicine, Hacettepe University Faculty of Medicine; 2Rheumatology, Hacettepe University of Medicine, Ankara, Turkey.

Background: Takayasu Arteritis is a rare large-vessel vasculitis variant that affects the aorta and its main branches and the pulmonary arteries. Antiphospholipid syndrome is characterized by obstetric and thrombotic complications in the presence of antiphospholipid antibodies, which consist of anticyclidapin antibody, lupus anticoagulant and anti-β2 glycoprotein 1. The association of antiphospholipid antibodies and Takayasu arteritis is very rare and few cases documented it, while others argued against such association.

Objectives: This study was planned to find out the prevalence of immunoglobulin-lgM anti-cardiolipin antibodies, anti beta 2 glycoprotein-1 antibodies and lupus anticoagulant in TA patients. In conclusion we can not suggest the routine evaluation of antiphospholipid antibodies or lupus anticoagulant test during the follow-up Takayasu arteritis patients. These antibodies may only be measured in the presence of clinical suspicion.

AB0587 ANTINEUTROPHILIC CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS AND HYPOCOMPLEMENTEMIA: CLINICAL IMPACT AND OUTCOME

S. Dhesayes1, A. Aouba2, K. Khoy2, D. Mariotte3, T. Lobbedez4, N. Martin Silva1, 5

1Department of Internal Medicine; 2Department of Immunology; 3Department of Nephrology, CHU Côte de Nacre, Caen, France.

Background: Although their pathophysiology are still largely unknown, there are growing evidences that complement (C) alternative pathway activation is implicated in antineutrophilic cytoplasmic antibody-associated vasculitides (AAV) pathogenesis.

Objectives: The aim of our study was to evaluate the clinical characteristics and outcome of AAV patients, according to their serum C levels at diagnosis.

Methods: A retrospective monocentric study carried out in Caen University Hospital led to identify proteinase-3 (PR3) or myeloperoxidase (MPO)-ANCA AAV patients (via an ELISA technique). All patients with available C3 and C4 levels (by nephelometry) at diagnosis were included, except for eosinophilic granulomatosis with polyangiitis (EGPA), which has a different pathophysiology. AAV were classified between granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA), and limited or severe forms according to respectively European Medicines Agency vasculitis algorithm and WGET group. Patients were categorized in the hypocomplementemia group if the C3 or C4 level at diagnosis was below the lower limit of the normal range (respectively 750–1400 mg/l and 100–340 mg/l). Categorical variables were reported as percentages and compared using Fisher’s tests. Continuous variables were expressed as means and analyzed using Student’s t-test. Associations between survival, renal survival and relapse-free survival, and low serum C levels were evaluated by the log-rank test. A p-value <0.05 was considered to be statistically significant.

Results: Among the 157 AAV patients identified, 81 were excluded (8 EGPA, 73 without C3 and C4 determinations before treatment initiation). On the 76 AAV included (43 GPA, 33 MPA), median age at diagnosis was 65 years (M/F, 38/38). Clinical presentations included constitutional symptoms (56, 73.3%), pulmonary (52, 68.4%), renal (50, 65.8%), rheumatologic (43, 56.6%), and ear, nose or throat (37, 48.7%) involvements, without statistical differences between groups. Twelve (15.8%) deaths and 41 relapses in 25 (32.9%) patients were noted (median follow-up: 38 months). Four patients (5.3%) had hypocomplementemia: 1 patient had isolated low C3 level, 1 had isolated low C4 level, and 2 had both low C levels. All 4 patients had renal involvement. The G level, controlled in 1 patient, became normal 1 month later. No thrombotic microangiopathy (TMA) features were found on the 2 performed kidney biopsies.

Survival and renal survival were significantly lower in the hypocomplementemia group (p=0.0011 and p<0.001, respectively), but relapse-free survival was similar (p>0.05).

Conclusions: Hypocomplementemia at AAV diagnosis may be responsible for worse survival and renal prognosis. This particular phenotype may confer resistance to common immunosuppressive approaches as in thrombotic microangiopathy caused by abnormalities in the regulation of the C system. These results also argue for larger studies and for investigating C pathway targeting.

AB0589 THE ROLE OF ANCA SPECIFICITY IN THE CLINICAL MANIFESTATIONS AT DISEASE ONSET: COMPARISON BETWEEN PATIENTS WITH GRANULOMATOUS WITH POLYANGIITIS AND MICROSCOPIC POLYANGIITIS

S. Monti 1, M. Felicetti 1,2,3, S. Balduzzi 1, R. Padovan 2, A. Bert 2, G. Paoluzzi 2, G. Brunori 2, F. Schiavon 2, R. Caporali 1.

1. Rheumatology, University of Padua, Padova, 2. Rheumatology, Santa Chiara Hospital, Trento, Italy

Background: ANCA specificity, rather than clinical diagnosis, has been suggested to influence the phenotype and clinical course of ANCA associated vasculitides (AAV) (1,2).

Objectives: To investigate differences in clinical presentation at disease onset between MPO-ANCA-positive granulomatosis with polyangiitis patients (MPO- GPA), PR3-ANCA-positive (PR3-GPA), and MPO-ANCA-positive microscopic polyangitis (MPO-MPA).

Methods: Clinical records of AAV patients from three tertiary rheumatologic centers in Northern Italy were retrospectively analyzed.

Results: Of the 133 AAV patients included, 84 were PR3-GPA, 24 MPO-GPA, and 25 MPO-MPA. Patients with MPO-MPA were significantly older at diagnosis compared to both PR3-GPA and MPO-GPA (average age 63±10, 49±15, 55±29, respectively) (Table 1). Patients with MPO-GPA experienced a significant diagnostic delay compared to PR3-GPA (17±30 vs 7±14, p<0.02). ENT involvement was equally frequent in both MPO-ANCA-positive AAV variants, whereas more represented than the MPO-MPA group (68%, 71% and 17% respectively; p<0.001). Figure 1. Renal involvement was significantly more frequent in MPO-MPA patients (100%) compared to GPA (p<0.001), without differences between MPO-GPA (46%) and PR3-GPA (46%), both with significantly lower renal involvement compared to GPA (53% vs 16% respectively; p=0.02). Cauterous manifestations, mainly purpura, were significantly more reported in PR3-GPA compared to MPO-GPA (29% vs 4%; p=0.03).

Conclusions: Clinical phenotype of GPA at disease onset did not seem to be influenced by ANCA specificity. Despite ANCA positivity (PR3 or MPO), GPA patients were significantly different from MPA.

AB0580 PERFORMANCE OF 2017 ACR/EULAR PROVISIONAL CLASSIFICATION CRITERIA FOR GRANULOMATOSIS WITH POLYANGIITIS IN CHILEAN POPULATION

S.F. Elgueta, L. Ricci Larrea, D. Vargas, P. Wurmman, I. Goedce. Hospital Clínico Universidad de Chile, Santiago, Chile

Background: Anca Associated Vasculitis (AAV), are a group of necrotizing primary vasculitis, with multisystemic manifestation, of unknown etiology. The variants are: Microscopic Polyangiitis (MPA), Granulomatosis with polyangiitis (GPA), Granulomatosis with Polychistitis and Eosinophilic Pneumonia (GPE) and AAV limited to one organ. Until now, there are no diagnostic criteria for AAV. Therefore definitions, as Chapel Hill consensus Conference Nomenclature, classification criteria and the physician judgement are used for diagnosis. Currently the DCVAS (Diagnosis and Classification Criteria in Vasculitis) project is developing diagnostic criteria for AAV, using data-driven methods. The preliminary DCVAS classification criteria for granulomatosis whith polyangiitis has been recently realased.

Objectives: To evaluate and compare the accuracy of ACR/EULAR 2017 provisional Classification Criteria for GPA whith the ACR 1990 Classification Criteria In Chilean patients with AAV.

Methods: All adult patients (>18 yo) with diagnoses of AAV according to their rheumatologist judgment, from 2000–2016 at the University of Chile, Clinical Hospital (UCHC), were included. Clinical variables of interest were extracted from medical chart and AAV database, which is kept for these patients at the Rheumatology Section of UCHC. Based on that data, the Classification criteria ACR 1990 and 2017/preliminary ACR/EULAR (DCVAS) classification criteria for GPA were applied to each individual. Sensibility, specifity, Likelihood ratio (LR +/-), predictive values (PPV/NPV) and accuracy were calculated for both sets of Criteria as compared to Clinical diagnosis.

Results: 93 patient were included in the study. 59 patients with GPA, 33 with...
Efficacy and Safety Profile of Intravenous Cyclophosphamide Treatment in Elderly Patients with Systemic Vasculitis

S. Shimoyama, T. Kurita, S. Fukaya, M. Kanda

Background: Intravenous cyclophosphamide is mainstay of remission induction and dose reduction of glucocorticoid in patients with systemic vasculitis. However, little evidence has yet shown the safety profile of intravenous cyclophosphamide, especially in elderly patients.

Objectives: To evaluate efficacy and safety of patients diagnosed as systemic vasculitis and treated with intravenous cyclophosphamide.

Methods: This retrospective study comprised the patients with active systemic vasculitis who were admitted to Kitami Red Cross Hospital and Obihiro Kosei General Hospital from April 2009 to March 2016. These patients were treated with intravenous cyclophosphamide plus conventional therapy (IVCY group) or only with conventional therapy (glucocorticoid/azathioprine/tacrolimus and methotrexate) (conventional therapy group). The patients treated with oral cyclophosphamide or rituximab were excluded. Primary endpoint was defined as death or serious infections. Prognostic factors in IVCY group were analyzed by multivariate Cox regression methods.

Results: This study comprised 90 patients with active systemic vasculitis (61 microscopic polyangiitis, 9 eosinophilic granulomatosis with polyangiitis, 10 granulomatosis with polyangiitis, and 10 polyarteritis nodosa). Fifty-one patients were over 70-year-old (26 patients in IVCY group). The mean observation period was 31.1±13 months. IVCY group had a trend for higher event-free survival rate as compared with conventional therapy group (p=0.19).

Conclusions: Intravenous cyclophosphamide treatment had acceptable safety profile even in elderly patients.

AB0592 PULMONARY ARTERY ANEURYSM IN BEHÇET’S DISEASE: RETROSPECTIVE MONOCENTRIC TUNISIAN STUDY

S. Hammami, A. Sondes, R. Kili, M. Kechida, M. Ben Nasr, I. Kochtali

Background: Behçet’s disease (BD) is a chronic inflammatory disorder. Arterial inflammatory involvement includes predominantly aortic and pulmonary aneurysms, lesions affects about 10% of patients with BD. They account for the severity of the disease and a leading cause of death.

Objectives: To investigate the frequency of Behçet’s disease with pulmonary artery aneurysm (PAA). We aimed to review PAA and other systemic involvements associated with PAA in BD and to provide a review of diagnostic techniques, treatment and prognosis.

Methods: 243 BD patients were recruited for this study (152 men, 91 women, mean age 31.7±7 years). Diagnosis of BD was made according to the international study group for Behçet’s disease [International Study Group for Behçet’s Disease, Lancet 1990; 335: 1078–80]. All patients underwent full clinical examination, routine laboratory investigations. Chest X-rays and pulmonary CT angiography were performed on all patients with pulmonary involvement.

Results: Eight of the patients have pulmonary aneurysm, all of them are male, mean age 32.6±13. The mean disease duration until PAA appear was 2.8±3.5 years. The main pulmonary symptoms were as follows: dyspnea 87%, cough 50%, hemoptosis: 75%, fever 37%. Other systemic involvements associated PAA were as follows: bacular (100%) and genital (75%) ophthalmic 25%, neurological 50%, cardiac 25%. 3 patients presented with Hughes Stovin syndrome. The treatment includes corticosteroids, colchicine and immunosuppressant agents (Cyclophosphamid or azathiopeine), only two patients receive coil embolization. At follow up for a median of 4 years (1 to 25 years), three patients died because they stopped their medical treatment.

Conclusions: The prognosis of PAA is poorer than other lesions involved in BD, treatment (immunosuppressant agents, colchicine) seems to improve the prognosis. It is important to maintain the immunosuppressive therapy and a regular follow-up to prevent these complications.

ANCA-ASSOCIATED VASCULITIS WITH BOTH MPO-ANCA AND PR3-ANCA: Shares of Characteristics of ANCA-ASSOCIATED VASCULITIS WITH SINGLE ANCA

S.M. Kim, J. Kim, S.W. Kang, S.-C. Shim, S.-J. Yoo, *Internal Medicine, Chungbuk National University Hospital, Cheongju; † Internal Medicine, School of Medicine Chungnam National University; ‡ Internal Medicine, Chungnam National University Hospital, Daejeon, Korea, Republic Of

Background: The anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides are heterogeneous group of necrotizing inflammation of small vessel and the presence of the ANCA. ANCA refers to the target antigens, leucocyte proteinase 3 (PR3) and myeloperoxidase (MPO). Recently, the ANCA specificity could be better for classification of ANCA-associated vasculitides than the clinical diagnosis. A few patients have both MPO- and PR3-ANCA. However, the clinical characteristics of these patients were not well described by ANCA type.

Objectives: To analyze organ involvement of patients with ANCA-associated vasculitides according to ANCA type focusing both MPO- and PR3-ANCA (both-ANCA) positive vasculitis

Methods: The medical records of the patients with positive ANCA and clinical diagnosis of the patients with positive ANCA and vasculitis diagnosis confirmed by biopsy were reviewed at two regional tertiary hospitals. The age at diagnosis, sex, and the organ involvement of kidney, lung, upper airway (nose/sinus/ear), skin, peripheral nervous system, central nervous system, and gastrointestinal tract were collected. The clinical variables were analyzed by ANCA type.

Results: Total 82 patients with positive ANCA and clinical diagnosis or the patients with positive ANCA and vasculitis diagnosis confirmed by biopsy were reviewed at two regional tertiary hospitals. The age at diagnosis, sex, and the organ involvement of kidney, lung, upper airway (nose/sinus/ear), skin, peripheral nervous system, central nervous system, and gastrointestinal tract were collected. The clinical variables were analyzed by ANCA type.

Conclusions: ANCA-associated vasculitides (AV) are a group of multi-system autoimmune diseases characterized by inflammation and necrosis in small and medium vessels. AV could respond to different therapeutic protocols depending on diverse levels of clinical severity and early treatment could improve the outcome of the disease. In spite of recognized efficacy of regimens consisting of cyclophosphamide and high-dose corticosteroids to control the AV efforts to minimize drugs-related toxicity led to consider targeted therapies. We identified the latest quality evidence in treatments novelly proposed to AV and the severity of renal disease presentation, we suggest new rational approaches targeting B-cells therapy and preventing disease relapse.

Methods: We identified the latest quality evidence in treatments novelly proposed to AV and the severity of renal disease presentation, we suggest new rational approaches targeting B-cells therapy and preventing disease relapse.

Results: Rituximab (RTX), a monoclonal anti-CD20 antibody, has emerged as the biologic agent more using in AV patients in current publications and unlike latest Guides and Recommendations published, RTX would be recommended in induction and maintenance AV with renal involvement treatment (Table 1).

References:
Of the 175 BD patients, the positive rate of tuberculosis infection in BD patients between January 2010 and March 2015. Statistical analysis was carried out using IBM SPSS version 20.

Results: Of the 175 BD patients, the positive rate of tuberculosis infection in BD patients was 34.3%. The sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) of the T-SPOT.TB test for the diagnosis of ATB were 87.5%, 73%, 36.8%, 98.3%, respectively. Positive likelihood ratio (PLR) of ATB was 11.93, 95% CI 2.108–67.508, p=0.005. The kappa coefficient was poor (kappa = 0.37). Multiple logistic regression analysis revealed that BD patients with positive T-SPOT.TB had the highest likelihood of LTBI infection. The OR of BD patients having LTBI was 11.93, 95% CI 2.108–67.508, p=0.005. The rates of LTBI infection had no significant difference between BD patients and healthy controls. Agreement between T-SPOT.TB and TST in BD patients measured by the kappa coefficient was poor (kappa = 0.37). Multiple logistic regression analysis revealed that BD patients with positive T-SPOT.TB had the highest likelihood of ATB. Positive likelihood ratio (PLR) of ATB was 11.93, 95% CI 2.108–67.508, p=0.005. No significant difference was found in cumulative CR rate between HD and LD RTX (p=0.15). There was an negative correlation between circulating alpha defensin and Rodnan score (r=0.30) and CRP (r=0.34).

Conclusions: The combination of T-SPOT.TB and other diagnostic tests should be used to determine the LTBI and ATB in BD patients. The use of RTX in patients with BD may increase individual susceptibility of BD patients to LTBI and ATB. Immunocompromised BD patients should be closely monitored for LTBI and ATB infection.

LOW-DOSE RITUXIMAB AS INDUCTION THERAPY FOR JAPANESE PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

Y. Takakawa 1, H. Hanakoa 1, T. Kiyokawa 1, K. Ishimori 1, H. Iida 1, H. Nagafuchi 2, T. Okazaki 1, S. Ozaki 1. Division of Rheumatology and Allergy, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Four times of once-weekly doses of 375 mg/m² rituximab (RTX) are frequently used as remission induction therapy for ANCA-associated vasculitides (AAV). Since this regimen has been basically generated from experience of B-cell non-Hodgkins' lymphoma in the Europe and North America, appropriate dose and interval for patients with AAV in other population have been poorly investigated. Here we comprehensively analyzed the efficacy and tolerability of low or low dose regimen of RTX in Japanese patients with AAV.

Methods: We retrospectively examined AAV patients who met the 2012 Chapel Hill classification from 2006 to 2016. We divided them into 2 groups, those treated with high-dose (HD) and low-dose (LD) RTX. HD RTX was the original regimen and LD RTX consisted of twice of one-weekly dose of 375 mg/m². We evaluated cumulative complete remission (CR) rate and relapse-free rate for 1.5 years. CR was defined as BVAS=0 and relapse was defined as BVAS>1.

Results: We evaluated 17 patients with HD and 11 patients with LD RTX. Higher percentage of elderly patients was observed in LD group (p<0.01). No significant difference was found in BVAS (p=0.49) and VDI (p=0.15) before treatment. No significant difference was found in cumulative CR rate (p=0.90) (Fig. 1A), relapse-free rate (p=0.48) (Fig. 1B), B cells counts and serious adverse events. We found patients with nasal involvement and pulmonary module cavity formation had higher relapse rate in LD group than those with HD group (p=0.05, and p=0.09 respectively).

Scleroderma, myositis and related syndromes

SERUM DEFENSIN LEVEL IN SYSTEMIC SCLEROSIS PATIENTS

T. Emiroglu 1, H. Kucuk 2, B. Goker 2, S. Haznedaroğlu 1, H. Pasaoğlu 1, O. Varan 2, M. A. Öztürk 3, O. T. Pasaoğlu 2, A. Tufan 3. Department of Internal Medicine, 2Department of Internal Medicine, Division of Rheumatology, 3Department of Biochemistry, Gazi University Faculty of Medicine, Ankara, Turkey

Background: Scleroderma is an autoimmune disease characterized by fibrosis of skin and lung as well as involvement of kidney, gastrointestinal system and heart (1). Etiology and exact mechanism of disease is poorly understood. A small number of studies have examined the role of AMPs on autoimmune diseases. It has been demonstrated that the amount of alfa- and beta-2 defensin serum levels are increased in systemic lupus erythematosus patients (2, 3). Likewise, the association between AMPs and other diseases such as idiopathic pulmonary fibrosis, diffuse panbronchiolitis, pulmoner alveolar proteinosis and psoriasis has been reported (4).

Objectives: No study investigated the role of AMPs on scleroderma patients. Hence, we aimed to investigate AMP serum levels and their possible association in these patients.

Methods: There were 42 patients (40 female, mean age 42 years) and 38 healthy subjects (32 female, mean age 38 years) in the study. For SSc patients, the following data were recorded at enrollment: disease subset (limited/diffuse), autoantibodies (anti-nuclear, anti-centromere (ACA), and anti-scl DNA, erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP), modified Rodnan skin score, presence and history of digital ulcers, presence and history of interstitial lung disease, kidney and gastrointestinal system, intestinal blood detected by chest HRT and pulmonary function tests, estimated pulmonary arterial systolic pressure at echocardiography.

Results: There were 42 patients (40 female, mean age 42 years) and 38 healthy subjects (32 female, mean age 38 years) in the study. Twenty-nine of the patients had diffuse systemic sclerosis and thirteen of the patients had limited systemic sclerosis. Average disease duration is 5.5 years. Pulmonary involvement was detected in twenty patients. The levels of beta 1 and beta 2 defensin that are epithelial defensins were higher than control group but it has not reached statistical significance. (beta-1 defensin 235±178 vs 185±24 pg/ml, p=0.08 and beta2 defensin 253±453 vs 152±101 pg/ml, p=0.18). Alpha defensin levels in scleroderma patients were significantly higher than control group (563±415 vs 377±289 pg/ml, p=0.02). In sub-group analysis patients with interstitial lung disease had a higher level of alpha defensin than those without involvement (684±473 vs 430±299 pg/ml, p=0.04). There was a negative correlation between alfa defensin and Rodnan score (r=-0.30) and CRP (r=0.34).

Conclusions: Alpha defensin levels in scleroderma patients were significantly higher than control group. There may be an increase in the level of alpha defensin in a cause of vasulopathy in scleroderma patients

AB0599 COMBINATION OF CAPILLAROSCOPIC AND ULTRASONOGRAPHIC EVALUATIONS OF THE HAND TO DETECT SEVERE VASOPATHY IN SYSTEMIC SCLEROSIS: RESULTS OF A CROSS-SECTIONAL STUDY

A. Lescot 1, G. Coiffier 2, M. de Carlan 1, C. Droitcourt 3, C. Cazalets 1, I. Gkougkourelas 1, A. Pataka 2, I. Stanopoulos 2, I. Koulas 1, A. Perdigué 1, I. Jego 1, Internal Medicine 1, Rheumatology 1, Dermatology 1, CHU Rennes, France

Background: Although micro-vein alterations have been largely described, macrovascular involvement is also frequent in Systemic Sclerosis (SSc). Macrovascular damages specifically involve narrowing or occlusions of proper palmar digital arteries and ulnar artery. On the contrary, radial artery is rarely concerned. Ulnar artery occlusion (UAO) assessed by power doppler ultrasonography has proven to be predictive of the onset of new ischaemic DUs in longitudinal studies (1). PDUS could also be a reliable tool to evaluate finger pulp blood flow (FPBF). Only few studies have explored the association between macrovascular damages evaluated by PDUS and microvascular involvement assessed by nailfold capillaroscopy (NC) (2). The association between macrovascular disease and calcinosclerosis or Acro-osteosclerosis is still to be determined in SSc.

Objectives: to confront microvascular damages on NC with macrovascular manifestations evaluated by PDUS in SSc patients. Micro and macro-vascular damages were confronted with the main digital manifestations of the disease: digital ulcers (DU), Acro-osteosclerosis and Calcinosis.

Methods: NC, hand X-Rays and PDUS were systematically performed in 64 unselected SSc patients. PDUS evaluation with assessment of Ulnar Artery Occlusion (UAO) and finger pulp blood flow (FPFB) was performed blinded for the results of X-Rays and NC.

Results: UAO and pathologic FPFB were associated with severe capillary loss (<4 capillaries/mm) on NC (respectively OR=4.04 (1.23–13.29); p<0.05 and OR=3.38 (1.03–11.05); p<0.05). UAO was significantly associated with Cutis laxa late NC pattern (OR=3.80 (1.31–11.01); p<0.05). A DU history was associated with UAO (OR=10.71 (3.36–34.13); p<0.0001), pathologic FPFB (OR=7.67 (2.52–23.28); p<0.0001), late pattern (OR=6.33 (2.03–19.68) and severe capillary loss (OR=8.52 (2.15–33.78); p<0.001). Acro-osteosclerosis was also associated with UAO (OR=15.15 (3.95–63.54); p<0.001), pathologic FPFB (5.52 (1.71–17.90) p=0.003), late NC pattern (OR=6.86 (2.18–21.53); p<0.001) and severe capillary loss (OR=7.20 (2.16–24.02); p<0.001). Calcinosis on X-rays were associated with late NC pattern (5.41 (1.82–16.12); p=0.002), severe capillary loss (OR=12.69 (3.14–51.26); p<0.0001) and UAO (3.19 (1.14–8.92); 0.025) but not with pathologic FPFB. Combination of UAO and severe capillary loss in a same patient was especially associated with DU history (OR=18.60 (2.24–154.34); p<0.001) and Acro-osteosclerosis (OR=10.83 (2.56–45.88); p<0.001).

Conclusions: The combination of macro and microvascular evaluations by PDUS and NC can help to detect patients with a more severe vasopathology.

AB0600 CLINICAL RELEVANCE OF AUTOANTIBODY PROFILES IN SYSTEMIC SCLEROSIS

A. Burfu 1, A. Cardoneau 1, E. Rezus 1,2, Rheumatology, Grigore T. Popa University of Medicine and Pharmacy, Iasi, Romania

Background: Systemic sclerosis (SSc) is a connective tissue disease accompanied by immune abnormalities. A number of autoantibodies such as anti-centromere, anti-topoisomerase I, anti-RNA polymerase III and anti-U3 (fibrilin) antibodies were proven to be of great diagnostic and prognostic factors in patients with scleroderma. Certain studies have reported the presence of antinuclear, anti-SSA (Ro) and/or anti-SSB (La), anti-Pm/Sc, anti-endothelial cell and anti-nucleosome antibodies in patients with systemic sclerosis. However, the clinical relevance of these autoantibodies is yet to be fully elucidated.

Objectives: Our aim was to assess clinical features, capillaroscopic abnormalities and autoantibody titers in patients with systemic sclerosis as well as analyze relationships between these three parameters for the disease.

Methods: We conducted a prospective observational study on 36 adult patients who satisfied ACR/EULAR 2013 criteria for systemic sclerosis. We recorded disease duration, current symptoms and classified patients as limited cutaneous (lc) SSc and diffuse cutaneous (dc) SSc. Skin involvement was assessed using the modified Roden-Nolan skin score. We performed nailfold videocapillaroscopy using a FEDMED Digital 100N at a magnification of 200X. Thoracic Xrays were done to establish the presence of pulmonary fibrosis. Ultrasounds were performed by a single examiner to evaluate pulmonary artery pressure. Blood samples were drawn to measure anti-topoisomerase 1, anti-centromere, anti-SSA (Ro), anti-SSB (La), anti-U1RNP and anti-nucleosome antibody titers (ELISA). Patient characteristics were included in a database and analyzed using IBM SPSS Statistics v20.

Results: Our study group was composed of 20 dc SSc (55.6%) and 16 lc SSc (44.4%) patients. Severity of capillary changes correlated with mRSS values (p<0.01), anti-topoisomerase I (p<0.006), anti-SSA (p<0.01) and anti-nucleosome antibodies (p<0.02). We found positive associations between the presence of dyspahgia, anti-centromere (p<0.009) and anti-SSA (p<0.01) titers in patients with lc SSc. Anti-centromere antibody positivity also correlated with pulmonary hypertension (p<0.011) and pulmonary fibrosis (p<0.04) in these patients. Anti-SSA antibodies correlated with pulmonary hypertension (p<0.01) and capillaroscopic changes (p=0.024) in dc SSc.

Conclusions: Our findings support the relationship between autoantibody titers, systemic involvement and microvascular changes in scleroderma patients. Non-specific autoantibodies such as anti-nucleosome and anti-SSA antibodies were associated with microvascular changes in our study group. Further studies in this field may provide new information on SSc pathogenesis and possibly novel targets for treatment in scleroderma patients.

AB0601 ANATOMIC AND FUNCTIONAL ASSESSMENT OF PERIPHERAL PERFUSION IN PATIENTS WITH SYSTEMIC SCLEROSIS. IS THERE ANY CORRELATION BETWEEN CAPILLAROSCOPIC FINDINGS AND ERGOSPIROMETRY?

A. Sarantopoulos 1, A. Gkougkourela 1, A. Pataka 2, I. Stanopoulos 2, I. Koulas 1, P. Boura 1.
1Clinical Immunology Unit, 2nd Dpt of Internal Medicine, 2Pulmonary Department, “G. Papanikolau” General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece

Background: Microvasculopathy of systemic circulation in patients with Systemic Sclerosis (SSS) is widely assessed by digital capillaroscopy (DC), a method that evaluates the architecture of capillary network and reveals changes of vascular anatomy. On the other hand, ergospirometry (ERG) reveals functional impairment of microcirculation by assessing indirect measures of peripheral tissue ischemia (1). Today, there has been an increase in the use of capillaroscopy in correlation with spirometric parameters (2). Nevertheless, no reports have been published correlating the same DC findings with ERG parameters (functional microvascular perfusion).

Objectives: To propose the use of DC as a screening tool for impaired functional microvasculopathy by investigating correlations between patterns of capillaroscopic findings with ergospirometric values of peripheral tissue blood perfusion.

Methods: 11 patients (11 women mean age 43±12 y) with SS were evaluated contemporarily with High Resolution Computed Tomography of the chest, ERG, and DC. Parameters were correlated using SPSS (3). Statistic significance was considered p<0.05.

Results: Patient data are shown in the table. Patients with late pattern in capillaroscopy had less endurance in exercise test (P=0.05) but no correlation was found between capillaroscopic pattern and ERG parameters (VE/VC02) (P=0.05).

Conclusions: The correlation of late pattern capillaroscopy findings with reduced ergospirometric endurance in 11 patients indicates that in a larger cohort, specific parameter associations between DC and ERG are probable to emerge.
We conducted a cross-sectional study that included 78 SSc patients. The aim of this study was to assess the presence of subclinical atheroma- tization by carotid Doppler ultrasound in SSc patients under 55 years. The background: In Systemic sclerosis (SSc), as in other autoimmune diseases such as rheumatoid arthritis or systemic lupus erythematosus, cardiovascular events are one of the most frequent causes of mortality not attributed to the disease itself. The objectives: The aim of this study was to assess the presence of subclinical atherosclerosis by carotid Doppler ultrasound in SSc patients under 55 years. The methods: We conducted a cross-sectional study that included 78 SSc patients without cardiovascular events from H. Vall d’Hebron cohort (Barcelona). Carotid Doppler ultrasound was performed to measure the Carotid Intima Media Thickness (CIMT) of common carotid artery (CCA) and detection of cholesterol plaques in CCA, bulb and internal and external carotid arteries, according to Mannheim consensus criteria. The results were compared to a healthy cohort from Barcelona, adjusted to age and sex. We used SCORE for populations with low risk and REGICOR as cardiovascular risk assessment charts. The results: Risk factors and SSc related features are described in table 1. Twenty-three patients (29.5%) had carotid plaques (CP) being the presence of CP statistically significant compared to the healthy cohort (29.5% vs 15.6%; p < 0.05). The intermediate risk patients had CP. Carotid Intima Media Thickness mean (CIMTm) and maximum (CIMTmax), were statistically significant increased compared to the healthy cohort (CIMTm 0.57 vs 0.53; p < 0.05 and CIMTmax 0.74 vs 0.61; p < 0.05). We performed multivariate regression analysis. Age, CIMTmax, low High Density Lipid (HDL), the presence of pulmonary hypertension, and diffuse cutaneous SSc patients were independent factors for the presence of CP.

### AB0604 RITUXIMAB EXPERIENCE IN PATIENTS WITH LONGSTANDING SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: A SERIES OF 14 PATIENTS

A. Sari 1, D. Guven 2, B. Armagan 1, L. Kilic 1, A. Erden 1, A. Akdogan 1

1Rheumatology; 2Internal Medicine, Hacettepe University School of Medicine, Ankara, Turkey

**Background:** Interstitial lung disease (ILD) is the leading cause of mortality in systemic sclerosis (SSc) patients. Treatment options are rather limited in SSc patients and in whom unsatisfactory response in lung functions was noted under conventional treatments.

**Objective:** The objective of this study was to report the experience of RTX treatment in a series of patients with longstanding SSc-ILD in whom unsatisfactory response in lung functions was noted under conventional treatments.

**Results:** A retrospective review of charts of 197 SSc patients evaluated between April 2015 and November 2016. 14 patients who received rituximab (RTX) for SSc-ILD participated in this analysis. The severity of ILD based on FVC was defined as follows; mild (FVC between 71% and 80% of predicted), moderate (FVC between 51% and 70% of predicted) and severe (FVC <50%). The extent of skin disease was clinically measured using Modified Rodnan Skin Score (mRSS) tool. End of follow-up was considered as six months after the last RTX dose.

**Results:** Median (IQR, interquartile range) age was 53.2 (46.8–55.5) and median disease duration was 9.1 (5.1–13.6) years. Median FVC was 52.5 (41.5–64.0)

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.4612
prior to RTX. At the end of follow-up, no significant change was revealed in FVC when compared with pre-RTX values [58.0 (44.7–58.7), p=0.069]. FVC was improved in four patients and stabilized remaining ten patients. All of the patients with improvement of PFTs had moderate or severe restrictive lung disease. High resolution thorax computed tomography (HRCT) findings remained stable in 7 and improved in the remaining 3 patients. In total, mRSS remained stable at the end of follow-up when compared with baseline [8.0 (5.2–12.2) vs. 6.0 (4.0–12.2), p=0.026].

FVC, forced vital capacity; ANA, antinuclear antibody; Scl-70, antiparaneoplasmin-1 antibody; CYC, cyclophosphamide; MMF, mycophenolate mofetil; RTX, rituximab.

Conclusions: In this case series of SSc patients treated with RTX, improvement or stabilization of pulmonary functions was observed in most of SSc patients. RTX may be useful in SSc-ILD patients with longer disease duration and resistant to conventional immunosuppressive therapies.

**AB0605 VITAMIN D SERUM CONCENTRATION IN EUROPEAN SYSTEMIC SCLEROSIS PATIENTS: CORRELATIONS WITH SEASONALITY, ORGAN INVOLVEMENT AND STANDARD ORAL SUPPLEMENTATION**

A.C. Trombetta1, V. Smith1, E. Gotelli1, M. Ghio1, S. Paolino1, C. Pizzorni1, A. Sulli1, M. Cutolo1.1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy; 2Department of Internal Medicine, Faculty of Medicine and Health Sciences; Department of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium.

Background: Vitamin D deficiency is reported to interfere with immune responses and to correlate with course and outcome in several autoimmune diseases. In systemic sclerosis (SSc), low 25-hydroxyvitamin D (25(OH)D) serum concentration has been recognized.

Objectives: To investigate relations between 25(OH)D serum concentration and seasonality, clinical parameters as well as standard oral supplementation, in SSc patients.

Methods: 154 SSc patients (mean age 59±15 years, 24.7% diffuse form and 75.3% limited form) were evaluated, at any time of the year, in a retrospective survey. Serum 25(OH)D quantification was performed using the LIAISON 25-OH vitamin D assay (DiaSorin, Italy). Pulmonary function test, chest x-ray, lung CT scan, electrocardiography, renal artery resistive index by eco color Doppler, Dual x-ray absorbtiometry, were performed at the time of sample collection. Disease severity scale (DSS) was performed according to Medsger. Drug assumption (glucocorticoids, calcium channel blockers, cyclic intravenous loop diuretics, endothelin receptor antagonists) and supplementation with vitamin D analogues, were recorded. Non-parametric tests were used for statistical analysis.

Results: Average 25(OH)D serum concentration was found to be 18.7±9 ng/ml (<20 classified as deficiency). A significant difference was observed among seasonal 25(OH)D serum concentration (winter: 14.6±7.8 ng/ml, spring: 17.2±7.9 ng/ml, summer 21.4±10 ng/ml, autumn 20.2±10; p=0.032) (Figure 1). A significant correlation was found between 25(OH)D serum concentration and presence/absence of bi-astral fibrotic changes at lung computed tomography (CT) scan (Pearson correlation coefficient 0.16, p=0.04). Peripheral vascular (p=0.03), kidney (p=0.02), gastrointestinal (p=0.05) Medsger’s DSS parameters also were found to correlate with 25(OH)D serum concentration (Figure 1). Interestingly, no influence of treatment with vitamin D analogues (1,000 UI daily) was found regarding 25(OH)D serum concentration in treated (18.8±10 ng/ml) and not treated (18.7±9 ng/ml) SSc patients (p=0.81).

Conclusions: In SSc is confirmed a serum 25(OH)D deficiency that we report to be associated with lung involvement, peripheral vascular, kidney and gastrointestinal Medsger’s DSS parameters, as well as with seasonality. Supplementation with vitamin D analogues did not influence present results.
Mortality was 22.5% (20/89 patients), CI95 (14.3–32.5). Mean time from diagnosis to the event was 18 months. The primary cause of death was sepsis 14/20 (70%).

Conclusions: Mortality of patients with inflammatory myopathies was 22%, and the primary cause was infectious. In the analysis of multiple variables, male sex, presence of neoplasms and serious infectious complications were significantly factors associated with mortality.

AB0608 PREDICTIVE FACTORS FOR LONG-TERM SURVIVAL AND DISEASE PROGRESSION OF SYSTEMIC SCLEROSIS – A LONGITUDINAL ANALYSIS

A.M. Gheorghiu 1,2, A. Radu 1,2, R. Oneata 1,2, A. Soare 1,2, R. Dobrota 1,2, S. Magda 1,2, R. Constantinescu 1, R. Jurcut 2,5, R. Sfrenˇt-Corn˘a¸teanu2,6, M. Bojincă 1,2, V. Stoica 2, C. Mihă1,2, R. Internal Medicine and Rheumatology, Carol Daviu University of Medicine and Pharmacy; 2Emergency University Hospital; 3Marius Nasta Institute of Pneumology; 4C.C. Iliescu Institute for Cardiovascular Diseases; 5Physiopathology and Immunology Department, Bucharest, Romania

Background: Systemic sclerosis (ScS) has unpredictable course and high mortality. Generalised Estimating Equations (GEE) is a technique useful for longitudinal data analysis, using data from all time points and adjusting for within-patient correlation, and comparison between time points within the same patient. GEE does not require a normal distribution of dependent variables, making it attractive for analyzing ScS data.

Objectives: To identify predictive factors for death and unfavorable outcomes.

Methods: Data of ScS patients was collected from our EUSTAR centre in 2004–2016 were analyzed. GEE investigated the relationship over time between outcomes (death, digital ulcers (DUs), forced vital capacity (FVC), modified Rodnan skin score (mRSS)) and potential predictors (age, gender, disease duration, cutaneous subset, mRSS at baseline, DUs history, DLCO, left ventricle ejection fraction (LVEF), proteinuria), separately for each predictor and in combined models.

Results: 89 patients (12.4%males, mean±SD age 49.2±12.5years, disease duration 4.1±7.5years) were included, with a follow-up of up to 13 years. There were 14deaths, most due to lung involvement (7/14). In multivariable GEE analysis (Table 1), predictors of death were a shorter disease duration, DUs history, and a lower LVEF. Predictors for FVC decrease over time were diffuse cutaneous subset (dcSSc), younger age and lower DLCO. Younger age, shorter disease duration and higher baseline mRSS were the most important predictors for higher mRSS at follow-up. The only predictor for the development of new DUs was a history of DUs.

Table 1. Prediction factors for death and for evolution over time of parameters reflecting disease severity in ScS

Additional predictors for DUs:
- p<0.05, **p<0.01, ***p<0.001.

Conclusions: Patients with shorter disease duration, dcSSc, higher mRSS, lower DLCO and LVEF and a history of DUs had a worse unfavorable course. GEE is a robust technique for longitudinal data analysis, excellent for identifying prediction factors in ScS.

AB0609 CORRELATION OF PSYCHOLOGICAL PROFILE (MMPI-II A BDI TESTS) OF SCLERODERMA PATIENTS WITH ORGAN MANIFESTATION AND IMMUNOLOGICAL PROFILE

A. Smrdová 1, L. Hubáˇcková2, S. Kreisellová2, J. Zapletalová2, P. Horák1, 3Rd Department of Internal Medicine – Nephrology, Rheumatology and Endocrinology; 2Department of Psychology; 3Department of Medical Biophysics; 4Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, Czech Republic

Background: There is high prevalence of mood disorders in patients with systemic scleroderma. Psychosocial distress can influence some of clinical manifestations and can worsen the course of the disease and socioeconomical status of patients.

Objectives: The aim of study is detection of correlations of depression and psychological profile measures by MMPI-II (The Minnesota Multiphasic Personality Inventory) and BDI-II (The Beck Depression Inventory-II) and organ manifestation and immunological profile of patients with systemic sclerosis.
Methods: From March 2015 to July 2017 we examined 42 patients with scleroderma, from which 37 filled the valorisation criteria of MPM-II test. The data of MPM-II scales and BDI-II was correlated with antropometric data, form of disease, disease duration, duration of RP, organ major manifestation, comorbidities, use of medication and immunological profile.

Results: Of 37 patients, 30 female patients (81%) and 7 male patients (19%) were included. Mean age was 58.8±10.6y, duration of disease 8.9±9.1y, duration of RP 13.9±13.4y. 10 patient have diffuse, 27 patient limited form. Subjective perceived depression detected by BDI II test was present in 11 patients (35%), mild 6, moderate 3 and 2 severe. Total BDI-II score correlated with anticontermon Abs (p=0.05), total cholesterol (p=0.008), LDL (p=0.05) and gastrointestinal manifestation (p=0.002).

Conclusions: In addition to well-known thermoregulatory abnormalities, clear psychometric and clinical manifestations of more abnormalities on NCM may occur independently of the presence or development of a CTD and may be unknown. The presence of more abnormalities on NCM, assessed by widefield videocapillaroscopy, was retrospectively correlated with primary RP. BMI was negatively associated with NCM pattern, number of dilated capillaries with primary RP. Patients were included when they had negative serology and did not develop any definite connective tissue disease. Disease duration and duration of RP correlated with psychometric retardation.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.6327

AB0610 NAILFOLD CAPILLARY MICROSCOPY AND LOW BODY MASS INDEX IN RAYNAUD’S PHENOMENON PATIENTS

A.M. Van Roon 1, A. Eman Abdulle 1, A.M. van Roon 1, A.J. Stei 2, A.J. Smit 3, H. Bootsma 4, D.J. Mulder 5.

Background: Underweight patients develop Raynaud's phenomenon (RP) more frequently. [1] In a small study, skin temperature and perfusion in RP patients was positively associated with body mass index (BMI). [2] In clinical practice, we frequently observe an abnormal nailfold capillary microscopy (NCM) in underweight subjects with presumably primary RP, from which the implications are unknown.

Objectives: The aim is to study whether being underweight is associated with the presence of more abnormalities on NCM.

Methods: NCM, assessed by widefield videocapillaroscopy, was retrospectively assessed in consecutive patients with suspected RP. Patients were included when they had negative serology and did not develop any definite connective tissue disease or organ involvement after a maximum of 5 years follow-up. NCM pattern was classified as normal, non-specific, early, active or late, based on the Cutolo patterns. Weight and height were measured for clinical practice and patients were divided into BMI categories: underweight (BMI<18.5 kg/m²), normal weight (BMI 18.5–25 kg/m²), dilated and giant capillaries were counted as well as the number of capillaries.

Results: A total of 352 patients were included (median age 40.6 years (24.9–52.9)), male:female 11:1 (41%), of which 47 were underweight (BMI<18.5 kg/m²), 65 normal weight (BMI 18.5–25 kg/m²), and overweight (BMI >25 kg/m²). Dilated and giant capillaries were counted as well as the number of capillaries.

Conclusions: In addition to well-known thermoregulatory abnormalities, clear NCM pattern aberrations are more frequently observed in underweight patients with primary RP. BMI was negatively associated with the number of dilated capillaries (p=0.021) and positive with capillary density. These data potentially suggest that damage to the microvasculature in underweight patients with primary RP may occur independently of the presence or development of a CTD and may be explained by other mechanisms.

AB0611 MYCOPHENOLATE MOFETIL FOR THE TREATMENT OF INFLAMMATORY MYOPATHY RELATED INTERSTITIAL LUNG DISEASE: A SYSTEMATIC REVIEW

B. Lopez 1, D.A. Isenberg 2, P.A. Gordon 1. Rheumatology, King’s College Hospital; 2Rheumatology, UCL, London, United Kingdom

Background: Inflammatory myopathies (IMI) are a heterogeneous group of rare autoimmune rheumatic diseases in which extramuscular manifestations, especially interstitial lung disease (ILD), are common and may occur in the absence of muscle symptoms. ILD has been identified as a marker of poorer prognosis, with sparse, mainly observational evidence, supporting the use of immunosuppressant therapies. Despite the lack of clinical trial evidence, corticosteroids are considered first-line therapy. Ciclosporin is frequently used for severe disease and Azathioprine as maintenance therapy. Mycophenolate Mofetil (MMF) has emerged as a promising treatment, encouraged by data published from a randomised controlled trial comparing Ciclosporin with MMF in patients with systemic sclerosis and ILD, which showed similar efficacy and better tolerability in the MMF group compared with Ciclosporin.

Objectives: To examine the evidence supporting the use of MMF in patients with IMI associated ILD.

Methods: An electronic literature search was performed using the Ovid platform. Population: Adults diagnosed with IMI according to validated criteria (2, 3) or antistreptase syndrome (defined by the presence of anti-streptase antibodies), with ILD demonstrated by HRCT or lung biopsy and treated with MMF, with extractable outcomes regarding ILD. Outcomes were recorded as positive (improvement/stabilisation) and negative (deterioration) as defined by the American Thoracic Society consensus guidelines (4).

Results: 506 initial citations were identified, with 23 studies included in the review comprising a total of 82 patients. Median follow-up was 12 months, median age 55 years. There was sufficient data to apply American Thoracic Society criteria in 37 patients: improvement/stabilisation n=29, deterioration n=8. Although the criteria could not be applied in 45 patients, improvement/stabilisation was reported in 44 with deterioration in one patient. A non-significant trend to better outcomes was observed when MMF was prescribed as first line therapy, in Jo-1 positive patients and non-Usual Interstitial Pneumonia pattern. Mean Prednisolone dose reduced from 40 mg/day to 10.1 mg/day. No significant toxicity was reported.

Conclusions: Mycophenolate Mofetil is a promising drug with encouraging results, but randomised controlled clinical trials are needed to prove its efficacy.

AB0612 EFFICACY OF LOW DOSE AND SHORT-TERM IL-2 TREATMENT TO EXPAND ENDOGENOUS REGULATORY T CELLS IN PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE

B. Zhang1, L.L. Shang1, J.P. Cao2, H.Y. Gao2, C. Gao3, X.F. Li1. 1The Second Hospital of Shanxi Medical University, Taiyuan, China; 2Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China; 3Brigham and Women’s Hospital/Children’s Hospital Boston, Harvard Medical School, Boston, American Samoa

Background: The concept of Mixed Connective Tissue Disease (MCTD) was first proposed by Sharp and his colleagues in 1972.1 MCTD has overlapping features between at least two autoimmune diseases, such as SLE, SSC, PM/DM and RA. Regulatory T cells (Treg cells) play a critical role in the maintenance of immune tolerance and the regulation of immune responses. Treg cell dysfunction contributes to the initiation of pathogenesis and the maintenance of high disease activity in RA and SLE.2 Recently, some studies have indicated that the proportion of Treg cells was different from healthy controls in SSC patients.3 Therefore, MCTD may be associated with Treg cells.

Objectives: To explore the status of CD4+ T cells in peripheral blood of patients with MCTD; to explore the effect of low dose interleukin-2 (IL-2) treatment on the balance of Treg cells and Th17 cells in patients with MCTD; and to observe the short-term curative effect.

Methods: CD4+ T cells in the peripheral blood of 58 MCTD patients and 33 healthy controls were analyzed by flow cytometry. All of 58 cases were treated with standard therapy, including corticosteroids, NSAIDs, immunosuppressants, or combination therapy. Among them, 26 cases of MCTD without using immunosuppressant (CYC, MTX, LEF, MMF), were as untreated group, another 32 cases were as treated group. Then we compared the difference of CD4+ T cells between two groups. In 58 patients with MCTD, a total of 27 patients were treated with low-dose IL-2 (50WIU) on the basis of standard treatment for 5 days. The difference of CD4+ T cells before and after treatment with IL-2 was compared.

Results: The absolute count of CD4+CD25+FOXP3+ Treg cells in peripheral blood of patients with MCTD was significantly lower than those in healthy controls. There was no significant difference in the absolute count of CD4+CD25+FOXP3+ Treg cells in the peripheral blood of the treated group and the untreated group. The absolute count of CD4+CD25+FOXP3+ Treg cells significantly increased higher than those before treatment with IL-2.

Conclusions: The absolute count of CD4+CD25+FOXP3+ Treg cells in peripheral blood of patients with MCTD were significantly reduced, which may be the mechanism of immune imbalance in MCTD patients. The decrease of the absolute count of CD4+CD25+FOXP3+ Treg cells in peripheral blood of patients with MCTD was not associated with the use of immunosuppressive agents. Low dose and short-term IL-2 treatment may increase the absolute count of CD4+CD25+FOXP3+ Treg cells in the peripheral blood in patients with MCTD, so as to restore the immune balance in patients with MCTD.

AB0614 ANTISYNTHETASE SYNDROME: AUTOANTIBODIES, CLINICAL PATTERN AND MANAGEMENT OF 17 SPANISH PATIENTS

C. Busca, Á. Robles, I. Vives, J.A. Troncoso, L. Bailón, J.J. Ríos, A. Noblejas, F. Arnalich. Internal Medicine, la Paz Hospital. Madrid, Spain

Background: Antisynthetase syndrome (ASS) is a heterogeneous rare inflammatory condition characterized by myopathy, interstitial lung disease (ILD), arthritis, mechanic hands and Raynaud phenomenon (RP). The hallmark of ASS is the presence of antibodies against aminoacyl-transfer RNA synthetases (anti-ARS). Eight different anti-ARS have been described: anti-Jo1, anti-PL7, anti-PL12, anti-EJ, anti-OJ, anti-KS, anti-Zo, anti-TyrYRS. Despite recent publications, correlation between autoantibodies clinical pattern and management in ASS is not entirely well-known.

Objectives: The aim of this study was to define clinical features, autoantibodies and outcomes of a series of ASS patients.

Methods: We retrospectively analyzed the epidemiology, clinical data, lung function parameters, muscle enzymes, electromyogram (EMG) and autoantibodies pattern and its relationship with clinical manifestations, treatment management and outcomes of 17 patients recruited between 2005 and 2016 from the Autoimmune Diseases Division of a Spanish hospital.

Results: A total of 17 patients were reviewed (15 female). Mean age at diagnosis was 55 years. Median time delay to diagnosis was 5 months. Median follow-up was 65 months. Main clinical symptoms were dyspnea (76.5%), polyarthritis (58.8%), muscle weakness and myalgias (52.9%), RP (41.1%) and mechanic

Conclusions: The CT determined MPAD correlates strongly with the presence of pulmonary hypertension in patients with systemic sclerosis.

Disclosure of Interest: None declared

hands (23.5%). Lung involvement was defined by HRCT compatible with ILD (64.7%) and abnormal functional exploration (47.1%); restrictive pattern (87.5%) and diminished DLCO (61%). Muscle involvement was defined by elevated CK (52.9%) with a median maximum value of 517 IU/L, myopathic pattern on 8 of 13 performed EMG (61.1%) with myositis found in 4 of them (50%), and inflammatory myositis in 5 of 8 performed biopsies (62.5%). Anti-ARS findings were anti-Jo-1 (11), PL-12 (2), PL-7 (1), anti-EJ (2) and one patient with both PL-7 and PL12. Anti-Jo-1 predominant clinical pattern was ILD (72.7%), followed by myopathy (63.6%) and concomitant myopathy and ILD (45.5%). Anti-PL12 was associated with ILD, RP, and esophageal involvement and no myopathy. Anti-PL7 patient showed mild muscle involvement and cutaneous association alone. A combination of anti-PL12 and PL7 was described in one patient who developed ILD with severe myopathy. Anti-EJ patients had pulmonary involvement but no evidence of muscle disease. There was no evidence of cancer in any of our patients. Corticosteroids therapy was administered in 20 patients (88.9%), and corticosteroids dependence was highlighted, being necessary at times to associate one or more immunosuppressants.

Conclusions: Regardless of ASS being a rare disease, 17 patients were collected. Anti-Jo-1 was the most described antibody. It is important to note that one patient was found to be positive for both anti-PL7 and PL12 meanwhile they were described as exclusive, showing overlap of clinical pattern with severe muscle injury. This finding suggests that positive results for more than one ASS antibody infer more severity. In contrast with previous literature, pulmonary was more frequent than muscle involvement. The coexistence of both was observed in a small group (35.3%), mostly in anti-Jo1 patients (45.5%). Therefore, we suggest the need to reevaluate the association in patients with pulmonary or muscle involvement at onset although classic clinical pattern is missing.

Rheumatology Unit, University of Modena and Reggio Emilia, Modena, Italy

Background: Persistent infection by high-risk oncogenic Human Papillomavirus (HPV) is the main cause of the development of dysplastic or malignant lesions of the cervix. Furthermore, a few life habits, such as smoking, sexual habits and hormonal contraception, are known risk factors for cervical HPV infection. Persistent infection or high-grade intra-epithelial lesion rates was anecdotally described in patients affected by immune-mediated diseases, such as systemic lupus erythematosus, rheumatoid arthritis and systemic sclerosis (SSc), in comparison with the general population.

Objectives: To determine the prevalence of persistent HPV infection in an SSc patients series and its possible correlation with the disease clinical features.

Methods: The study retrospectively evaluated 52 consecutive female SSc patients (age 56.7±11.2SD years, disease duration 12.1±7.4SD years), classified into three groups using the Bethesda system.

Results: Seventeen (32.7%) patients were diagnosed with high-grade intra-epithelial lesion. Only tabagism was significantly correlated to HPV infection; namely, smoking habit was observed in 41.6% of SSc patients with and in 21.7% of those without HPV infection, respectively; (p=0.008); moreover immunosuppressive therapies, namely melofen, mycophenolate, cyclophosphamide or rituximab, tended to be associated with HPV infection (presence/absence 21.4 vs 21.7%; p=0.055).

More interestingly, among SSc patients over 50, HPV infection was found in 9/38 (23.7%) individuals, a frequency markedly higher than that expected in age-matched general population from the same geographical area (5%).

Conclusions: Persistent HPV infection was observed in over a quarter of SSc patients, notably in women over 50. The HPV positivity was not related to SSc clinical features, while a significant association with tabagism and immunosuppressive therapies was evidenced. Considering the possible clonico-prognostic implication on the overall disease outcome, routine gynaecological screening of SSc female patients is highly recommendable.

Rheumatology Unit, Universita di Modena e Reggio Emilia, Modena, Italy

Background: Intravenous Immunoglobulins (IVig) represent a relevant treatment option in various immune-mediated disorders such as idiopathic inflammatory muscle diseases (IMIDs), immune-mediated chronic neuropathies (IMCN), hema-toplogic autoimmune diseases, Still disease, Felty syndrome, systemic lupus erythematosus, vasculitis, some organ-specific autoimmune disease, and atopic diseases. The IVig treatment is expensive and need of hospital-based assistance for its administration; therefore, the use of home-thrapy and concomitant intravenous immunoglobulins (SCIg) may significantly reduce costs and improve the patient's quality of life.

Objectives: The primary objective was to perform an analysis of costs of SCIg administration in patients affected by IMID or IMCN compared to that of previous IVig treatments.

Methods: We prospectively evaluated 6 consecutive patients (3 males and 3 females, mean age 65.3 years, range 63 - 77), 2 affected by IMID in the context of polymyositis and 4 by IMCN, 3 in the context of vasculitis and 1 in the context of a Sjögren's disease. All patients were previously treated with IVig at the dosage of 2g/Kg monthly. (mean monthly dosage 143 g, range 98 – 160, average patient weight 71.5 kg, range 49 - 80), with good clinical and humoral response. After a mean therapy duration of 49.8 months (range 12 – 125) all patients were shifted to SCIg at the dosage of 10 g twice a week (80 g monthly).

Each patient was followed up by hemurgical and clinical evaluation, including Medical Research Council (MRC) score to quantify muscle strength and INCAT Sensory Score to evaluate sensory symptoms. The costs of the two therapeutic strategies were also compared, excluding indirect costs (absecces from work and productivity losses, transport and parking, health care sector cost for healthcare assistance).

Results: In 5/6 patients, we observed the maintenance of clinical and humoral status after a mean follow-up of 21 months (range 4 - 51), in particular we observed a stability in MRC score in patients presenting loss of strength and INCAT score in patients presenting sensory symptoms. Furthermore, the treatment with SCIg was well-accepted and preferred to IVig by all patients. In one patient SCIg were discontinued after 2 weeks, because of the appearance of a haemorrhagic lesions nearby the injection site (in the same patient IVig have been stopped because of a hypertensive crisis during the infusion). Direct cost associated to IVig amount to 25246 for 5 g of immunoglobulins (7.09€/g monthly, considering a protocol of 2 g/kg/monthly and a patient-weight of 70kg), while direct costs associated to SCIg (20g weekly) amount to 6,40€/month, with a saving of 656€/monthly and 7.872€/yearly.

In our case-series the annual saving was 9,686.40€/patient (from 86,846.40€ to 76,800€, for IVig and SCIg, respectively).

Conclusions: Our experience suggests that the shift to SCIg from IVig in patients affected by IMID and IMCN is feasible, cost-effective, safe and well-accepted by patients. Further studies are needed to evaluate the effectiveness of SCIg in first-line therapy of these diseases.

Disclosure of Interest: None declared.

C. Varju1, D. Kovacs1, B. Gárðr1, E. Kalmán2, L. Cziják1, B. Bódis3, V. Csonka1,1 Department of Rheumatology and Immunology; 2 Department of Pathology; 1st Department of Internal Medicine, University of Pécs, Pécs, Hungary

Background: Scleredema adultorum Buschke is a rare disorder characterized by multiple hardening of the skin around the neck, shoulders, occasionally the face and the trunk. The most frequent form of scleredema is associated with diabetes mellitus (DM). The histopathological features of scleredema are characterized by thickened collagen bundles within the reticular dermis that are separated by mucopolysaccharides (mainly mucin) containing fenestrations.

Objectives: To compare clinical data of patients with Buschke-scleredema DM to diabetic patients without skin involvement patients (Control-DM) with a focus on the late vascular and neurological complications.

Methods: Clinical data of 105 diabetic patients were investigated based on medical history, physical examinations. All subjects met the following inclusion criteria: each of their disease duration time of DM had to be more than three years. Twenty-eight patients with Scleredema-DM were collected (three of type 1 and 25 of type 2 diabetes, 19 female, nine male; their mean age (zSD) was 63.0±9.3 and mean DM-duration time was 17.9±9.6 years). Seventy-seven consecutive, age and DM-duration matched patients without skin involvement were investigated as controls (nine patients with type 1 and 68 with type 2, 50 female, 27 male, their mean age was 63.3±11.9 and mean DM-duration time was 17.4±10.7 years). For statistical analysis Pearson’s Chi-squared, Fisher and McNemar tests were used.

Results: In the medical history of the Scleredema-DM group stroke occurred more frequently (8 of 28 cases, 28.6%) compared to the Control-DM group (5/77, 6.5%, p<0.01). There were no significant differences in the occurrence of myocardial infarction (5/28, 17.9% vs. 10/77 cases, 13.0%), nephropathy (5/28, 17.9% vs. 10/77 cases, 13.0%), retinopathy (2/28 cases, 7.1% vs. 7/77 cases, 9.0%), nor in peripheral neuropathy (23/28 patients, 75.0% vs. 49/77, 63.6%) respectively. Higher level of cholesterol and triglycerides was present in the Scleredema-DM group compared to the Control-DM cases (mean cholesterol was: 5.7±1.5 mmol/l vs. 4.8±1.2 mmol/l, p<0.01; triglyceride: 2.3±1.1 mmol/l vs. 1.8±1.6 mmol/l,

Background: Intravenous Immunoglobulins (IVig) represent a relevant treatment
A UNIQUE ULTRASOUND PATTERN OF ADIPOSE TISSUE IN CONNECTIVE TISSUE DISEASE-ASSOCIATED INTERSTITIAL LUNG DISEASE TREATED WITH CYCLOPHOSPHAMIDE OR RITUXIMAB: A UNICENTRE, OPEN-LABEL AND COMPARATIVE STUDY

Background: To date, rheumatologists do not have curative treatments for connective tissue disease-associated interstitial lung disease (CTD-ILD). Therefore, an stabilization of the disease is considered as a therapeutic success. One of the most frequent drugs used for achieving this goal is Cyclophosphamide (CYC); however, in the last years there has been an increasing interest in the use of Rituximab (RTX) as a treatment for CTD-ILD.

Objectives: To compare long-term effectiveness of CYC vs. RTX as a treatment in patients with CTD-ILD.

Methods: Unicentre and retrospective study in which it was analyzed clinical and image data of 26 CTD-ILD patients treated with CYC or RTX between June 2004 and December 2016. Previously, we checked that baseline characteristics and baseline levels of Pulmonary Function Tests (PFTs) in both groups were similar by using Fisher and T-student tests.

The primary outcome of the study was the stabilization of PFTs or HRTC (High Resolution Tomography Computed Tomography) considering as relapse: a) a deterioration ≥10% in FVC ( Forced Vital Capacity), or b) a decrement ≥15% in DLCO (diffusing capacity of carbon monoxide), or c) a worsening in HRTC. The prognostic effect of each treatment on stabilization was evaluated using the Kaplan-Meier method and Long Rank test. The prognostic effect of each treatment on stabilization was evaluated using the Kaplan-Meier method and Long Rank test.

Results: The study includes 20 women and 6 men with an average age of 58.9±14.2 years. 14 patients had a diagnosis of Systemic Sclerosis whereas 12 had other types of CTD.

From the 26 patients, 15 received CYC and 11 RTX, according to the physician's decision. Both groups presented similar baseline characteristics and levels in PFTs. The Kaplan-Meier method showed that the treatment had an influence on the stabilization of CTD-ILD, although long Rank test was non-significative. The average of months without relapse in CYC and RTX group was 59.7±9.50 and 79.2±7.81 respectively.

Patients in the CYC group did not present any changes in FEV1, FVC, DLCO and DLCO/VA levels during the first year of treatment. In contrast, patients in RTX group showed an increase of all PFTs levels during the first year of monitoring, although these differences were non-significatives. A direct comparison between both treatment groups after 12 months showed lower levels of all PFTs in CYC vs RTX, been DLCO/VA (67.30±10.69 and 86.25±4.59, respectively) statistically significative.

Conclusions: This study suggests, in patients with ILD-CTD, that CYC treatment stabilizes the lung function, whereas RTX shows a tendency to improve it. Also, patients with RTX treatment shows a larger mean time of stabilization than CYC group. However, large scale randomized controlled trials are needed to confirm these results.

**AB0620** ORAL HEALTH IN PATIENTS WITH SYSTEMIC SCLEROSIS: AN EUSTAR CENTER EXPERIENCE

C. Ancuta 1,2, M. Antohe 3, E. Ancuta 3, R. Chirlea 4, C. Iordache 2,
1Rheumatology 2, Clinical Rehabilitation Hospital; 2University of Medicine and Pharmacy Grigore T Popa Iasi; 3Research Department, Elena Doamna Clinical Hospital; 4Sanocare Medical and Research Center, IASI, Romania

**Background:** Although the orofacial manifestations are commonly reported among patients with systemic sclerosis (SSc), only few studies have adequately addressed the issue of oral health-related quality of life (QoL) in such pathobiological settings.

**Objectives:** The aim was to characterize the oral health status (OHS) of adults with SSc and to compare with the general population.

**Methods:** A cross-sectional prospective observational study in 37 consecutive SSc in a EUSTAR cohort (EUSTAR 162 center) and 37 gender and age-matched controls without SSc. A standardized oral exam meaning OHS (periodontal, dental, mucosal and microbial), oral health-related behaviors and oral HRQoL (Oral Health Impact Profile, OHIP) were evaluated in all recruited individuals, while oral manifestations such as size of oral aperture, oral dryness, manual dexterity for oral hygiene and HRQoL only in SSc.

**Results:** Multivariable regression analysis was done to evaluate association between SSc, oral abnormalities, oral health status and QoL.

**Conclusions:** SSc patients are at risk to develop impaired oral health and oral HRQoL compared with the general population.

**Disclosure of Interest:** None declared.

**AB0621** DEVELOPMENT OF SYSTEMIC SCLEROSIS IN TRANSGENDERED FEMALES: A CASE SERIES

C. Campochiaro, C. Fonseca, E. Derrett-Smith, V.H. Ong, C.P. Denton. Centre for Rheumatology and Connective Tissue Diseases, Royal Free Hospital and UCL Division of Medicine, London, United Kingdom

**Background:** Scleroderma (SSc) is an autoimmune connective tissue disease with a female preponderance (female to male ratio of 9.7:1) [1]. Sex hormones are thought to play a role in the susceptibility to autoimmune diseases [2].

**Objectives:** We report 3 cases of SSc in male-to-female transsexuals diagnosed following their male-to-female transition.

**Methods:** Medical records of 3 patients diagnosed with SSc after male-to-female transition were reviewed. Disease features, hormonal therapies and surgical interventions related to gender reassignment were collected.

**Results:** At our tertiary University Hospital clinical service, 3 male-to-female transsexual patients were diagnosed with SSc following their surgery between May 1997 and October 2016. All 3 patients had started their transition before the onset of the disease and had not been diagnosed with any autoimmune disease before either starting the hormonal therapy required for the transition or before underwent surgery interventions. The first case was diagnosed with anti-RNA Pol III +ve diffuse cutaneous SSc at the age of 35 years after the first surgical intervention for infected silicone buttlock implants and approximately 5 years of hormonal therapy with combination of mestranol and norethisterone (Norvestin®). She experienced scleroderma renal crisis 2 years after the diagnosis and severe vascular involvement with frequent and severe digital ulcers (DU), Raynaud’s phenomenon (RP), gastroesophageal reflux disease (GERD), pulmonary arterial hypertension and telangiectasiae. She required chronic dialysis and was treated with mycophenolate mofetil (MMF), raparacyn, bosentan and proton-pump inhibitors (PPI). She eventually died 8 years after the diagnosis. The second case was diagnosed at the of 49 years, approximately 6 months following her gender reassigment and 5 years after having started hormonal therapy initially with conjugated estrogen isolated from pregnant mares (Premarin®) and later with estrogen and progestin agents (Exemestane). She developed ANA +ve, anti-RNP, M2, Scl-70 antibodies and anti-centromere antibodies. Renal diffuse scleroderma pattern were associated with RRI (Figure 1). Pathologic and immunologic assessment for internal organ involvement were collected and analysed as appropriate with SPSS vers 20.0. Considering that age-adjusted mean values were higher in the SSc population in comparison to literature values for the general population, we created SSc-specific age-adjusted pathologic cut-offs in reflecting renal and other disease-related organ damage.

**Objectives:** to describe RRI in a larger scleroderma population and to test both the fixed 0.70 RRI cut-off and age-adjusted cut-offs in reflecting renal and other disease-related organ damage.

**Methods:** SSc patients attending classified according to ACR/EULAR 2013 criteria were enrolled. Data on renal arteriy Doppler ultrasound (RRI), autoantibodies status and biochemical tests for renal function/damage, subset and extent of skin fibrosis, instrumental assessment for internal organ involvement were collected and analysed as appropriate with SPSS vers 20.0. Considering that age-adjusted mean values were higher in the SSc population compared to literature values for the general population, we created SSc-specific age-adjusted pathologic cut-offs in reflecting renal and other disease-related organ damage.

**Results:** 190 SSc patients (age 56.3±15.0 years, disease duration 6±8.20 years) were eligible for the study. In the SSc population significant positive correlations between RRI and age, as well as significant associations between RRI and above mentioned general population comorbidities [1], were confirmed. When considering absolute value of RRI, the 0.70 pathologic cut-off and age-adjusted cut-offs validated in the general population [1], only renal function, systolic PAS and late nailfold scleroderma pattern were associated with RRI (Figure 1). Pathologic RRI identified among those who did not detect early renal damage, but was significantly associated with various fibrotic (interstitial lung disease [p<0.015], tendon friction rubs [p=0.032], skin fibrosis vs no skin involvement [p=0.001], disease-related organ damage.

**Disclosure of Interest:** None declared.

**AB0622** RENAL RESISTIVE INDEX (RRI): PROPOSAL FOR AGE-ADJUSTED CUT-OFF VALUES IN SYSTEMIC SCLEROSIS PATIENTS

C. Bruni 1, V. Maestripieri 2, G. Tesi 1, M. Chiostri 3, C. Sambalino 3, S. Guiducci 1, S. Bellando-Randone 1, M. Boddi 3, M. Matucci-Cerinic 1,
1Department of Experimental and Clinical Medicine, Division of Rheumatology; 2Department of Internal Medicine, Division of Medicine for Care Complexity III, Division of Heart and Vessels, Division of Cardology I, Azienda Ospedaliera Universitaria Careggi, Firenze, Italy

**Background:** Renal resistive index (RRI) by Doppler ultrasound, reflects changes in both renal vascular and tubular-interstitial compartments and systemic vascular compliance related to physiological (age) and pathological conditions among which hypertension, diabetes mellitus, hyperuricaemia, dyslipidaemia and chronic kidney disease is a major role [1]. Because of the age-related changes in RRI reported in literature [2,3] the use of a 0.70 cut-off to detect renal damage, as proposed [4], was questioned: renal injury in younger decades (<60yrs) may occur also for RRI value < 0.70 and be underestimated. In systemic sclerosis (SSC), RRI was previously correlated with disease duration, glomerular filtration rate and nailfold videocapilloscopy pattern [5-7], although were collected on small samples and not investigating the possible confounding role of age-related RRI values.

**Objectives:** to describe RRI in a larger scleroderma population and to test both the fixed 0.70 RRI cut-off and age-adjusted cut-offs in reflecting renal and other disease-related organ damage.

**Methods:** SSc patients attending classified according to ACR/EULAR 2013 criteria were enrolled. Data on renal arteriy Doppler ultrasound (RRI), autoantibodies status and biochemical tests for renal function/damage, subset and extent of skin fibrosis, instrumental assessment for internal organ involvement were collected and analysed as appropriate with SPSS vers 20.0. Considering that age-adjusted mean values were higher in the SSc population compared to literature values for the general population, we created SSc-specific age-adjusted pathologic cut-offs in reflecting renal and other disease-related organ damage.

**Results:** 190 SSc patients (age 56.3±15.0 years, disease duration 6±8.20 years) were eligible for the study. In the SSc population significant positive correlations between RRI and age, as well as significant associations between RRI and above mentioned general population comorbidities [1], were confirmed. When considering absolute value of RRI, the 0.70 pathologic cut-off and age-adjusted cut-offs validated in the general population [1], only renal function, systolic PAS and late nailfold scleroderma pattern were associated with RRI (Figure 1). Pathologic RRI identified among those who did not detect early renal damage, but was significantly associated with various fibrotic (interstitial lung disease [p<0.015], tendon friction rubs [p=0.032], skin fibrosis vs no skin involvement [p=0.001], disease-related organ damage.

AB0623 PROGNOSTIC VALUE OF RENAL RESISTIVE INDEX (RRI) IN SYSTEMIC SCLEROSIS: PRELIMINARY DATA FROM A SINGLE CENTRE

C. Bruni 1, Y. Maestripreri 2, G. Tesi 3, M. Chiosi 3, C. Sambalino 3, S. Guiducci 3, S. Bellando-Randone 1, M. Boddi 1, M. Matucci-Cerinic 1.
1 Department of Experimental and Clinical Medicine, Division of Rheumatology; 2 Department of Internal Medicine, Division of Medicine for Care Complexity II, University of Florence; 3 Department of Heart and Vessels, Division of Cardiology I, Azienda Ospedaliera Universitaria Careggi, Firenze, Italy.

Background: Renal Resistive Index (RRI—measured with Renal arteries Doppler ultrasound) is a useful technique to evaluate vascular and tubular-interstitial damage in both general and systemic sclerosis (SSc) population, where increased RRI values correlates with longer disease duration [1], lower glomerular filtration rate and more advanced naldiloid-vascularcapillaroscopy pattern [2]. Moreover, higher RRI values were seen in SSc patients with new occurrence of digital ulcers [3].

Objectives: to test the prognostic value of RRI (absolute, ≥ 0.70 and SSc age-adjusted pathologic value (Table1)) and RRI delta change in predicting general and organ-specific worsening in scleroderma patients.

Methods: SSc patients classified according to ACR/EULAR 2013 criteria were enrolled. Demographics, Doppler ultrasound and renal and cardiac data were collected. Data on clinical worsening had been collected as herewith specified: a) Skin worsening as an increase of mRSS≥5 units, b) Peripheral vascular worsening as the appearance of new digital ulcers or the worsening of naldiloid-vascularcapillaroscopy scleroderma pattern, c) Lung worsening as decline of FVC>15% or FVC<80% with new detection of ILD on chest HRCT or worsening of HRCT-ILD extent, d) Cardiac worsening as new onset of left ventricular failure requiring treatments or new onset of PAH confirmed on RHC or detection of severe ventricular arrhythmias on 24h EKG, e) Renal worsening as a new scleroderma renal crisis or reduction of creatinine clearance <30 ml/min. General worsening was recorded in case of death due to SSc or for any of the above organ-specific worsening.

Data were analysed as appropriate with SPSS vers. 20.0.

Results: 190 SSc patients (age 56±15.0 yrs, 170 women, disease duration 6±10 yrs) were followed up with a follow up RRI measurement after 2.8±0.9 years) were enrolled. After a mean clinical follow-up of 3.6±2.6 years, 89 (46.8%) pts showed general worsening (Table 1). wider RRI changes were associated with general worsening (p=0.029) and cardiac worsening (p=0.006). The significance of these associations increased when sub-analysis was repeated focused on patients with normal SSc age-adjusted RRI values at baseline (p=0.017 and p=0.001 respectively, Figure 1).

AB0624 INTERSTICIAL LUNG DISEASE IN SCLERODERMA: SEVERITY ASSOCIATED FACTORS. OBJECTIVES

D. Sanchez Carreño 1, N. Ortego Centenero 2, M.T. Cruces Moreno 1, I. Sáez Comes 1, M. Frérea 3, J.A. Toledano Parra 3, M. Rodríguez Caballero 1, C. Simeón Aznar 1 on behalf of RESCLE. 1 Internal Medicine; 2Systemic Autoimmune Diseases Unit, Hospital Campaus de la Salud, GRANADA; 3Internal Medicine, Hospital Universitario Miguel Servet, Zaragoza; 1 Unidad Trombosis y Vasculitis, Hospital Xeral de Vigo, VIGO; 2 Internal Medicine, Hospital Universitario la Fe, Valencia; 3 Internal Medicine, Hospital Universitario Mutua de Terrassa, Terrassa; 4Systemic Autoimmune Diseases Unit, H. Universitari General de la VALL D’Hebron., Barcelona, Spain.

Background: Systemic sclerosis (SSc) can virtually affect any organ system (such as lungs, kidneys, gastrointestinal tract, and heart). However, it is the pulmonary manifestations that account for the majority of deaths, especially interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH).

Objectives: Our aim was to assess the differences between severe and mild-to-moderate ILD in SSc.

Methods: A descriptive study was performed, using the available data from the Spanish Scleroderma Study Group (RESCLE). ILD was deemed as serious when forced vital capacity (FVC) ≤ 50% capacity. Patients were classified attending the modified classification criteria proposed by LeRoy and Medgser.

Results: Fourteen referral centers for SSc participated in the registry. By April 2014, 1374 patients with SSc had been enrolled, 541 of whom (39.4 %) had ILD, 275 severe ILD. In detail, 91% had ILD they were severe ILD more frequently than those with limited SSc (57% vs. 35%, p=0.002), as well as those who had tested positive for ATA (51% vs. 33%, p=0.005).

Additionally, prevalence of FVC<50 was higher in patients with myopathy (22% vs. 15%, p=0.002). Mean FVC percentage was 62±16.4 in the severe ILD group, whilst it was 80.8±18.9 in the mild-to-moderate one (p<0.001), and mean DLco was 36.7±15.2 and 62.9±34.5, respectively (p<0.001). Likewise, DLco~70% was also more frequent among patients with severe ILD (100% vs. 69%, p<0.001), as well as mean DLco (56.2±24.2 vs. 74.2±42.0, p=0.002). PAH was equally higher when FVC~50% (42.2±18.2 vs. 35.1±13.4, p=0.034), and so was the frequency of PAPs~40mmHg (66% vs. 29%, p<0.001) and PAH by right heart catheterism (19% vs. 11%, p=0.050). Finally, by means of a multiple logistic regression, both ATA positivity [OR 0.17 (0.05–0.58), p=0.005] and low DLco [0.93 (0.91–0.95), p=0.000] were found to be related to ILD.

Conclusions: Patients with ACA positivity and with a limited variant of SSc seem to be at lower risk of severe interstitial lung involvement. Furthermore, the presence of myopathy may contribute to explain the decrease of FVC in SSc patients.

AB0625 AUTOANTIBODY PROFILE IN PATIENTS DIAGNOSED WITH IDIOPATHIC INFLAMMATORY MYOPATHY: MULTICENTER REGISTRY ON INFLAMMATORY MYOSITIS FROM THE RHEUMATOLOGY SOCIETY IN MADRID, SPAIN

D.C. Hernández Fábregas1, L. Valor1, J. Martínez1, B. Joven1, L. Nuno3, N. García2, I. Llorente2, C. Barbadoro3, P. García de la Pena1, L. Ruiz4, H. Moruno1, T. Cobo10, R. Almodovar11, L. Lojo12, M. García13, F. López-Longo1, H. Gregorio Maranon1, H.12 de Octubre, H.13 La Paz; H. Ramon y Cajal; H.14 La Princesa; H.15 Puerta de Hierro; H.16 Norte Sanchinarro; H.17 Nino Jesus; H.18 Principe de Asturias, Madrid; H.19 Infanta Sofia, Asturias; H.20 Infanta Leonor, Leonor, 1InMus, Madrid, Spain

Background: Inflammatory myopathies (IM) are a heterogeneous group of autoimmune rheumatic diseases characterized by muscle inflammation and progressive weakness. They include any kind of primary inflammatory muscle disease that is not otherwise better explained by metabolic, toxic, infectious, neurologic or inherited causes. The presence of autoantibodies (AA) in IM is variable and they can recognize linear and cytoplasmic cellular components. Objectives: To evaluate the AA profile in patients diagnosed with IM.

Methods: We evaluated 479 patients that included 12 hospitals belonging to the IM registry of the Rheumatology Society in Madrid (SORCOM-REMIMAC) with diagnosis from January 1980 to December 2014. All patients were diagnosed of IM according to Bohan and Peter criteria. The AAs evaluated were ANA (n=476), anti-Jo1 (n=457), anti-RNP (n=427), anti-Mi2 (n=159) and ACA (n=293), according to the standard techniques in the respective laboratories. The presence of ANA was considered valid with at least two positive determinations. The AAs were compared according to the classification I) as dermatomyositis (primary...
and secondary dermatomyositis) (DM) and polymyositis (PM) including the rest of the patients. Also, IIM were classified (II) as primary polymyositis (PPM) primary dermatomyositis (PDM), overlap syndrome (OSd), juvenile myopathies (JM), cancer-associated myopathies (CAM), autoimmune necrotizing myopathy and inclusion body myositis (these were grouped as other myositis; OM).

Results: In the PM and DM groups 250 and 229 (52.2% and 47.8%) patients were included respectively. Positive ANA, anti-Jo-1 and anti-RNP were higher in the PM than in the DM group (67, 22 and 19% vs. 56, 11 and 6% p<0.021, p=0.002, p=0.0001, respectively). The presence of anti-Mi-2 was higher in the PM group (p=0.024), according to the classification II, we found statistically significant differences in ANA, anti-Jo-1, anti-RNP and anti-CAM. The OSt group had the highest proportion of ANA, anti-RNP and ACA positive AA and the JM group had the lowest frequency of Anti-Jo1 (see Table 1).

Conclusions: The AA associated with the IIM subtypes is consistent with published scientific evidence on other cohorts for ANA, anti-Jo1, anti-RNP and anti-Mi2, in spite of the small sample size. The OsD group showed higher ANA and anti-RNP frequencies which might be explained by the coexistence of SLE and MCTD patients. It could be interesting to follow up those PPM patients with positive AA because they could be in the future diagnosed with a connective tissue disease. Carrying out longitudinal studies that include a greater proportion of patients may help to evaluate and predict the clinical course of IIM. References:

EPITOPE PROFILING OF ANTI-RO52 ANTIBODIES IN PATIENTS WITH SYSTEMIC SCLEROSIS, SYSTEMIC SCLEROSIS-ASSOCIATED PRIMARY BILARY CIRRHOSIS, AND PRIMARY BILARY CIRRHOSIS ALONE

C. Liaskos 1, A. Gkoutzourelas 1, T. Simopoulou 1, E. Marou 1, T. Scheper 2, W. Meyer 2, L. Sakkas 1, D.P. Bogdanos 1

Rheumatology and Clinical Immunology, University of Thessaly, School of Health Sciences, Larissa, Thessaly, Greece; 1Institute of Immunology, Euroimmun AG, Lubeck, Germany

Background: Anti-Ro52 antibodies are detected in patients with Sjogren’s syndrome (SS), systemic sclerosis (SSc) and other autoimmune rheumatic diseases. Epitope mapping studies of anti-Ro52 in autoimmune rheumatic diseases have failed to find any difference on epitope recognition suggesting a common stimulus for the loss of tolerance to Ro52. Such epitope differences, however, were noted between SS and non-rheumatic IIM and in particular, SS-associated primary biliary cirrhosis (SS-PBC) or PBC alone (1).

Objectives: To assess whether or not the Ro52 epitope profile in anti-Ro52+ SSc patients differs from that of SSc-associated PBC (SSc-PBC) or PBC. Methods: Serum samples were obtained from 63 anti-Ro52 positive (by ELISA) patients with systemic sclerosis (33 SSc), systemic sclerosis (SSc) and other autoimmune rheumatic diseases. Antibody reactivity to full length Ro52 in autoimmune rheumatic diseases have failed to find any difference on epitope recognition suggesting a common stimulus for the loss of tolerance to Ro52. Such epitope differences, however, were noted between SS and non-rheumatic IIM and in particular, SS-associated primary biliary cirrhosis (SS-PBC) or PBC alone (1).

Objectives: To assess whether or not the Ro52 epitope profile in anti-Ro52+ SSc patients differs from that of SSc-associated PBC (SSc-PBC) or PBC. Methods: Serum samples were obtained from 63 anti-Ro52 positive (by ELISA) patients with systemic sclerosis (33 SSc), systemic sclerosis (SSc) and other autoimmune rheumatic diseases.

Results: Reactivity was present to: full length Ro52 in all anti-Ro52 positive patients differs from that of SSc-associated PBC (SSc-PBC) or PBC. Ro52–1 in 6/33 (18.2%) patients (33 SSc, 10 SSc-PBC, 20 PBC alone). Antibody reactivity to full length Ro52 in autoimmune rheumatic diseases have failed to find any difference on epitope recognition suggesting a common stimulus for the loss of tolerance to Ro52. Such epitope differences, however, were noted between SS and non-rheumatic IIM and in particular, SS-associated primary biliary cirrhosis (SS-PBC) or PBC alone (1).

Objectives: To assess whether or not the Ro52 epitope profile in anti-Ro52+ SSc patients differs from that of SSc-associated PBC (SSc-PBC) or PBC. Methods: Serum samples were obtained from 63 anti-Ro52 positive (by ELISA) patients with systemic sclerosis (33 SSc), systemic sclerosis (SSc) and other autoimmune rheumatic diseases.

Results: Reactivity was present to: full length Ro52 in all anti-Ro52 positive SSc, PBC-SSc, or PBC patients by line immunoassay; Ro52–5 in 0/33 (0%) SSc, 0/10 (0%) SSc-PBC, or PBC; Ro52–4 in 0/22 (0%) SSc, 0/22 (0%) SSc-PBC, or PBC; Ro52–3 in 0/33 (0%) SSc, 0/10 (0%) SSc-PBC and 0/20 (0%) PBC; Ro52–2 in 4/33 (12.1%) SSc, 2/20 (10%) PBC; Ro52–1 in 18/33 (54.5%) SSc, 18/20 (90%) PBC and 18/33 (54.5%) PBC. Swollen and tender joint counts were present in 38 (31.4%) and 25 (20.6%) patients, respectively, while 35 patients (28.9%) had tendon friction rubs. Digital ulcers were present in 15 patients (12.4%) at baseline.

Conclusions: RISE-SSc has a unique trial design with a cohort enriched for diseased progressed, which is reflected in the baseline characteristics of the randomised patients. Results of the RISE-SSc study will provide data to inform not only the efficacy, safety and tolerability of riociguat treatment in patients with dcSSc, but also the feasibility of a new trial design based on cohort enrichment.

MACROVASCULAR DYSFUNCTION OF UPPER AND LOWER LIMBS CORRELATES WITH DIGITAL ULCERATIONS IN PATIENTS WITH SYSTEMIC SCLEROSIS

E. Maroudhan1, S. AleSaeidi2, F. Gharibdoost3.

Background: Systemic sclerosis (SSc) is a chronic connective tissue disorder of unknown etiology characterized by tissue fibrosis and vascular damage [1]. Digital ulcerations (DUs) are common manifestations of vascular involvement [2]. Although the role of macrovascular disease of LoS and SSc has been considered mainly to affect the microvasculature [3], there is recent evidence showing that SSc is associated with the prevalence of large vessel disease [4]. However, only a few studies investigated the relationship between macrovascular disease and its role in the clinical manifestations of SSc such as ulcers.

Objectives: To assess the relationship between the Macrovascular dysfunction of upper and lower limbs with digital ulcerations in patients with systemic sclerosis.

Methods: Ninety patients with SSc (45 cases with DUs and 45 cases without DUs) enrolled in this study. Patients with other rheumatologic diseases and diabetics patients were excluded from the study. Data were collected from the patients, included age, sex, date of disease onset, history of cardiovascular disease and dyslipidemia, SSc disease duration, type of SSc (lcSSc or dcSSc), Raynaud’s phenomenon (RP), RP duration and digital ulcerations (DUs), Body weight (BW), Height, Waist circumference (WC), Body mass index (BMI), Blood pressure (BP), serum levels of SCL-70 antibody and Anti-Jo-1 microglobulin antibody. Then Doppler sonographies were performed. The outcome variables were the peak systolic velocity (PSV) and resistance index (RI) of ulnar, radial, popliteal, dorsalis pedis and tibial artery.

Results: The SSc patients with DUs have significantly lower PSV and higher RI in tibiopercal artery (PSV:52.1±7.9 vs 55.7±7.4, p=0.006 and RI: 0.58±0.15 vs 0.52±0.06, p=0.003), dorsalis pedis (PSV: 33.9±1.9 vs 34.5±0.4, p=0.027 and RI: 0.54±0.11 vs 0.50±0.04, p=0.045) and tibial artery (PSV: 32.6±3.1 vs 34.4±0.9, p=0.01 and RI: 0.62±0.16 vs 0.51±0.07, p=0.001) in comparison to SSc patients without DUs. PSV and RI of ulnar artery were significantly correlated with age (p=0.012 and p=0.019), disease duration (p=0.001 and p=0.001) and Raynaud’s phenomenon (RP) duration (p=0.048 and p=0.028), PSV and RI of tibial artery had significant correlation with age (p=0.038 and p=0.009), systolic blood pressure (p=0.022 and p=0.037) and diastolic blood pressure (p=0.015 and p=0.010).

Conclusions: We concluded that digital ulceration in patients with SSc might be frequently related to the macrovascular dysfunction in below the elbow and knee.

Conclusions: Our study seems to indicate that clinical spectrum time course of anti PL-12 positive ASSD is different from that of anti PL7 and of anti EJ positive ASSD. The clinical pattern associated with these two latter antibodies was very similar. Furthermore, anti PL-12 positive patients seems to have a more stable disease, with a less common occurrence of ex-novo triad findings during the follow-up.

AB0631 THE CLINICAL CONSEQUENCES PRESENCE OF ANTI-PM/SCL ANTIBODIES IN SYSTEMIC SCLEROSIS

E. Wielicz, M. Drygiewska, M. Majdan. Department of Rheumatology and Connective Tissue Diseases, Medical University of Lublin, Lublin, Poland

Background: Anti-PM/Scl (a-PM/Scl) antibodies are found in different systemic autoimmune disease such as polymyositis, dermatomyositis, systemic sclerosis (SSc), and overlap syndromes. According to literature they are detected in about 2% of patients with SSc, but their presence are more common in SSc with myositis overlap. Features positively associated with the presence of a-PM/Scl antibodies included younger age at disease onset, skeletal muscle involvement, calcinosis, inflammatory arthritis, and overlap disease. On the other hand interstitial lung disease and gastrointestinal symptoms were less frequent in SSc patients with a-PM/Scl.

Objectives: The aim of the study was to assess the clinical consequences presence of a-PM/Scl antibodies in patients with SSc.

Methods: The study was performed in 126 European Caucasian SSc pa-tients (98-female and 28-male) hospitalized consecutively in the Department of Rheumatology and Connective Tissue Diseases. Patients fulfilled the ACR classification criteria of SSc (59 have diffuse cutaneous SSc and 67 limited SSc). The study group were studied according to the presence of a PM/Scl antibodies applying commercial test – EUROLINE Systemic Sclerosis Profile. Detection and other cytokine and chemokine milieu in the tear of SSc patients has not yet been evaluated.

Conclusions: In SSc anti-PM/Scl antibodies are frequently associated with myalgia or myositis, contractures and overlap syndrome.

AB0632 ASSESSMENT OF VEGF AND OTHER CYTOKINES IN THE TEAR OF PATIENTS WITH SYSTEMIC SCLEROSIS

A. Rentka1, J. Hárfsfalvi2, K. Köröskényi3, G. Szűcs4, Z. Szekeanecz4, P. Szodoray5, A. Berta5, Á. Kemeny-Beke5,1Department of Ophthalmology, University of Debrecen, Faculty of Medicine, Debrecen; 2Department of Biophysics and Radiation Biology, Semmelweis University, Budapest; 2Department of Rheumatology and Molecular Biology; 4Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary; 1Institute of Immunology, Rikshospitalet, Oslo, Norway

Background: Systemic sclerosis (SSc) is an autoimmune disease, characterized by widespread small vessel vasculopathy, immune dysregulation with production of autoantibodies, and progressive fibrosis. SSc may be associated with sicca syndrome. Changes in levels of proangiogenic and proinflammatory cytokines has already been determined largely in serum, however, the local inflammatory and cytokine milieu in the tear of SSc patients has not yet been evaluated.

Objectives: We wished to determine VEGF and other cytokine and chemokine levels in tear samples of SSc patients.

Methods: First, forty-three patients (40 female and 3 men, mean (SD) age 61 (48–74) years) with SSc and 27 healthy controls were enrolled in the VEGF study. Basal tear sample collection and tear velocity investigations were carried out followed by an ophthalmological examination. Total protein concentrations and VEGF levels were determined in tear samples. In the multiple cytokine study, unstimulated tear samples were collected from nine patients with SSc and 12 age and gender-matched controls. The relative levels of 102 different cytokines were determined by a cytokine array, and then absolute levels of four key cytokines were determined by a magnetic bead assay.

Results: In the first study, the mean collected tear fluid volume developed 10.4 L (1.0–20.6) in patients and 15.6 L (3.88–34.5) in control subjects. The mean total protein level was 6.9 g/L (1.8–12.3) and 4.1 g/L (0.1–14.1) in tear samples of SSc patients and controls, respectively. In patients with SSc, the mean VEGF tear concentration was 4.9 pg/L (3.5–8.1) compared to 6.15 pg/L (3.84–12.3) in healthy samples. Multicytokine-array studies revealed shifted cytokine profile characterization by predominant proinflammatory cytokines in the tear samples of SSc patients. Out of the 102 analyzed proteins, nine were significantly increased in tears of patients with SSc. Based on the multiplex bead results, CRP, interferon-inducible protein 10 (IP-10) and monocyte chemotractant protein-1 (mcp-1) levels were significantly higher in tears of patients with SSc compared to controls.

Conclusions: Impaired angiogenesis has been found by other investigators in SSc. This is reflected by lower VEGF levels in the tear samples of SSc patients compared to controls. The multi-cytokine array study revealed increased production of CRP and two important pro-inflammatory chemotaxins in the tears of SSc patients. Our current data depict a group of inflammatory mediators, which may play a significant role in ocular pathology of SSc.

AB0633 RITUXIMAB IN SCLERODERMA RELATED INTERSTITIAL LUNG DISEASE: A SINGLE CENTRE EXPERIENCE FROM NORTH INDIA

G. Naidu, S.K. Sharma, V. Dhir, S. Jain. Internal Medicine, PGIMER, Chandigarh, India

Background: Pulmonary involvement is one of the major causes of morbidity and mortality in patients with progressive systemic sclerosis (PSS). Clinically significant interstitial lung disease (ILD) is noted in 25% of patients and accounts for 33% of deaths in PSS patients [1, 2]. Cyclophosphamide (CYC) and mycophenolate mofetil (MMF) have been shown to retard progression of ILD [3, 4]. The limited data on rituximab indicate that rituximab might be effective in PSS related ILD [5].

Objectives: To study the efficacy of rituximab in patients with PSS related ILD.

Methods: The clinical details of all patients of PSS related ILD who were treated with rituximab were noted from the case files. EULAR criteria were noted respectively from the case files. Forced vital capacity (FVC) value before and 1 year after administration of rituximab were noted. Increase in FVC by 10% from baseline was considered as improvement and fall in FVC by 10% or absolute value less than 40% of predicted was considered as worsening. Patients with FVC ±10% from baseline were considered to have stabilized lung functions.

Results: A total of 11 patients received rituximab between 2013 and 2016. Six (54.5%) patients were females. Median age of the subjects was 44 years (range: 31–75 years). All patients received intravenous CYC at least 1 year before rituximab. Rituximab was given either not responded to CYC or worsened after initial response to CYC. All patients received 2 doses of rituximab (1g each) at 2 weeks interval. Median FVC before rituximab was 57% of predicted. Two patients did not have post rituximab FVC values. Median FVC 1 year after rituximab was 54% predicted. Out of the remaining 9 patients, 2 (22.2%) patients had improvement in FVC 6 (66.7%) patients had stabilization of FVC and 1 patient worsened. One patient, who had stabilization of FVC with rituximab expired after 2 years of receiving rituximab.

Conclusions: Rituximab was effective in stabilization of lung functions in patients of PSS with ILD who did not have favourable outcome with intravenous CYC.
Efficacy of rituximab in treatment naïve PSS related ILD patients needs to be studied.

AB0634
RITUXIMAB IN SYSTEMIC SCLEROSIS-INTERSTITIAL LUNG DISEASE, A CASE SERIES OF 18 PATIENTS
G. Guzelant1, M. Melikoglu 1, B. Museli2, D.D. Yilmaz2, I. Fresko1, E. Seyahi1, G. Haterm1, S. Ugurlu1, V. Hamuryudan1, 1Cerrahpasa Medical Faculty Department of Internal Medicine Division of Rheumatology; 2Cerrahpasa Medical Faculty Department of Pulmonology, Istanbul University, Istanbul, Turkey.

Background: Interstitial lung disease (ILD) is a severe complication of systemic sclerosis (SSc). Immunosuppressives such as cyclophosphamide (CYC) and mycophenolate mofetil (MMF) are used in its treatment with no proven efficacy (1). Rituximab (RTX) appears to be an emerging agent according to case series.

Objectives: This retrospective study aims to evaluate the efficacy of RTX on SSc-ILD in a group of patients followed in our center.

Methods: A chart review revealed 18 patients (16 women, 2 men; mean age 50.3±12.1 SD years (range 30–72), mean disease duration 8.3±9.3 SD years) with SSc who have been diagnosed as having ILD (confirmed by high-resolution thorax computed tomography and pulmonary function tests) and have been treated with one or more cycles of RTX. Efficacy was evaluated according to the criteria of the American Thoracic Society: Improvement= an increase in FVC>10% or DLCO>15%; worsening= a decrease in FVC>10% or DLCO>15%; stabilization= changes in FVC less than 10% or DLCO less than 15% (2).

Results:

Table 1 Demographic findings of the patients and their response to RTX treatment

![Table 1](image)

Four patients were treatment naïve for ILD when they received RTX (Group 1). The mean duration between the diagnosis of ILD and RTX treatment in Group 1 was 3.5 months (range 6–14 months). The average RTX cycle in this group was 3.5 months (range 0–14 months). The average RTX cycle in this group was 3.5 months (range 0–14 months). The average RTX cycle in this group was 3.5 months (range 0–14 months). The average RTX cycle in this group was 3.5 months (range 0–14 months). The average RTX cycle in this group was 3.5 months (range 0–14 months). The average RTX cycle in this group was 3.5 months (range 0–14 months).

Conclusions: RTX appears to be modestly effective for ILD of SSc. The duration of ILD as well as the presence or absence of previous immunosuppressive therapy do not appear as playing a role in response.

AB0635
THE CLINICAL FEATURES AND PROGNOSIS OF PULMONARY ARTERIAL HYPERTENSION ASSOCIATED WITH SCLERODERMA AND OTHER CONNECTIVE TISSUE DISEASE DURING THE MODERN MEDICAL ERA IN JAPAN
H. Maki1, M. Hatano2, S. Minatsuki3, T. Inaba1, I. Komuro1, Y. Asano3, S. Sato3.

While PAH has been recognized as a serious adverse event in patients with systemic sclerosis (SSc), the incidence and the clinical features of SSc-related PAH have been reported from diverse populations. This study intends to clarify the clinical features and prognosis of SSc-PAH in modern era where multiple PAH drugs are available, in addition, compare between SSc-PAH and PAH associated with other CTD-PAH (non SSc-PAH). Methode: Fifty-seven consecutive CTD-PAH patients were enrolled to this study, who received hemodynamic examination with right heart catheterization between 2004 and 2016. Thirty of 57 patients were SSc-PAH patients and other 27 patients were non SSc-PAH patients (11 mixed connective tissue disease, 8 systemic lupus erythematosus, 5 primary scleroderma, 1 polymyositis, 1 rheumatoid arthritis and 1 Still's disease were included). We retrospectively analyzed the relationship between clinical parameters at baseline and the prognosis of CTD-PAH patients.

Results: Mean age at entry were 65±10.3 and 48±15.5 years old each other (SSc-PAH vs non SSc-PAH P<0.05). Twenty-eight SSc-PAH patients (96%) took at least one vasodilator, among them, 18 SSc-PAH (60%) and 13 non-SSc-PAH (48%) patients took multiple vasodilators at the end of follow-up period. Comparing the baseline clinical parameters between two groups, vital capacity and diffusing capacity of the lung for carbon monoxide (DLCO) were significantly lower in SSc-PAH patients than non SSc-PAH patients and brain natriuretic peptide and creatinine level were higher in SSc-PAH patients than non SSc-PAH patients (P<0.05). However, there were no significant differences in hemodynamic indices between two groups. During a mean follow-up period of 42.5±31.5 months, 22 patients (18 SSc-PAH and 4 non SSc-PAH) died or received lung transplantation. The SSc-PAH patients had worse prognosis than non SSc-PAH patients (figure: P<0.001). Only 6 of 18 SSc-PAH patients and 1 of 4 non SSc-PAH patient died of PH related cardiovascular event and other principal causes of death included interstitial lung disease (ILD), neoplasm and infection. Applying multivariable Cox-proportional hazard regression, mean pulmonary arterial pressure, right atrial pressure, creatinine level and %DLCO were extracted as the independent risk for all-cause mortality.

Conclusions: SSc-PAH patients had poor prognosis among CTD-PAH patients despite the progression of PAH drugs. As well as the report from REVEAL registry, not only PAH severity but also respiratory dysfunction may predict the prognosis of CTD-PAH patient. Scleroderma is multorgan disease affected by complex pathology of vasoconstriction (ischemia), proliferation, inflammation, autoimmune disorder and fibrosis. Our data suggest that vasodilator alone is not enough to improve the prognosis of CTD-PAH patients. Comprehensive therapeutic strategy for SSc-PAH is needed.

A COMPARISON STUDY OF PREVALENCE OF TRADITIONAL CARDIOVASCULAR RISK FACTORS AND FRAMINGHAM RISK SCORE IN SYSTEMIC SCLEROSIS PATIENTS AND MATCHED CONTROLS

J. Sousa-Neves, M. Cerqueira, D. Santos-Faria, J. Leite Silva, C. Afonso, F. Texeira. Rheumatology, Hospital Conde de Berlangas, ULSAM, Ponte de Lima, Portugal

Background: In Systemic Sclerosis (SSc), data on prevalence of traditional cardiovascular (CV) disease risk factors is scarce and conflicting (1). Therefore, SSc patients CV risk attributed to traditional CV risk factors remains an issue of debate.

Objectives: To evaluate if patients with SSc have a higher prevalence of traditional CV disease risk factors and a higher risk of long-term CV events based on the risk prediction tool of the Framingham risk score (FRS) in comparison with age, race and sex matched control subjects.

Methods: The study comprised patients diagnosed with SSc, fulfilling both the 1980 ACR and the 2013 ACR/EULAR criteria for the disease, and followed-up at our institution for 1 year using a group of age, race and sex-matched controls. Inclusion criteria were age 30 to 74 and no history of CV events in order to calculate FRS. In total, 46 out of 62 patients were eligible for the study. Traditional CV disease risk factors (diabetes, arterial hypertension and smoking) were compared among the 46 patients with SSc and 51 matched controls. Systolic blood pressure (SBP) values and total and high-density lipoprotein (HDL) cholesterol levels were also collected. The 10-year risk for CV events according to FRS was calculated and means of patients and controls were compared. Subjects’ distribution into 3 categories of risk – low (<10% risk), medium (10–20% risk) and high (>20% risk) was also compared. Parametric and nonparametric tests were used for comparison between groups. P value <0.05 was defined as statistically significant.

Results: Mean risk for CV events in 10-years assessed by FRS was 10.00%±8.61 for SSc patients and 7.76%±8.30 for matched controls. Differences were not statistically significant (p=0.196). Additionally, prevalence of diabetes, arterial hypertension and smoking did not differ significantly between the two groups (p=0.890, p=0.443, p=0.651, respectively). Total and HDL cholesterol levels were also similar between groups (p=0.963 and p=0.506, respectively). Only SBP values (mmHg) of SSc patients were significantly higher (128.50 mmHg [113.5 to 139.3]) (median [interquartile range]) compared with controls (120.00 [110 to 130]), p=0.031. Subjects’ distribution into the 3 groups of risk defined was similar for both groups (p=0.205).

Conclusions: In our study, prevalence of traditional CV disease risk factors and 10-year risk for CV events based on FRS assessment tool did not differ significantly between SSc patients and age, sex and race matched controls.

SUBCLINICAL AtherosMATosis and Vitamin D DeficienCy In PaTients with Scleroderma

J.J. Gonzalez Martin 1, O. Carrion2, A. Abdelkader 2, E. Calvo1, F. Aramburu1, J.J. Gonzalez Martin 1, O. Carrion2, A. Abdelkader 2, E. Calvo1, F. Aramburu1

Objectives: To study whether patients with systemic sclerosis (SSc) have an increased cardiovascular risk (CVR), measured on the basis of analytical, angiodynamic and/or vascular lesions on carotid ultrasound. The carotid IMT is a marker of cardiovascular morbidity and mortality, allowing measurement and monitoring of atherosclerosis in asymptomatic individuals, being surrogate markers of future coronary disease, stroke and general death in the general population and in inflammatory rheumatologic diseases.

Methods: Epidemiological and analytical data were collected, including the determination of the CRV SCORE index. Vascular ultrasound protocol included assessment of carotid intima-media thickness (IMT), presence of atheromatous plaques, and exploration of peripheral arteriopathy using the ankle arm index (ABI).

Results: Seventy adult patients with ES diagnosis (ACR-EULAT 2013 criteria) were included. 94% of the women had a mean age of 50.2±12.5 years, and an average evolution time of 3.0±4.4 years. The distribution by subgroups was: limited SSc (48%), diffuse SSc (34%), pre-SSc (4%), sine SSc (2%), MCTD (5%) and overlap syndrome 4%). The mean SSRm was 9.3±7.0 (range 0–42).

The ANA were positive in 91.4%, ACA (51.4%), ATA (10%), RNA polymerase (42%), 4% were DM, 7% were obese, 11% were active smokers, 13% were HTN, and 28% were ex-smokers. 28% had hypercholesterolemia with a mean total cholesterol of 192.5 ± SD (31 ± 9) and LDL of 102.4 (SD ± 29.4 mg/dL).

57% received vasodilators, most of them APA-II. 10% bosentan, 4.2% sildenafil, and a 2.8% combination therapy.

The percentage of immunosuppressive drugs was corticoid (50%), MTX (34%), mycophenolate (3%), AZA (11%), HCQ (14%), CP %.

The IMT presented pathological values (>0.9 mm) in 39% of the sample, 23% had atherothrombotic plaques (being bilateral in 40%). Subclinical atherosclerosis affected 41.4% (patients without cardiovascular events, pathological IMT and/or atheroma plaques). The ABI had pathological values (<0.9) in 17% of the patients.

In the bivariate analysis, the pathological GIM was related to the presence of ACA antibodies (OR =3.80, 95% CI: 1.15–12.52, p=0.028) and with the SCORE index of CVR (OR =2.93, 95% CI: 1.12–7. 64, p=0.028); And the presence of atherothrombotic plaques was associated with increased SSRm score (OR 1.09, 95% CI 1.00–1.19, p=0.046), and the highest CVR SCORE index (OR 3.90, 95% CI: 1.31–11.56, p=0.014).

In the multivariate analysis, the serum vitamin D concentration showed a protective effect on IMT (OR =0.94, 95% CI 0.89–0.99, p value =0.025). And the main determinant of atheromatous plaques is the SCORE index, since the increase of one unit in SCORE index multiples by 4 the probability of presenting plaques (OR =4.06, 95% CI: 1.31–12.60, P=0.015), once the effect of SSRm was controlled.

Conclusions: 40% of the patients had pathological IMT values, showing association with the presence of positive AAC and the SCORE risk index.

The serum concentration of 25-OH-vitamin D showed a protective effect on IMT. Sixty percent of the sample had vitamin D deficiency.

The presence of atheromatous plaques (23% of patients) was associated with higher SSRm indexes and SCORE cardiovascular risk.

CARDIAC TRANSPLANT IN SYSTEMIC SCLEROSIS-ASSOCIATED CARDIOMYOPATHY: MONOCENTRIC EXPERIENCE OF 3 CASES

J. Lenaerts 1, J. Lenaerts 2, R. Westhovens 2, W. Drooghe 3, A. Ciarka 3, J. Van Cleemput 4, E. De Langhe 2

Background: Cardiac involvement in systemic sclerosis (SSc) is a frequent complication, but end-stage cardiac failure remains uncommon and represents a poor prognosis. Heart-lung and lung transplant is an established treatment option for SSc-related pulmonary disease. Due to the limited published data, no recommendations exist for cardiac transplant in the context of SSc.

Objectives: We present our monocentric experience of 3 patients with SSc who underwent cardiac transplant for SSc-related end-stage heart disease (multiple hospitalisations due to failure of medical therapy and life-threatening complications).

Results: Case 1 is a 59-year-old male with limited cutaneous SSc. Antinuclear antibody (ANA) was negative. He had vascular (digital ulcers) and cardiac (heart failure (left ventricular ejection fraction (LVEF) 20%, NYHA class IV)) involvement, without major gastrointestinal or pulmonary involvement (no interstitial lung disease (ILD) or pulmonary arterial hypertension (PAH; assessed by right heart catheterization (RHC))). He underwent a cardiac transplant at the age of 51, after a disease duration of 6 years. Post-transplantation immunosuppressant therapy consists of tacrolimus and mycophenolic acid, initially associated with methylprednison, which is the standard immunosuppression protocol at our institution.

Case 2 is a 55-year-old male with limited cutaneous SSc. ANA was positive,
SUPERIOR TREATMENT RESPONSE OF INTERSTITIAL LUNG DISEASE IN INFLAMMATORY MYOPATHIES COMPARED TO OTHER CONNECTIVE TISSUE DISEASES – A PROSPECTIVE COHORT STUDY

J.J. Maya1, A. Borja2, A. Abril1, I. Mira-Aviendoa2, 1Rheumatology; 2Pulmonary, Mayo Clinic Florida, Jacksonville, United States

Background: Intersitial Lung Disease (ILD) associated to Connective Tissue Disease (CTD) represent a challenge for clinicians and researchers because of their significant morbidity and mortality. Although the different types of ILD associated to CTD are often studied and managed as one because of their autoimmune background, there are considerable differences in their etiopathogenesis and therefore it can be assumed that there are differences in their response to treatment (1). Even though previous studies have analyzed the impact of immunosuppression in ILD secondary to scleroderma, additional studies are needed in order to determine the response to treatment of the different forms of ILD associated to CTD (2–3).

Objectives: To characterize and analyze the response to treatment of different types of ILD associated to CTD. The primary endpoint is the Functional Vital Capacity (FVC) change at 6 months and 1 year, and secondary endpoints are the change in Diffusion Capacity of the Lung for Carbon Monoxide and in a 6 Minute Walk Test.

Methods: A prospective cohort study is being carried out where all patients who present to the Mayo Clinic Florida pulmonary clinic, age 18 to 80, with established ILD and with ILD who meet the criteria for immunologic mediated process, are being followed for a year in order to evaluate their clinical and functional outcomes to treatment. Patients with moderate or severe Pulmonary Hypertension and, and active smokers with bronchiolitis pattern are being excluded. Exploratory analysis were performed on the first group of patients enrolled in the study, continuous variables were described with central tendency measures and the mean absolute difference in adjusted 12-month FVC was analyzed between the different types of CTDs using student’s t-test.

Results: Thirteen patients with ILD were enrolled in the study’s initial phase. Five of the patients had been diagnosed with an Inflammatory Myopathy (IM), 2 with Rheumatoid Arthritis, 1 with an Undifferentiated Connective Tissue Disease, 1 with Churg-Strauss Syndrome, and one with Systemic Sclerosis. One patient was treated with Rituximab only, 2 with Rituximab and a steroid; 3 with Myophenolate Mofetil (MMF) only; 2 with steroids, MMF, and Rituximab; 1 with a TNF inhibitor and MMF; 1 with MMF and steroids; 1 with Azathioprine and steroids; and 1 received only steroids. IMs were compared to the rest. At year 4, after a disease duration of 7 years Standard immunosuppressants were initiated.

At present, 1.5 years (case 2 and 3) and 8 years (case 1) after transplant, the donor hearts are still functioning well. No other SSC-related organ manifestations have been observed nor signs of rejection.

Conclusions: We present 3 patients with SSC who successfully underwent cardiac transplant for SSC-related end stage heart disease. None had other major SSC-related organ involvement. This supports the limited published data that cardiac transplant is feasible and can be considered in end-stage SSC-related cardiomyopathy.

AB0640 DOES MIXED CONNECTIVE TISSUE DISEASE WITHOUT ANTI-U1RNP EXIST?

J. Martinez-Barrío1,2, E. Estrada3,4, J.G. Ovalles-Bonilla1, L. Valor1, D. Hernández-Flores1, T. del Rio1, J. Janta1, J.C. Nieto Gonzalez1, B. Serrano1, R. González Benítez1, C. Sáenz Tenorio1, L. García-Montoya1, M. Correoyero1, A. Silva1, A. López-Cerón1, C. González1, I. Monteagudo1, F.J. López-Longo1, 1Department of Rheumatology, Hospital General Universitario Gregorio Marañón; 2Universidad Complutense de Madrid; 3Fisioterapia; 4Facultad de Salud, Universidad Camilo José Cela; 4Facultad de Psicología, Universidad Autónoma de Madrid, Madrid, Spain

Background: Mixed Connective Tissue Disease (MCTD) is a systemic autoimmun rheumatic disease (SARD) characterized by clinical manifestations of systemic lupus erythematosus (SLE), systemic sclerosis (SSc) and polymyositis (PM) with the presence of anti-U1RNP antibodies. Objectives: To determine whether there are patients with symptoms of MCTD in the absence of anti-U1-RNP antibodies.

Methods: This was a monocentric, prospective, observational study of patients with SARD. All patients diagnosed of MCTD according to Kasukawa and/or Alarcón-Segovia’s criteria, SLE, SSc, PM, overlap syndromes (simultaneous or sequential criteria of 2 or more SARD), Sjögren’s syndrome, Antiphospholipid syndrome, systemic vasculitis and undifferentiated or incomplete SARD (at least one clinical criterion of the classification criteria and a related antibody of any of the SARD) were included. The data was collected in the Immunology and Systemic Rheumatic Diseases Registry of the Hospital General Universitario Gregorio Marañón Rheumatology Department from 1986 to 2012. The registry includes 2406 patients diagnosed with SARD. Patients with rheumatoid arthritis were excluded. Patients with clinical MCTD criteria were divided into seropositive (MCTD, with anti-U1RNP) and seronegative (possible MCTD, without anti-U1RNP). The registry counts with the local Institutional Ethics Board approval.

Results: A total of 692 patients were recruited, 608 women (87.9%), Seventy (70, 10.1%) patients were classified as seropositive and 75 (10.8%) as seronegative by Kasukawa’s criteria. Sixty-two (62, 8.9%) patients were classified as seropositive and 54 (7.8%) as seronegative according to Alarcón-Segovia’s criteria. There were no significant differences in age at disease onset, age at diagnosis or disease duration (p=0.05) between seropositive and seronegative patients. Seropositive patients with Kasukawa’s criteria presented more frequently: lymphadenopathy, malar rash, leucopenia, Raynaud’s phenomenon, muscle weakness and increase of muscle enzymes (Table 1). By Alarcón-Segovia’s criteria, patients who developed myositis were more frequent in the seropositive group (p=0.007, OR 3.25, 95% CI, 1.44–7.32).

Conclusions: Some patients with SARD manifestations fulfill MCTD clinical criteria, both Kasukawa’s and Alarcón-Segovia’s, in the absence of anti-U1-RNP antibodies from the onset of the disease and throughout its evolution (seronegative MCTD). The frequency of seronegative MCTD was similar to the frequency of seropositive MCTD. Patients with seropositive MCTD presented more frequently manifestations of SLE (lymphadenopathy, malar rash and leucopenia) when using Kasukawa’s criteria and of PM when using both criteria.

AB0641 ARTERIAL STIFFNESS AND CLINICAL ASSOCIATION IN PATIENTS WITH SYSTEMIC SCLEROSIS

K de la Cruz Rodriguez1, O. Martinez Bonilla2, V. González Díaz2, K. García Osuna3, J. Reyes Rueda1, C. Gómez López2, J. Polanco Cruz2, A. Bernard Medina1, E. Cárdona1, A. Macínezuma2, C. Ramos Becerra1, S. Gutiérrez Ureña2, S. Cerpa Cruz1, 1Rheumatology Service; 2Hospital Civil Francisco Alcántara Alcalde; 3Mechanical Vascular Service; 4CUCS, Guadalajara, Jalisco, Mexico

Background: Systemic sclerosis is an autoimmune disease characterized by microvascular damage and fibrosis. There are several studies that shown microvascular damage with arterial stiffness (AS) and the risk of cardiovascular complications. Carotid-femoral pulse wave velocity (CF-PWV) and augmentation index (AIx) are two competent methods to determine AS and predictors of macrovascular damage with arterial stiffness (AS) and the risk of cardiovascular complications. Carotid-femoral pulse wave velocity (CF-PWV) and augmentation index (AIx) are two competent methods to determine AS and predictors of macrovascular damage. Carotid-femoral pulse wave velocity (CF-PWV) and augmentation index (AIx) are two competent methods to determine AS and predictors of macrovascular damage. Carotid-femoral pulse wave velocity (CF-PWV) and augmentation index (AIx) are two competent methods to determine AS and predictors of macrovascular damage.

Objectives: To determine the frequency of arterial stiffness in patients with systemic sclerosis and its association with clinical manifestations.

Methods: We performed a cross-sectional study; patients with diagnosis of systemic sclerosis according to ACR/EULAR 2013 criteria were included and the control group was selected from a database of mechanical vascular service. AS
TTHICKNESS OF THE INTIMA-MEDIA COMPLEX AND DOPPLER FINGERPRINT ABNORMALITIES IN SYSTEMIC SCLEROSIS:

Objectives: The aim of the study was to determine if there is any difference in the intima-media complex thickness as well as in blood flow parameters measured using Doppler ultrasound examination in scleroderma patients and the general population.

Methods: 215 patients, aged 19–75, with diagnosed systemic scleroderma were examined using a Doppler ultrasound examination. Thickness of intima-media complex (IMT) approximately 2 centimeters from the carotid bulb was assessed for both right and left common carotid artery (CCA). The standard parameters of blood flow were measured – including peak systolic velocity (PSV), end diastolic velocity (EDV), as well as resistive index (RI), pulsatile index (PI) and standard deviation (SD) was measured in the common carotid arteries, internal carotid arteries (ICA) as well as in the vertebral arteries (VA).

Results: The mean IMT value in CCA was approximately 0.68 mm (0.35–0.9 mm).

Conclusion: A positive correlation between the age of examined subjects and the IMT was found (p<0.002; R=0.49). Additionally, a negative correlation between the IMT and the EDV was found (p=0.058; R=0.44).

AB0643 MALIGNANCY SCREENING IN AUTOIMMUNE MYOSITIS AMONGST AUSTRALIAN RHEUMATOLOGISTS

K. Dutton 1, M. Soden 2, R. Rheumatology, RBWH, Brisbane; 2 R. Rheumatology, Townsville Hospital, Douglas, Australia

Background: The association between cancer and autoimmune myositis is well established and has led to the common practice of malignancy screening in asymptomatic individuals. The international literature advocates widely for cancer screening in autoimmune myositis however no consensus or guideline has been published to set forth a process for screening standardisation.

Objectives: To explore the current trends in malignancy screening in autoimmune myositis amongst Australian Rheumatologists using an online questionnaire.

Methods: Research approval was granted by The Townsville Hospital. An invitation containing the survey link was sent twice to 386 Australian Rheumatologists between August 2015 and August 2016. Voluntary participation and anonymity were guaranteed. The questionnaire contained a fixed set of multiple choice questions that requested data on respondent demographics, practice setting and screening preference, practice and concerns. Open entry comments allowed an option to provide any other questions.

Results: 58 respondents (N=58) were in private (67%) and/or public practice (33%). The majority (72%) performed cancer screening independent of patient characteristics. Determinants that triggered screening (in descending order of popularity) were: tobacco use (N=11), history of cancer (N=10), age ≥ 40 (N=7), cancer family history (N=7), age ≥ 50 (N=3) and age ≥ 60 (N=1). The majority (N=57) indicated that cancer screening was problematic due to a lack of clinical practice consensus & guideline (77%), test selection knowledge (37%) and knowledge regarding appropriate frequency of screening (53%). The potential for harm in conducting screening was identified to be a problem by most respondents (62%).

Conclusions: The practice of malignancy screening in autoimmune myositis amongst Australian Rheumatologists is highly variable. Practice is driven by patient factors and clinician preferences. The cancer screening process is felt on several fronts to have inherent problems. Guideline, consensus and further research is needed in this area to address the challenges and evidence gap.

AB0644 FINGERPRINT ABNORMALITIES IN SYSTEMIC SCLEROSIS: A SINGLE CENTER SURVEY FROM INDIA

K. Chanchaya, P.K. Devarasetti, R.V.P. Irapati, L. Rajasekar. Rheumatology, Nizams institute of medical sciences, Hyderabad, India

Background: Fingerprint [FP] abnormalities are known in patients with Systemic Sclerosis [SSc]. Little has been described about their frequency, systemic associations and social impact in literature.

Objectives: To study the fingerprint abnormalities in Systemic Sclerosis patients.

Methods: Raynaud’s phenomenon [RP] was taken as the inclusion criteria. Patients with SSc [limited LcSSc and diffuse DcSSc], SSc overlap with other Connective Tissue Diseases [CTDs] and other CTDs with RP were screened for FP abnormalities using a Standardization Testing and Quality Certification (STQC) approved and certified fingerprint scanner. FP quality assessments were done by recording The National Institute of Standards and Technology [NIST] fingerprint image quality [NFIQ] scores1. NFIQ’s 5 levels of quality are intended to be predictive of fingerprint matching. NFIQ<1 indicates high quality samples and NFIQ>5 indicates poor quality samples. Other associated systemic features of
the disease were noted. Also the social difficulties due to fingerprint abnormalities were noted. Healthy controls with no RP were included for comparison.

Results: 40 consecutive patients with RP attending Rheumatology outpatient services of our institute were screened for FP abnormalities. 29 with SSc [20- DsSSc, 9-LcSSc], 8 with overlap syndromes and 1 each of SLE, Unilateral Diffuse Vasculitis and Undifferentiated Connective Tissue Disease. It was noted prior to screening that 15 patients experienced some difficulty in the past with biometric recognition of their FPs at various times. On screening with biometric scanner, 15 of 40 [37.5%] had FP abnormalities in the form of non recognition of at least one finger with a median of 2 [range 1–6 fingers]. Of these 15, seven had DsSc, six had LcSSc and two had overlap syndromes. The mean NFIQ score of these 15 patients was 4.5 [poor] and the mean NFIQ scores in SSc was 3.8. Eleven [27.5%] patients could not get government identity cards based of FP scanning, four could not avail various government benefit schemes which needed their fingerprints as identity. Sixteen [40%] had history of digital vasculopathy in the form of livedo, digital ischemia or ulcers. PAH was found in one and eight had interstitial lung disease. Among the 10 controls all FPs were recognized and the mean NFIQ score was 2.2 indicating a better quality of FPs.

Conclusions: Fingerprint abnormalities occur frequently in patients with systemic sclerosis causing social disabilities in few. The quality of FPs in SSc patients is poor. Raynaud's phenomenon and vasculopathy are frequently associated. Documentation of this abnormality should allow the use of other biometric tools for personal identification.

AB0645 LYMPHOCYTE SUBSETS T, B AND NK CELLS IN SYSTEMIC SCLEROSIS
L. Schneider 1, V. Hax 1, N. Marcondes 1, R.M. Xavier 2, R. Chakr 1, 2
1Rheumatology, 2Rheumatology, HCPA, Porto Alegre, Brazil

Background: Systemic sclerosis (SSc) is a rare multisystem disease with underlying immune mechanisms, whose pathogenesis remains unclear. Few previous reports have evaluated lymphocyte subpopulations in SSc and your results are conflicting.

Objectives: The present study aimed to analyze the lymphocyte subsets in SSc patients in comparison to healthy individuals.

Methods: Peripheral blood (PB) samples to analyze lymphocyte subsets were obtained from a non-random convenience sample of 20 SSc patients. Twenty healthy individuals recruited from the blood bank were used as sex and age-matched controls. Blood samples were analyzed by flow cytometry for total T cells, CD4+ and CD8+ T cells subsets, CD19+ B cells and total NK cells. Statistical analyses were performed using the IBM Statistical Package for Social Sciences (SPSS 18.0). Data are expressed as mean ± SD and median and range. Non-parametric Mann–Whitney U test was used for analyses of the flow cytometry. A probability p<0.05 was considered statistically significant.

Results: The mean (SD) age of SSc patients was 57.9 (14.2) years; 95% were female and 31.6% presented diffuse cutaneous SSc (dcSSc). Patients presented Raynaud’s phenomenon and vasculopathy are frequently associated. Documentation of this abnormality should allow the use of other biometric tools for personal identification.

Conclusions: Fingerprint abnormalities occur frequently in patients with systemic sclerosis causing social disabilities in few. The quality of FPs in SSc patients is poor. Raynaud's phenomenon and vasculopathy are frequently associated. Documentation of this abnormality should allow the use of other biometric tools for personal identification.

References:

Conclusions: Our data support previous reports indicating that depletion of lymphocyte in the PB of SSc patients. However, we found no significant difference in relation to lymphocyte subtypes, which differs from the literature data.

AB0646 DETERMINANTS OF QUALITY OF LIFE IN SYSTEMIC SCLEROSIS AND PATIENT’S PERCEPTION OF THEIR ILLNESS
L. Groseanu 1, 2, A. Balanescu 1, 2, D. Predeteanu 1, 2, D. Opris-Belinski 1, 2, V. Bojinca 1, 2, I. Saulescu 1, 2, A. Borangiu 1, 2, D. Mazilu 1, 2, C. Constantinescu 1, 2, F. Berghera 1, 2, R. Ionescu 1, 2 .1, 2Internal Medicine and Rheumatology, St Maria Clinical Hospital; 2Department 5- Internal Medicine, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania

Background: Systemic sclerosis (SSc) is a chronic multi-system autoimmune disease associated with disability and reduced quality of life. Objectives: The purpose of this study was to assess health-related quality of life and disease perception in a group of SSc patients.

Methods: We performed a case-control study on 50 SSc patients from EUSTAR cohort 2016. Socio-demographic data, disease characteristics and self-assessment questionnaires: Health assessment questionnaire (HAQ), EuroQol-5D (EQ5D) and the Brief Illness Perception Questionnaire were collected.

Results: The group included 41 females, 31 limited SSc subsets. None of the mean EQ-5D value was 0.66. Baseline HAQ score was 0.02. synovitis (p<0.02), late capillaroscopic pattern (p<0.03), muscle weakness (p<0.01), gastrointestinal involvement (p<0.01) and those on immunosuppressants (p<0.02) have a poor quality life. According to EQ-5D, the quality of life was related to specific organ involvement. 48% of the patients had some mobility problems, 8% were confined to bed; mobility was influenced by lung involvement (p=0.008), digital ulcers (p<0.03) and Medsger score (p<0.01). 48% of the patients had some self-care problems and 8% were not able to wash/dry themselves; self-care was influenced by the Rodnan score (p<0.02), diffuse subset (p<0.02), muscle weakness (p<0.03) and gastrointestinal involvement (p<0.02). 64% of the patients do not feel they have a good control on their disease, 6.3 (3.3/10) and unfortunately they do not think that the treatment is very helpful 7.9 (2.7)/10. The intensity of the symptoms is quite severe 7.5 (2.7)/10, related to digital ulcers (p<0.04) and gastrointestinal involvement (p<0.02). Patients are very concerned about their disease 9.1 (2.3)/10, most of them feel emotionally affected 7.6 (2.6). Conclusions: This study confirms the presence and magnitude of impaired quality of life in patients with SSc with impact on mobility, self-care, usual activities. The major determinants were the extend of skin involvement, muscularoarticular, gas- trointestinal involvement and arthritis. Often patients are anxious/depressed, had a high pain intensity and the perception of this illness is pessimistic.

AB0647 DIAGNOSIS OF SYSTEMIC SCLEROSIS – “A TANGLED STORY”
L. Groseanu 1, 2, A. Dima 1, T. Gudu 1, A. Balanescu 1, 2, D. Predeteanu 1, 2, D. Opris-Belinski 1, 2, V. Bojinca 1, 2, I. Saulescu 1, 2, A. Borangiu 1, 2, D. Mazilu 1, 2, C. Boimbuc 1, 2, M. Abobuliu 1, 2, R. Ionescu 1, 2 .1, 2Internal Medicine and Rheumatology, St Maria Clinical Hospital; 2Department 5- Internal Medicine, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania

Background: Proper diagnosis of scleroderma is often long and difficult, since it is a rare disease, and one which few doctors or patients are familiar with. Objectives: To establish the interval between the symptoms’ onset of systemic sclerosis and the final diagnosis of a rheumatologist Methods: This is a cross-sectional study that included randomly selected patients with diagnosis of SSc which were evaluated based on a questionnaire about symptoms at onset, specific consuls and investigations. Descriptive statistics were used.

Results: The study group included 47 patients, of which only 5 were males and 17 from rural areas. The medium age was 53 (14.4) years.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.4178
DISEASE-RELATED AUTOANTIBODY PROFILE IN SYSTEMIC SCLEROSIS IN GREECE

C. Liaskos 1, E. Marou 1, T. Simopoulou 1, M. Barmakoudi 1, G. Efthymiou 1, T. Scheper 1, W. Meyer 1, D.P. Bogdanos 1, L. Sakkas 1, 2, Rheumatology and Clinical Immunology, University of Thessaly, School of Health Sciences, Larissa, Greece; 3Institute of Immunology, Euroimmun AG, Lubeck, Germany

Background: Anti-Topo I abs were strongly associated with dcSSc, interstitial lung disease (ILD) and pulmonary hypertension.

Methods: Twenty two patients with primary Raynaud phenomenon and 113 SSc patients were positive against 13 SSc-related antigens. Twenty two patients with SSc. Excluding anti-Ro52, 113 (89.3%) SSc patients were positive with ILD.

Results: Anti-Topo I abs were strongly associated with dcSSc, interstitial lung disease (ILD) and pulmonary hypertension (PH): PSAP>25 mmHg by right heart catheterization; Interstitial Lung Disease (ILD): compatible HRCT or >70% predicted FVC or 40% predicted DLCO; Heart: ventricle dysfunction without PH or anterior hypertension, pericardial effusion; Digital ulcers and pitting scars; History of scleroderma renal crisis (RSC); calcinosis. Anti-Scl-70 was determined by ELISA and anti-Centromere (ACA) by RIPA.

Conclusions: The median duration from the first symptom until the correct diagnosis was 39.2 (74) months. The first investigations recommended were blood tests in almost all of the patients (95.7%), but only a third of them included specific scleroderma autoantibodies. The first capillaroscopy was performed as an initial diagnostic test in only 6 patients (12.8%). The mean interval from disease onset until the patient was referred to the first capillaroscopy was 13.5 (28.8) months, to specific autoantibodies was 40.17 (61.3) month, to echocardiography was 36.36 (54) months, to lung function tests and lung CT – 41.76 (65.8) months.

There were no significant statistical differences between patients coming from rural environment and those coming from urban environment. The only significant statistical difference between diffuse and limited subset was the time the patient was referred to echocardiography (19.8 (47.6) months for the diffuse subset, 66.8 (94.1) months for the limited subset, p=0.04).

Conclusions: Scleroderma is a less well-known disease. This lack of awareness contributes to delayed diagnosis and delayed onset of therapy. Often such diagnostic uncertainty and frustration takes a huge toll on the psychological well-being of these patients, who describe their journey to diagnosis as being one of the most difficult part of their illness. One of our missions as rheumatologist is to increase recognition of this disorder.

AB0649 SYSTEMIC SCLEROSIS IN ARGENTINA: EVALUATION OF A SINGLE CENTER COHORT AND COMPARISON WITH INTERNATIONAL SERIES

M. Garcia Carrasco 1, L.O. Roa Perez 1,2, R. Gomez 1,2, S. Leal 1,2, F. Paniego 1, N. Perez 1, G.G. Nasswetter 1, D. Diana 1, 2, Rheumatology Division; 2Hospital de Clínicas José de San Martín, Buenos Aires, Argentina

Background: Systemic sclerosis (SS) is an autoimmune disease with generalized vascular dysfunction and a myriad of clinical and laboratory manifestations. Spreading of thickening of the skin, serological characteristics and the pattern of compromise of the internal organs help to classify them as diffuse scleroderma, localized scleroderma and systemic sinus scleroderma. Reports of Latin American cohorts published to date are scarce.

Objectives: To describe the clinical and serological data for a single center cohort and to compare those with national and international cohorts.

Methods: Descriptive, observational, cross-sectional study. We analyzed our SS database. Patients were evaluated since 01/15 to 05/2016 and fulfilled SS classification criteria (ACR 1980/ACR-EULAR 2013). Patients were classified according to Le Roy criteria in Limited Systemic Sclerosis (ISS), Diffuse Scleroderma (dSS), Systemic Sclerosis sine scleroderma (SSnS) and pre-systemic sclerosis (pSS). Organic compromise was defined as follows: Gastrointestinal (GI): esophageal dysmotility by manometry or esophagitis by endoscopy; Lungs: Pulmonary hypertension (PH): PSAP>25 mmHg by right heart catheterization; Interstitial Lung Disease (ILD): compatible HRCT or >70% predicted FVC or 40% predicted DLCO; Heart: ventricle dysfunction without PH or anterior hypertension, pericardial effusion; Digital ulcers and pitting scars; History of scleroderma renal crisis (RSC); calcinosis. Anti-Scl-70 was determined by ELISA and anti-Centromere (ACA) by RIPA.

Results: 123 patients were included: 74% with ISS, 24% dSS and 2% SSnS; age at diagnosis (years): 49.7 (18–79; DS: 12.27) and 48.7 (27–79; DS: 13.01) in ISS and dSS respectively. Raynaud’s phenomenon previous to diagnosis (years): 7.7 (0–54 DS: 12.81) in ISS and 4.03 (0–22; DS: 5.5) in dSS. 49.5% ISS were ACA positive vs 17% in dSS as well also 41.4% had Scl-70 positive (p<0.05). Lung:58.6% of dSS presented ILD and 3.4% RSC, according to published reports. No statistically significant differences were found between the presence of calcinosis, digital tip ulcers or PH between ISS and dSS. ISS: GI was studied in only 39/123 patients with 84.6% affected among those.

Conclusions: Our data showed similar results to the local and european cohorts. We found fewer calcinosis and digital tip ulcers in both ISS and dSS than international cohorts. A lower prevalence of PH was reported in ISS respect to other series, and it might be atributed to the method wich it was measured. (right heart catheterism).

AB0650 ANTI-TOPOISOMERASE POSITIVE SYSTEMIC SCLEROSIS PROGNOSIS INFIAUT?

Rheumatology, LUMC, Leiden, Netherlands

Background: Anti-topoisomerase antibodies (ATA) in systemic scleroderma (SSc) have been associated with poorer prognosis including diffuse skin involvement, pulmonary fibrosis, cardiac involvement and increased mortality. However, 30–60% of ATA-positive SSc patients demonstrate limited skin involvement and some have only mild disease course. In SSc, optimal risk stratification is of utmost importance for tailored clinical care management at the patient level.

Objectives: We aimed to determine the prevalence of mild disease among ATA positive patients and to investigate which readily available clinical parameters best identify patients with highest disease severity.

Methods: Clinical baseline data from SSc patients included in the Combined Care In Systemic Sclerosis (CCIS) cohort of the Leiden University Medical Center were collected. Patients fulfilling ACR 2013 criteria and ATA positive were included. Descriptive statistics were used to summarize sociodemographic, clinical and serological features. Patients with grade 3 or 4 disease on any of the Medsger severity subscales were considered to be severely diseased. We compared presence of diffuse cutaneous involvement, Raynaud’s, pitting scars, calcinosis, proximal muscle weakness, >10% weight loss, interstitial lung disease and pro-BNP between the severity groups and corrected for confounding by disease duration (time since non-Raynaud) by stratifying into quartiles.
Results: Of 422 SSc patients in the database, 344 patients had SSc meeting ACR criteria. 89 patients were exclusively ATA-positive, of which n=42 with mild disease and n=47 with severe disease. Patients with severe disease appeared to be younger (mean age 50 vs 55 yr), more often non-caucasian (51 vs 12%), with a longer time since non-Raynaud (median 4 vs 2 yr) and more often diffuse skin involvement (dSSc, 65% vs 41%), calcinosis (6 vs 0%) and weight loss (23 vs 7%). Stratification by disease duration, however revealed there are no real differences between mild and severe disease. Overall 47% of ATA+ patients in our cohort presented with mild SSc. When stratifying patients according to time of non-Raynaud, 55% of ATA+ patients presented with mild disease in the first disease duration quartile (median follow-up 12,7 years, range 8.2–44.1) the percentage with mild disease was still 27% (Figure 1).

Conclusions: In our cohort, 47% of ATA-positive patients presented with mild systemic sclerosis, which could not be explained by disease duration. This suggests that solely the presence of ATA is of limited clinical relevance. Readily available sociodemographic and clinical parameters including type of skin involvement seem to have only limited value in identifying ATA patients with more severe SSc. More complex serological findings as antibody titers and fine-specificity of ATA should be defined for optimal serological subsetting.

AB0651 THE EFFECT OF CYCLOPHOSPHAMIDE ON PULMONARY FUNCTION AND DEPENDENCE ON DISEASE ACTIVITY OF INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS

M. Vonk 1, W. van den Hombergh 1, H. Knaapen 1, S. Simons 2, J. Fransen 1, F. van den Hoogen 1. 1. Department of Pulmonology, Radboud University Nijmegen, Nijmegen, Netherlands

Background: The pathogenesis of interstitial lung disease associated with systemic sclerosis (SSc-ILD) is not completely elucidated, although it is believed that chronic alveolar inflammation leads to increasing fibrosis. Treatment strategies using cyclophosphamide (CYC) have been focusing on the inflammatory pathway of SSc-ILD. We hypothesized that CYC is more effective in the early phase of SSc-ILD.

Objectives: To assess the occurrence of organ involvement and death in a large, unselected cohort of Dutch SSc patients at the moment of diagnosis and during 5 years of follow-up, stratified by disease subtype and auto-antibodies.

Methods: Up to 2015, 690 SSc patients were included in the Nijmegen SSc cohort. Occurrence of interstitial lung disease (ILD), pulmonary arterial hypertension (PAH), cardiac involvement (CI), scleroderma renal crisis (SRC) and occurrence of death were determined using survival analysis, stratified by disease subtype (limited cutaneous SSc and diffuse cutaneous SSc) and auto-antibodies (ACA, ATA, anti-RNP).

Results: Organ involvement was already present at SSc diagnosis in 32% of patients. In 25%, organ involvement developed during follow-up, mostly ILD (22%). Significant differences between lcSSc and dcSSc were found in CI at baseline and ILD, PAH and SRC during follow-up. Between the autoantibody subgroups, the occurrence of ILD, PAH and SRC at baseline and ILD during follow-up differed. There were no differences in survival between subtypes and auto-antibodies. The overall 5-year survival rate was 89%. Patients without organ involvement at SSc diagnosis had a better 5-year survival rate than patients with organ involvement at SSc diagnosis: 95% versus 73% respectively (p<0.001). (figure 1)

Conclusions: In many SSc patients, organ involvement is already present at diagnosis or develops in the first 5 years after diagnosis. Survival is significantly worse in patients who already have involvement at the moment of SSc diagnosis.

AB0653 EFFICACY OF AN INTENSIVE 24-WEEK PHYSIOTHERAPY PROGRAMME IN MYOSITIS PATIENTS - PRELIMINARY DATA FROM A SINGLE-CENTER CONTROLLED STUDY

M. Spiritovic 1, 2, 3, 4, O. Sorensa 1, H. Starkonova 1, P. Cesak 1, A. Rathouska 1, K. Kubinova 1, M. Klein 1, L. Vernerova 1, O. Ruzickova 1, R. Becvar 1, H. Mann 1, I. Pavelka 1, L. Senott 1, J. Vencovsky 1, M. Tomcik 1. 1. Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology, 2. Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

Background: Involvement of musculoskeletal system (inflammation, atrophy and permanent damage to the muscle) in idiopathic inflammatory myopathies (IIM) leads to impaired function and reduced muscle strength, endurance, aerobic capacity and decreased quality of life. Data on efficacy of non-pharmacologic care in IIM is very limited due to rarity, is not studied in sufficient detail.

Objectives: To address the limitations of existing studies, and evaluate the effect of a controlled, long-term (24-week intervention, 24-week follow-up), intensive (1h physiotherapy twice weekly, and home-exercise for 1h 5x weekly), tailored physiotherapy program to improve muscle strength, endurance and deep stabilizer system, and quality of life/disability in cohorts with a substantial number of IIM patients.

Methods: All patients fulfilled the Bohan and Peter 1975 diagnostic criteria for dermatomyositis (DM) or polymyositis (PM), had skeletal muscle involvement, and were consecutively recruited from 2014 to 2016 at the Institute of Rheumatology in Prague. Both groups received educational materials and instructions for home exercise at baseline, however, only intervention group underwent the intensive physiotherapy programme. At months 0,3,6,12 all patients were assessed by a physician [physical examination, Myositis intention to treat index (MITAX), Myositis disease activity assay, visual analogue scale (MVACT), and Myositis damage index (MDI)], and a physiotherapist blinded to intervention [standardized tests evaluating the level of muscle strength [Manual muscle test-8 (MMT-8)], and endurance [Functional index-2 (FI-2)], patients filled out patient reported outcomes (PROM/questionnaires [HAQ, SF-36, Beck’s depression inventory-II].
AN ULTRASOUND ASSESSMENT OF THE HAND AND WRIST IN EGYPTIAN PATIENTS WITH SYSTEMIC SCLEROSIS

M. Hassanien, S. Rashad, A. Aljohee. Rheumatology Department, assuit, Egypt

Background: Systemic sclerosis (SSc, scleroderma) is a systemic disease characterized by fibrosis, progressive vascular obliteration and the production of autoantibodies. Ultrasound (US) imaging has advantages of simplicity, low cost, non-invasiveness, real-time capability and portability compared with traditional EDX. US imaging also offers high temporal and spatial resolutions, and can potentially provide diagnostic, anatomical information regarding local structures and kinesiology, few studies evaluate joint and tendons involvement in SSC by US study.

Methods: Randomly selected 50 Egyptian SSC patients were enrolled in the study in outpatient clinic Rheumatology department, Assuit university hospital. Consecutive patients were assessed by US evaluation (Sonostar Scale and Power doppler PD) of the tendons and joints of hands and wrists, were performed bilaterally on both dorsal and palmar sides. Joint assessment was performed on all MCP and PIP joints as well as the wrist and tendon assessment included finger flexors and extensors, wrist extensors and flexors. The Scoring for synovitis was based on the EULAR/OMERACT scoring system.

Results: Within the cohort, 100% of the patients were female; mean age and range disease duration were 40.93±11.71 (20–61) years and 8.13±5.56 (0.5–25)years, respectively. Modified Rodnan Skin Score mean and range were 40.93±11.71 (20–61) years and 8.13±5.56 (0.5–25)years, respectively. Modified Rodnan Skin Score mean and range were 23.17±9.14 (13–43), 22 patients were diffuse type (44%) and 28 patients were limited type (56%), 67% had inflammatory arthritis as reported by patients. US examination revealed abnormalities in 76% of all cases. Synovitis was present in 74% of patients (22% wrist; 15% MCP/PIP, 63% both); with a grade 2 and 3 synovitis in 29% of cases. The grade 2 or 3 synovitis was associated with a higher age (p<0.05) and disease duration (p<0.03) but not with inflammatory markers (CRP, ESR) and C3 nor with anti-CCP antibodies.

Furthermore, patients with US proven grade 2 or 3 synovitis had interstitial lung disease involvement (ILD) (74%) and elevated systolic pulmonary artery pressure (>35 mmHg in 46%). Grade 1 synovitis did not correlate with tenderness or joint swelling. Synovitis using PD abnormalities were present in 20% patients, but only a 25% had concomitant clinical synovitis. Bone erosions (≥1mm) were observed in 15%, which located at the second and third MC heads and at the styloid processes of the ulna. The presence of bone erosions was associated with the presence of grade 2 or 3 synovitis. US identified tenosynovitis in 40% of patients, involving the wrist extensors in the vast majority of cases (70%), especially of the 2nd extensor compartment.

Conclusions: US examination detects significant synovitis of the hand and wrist in the absence of clinical findings, and reveals structural damage in a number of patients. The grade 2 or 3 synovitis was associated with a higher age, and ILD involvement. Tendon involvement is frequent with specific pattern of wrist extensors. Thus, US seems to be a valuable tool to identify subclinical joint manifestations in Egyptian SSC patients.

NAILFOLD VIDEOCAPILLAROSCOPY FEATURES OF PATIENTS WITH ANTISYNTHETASE SYNDROME

M. Sebastiani, V. Codullo, A. Manfredi, A. Selva O'Callaghan, F. Furini, A. Iuliano, A. Schwarting, L. Cavagna, K. Triantafyllis. On behalf of NASCAR Study Group. 1Polichinico di Modena, University of Modena and Reggio Emilia, Modena; 2University of Pavia, Pavia, Italy; 3University Autonoma de Barcelona, Barcelona, Spain; 4University of Ferrara, Ferrara; 5Azienda Ospedaliera San Camillo-Portioli, Rome, Italy; 6University of Mainz, Mainz; 7AUCRA Rheumatology Clinics, Bad Kreuznach, Germany

Background: Antisynthetase syndrome (ASSD) is an autoimmune disease characterized by the clinical triad arthritis, myositis, and interstitial lung disease (ILD). As in inflammatory myopathies, nailfold videocapillaroscopy (NVC) alterations have been sporadically described also in ASSD patients, but no elucidating data are available.

Methods: Within the framework of a multicenter study, we retrospectively analyzed NVC images of ASSD patients, after excluding patients with overlap syndrome with systemic sclerosis. Two operators in a blind manner re-evaluated all the cut-off points with the greatest positive likelihood ratio (12.52) for the presence of SSC-ILD.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.6828
patients with at least one image per finger. For each patient, we examined number of capillaries (mean number of capillaries per mm in the distal row), enlarged and giant capillaries, micro-hemorrhages, avascular areas, ramified capillaries, and the presence of a scleroderma (SSc)-like pattern. In particular, eight patients were observed in 53.6% of ASSD patients. Nineteen patients (35.2%) showed a SSc-like pattern; the main features were disarrangement of hairpin and angiogenetic aspects (42.6%), avascular areas (39.8%), giant capillaries (27.6%), and microhemorrhages (20.4%). Finally, the mean number of capillaries was reduced (7.8±2/mm). No significant association was recorded between SSc-like pattern and the presence of arthritis, myositis, and ILD, nor with RP. Among other NVC features, angiogenetic was significantly associated to female gender (p=0.031), while microhemorrhages were inversely associated to the presence of arthritis (0.033). No association was observed between NVC features and autoantibodies profile. Of interest, in 56% of patients with IJD we observed at least a NVC alteration vs no patients without IJD (p=0.04). Finally, in patients with RP NVC alterations were recorded in 15/28 patients (53.6%) and a SSc-like pattern in 11/28 (39.3%), while only 57.9% of patients with SSc-like pattern had clinically manifest Raynaud’s phenomenon.

**Conclusions:** Despite the brevity, the present is the first study concerning NVC in ASSD patients. Regardless of the presence of Raynaud’s phenomenon, NVC alterations are frequently observed; in particular, a SSc-like pattern is recorded in more than 1/3 of patients. NVC should be performed in all ASSD patients at diagnosis regardless of the presence of RP in the patient history and duration of ASSD syndrome. ASSD should be always considered in the screening of RP. A prospective multicenter study has been planned to identify specific patterns and possible associations between NVC findings and clinical and serological features of ASSD.

### AB0657 SMALL INTESTINAL BACTERIAL OVERGROWTH IN RELATION TO GASTROINTESTINAL SYMPTOMS IN SYSTEMIC SCLEROSIS

**M.D.P. Cruz-Domínguez**, **G. García-Colloín**, **E. Madrigal-Santillán**, **A. Carranza-Muleño**, **L.J. Lara**, **D.H. Montes-Cortés**, **G. Medina-García**, **O. Vela-Lasstra**. **1Research Division; Instituto Mexicano del Seguro Social, Hospital de Especialidades CMN la Raza; 2Postgraduate, IPN, ESM; 3Research and Education Direction, Instituto Mexicano del Seguro Social, Hospital de Especialidades CMN la Raza; 4Emergency Room, Hospital General CMN la Raza; 5Internal Medicine, Instituto Mexicano del Seguro Social, Hospital de Especialidades CMN la Raza, Mexico City, Mexico**

**Background:** Autonomic dysfunction, smooth muscle fibrosis and vascular damage lead to small intestinal bacterial overgrowth (SIBO) in Systemic Sclerosis (SSc). SIBO is characterized by diarrhea, abdominal pain, bloating, malabsorption and malnutrition.

**Objectives:** To evaluate NIH PROMIS® gastrointestinal symptoms scales and SIBO by hydrogen breath test (HBT) in patients with SSc.

**Methods:** We include 68 patients with SSc (ACR-EULAR 2015) who signed informed consent. NIH PROMIS® questionnaires was applied to evaluate gastrointestinal symptoms and classified in not symptomatic, light, moderate and most symptomatic. Glucose HBT was applied after 14 hours fast, oral hygiene and 24 hours free of antibiotics. Patients who have a negative HBT with symptoms associated to glucose ingestion we repeat test with lactulose.

**Results:** We applied questionnaire to 58 SSc patients, age 52 (±75) years, 65 (98%) female and 3 (4%) males, disease duration 13 (1–40) years, limited SSC 41 (59%) and diffuse SSC 24 (38%). They are using prednisone (28%), micofenolate (14%), methotrexate (19%), azathioprin (5%), amldopine or nifedipine (33%). Patients had continuous and very high increase of parts per million (ppm) of exhaled Hydrogen: min0: 13 ppm (5–21), min15: 17 ppm (5–43), min30:17 (3–49), min45:18ppm (7–103), min 60:22ppm (5–145), min90:19ppm (2–250), min120:25ppm (3–212), males/females (ppm (3–253). Normal values: <10 ppm during total test (Figure1). Frequency of gastrointestinal symptoms were flatulence (7.5±9±12%), nausea/vomiting (72.7±37.6%), constipation (65.6±40%), diarrhea (45.2±33.4%), abdominal pain (%) and constipation (39.4±3.1%) respectively between SCB (+) positive and negative. Hyperproduction of hydrogen in breath had a direct correlation to severity of their symptoms (p<0.05). The severity of diarrhea was in close relation to the severity of its rectal incontinence (r=0.73,p<0.001), and greater abdominal pain with flatulence (r=0.72,p<0.001).

**Conclusions:** Gastrointestinal symptoms are common in SSc regardless of whether they have SIBO. However, a higher Row Score SGI or moderate severe status (NIH PROMIS) correlates with high H scores from the 30th minute, therefore, the questionnaire is useful within the SSC assessment.
**Conclusions:** Time to diagnosis from onset of RF is significantly shorter in diffuse SSc. Although mRSS is typically higher in diffuse SSc, no correlation has been found between mRSS and time to diagnosis. Therefore, duration of diagnosis may be affected by other organ involvement and other complications rather than skin changes due to lack of awareness of physicians about SSc related early skin changes. Referral to a proper physician by a familiar healthcare practitioner decreased the number of physicians attending till the diagnosis, although it did not affect the time to diagnosis.

### AB0659

**ASSOCIATION BETWEEN -12518A/G GENE POLYMORPHISM ENCODING MONOCYTE CHEMOTACTANT PROTEIN 1 (MCP-1) AND SERUM LEVEL OF C-REACTIVE PROTEIN IN DIFFERENT CLINICAL AND SEROLOGICAL PHENOTYPES OF SYSTEMIC SCLEROSIS IN THE RUSSIAN COHORT OF PATIENTS**

**Research Institute of Rheumatology, Moscow, Russian Federation**

**Background:** Immune system activation with associated up-regulation in the production of extra-cellular matrix proteins by fibroblasts are known specific features in the pathogenesis of systemic scleroderma (SSc). Most recent data indicate that MCP-1 and MCP-3 chemokines from the family of monocyte chemotactic proteins are also involved into SSc pathogenetic process. C-reactive protein (CRP) is known as the marker of acute-phase inflammation. The association between increased CRP levels and SSc clinical and serological parameters has been reported recently.

**Objectives:** To study the association between -2518 A/G gene polymorphism encoding MCP-1, and CRP levels in different clinical SSc phenotypes in the Russian cohort of pts.

**Methods:** PCR-RFLP method was used to identify MCP-1 genotype in 81 SSc pts aged 49±12.6 years, with mean SSc duration 11±5.0 years. CRP concentrations were measured with highly sensitive immunoturbidimetry method.

**Results:** CRP levels were correlated with MCP-1 genotypes in pts with limited (cSSc) and diffuse (dSSc) phenotypes, with interstitial lung disease (ILD+), with SSc duration >3 years, with increased CRP level (>5 mg/L), with positive antibody titers to DNA topoisomerase I (ATA+) and antibody to centromeres (ACA+). A total cohort analysis showed that carriers of -2518AA genotype had higher mean CRP level versus G allele carriers (12.6±7.5 mg/L vs 5.5±4.4 mg/L, respectively, p=0.040). In pts with -2518AA genotype and SSc duration >3 years mean CRP level was significantly higher than in G allele carriers (11±1.67 mg/L vs 4.5±4.4 mg/L, respectively, p=0.025). In (ILD+) and (ATA+) subgroup pts with -2518AAAA genotype demonstrated higher mean CRP levels as compared to G allele carriers (12.4±15.6 mg/L vs 5.5±4.1 mg/L, respectively, p=0.018; and 17.6±20.9 mg/L vs 5.5±5.5 mg/L, respectively, p=0.010). CRP levels (>5 mg/L) were found in 31 (38%) pts and were significantly different between AA genotype carriers and G allele carriers (27.4±19.2 mg/L vs 10.4±3.8 mg/L, respectively, p=0.003). No associations between genetic variations in the MCP-1 gene and CRP levels in lcSSc phenotype, SSc duration <3 years, CRP levels ≤5mg/L and (ACA+) pts were established.

**Conclusions:** Our data demonstrate that -2518A/G MCP-1 gene polymorphism is closely associated with CRP levels, thus, it can be considered as a new marker, reflecting the severity of the disease and unfavorable SSc prognosis.

### AB0660

**CHARACTERISTICS OF AL-I LIGHT-CHAIN AND AMYLOID A DEPOSITION IN PROGRESSIVE SYSTEMIC SCLEROSIS – A COMPARATIVE POSTMORTEM CLINICOPATHOLOGIC STUDY OF 12 PATIENTS**

M. Bély 1, A. Apáthy 2, 1Department of Pathology, Policlinic of the Order of the Brothers of Saint John of God; 2Department of Rheumatology, St. Margaret Clinic Budapest, Budapest, Hungary

**Background:** Different types of amyloid deposits may be present in systemic sclerosis (SSc), as consequences (complications) of basic or associated diseases.

**Objectives:** The aim of this study was to determine the type, prevalence and extent of amyloid deposits on different tissue structures in various organs in SSc.

**Methods:** We studied histopathologically 12 SSc patients (females 11, average age: 54.82 years, range 66–32, onset of SSc: 48.86, average disease duration: 6.43 year, one male, age 65.0 years at death, onset of SSc and average disease duration not known, who died at the National Institute of Rheumatology. SSc was diagnosed clinically according to the criteria of the ACR [1]. In 1 (8.0% of 12) 67 year old female patient (onset of SSc: 66 years, disease duration: 1 year) SSc was accompanied by B-cell lymphoma and complicated by systemic AL-I light-chain amyloidosis. In 1 (8.0% of 12) 53 year old female patient (onset of SSc: 41 years, disease duration: 12 years) SSc was complicated by systemic amyloid A (AA) deposition.

**Amyloid deposits on different tissue structures [arteriole, small artery, medium size artery, venule, small vein, medium size vein, interstitial collagen fiber, reticulin fiber (collagen IV), and nerve] of 6 organs [heart, lungs, kidney, gastrointestinal tract, skin and brain] were determined histologically. The extent of amyloid deposition was evaluated by semi-quantitative, visual estimation on a 0 to 3 plus scale, based on the number of involved tissue structures per light microscopic field [2].

The prevalence and extent of amyloid-I light-chain and amyloid A deposits on different tissue structures were compared by Student (Welch) t-probe.

**Results:** The involvement of different tissue structures (prevalence in %) and the average extent of AL-I light-chain and amyloid A deposits (absolute value) are summarized in Table 1.

**Table 1.**

**Conclusions:** In SSc patients the prevalence and extent of I light-chain and amyloid A deposits on different tissue structures changed parallel.

The higher prevalence and extent of I light-chain deposits in contrast to amyloid A may be explained with qualitative differences of I light-chain and amyloid A; I light-chain seems to have greater affinity for tissues than amyloid A protein. Infiltration of the vessel walls – regarding the amount of I light-chain and amyloid A deposits in arterioles and arteries in contrast to the veins – showed a converse tendency in SSc patients with AL-I or AAa. This may be related to sluggish blood flow or stasis (backward congestion and accumulation of circulating precursors) in both diseases.

### AB0661

**ORAL HEALTH-RELATED QUALITY OF LIFE MEASURED WITH OHIP 49 HIGHLY CORRELATES WITH DISEASE ACTIVITY AND SEVERITY IN SYSTEMIC SCLEROSIS PATIENTS**

K. Parat1, M. Radič2, K. Boríc2, D. Perkovic2, D. Biočina Lukenda1, D. Martinović Kaštelević2, 1Department of Oral Medicine and Periodontology, Study of Dental Medicine, School of Medicine, University of Split; 2Division of Rheumatology and Clinical Immunology, Center of excellence for Systemic Sclerosis in Croatia, University Hospital Split, Split, Croatia

**Background:** Systemic sclerosis (SSc) is associated with decreased salivary production and interincisal distance, more missing teeth, and periodontal disease. Orofacial manifestations of SSc contribute greatly to overall disease burden and still are regularly overlooked and under-treated. Previous studies did not confirm correlation between disease severity and oral health-related quality of life in SSc patients.
**Objectives:** The aim of this study was to determine possible correlation of the SSC clinical parameters with oral health-related quality of life measured with the Oral Health Impact Profile 49 (OHIP 49).

**Methods:** Subjects were recruited from the Center of excellence for systemic sclerosis in Croatia cohort. Detailed dental by the same dentist and clinical examination was performed according to ACR EULAR criteria. The results between oral health-related quality of life and disease characteristics were examined. We evaluated the disease severity using clinical and laboratory parameters according to the Mediger Severity Scale. The level of SSC activity was evaluated according to the Vdiff activity score. Oral quality of life was measured using OHIP-49 and the relationship was evaluated by Spearman's rank coefficient. (p=0.016, r=0.4303, Spearman's rank coefficient).

**Results:** Forty-seven SSC patients (Male to female ratio 12 (25.5%) to 35 (74.5%) (Duration 47 SSc patients (Male to female ratio 12 (25.5%) to 35 (74.5%) (Duration 4 years) were consecutively enrolled for this study between January 2014 and December 2015. All patients fulfilled the ACR criteria for the diagnosis of SSC. The distinction between limited cutaneous SSC (lcSSC) and diffuse cutaneous SSC (dcSSC) was made according to the Leroy et al. (28 dcSSC, 3 lcSSC). OHIP 49 scores highly positively correlated with disease activity (p=0.005, r=0.4872, Spearman's rank coefficient) and severity (p=0.016, r=0.4303, Spearman's rank coefficient). Furthermore, oral health-related quality of life positively correlated with disease severity and activity (p=0.02, r=0.391 for skin, gastrointestinal and joint/tendon involvement, p=0.003, r=0.506 for general involvement, p=0.003, r=0.511, p=0.001, r=0.5207, Spearman's rank coefficient). Impaired quality of oral health positively correlated with the severity of general involvement, skin, gastrointestinal and joint/tendon involvement in SSC patients. Disease subset and autoantibodies profile could play a role in the oral manifestation of SSC. Better collaboration between rheumatologists and the dental team is required to improve access to dental care and oral health outcomes for SSC patients.

**Conclusion:** Contrary to previous studies to MRSS study disease severity and activity were related to OHIP 49 scores. Our data suggest that OHIP scores correlate with severity of general involvement, skin, gastrointestinal, and joint/tendon involvement in SSC patients. Disease subset and autoantibodies profile could play a role in the oral manifestation of SSC. Better collaboration between rheumatologists and the dental team is required to improve access to dental care and oral health outcomes for SSC patients.

**AB0663**

**SYSTEMIC SCLEROSIS (SSC) COHORT IN ABU DHABI: FOCUS ON DIGITAL ULCERS (DU)**

M. Al-Maini1, H. Al-Mashari1, T. Khan1, N. Abutaha1, R. Anejia1, A. Las Alas1, S. Gonugunta1, M. Cerinc2, K. Khawaja1. 1Adult and Pediatric Rheumatology, Allergy and Immunology, Al-Matraq Hospital, Abu Dhabi, United Arab Emirates; 2Rheumatology Unit, University of Florence, Florence, Italy.

**Background:** DU are a significant burden for SSC patients affecting approximately 40–50% of patients (1). No data are available on the frequency of DU on SSC patients living in the United Arab Emirates.

**Objectives:** To identify the frequency of DU in a cohort of SSC in Abu Dhabi which is the capital city of the United Arab Emirates (UAE).

**Methods:** SSC patients identified according to ACR EULAR criteria through the hospital electronic medical records system, which was implemented from January 2011 for medical documentation in all public hospitals in Abu-Dhabi and districts. Using the International statistical classification of diseases and related health problems, usually called by the short form name international classification of Diseases (ICD), version 9 (710.1) from 1st of January 2011 to 31st of December 2016. Retrospective review of electronic medical records and paper case notes was performed on patients who presented during this period. The frequency of DU was searched. DU were defined (1) and categorised (2) (no digital ulcers, early (rarely recurrent), frequent (rarely recurrent) and chronic (>1 DU every follow up). Results and the incidence of gangrene were compared to data from DUO registry (3).

**Results:** 47 SSC patients (Male to female ratio 12 (25.5%) to 35 (74.5%) (Duration of disease from 2 to 24 years with peak age for ulcers between 40–50 years) were identified. No ulcers were detected in 34 patients (72.3%) while DU were found in 13 patients (27.7%): they were episodic in 9 patients (19%) and chronic in 4 patients (8.5%) of the total patients. No recurrent ulcers were found. Only one patient (2%) evolved to gangrene (she was a smoker). The other 12 patients were evaluated at the end of the follow up and the third of them were under 16 years of age.

**Conclusions:** In Abu Dhabi SSC population, the incidence of DU is 27.7%. This differs from the incidence in the western literature where it peaks from 40 to 50% (3). Our patients had episodic (19%) and chronic (8.5%) of the total patients. The incidence of gangrene in our cohort was lower when compared to the data reported in the DUO registry (20%) (2). Although patients live in a very warm climate, DU are still experienced in SSC in Abu Dhabi. Likely, the chronic exposure to air conditioning may explain this paradox.

**AB0664**

**THE RELATIONSHIP OF SERUM LEVEL OF ANTICCP ANTIBODY WITH SEVERITY OF DIGITAL ULCERS IN SYSTEMIC SCLEROSIS PATIENTS REFERRED TO TOHID HOSPITAL**

N. Moghim1, A. Saied2, 1Liver and Digestive Research Center; 2Master of Clinical Psychology, Kordestan Medical Sciences, Sanandaj, Iran, Islamic Republic Of

**Background:** Systemic sclerosis is a chronic systemic disease of unknown etiology. There are a number of autoantibodies that correlated with disease severity and severity of skin involvement (1). Various studies have shown that AntiCCP Ab can also be seen in other autoimmune diseases such as systemic sclerosis (2–4). Results Polimeni et al (4) and Morita et al (3) showed that AntiCCP Ab may be result from overlapping with RA.

**Objectives:** This study aimed to determine the relationship between serum levels of AntiCCP Ab with severity of skin involvement in systemic sclerosis patients referred to Tohid Hospital.

**Methods:** This study is a cross-sectional study, in the study population included all patients diagnosed with systemic sclerosis according to ACR 1980 criteria and subtypes according to Le Roy, that between 2013 and 2014 referred to Tohid hospital. We used from MRSS index to determine the extent of skin involvement. Sampling was available and we used to determine this association from chi-square statistics and to determine the amount of the connection from Phi statistics. Serum antibodies directed against CCP were assessed by ELISA.

**Results:** The results showed that the patients who were evaluated at the end of study were 50 patients, of whom 48 were women (96%) and 2% were male. The mean age of subjects is 38±10 years. The subtype of systemic sclerosis in 15 (%30 percent) of the patients were diffuse systemic sclerosis and 35 patients (%70 percent) have limited systemic sclerosis. Serum Anti CCP Abtivity was positive in 10% (5 patients). Also, there is no statistically significant relationship between the severity of skin involvement with AntiCCp Ab (p=0.164).Severity of skin involvement in both groups was more severe form, and there is no statistically significant relationship between the severity of skin involvement and subtypes of systemic sclerosis (p=0.233). Also we didn’t find no association between levels AntiCCP and joint symptoms and other symptoms.

**Conclusions:** In this study wasn’t observed a significant correlation between serum levels of Anti CCP Antibody with severity of skin involvement in patients with systemic sclerosis (p=0.164), also serum level of AntiCCP Antibody couldn’t be a predict factor to determine the severity of the disease. It seems that the relationship between other symptoms of systemic sclerosis and serum level of AntiCCP Antibody may be result from overlapping with RA.

**LEVEL OF SATISFACTION IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES**

N. Lohin-Oprea1, S. Verrelia2, L. Mazur-Nicorici2, M. Cebanu2, V. Salaru4, M. Mazur3. 1Internal Medicine; 2Cardiology; 3Emergency Medicine; 4Family Medicine, PI SLUMPI Nicoiea Testemitanu, Chisinau, Moldova, Republic of

**Background:** Idiopathic Inflammatory Myopathies (IIM) are the group of rare diseases that carry a significant impact on patient’s quality of life, influenced by the level of patient's satisfaction regarding medical services.

**Objectives:** To assess the patient's satisfaction and quality of life.

**Methods:** A cross-sectional study was performed from December 2015 to December 2016. There were included consecutive patients who fulfilled the Bohan and Peter1 criteria for IIM. The collected information was about demographic data, clinical and laboratory findings. The patient's satisfaction was assessed by self-administered Patient Satisfaction Questionnaire (PSQ III)2, which is a 50-item tool, covering 7 domains: general satisfaction, technical quality,
interpersonal aspects, communication, financial aspects, time spent with doctor, access/availability/convenience. To estimate the quality of life we applied Short Form-8 questionnaire with 8 items for 8 domains and two components: mental and physical.

**Results:** There were 32 patients enrolled in the study, including 23 females and 9 males, mean age 52.6±14.26 (range 25–78), the disease duration was 8.3±5.3 (range 0.5–12) years. The physical component was lower 37.49±8.49, than the mental component 44.96±6.24 points, we determined that the quality of patient’s life was reduced. The PSQ III results were: general satisfaction 12.9±2.72 (range 7–21), technical satisfaction 20±2.93, and high indirect costs.

**Conclusions:** Patients with idiopathic inflammatory myopathies have reduced quality of life; however they are satisfied of the medical attendance. The dissatisfaction was with the financial aspect, due to the long-term disease course and high indirect costs.

**AB0665 ASSOCIATION BETWEEN MICROVASCULATURE CHANGES AND PULMONARY INVOLVEMENT IN SYSTEMIC SCLEROSIS: A FOLLOW-UP STUDY**

**N. Novakova 1, 2, M. Cichova 3, H. Vastova 4, 5, 6, 7, 8, L. Kusnirova 1, 7, 8, M. Nosikova 1, 7, 8, A. Trouillet 1**, 9 **Department of Rheumatology; 2Institute of Rheumatology; 3Department of Dermatovenerology; 4Department of Pneumology, General Teaching Hospital, Praha 2, Czech Republic

**Background:** Lung involvement is the major cause of mortality in patients with systemic sclerosis (SSc). Gas transfer (DLCO) and FVC levels have traditionally been used as measures of disease severity and reductions of both parameters have been associated with increased mortality. In SSc repeated attacks of Raynaud’s phenomenon lead to the reduced capillary density leads with reduced blood flow and tissue ischemia. Raynaud’s phenomenon can occur also in the lungs. Tissue hypoxia usually initiates the formation of new blood vessels from the pre-existing microvasculature. Nailfold capillaroscopy is a safe, noninvasive routine way for the microvascular investigation.

**Objectives:** The aim of this study was to assess the correlation between capillaroscopic abnormalities and parameters of interstitial lung involvement at baseline and after one year follow-up in patients with SSc.

**Methods:** All patients underwent routine clinical examination (dyspnea, cough, crepitus), pulmonary function tests, DLCO (alveolar grade and fibrosis), blood gases and HRCT scan of chest (1). Microvascular changes were assessed using nailfold videocapillaroscopy (NVC) which was performed by two independent examiners. The obtained images were analysed anonymously by two investigators using nailfold videocapillaroscopy (NVC) which was performed by two independent examiners. The obtained images were analysed anonymously by two investigators using two independent examiners using Poisson’s correlation coefficient and T-test were used. All examinations were performed at baseline and after 12 months.

**Results:** Total 42 patients (38 females) were investigated: 30 individuals with limited form, 7 with diffuse form, 3 patients with scleroderma sine scleroderma, 1 with overlap syndrome and 1 with undifferentiated connective tissue disease. The mean age ± standard deviation (SD) of the whole cohort was 51±22 years and the mean disease duration ± SD was 10±7 years. In SSc patients with diffuse (>5% of the skin involved) involvement was quite low than reported in other cohort series, the results are similar to the more recent publications [3]. We showed that myopathy occurred more often in anti-Scl70 positive patients and that anti-centromere wasn’t present at all. All patients should be carefully assessed for muscle involvement in the first years of SSc diagnosis and screened for lung fibrosis, regardless of cutaneous subtype of the disease.

**Conclusions:** This study emphasizes the fact that male SSc patients are at increased risk of developing myopathy. Although the prevalence of muscle involvement was quite low than reported in other cohort series, the results are similar to the more recent publications [3]. We showed that myopathy occurred more often in anti-Scl70 positive patients and that anti-centromere wasn’t present at all. All patients should be carefully assessed for muscle involvement in the first years of SSc diagnosis and screened for lung fibrosis, regardless of cutaneous subtype of the disease.

Objectives: To characterize the disease in a Colombian cohort with idiopathic inflammatory myopathy, assessing differences in its classification, cutaneous and systemic manifestations, laboratory results, and therapeutic approach, according to the type of myopathy.

Methods: A cross-sectional study was conducted in 112 patients, in whom sociodemographic, clinical and therapeutic characteristics were analyzed based on the type of myopathy. Statistical association was examined by means of Chi-square tests, Mann-Whitney test, and logistic regression analyses.

Results: From the 112 patients recruited, 59 had polymyositis (PM) and 53 had dermatomyositis (DM). The patients were classified with Peter & Bohan criteria as: “definite” diagnosis 67 (60%), “probable” 35 (31%) and “possible” 9 (10%). A high proportion of males were found in this cohort. Our most notable findings included in Table 1, reporting for this population a high rate of polyautoimmunity and seropositivity to PM (OR 3.85 95%IC 2.1-7.3) and DM (OR 7.03 95%IC 1.8-28.3), and an association between ANA antibodies positivity and PMso (OR 7.03 95%IC 1.8-28.3). Patients with PM presented higher values of CK, LD and transaminases. Also, according to the therapeutic approach, PM was positively associated with the use of azathioprine and immunoglobulins (OR 2.59 95%IC 1.18-5.69 and OR 3.21 95%IC 1.19-8.19, respectively), while chloroquine and hydroxychloroquine were mainly used in DM patients.

Conclusions: In this Colombian sample, a high proportion of patients were classified as definite diagnosis, high frequency of male-gender compromise, low autoantibodies frequency and low serum creatinine levels. The idiopathic inflammatory myopathies (IIM) are a group of immune-mediated systemic conditions characterized by chronic muscle inflammation, resulting in muscle weakness [1].

ized in SSC. Patients fulfilling the ACR/EULAR 2013 criteria were prospectively included since 05/16 in the ongoing observational cohort study. Patients filled in the ScleroID questionnaire (Figure 1), as well as selected comparators SHAQ, EC52, SF36. Additionally, they weighted the 10 dimensions of the ScleroID by dividing among 100 points according to the perceived impact on their health. The final score calculation will be based on the ranking of the weights. The study includes a reliability arm (follow-up questionnaire 7–10 days from baseline), as well as a longitudinal arm, looking at sensitivity to change at follow-up visits after 6 and 12 months from baseline.

Results: As of 01/2017 the study cohort included 224 patients with valid baseline data, 44 also had a reliability visit and 6 a 6-months follow-up visit. 84.4% of patients were female, 54.4% had limited SSC, median age 58, and median disease duration 8 years. The highest preliminary median weights for ScleroID domains were for Raynaud, impaired hand function, fatigue and pain (Table 1).

Except for pain, these dimensions were also scored most highly in the ScleroID questionnaire at baseline.

Conclusions: The EULAR ScleroID score is a novel tool designed for use in clinical practice and clinical trials to display the disease impact of SSC. In this preliminary analysis, Raynaud syndrome, impaired hand function, and fatigue were the main patient reported drivers of disease impact, however, further recruitment and validation of this new instrument is ongoing.

Background: Among patients, who meet the classification criteria for systemic sclerosis (SSc), there are the patients without specific SSc anti-nuclear antibodies and who are positive for antibodies to ribonucleoprotein (RNP). The clinical significance of the RNP antibodies in SSc is not clear.

Objectives: To investigate clinical and laboratory characteristics of SSc patients positive for antibodies to RNP.

Methods: The study included 52 patients (49 women and 3 men, mean age 44±15 years, median disease duration from the beginning of Raynaud’s phenomenon 11.2±7years) who met the criteria for mixed connective tissue disease (MCTD) proposed by Kasukawa et al. (1987).

Results: All the patients met the criteria for classification of SSc ACR/EULAR 2013 (table 1). Other prevalent clinical manifestations were gastroesophageal reflux in 63, 5% of patients, joints involvement in 58%, myositis in 30, 7%, serositis in 27.5% (including 23% of pericarditis). All patients were positive for antinuclear factor (Hep-2) and in some cases RF, anti-SS-A, anti-SS-B, anti-Sm and anti-dsDNA antibodies were identified. The increased levels of GRP and/or ESR were found in 56% of cases. Among the SSc patients, there were 38 (73%) who satisfied for the classification criteria for mixed connective tissue disease (MCTD) proposed by Kasukawa et al. (1987).

Conclusions: In the group under study the limited form of SSc dominated, with high frequency of the different manifestations of vasculopathy, esophagus, joint and muscle disorders symptoms. A subtype of RNP-positive SSC patients often met the criteria for MCTD. This fact makes it reasonable to discuss the possibility of overlap-syndrome between these two diseases.

AB0671 INCREASED BODY FAT BUT DECREASED LEAN BODY MASS AND BONE MINERAL DENSITY IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES ARE ASSOCIATED WITH DISEASE DURATION, INFLAMMATORY STATUS, STELLATE MUSCLE INVOLVEMENT AND PHYSICAL ACTIVITY

S. Orssea,1 M. Spirito1,2, P. Cesak2, O. Marecek2, H. Storkanov2, K. Kubinova1, M. Klein1, L. Vernoiva1, O. Ruzickova1, R. Becvar1, K. Pavlev1, L. Senoil1, H. Mann1, J. Vencovsky1, M. Tomick1.1Department of Rheumatology, 1Medical Faculty, Charles University, Institute of Rheumatology, 2Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

Background: Idiopathic inflammatory myopathies (IM) are characterized by inflammation and atrophy of skeletal muscles, pulmonary and articular involvement, which limit the mobility/self-sufficiency of patients, and can have a negative impact on body composition.

Objectives: To assess body composition and physical activity of IM patients and healthy controls (HC).

Methods: 54 patients with IM (45 females/9 males; mean age 57.3; disease duration 5.8 years; polymyositis (PM,22)/dermatomyositis (DM,25)/necrotizing
myopathy (IMMFT).) and 30 age-sex-matched HC (25 females/5 males, mean age 54.9) without rheumatic/tumor diseases or manifest cardiovascular event were included. PM/DM patients fulfilled Bohan/Peter criteria for PM/DM. Anthropometric status. Compared to HC, IIM patients had significantly lower bone mineral density (BMD: 1.16±0.10 vs 1.05±0.11 g/cm², p=0.0010), and were currently able to perform less energetically demanding physical activities according to HAP score (86.3±5.9 vs 49.0±20.2, p<0.001). Disease duration negatively correlated with BMD (r=-0.292, p=0.032) and BIA (r=-0.236, p=0.05). CRP was positively associated with BMD assessed both by DXA (r=0.27, p=0.035) and BIA (r=0.306, p=0.025). MMT-8 score negatively correlated with BMD/BCM ratio (r=-0.385, p=0.006), and physical activity (HAP) negatively correlated with BMD/BCM ratio (r=-0.385, p=0.006).

Conclusions: Compared to healthy age-sex-matched individuals we found significant negative changes in body composition of our IIM patients, which are associated with their disease duration, inflammatory status, skeletal muscle involvement, and physical activity, and could reflect their impaired nutritional status, compromised aerobic exercise, and decreased fitness and performance.

AB0673 TESTING FOR ANTIBODIES SPECIFIC TO FIBRILLARIN (U3 RNP) SHOWS ADDED VALUE FOR DIAGNOSIS OF SYSTEMIC SCLEROSIS

I. Gehring 1, S. Sjölander 2, P. Höfäl 3, L. Swiniarski 1, L. Vinderslev Iversen 2

Methods: Blood samples from 187 female patients with established diagnosis of SSc were obtained. Antibodies against Fibrillarin (U3 RNP), a helicase found in both PM III and Fibrillarin using the ELIA platform (Thermo Fisher Scientific, Freiburg, Germany).

Results: In 149 out of the 187 patients one or more of the tested parameters were detected. Fibrillarin was identified in 7 out of the 149 patients including 6 women with SSc (17%).

Conclusions: Increased diagnostic sensitivity was shown in this cohort of 187 patients with SSc by adding the analysis of antibodies against Fibrillarin. Testing allowed additional identification of 6 SSc patients which correlates to an increase of 3.74% in sensitivity.

AB0674 YKL-40 IS THE BIOMARKER FOR THE PRESENCE OF INTERSTITIAL PNEUMONIA AND PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS

T. Furukawa, K. Matsui, M. Kitano, Y. Yokoyama, M. Sekiguti, N. Azuma, H. Sano. Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan

Background: SSc is a refractory of connective tissue disease that causes fibrosis of the skin and various organs. Recently, it is attention to 2013 ACR/ESR classification criteria because can diagnose early phase before causing skin involvement in SSc. Thus, we considered that YKL-40 which is known to be involved in inflammation, tissue fibrosis and remodeling, is useful marker for evaluating early diagnosis and complications in SSc. YKL-40 is a chitinase-like protein and expressed in the synovial membrane and cartilage fibroblast cells in Rheumatoid Arthritis. Several cases of relationship between SSc and YKL-40 have been reported overseas, but it is unclear. Our report is the first in Japan.

Objectives: We investigated serum YKL-40 levels and examined immunohistochemistry (IHC) with YKL-40 of cutaneous tissue in SSc patients. To clarify YKL-40 is useful biomarker in early diagnosis in the presence or absence of complications in Japanese SSc patients.

Methods: Between August 2014 and March 2016, we treated 57 SSc patients in our department. We excluded infection, malignant disease, and other active complication may be a factor that increases YKL-40 levels. The patients were divided into 4 groups depending on whether suffered IP or PAH, which can affect the prognosis. Group1 (n=30) did not suffer from either IP or PAH, Group2 (n=12) suffered from IP, Group3 (n=7) suffered from PAH, and Group4 (n=8) suffered from both IP and PAH. YKL-40 levels in 4 groups and a control group of healthy individuals (n=13) were measured by ELISA. And age percentile strata of YKL-40 were calculated because serum YKL-40 levels have reported to rise with age; YKL-40 age percentile = 100/(1 + (Serum YKL-40 levels-3) / 5000).

Results: YKL-40 levels in 4 groups and a control group of healthy individuals (n=13) were measured by ELISA. The patients were divided into 4 groups depending on whether suffered IP or PAH, which can affect the prognosis. Group1 (n=30) did not suffer from either IP or PAH, Group2 (n=12) suffered from IP, Group3 (n=7) suffered from PAH, and Group4 (n=8) suffered from both IP and PAH. YKL-40 levels in 4 groups and a control group of healthy individuals (n=13) were measured by ELISA. And age percentile strata of YKL-40 were calculated because serum YKL-40 levels have reported to rise with age; YKL-40 age percentile = 100/(1 + (Serum YKL-40 levels-3) / 5000).

Conclusions: Increased diagnostic sensitivity was shown in this cohort of 187 patients with SSc by adding the analysis of antibodies against Fibrillarin. Testing allowed additional identification of 6 SSc patients which correlates to an increase of 3.74% in sensitivity.

AB0672 RISK FACTORS AND TREATMENT OF RECURRENT DERMATOMYOSITIS AND POLYMYOSITIS

S. Yamada, H. Yamashita, Y. Takahashi, H. Kaneko. Division of Rheumatic Diseases, National Center for Global Health and Medicine, Tokyo, Japan

Background: Patients with polymyositis (PM) and dermatomyositis (DM) often have repeated exacerbations of myositis. Sometimes immunosuppressive agents are added to induce remission in steroid-resistant cases, with steroid reduction in maintenance therapy, and to prevent exacerbations. However, comparative clinical studies are difficult to conduct and the appropriate immunosuppressive agents are not known [1-2]. There are also no studies of the treatment in recurrent cases with repeated relapses.

Objectives: In this study, we defined myositis that relapses more than once as recurrent myositis and examined its risk factors and re-inductions treatments.

Methods: Patients from our PM and DM database who were hospitalised between January 1991 and September 2016 were reviewed. We included only patients who had followed longer than 1 year.

Results: There were 14 cases (13.1%) with recurrent myositis. The average observation period was 11.3 and 8.0 years in the relapsing and non-relapsing groups, respectively (P =0.18), and the average ages at onset were 46.2 and 55.0 years (P =0.17). The myositis relapse rate was significantly higher in the anti-aminoacyl-tRNA synthetase (ARS) antibody-positive group than in the group with other antibodies [8/24 (33.3%)] vs. 0/14 (0.0%) cases; P =0.02]. The myositis relapse rate was significantly lower in the group in which one more immunosuppressive agent was combined in the initial treatment than in the group without any [3/33 (5.7%) vs. 11/48 (22.9%) cases; P =0.02]. The myositis relapse rate did not differ significantly between DM and PM, men and women, the groups with or without malignancy, the groups with or without interstitial pneumonia (IP), and groups with or without the following initial findings: fever, joint pain, dysphagia, constipation, bedridden, muscle pain, distal muscle weakness, respiratory symptoms (Hagen-Zanker), V-signs, Raynaud's phenomenon, skin ulcers and necrosis, and itching sensation), cardiac complications, hypertension, diabetes, and smoking history. There was no significant difference in the serum creatine kinase and C-reactive protein between the relapse and non-relapse groups. Only 3 of 14 cases (21.4%) had successful re-remission induced and were on maintenance therapy. In two of these cases, two immunosuppressive agents other than glucocorticoid were added: tacrolimus and methotrexate in one and tacrolimus and mycophenolate mofetil in the other. The other 11 patients were treatment-resistant.

Conclusions: The presence of anti-ARS antibody and initial treatment with glucocorticoid only (without any other immunosuppressive agent) were the only two risk factors for recurrent myositis; none of the other factors examined were significant. Recurrent myositis is often treatment-resistant; if one immunosuppressive agent cannot introduce remission, it is worth trying two drugs.

a significant difference was found between the other groups (p<0.05). IHC with YKL-40 revealed staining of the vessels in the superficial dermis in SSC and normal skin remained un stained. The ROC curve for PAH showed an AUC=0.959, and the most valid cut-off levels of YKL-40 age percentile was 85.2 (sensitivity 86.7% and specificity 92.8%).

Conclusions: Our report is the first report of IHC with YKL-40 in SSC. IHC suggest that YKL-40 may be further elevated by angiogenesis caused by microcirculatory damage in SSC. Our results suggest that YKL-40 may be very useful biomarker for diagnosing SSC and complications associated with microvascular lesions.

AB0675 ANTI-MDA5 POSITIVE DERMATOMYOSITIS: AN EMERGING ENTITY
V. Ortiz-Santamaria, A. Ponce, N. Busquets, N. Del Castillo, X. Suris, Rheumatology Unit, Granollers General Hospital, Granollers, Barcelona, Spain

Background: Hypo or amyopathic dermatomyositis (DM) represent about 20% of the classic DM. Melanoma differentiation-associated gene 5 antibody or anti-MDA5 antibody, formerly known as anti-CADM140 antibody, has been reported in the last decade. This antibody is detected in more than 50% of patients with hypo or amyopathic DM and it has specific features such as the presence of ulcerative vascular lesions and rapid progression of the interstitial lung disease.

Objectives: To report anti-MDA5 positive DM cases diagnosed at a university county hospital, between 2012 and 2016.

Methods: Design: Retrospective descriptive study. Location: University county hospital. Reference area: 750,000 inhabitants. Clinical manifestations, analytical results, diagnostic approach, treatment administered and follow-up have been exposed.

Results: We report four anti-MDA5 positive DM with a mean age at diagnosis of 54 years (35–77), Caucasian origin in 2 men and Maghreb origin in 2 women. They had no relevant medical history neither neoproliferative process was detected. ANA were negative and CK values were normal in all the cases. Naiifold capillaroscopy was characteristic of DM pattern. Case B did not present cutaneous manifestations and he was diagnosed as anti-MDA5 DM after his death.

Discussion: B and C cases showed abnormal heart rhythm that could be related to myocardial involvement, as suggested in a recent publication of anti-MDA5 DM (1). In case C, sinus tachycardia was resolved with the clinical response to treatment. In the literature reviewed, anti-MDA5 positive DM has been reported as a dermatomyositis syndrome, but probably the clinical profile of these patients remains to be defined. In our cases, one of them did not present skin lesions and another case did not develop pulmonary involvement 18 months after the diagnosis.

Conclusions: Keep in mind anti-MDA5 antibody in patients with cutaneous manifestations of DM with vasculopathy lesions, minimal or absent muscular disease, heart rhythm abnormalities not explained by other causes and/or rapidly progressive pulmonary involvement. Anti-MDA5 positive DM may have a poor response to treatment and fatal outcome. It remains to be seen if early diagnosis could improve the life expectancy of these patients.

AB0676 RELATIONSHIP BETWEEN BIOLOGICAL BIOMARKERS AND CHANGES IN RIGHT VENTRICLE THAT PRECEDE PULMONARY HYPERTENSION IN PATIENTS WITH SYSTEMIC SCLEROSIS
V. Márquez Fernández1, C. Soto1, A. Robles1, A. Noblejas1, E. Martínez1, G. Guzmán2, C. Busca1, F. Arnalich1, J.J. Rios1, 1 Internal Medicine; 2 Cardiology; Hospital Universitario la Paz, Madrid, Spain

Background: A higher prevalence of Pulmonary Hypertension (HP) has been described in patients with Systemic Sclerosis (ES) diagnosis, so this fact significantly overshadows the prognosis, since it leads to the failure of the right ventricle (RV). In this context, it could be very useful to identify ES patients who are at greater risk of developing PH in the future to make an early diagnosis of this complication, and prescribing an early therapy to improve their prognosis.

Objectives: The purpose of this study is to investigate if certain fibrosis, inflammation and vasculopathy biomarkers could be associated to early functional changes in RV, assessed by echocardiography and cardiac nuclear magnetic resonance (MRI) in ES patients.

Methods: A cross-sectional study was performed on a cohort of ES patients diagnosed according to the LeRoy modified criteria, who were being follow-up in the Systemic Autoimmune Diseases Unit of the Internal Medicine Service of La Paz University Hospital. Serum levels of inflammation (IL-13, IL-6, TNF alpha), vasculopathy (VEGF), fibrosis biological markers (endoglin, PDRFR, TGFβ1, TGFβ2, TGFβ3) and cardiac biomarkers (NP-PROBNP, High sensitivity T troponin) were determined as well as hemodynamic and cardiac morphological variables, were measured by transthoracic echocardiography (systolic and diastolic eccentricity index, E/E' ratio, E/A, pulmonary artery systolic pressure, RV thickness) and cardiac MRI (Mean pulmonary artery velocity). We investigated how many patients had these markers elevated and how many of them had hemodynamic and morphological cardiac altered measurements.

Results: Twenty patients with a diagnosis of ES (18 females/2 males) aged between 41 and 77 years, with a mean of 56 years, were included. A control group of 9 patients with similar demographic characteristics was included. ES subjects had higher levels of PDRFR (fibrosis marker) compared to the control group. In addition, in the group of ES patients, two statistically significant associations were observed: troponin T levels (hs-cTnT), endoglin and TGFβ2 had higher levels in patients with a systolic eccentricity index >1, a negative correlation was evidenced between levels of NT-proBNP and the mean pulmonary artery velocity measurement (VELAP).

Conclusions: Hs-cTnT, Endoglin and TGF beta are biomarkers that could appear...
AB0677 INDIVIDUAL IMMUNOLOGICAL PREDICTORS OF THE RISK OF LUNG DAMAGE IN PATIENTS WITH SYSTEMIC SCLEROSIS

V. Hayevsky, V. Chopyak, V. Hayevsky on behalf of Chopyak Valentina, Hayevsky Volodymyr. Department of clinical immunology, Liviv National Medical University named by Danylo Halytsky, Liviv, Ukraine

Background: A significant role in the formation and development of systemic sclerosis (SSc) belongs to immunogenetic factors and immunopathological mechanisms, so nowadays become important to find immunological predictors of early diagnosis of the disease. An urgent task is timely diagnosing the pulmonary complications as the main causes of high mortality and appointment of adequate therapy and objective assessment of its effectiveness.

Objectives: The main purpose was to develop a personal way of forecasting the risk of damage of the lungs, including its subtype – pulmonary fibrosis (PF) and pulmonary hypertension (PH) in patients with SSc.

Methods: To address this goal, the following studies performed: clinical, general laboratory, instrumental, immunological, molecular genetics, statistical methods. Adequacy and reliability of the results of mathematical model of the risk of damage lungs were using criteria Wald and Xi-square. The results show that our model is correct with a probability of error less than 1% (p<0.001).

Results: We found that among the analyzed complex interrelated factors in the development of lung damage in patients with SSc significantly influenced: the duration of the disease, mRNa2b, expression levels in the blood concentration of IL17 in serum and blood, neutrophil phagocytic index 1 that we include in the predictive model.

We know that the most significant complications associated with damage to their lungs are pneumofibrosis and pulmonary hypertension, which threatened the rapid development of respiratory failure and a high mortality of these patients. In this regard analyzed immunological and molecular genetic parameters of patients with SSc depending on the development of PH and LH.

Conclusions: The application withdrawn prognostic clinical and immunological and molecular genetic criteria of lungs damage (pulmonary hypertension and pneumofibrosis) will enable medical practitioners to verify early visceral lesions in patients with SSc in time and justified the appointment of basic therapy.

AB0679 THE CLINICAL VALUE OF NAILFOLD CAPILLAROSCOPY IN THE EARLY DIAGNOSIS OF SYSTEMIC SCLEROSIS

W. Gao, G. Zhang, L. Zhang, K. Xu, B. Li, Y. Yang, M. Yan. Rheumatology, Shanxi Dai Hospital, Shanxi Academy of Medical Sciences, taiyuan, China

Background: Vascular changes was early pathological changes of SSc, gradually appearing with irreversible fibrosis of the skin and internal organs. Early diagnosis and assessment of the development and efficacy timely, could improve survival in patients with SSc.

Objectives: To assess the value of nailfold capillaroscopy in the early diagnosis of systemic sclerosis (SSc).

Methods: 60 patients with SSc and 55 patients with other connective tissue diseases.Data were extracted on clinical and laboratory parameters.2013 ACR/EULAR classification criteria and 1980 ACR criteria for SSc were evaluated.

Results: The sensitivity of the 2013 criteria was 91.7% compared to 56.7% for the 1980 criteria (P<0.001). The specificity of two criteria was no significant difference. This sensitivity of the 2013 criteria was higher compared to the 1980 criteria among those with icSSc (95.5% versus 50%),The pattern was consistent among those with disease duration <3 years (90.5% versus 57.1%, P<0.05) and disease duration ≥3 years (92.3% versus 82.4%, P<0.05). The sensitivity and specificity of nailfold capillaroscopy to determine SSc were 86.7% and 43.6%. Patients not fulfilling the two classification criteria were met the very early diagnosis of systemic scleroderma, and often suffering from RP, and had an SSc pattern on nailfold capillaroscopy.

Conclusions: The sensitivity of 2013 ACR/EULAR classification criteria was higher compared with 1980 ACR classification criteria. The specificity of two classification criteria was no significant difference. This sensitivity of two criteria was higher among those with icSSc and short disease duration.Scleroderma pattern were significantly associated with the development of systemic sclerosis.

ANALYSIS THE CAUSES AND COUNTERMEASURES OF IGNORING SWALLOWING DYSFUNCTION IN PATIENTS WITH POLYMYOSITIS AND DERMATOMYOSITIS

Y. Wen, Q. Minli, L. Yan. Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: The patients with Polymyositis and Dermatomyositis always ignored swallowing dysfunction and most of them eventually had no enough knowledge of this. For this situation, to find out the reasons and take appropriate measures was necessary.

Objectives: To analyze the causes of ignoring swallowing dysfunction in patients with Polymyositis and Dermatomyositis and to explore the corresponding preventive measures.

Methods: The clinical data of 47 patients with Polymyositis and Dermatomyositis in hospital from September 2012 to December 2013 was analyzed retrospectively. The swallowing function was evaluated by the water swallow test, and the patients’ knowledge of swallowing dysfunction was surveyed.

Results: Only 2 patients complained of choking during swallowing, with ignorance rate of 95.74%. Positive rate was 40.43% in water swallow test, of which grade II dysphagia proposition was 58%, III grade was 32%, IV grade was 10%. 100% of patients believed that sternal obstruction or dysphagia as swallowing dysfunction. 89.36% of patients didn’t think drinking water with bucking as swallowing dysfunction.

Conclusions: The symptoms of limb weakness in patients with Polymyositis and Dermatomyositis may obscure the presence of dysphagia. In addition, the patients do not have enough knowledge about dysphagia that to neglect the swallowing dysfunction. To improve detection rate of swallowing dysfunction in patients with Polymyositis and Dermatomyositis, earching detailed history by listing dysphagia performance and providing water swallow test is necessary.

AB0682

THE INCIDENCE RATE OF INFLAMMATORY MYOPATHIES IN SLOVENIA

Ž. Rotar1, A. Hočevar1, M. Krošel1, S. Praprotnik1, M. Tomšič1,2. Department of Rheumatology, University Medical Centre Ljubljana; 2Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Background: Annual incidence rates of inflammatory myopathies (IM) vary widely from 1.16–19.0 per 106 of adults.1 Our aim was to, for the first time, determine the incidence rate of IM in our population.

Objectives: To determine the incidence rate of IM in our population.

Methods: We retrospectively collected incident cases of IM from 1 January 2005 to 31 December 2016 at our department of rheumatology which is a part of an integrated secondary/tertiary university teaching hospital that is the only referral center for two well defined regions representing roughly a third of the national adult population. Tertiary cases are referred to our department from the entire country. We identified the cases by searching the electronic patient records (PRs) for ICD-10 codes M05, M33–35, M60, G73.7, G72.4. The paper and electronic PRs were scrutinized to assess clinical, laboratory and histopathological data. Descriptive statistics was used to describe our group of patients. The adult population size of the two regions served by our department was obtained from the national statistics institute database. The annual incidence rate for IM was then calculated.

Results: During the 12-year observation period we identified 117 new cases of IM from a well defined adult white Caucasian population aged 18 or above. 38 cases were excluded from analyses since they were referred to our department from outside the two regions we serve on the secondary and tertiary level. Thus, we analyzed 79 cases of IM (63% female; median (IQR) age 67 (55–75) years; 44% ever smokers). The median time to diagnosis was 5 (IQR 3–12) months. We diagnosed 29% patients with dermatomyositis, 25% with anti-synthetase syndrome, 18% with polymyositis, 9% with statin induced necrotizing autoimmune myopathy, 9% with concomitant myositis as a part of connective tissue disease, 6% with paraneoplastic myositis, and 4% with undifferentiated myositis. The IM cases were most often diagnosed in the summer months (32.9%), followed...

**AB0683** TROUGH INFlixIMAB LEVELS AND ANTI-INFlixIMAB ANTIBODIES IN SPONDYLOARTHRITIS PATIENTS ON TREATMENT WITH LOW DOSE INFlixIMAB: A SINGLE CENTRE CROSS-SECTIONAL STUDY

A. Patil, S.K. Upadhyaya, R. Dawar, B. Vaishnav, N. Dadhania, S.J. Gupta, R. Handa, *Rheumatology, Microbiology, Indraprastha Apollo Hospitals, Delhi, India*

**Background:** Infliximab (IFX) is an anti-TNF chimeric, monoclonal antibody approved for use in refractory spondyloarthritis (SpA). Studies done in patients with Rheumatoid arthritis and Inflammatory bowel disease have demonstrated the clinical utility of the measurement of serum trough IFX and antibodies to IFX (ATI). In India, many centres including ours use IFX at lower doses of 3–5 mg/kg and on demand IFX treatment without the use of the loading dose IFX in SpA patients. Data on the utility of measuring trough IFX and ATI levels and their correlation with disease activity in such group of patients is lacking.

**Objectives:** To evaluate the co-relation between trough Infliximab levels and disease activity measures, viz ASDAS ESR and ASDAS CRP in SpA patients on low dose IFX therapy

**Methods:** Thirty-nine adult spondyloarthrtitis patients in the age group of 18–70 years, meeting the ASAAS classification criteria for peripheral and/or axial negative patients were quantitated using ASDAS ESR and ASDAS CRP scores.

**Correlation between the mean ASDAS scores and the trough IFX levels was analysed by Pearson’s product moment correlation assay. The difference in mean trough IFX and ASDAS scores between the ATI positive and ATI negative patients was assessed using Welch two sample t-test.**

**Results:** There was a moderately significant negative correlation between the trough IFX levels and the ASDAS ESR (r = -0.69, p<0.001), ASDAS CRP scores (r = -0.67, p<0.001) (Fig 1). ATI positive patients in comparison to ATI negative, had significantly higher ASDAS ESR and ASDAS CRP scores (Table 1).

**Conclusions:** SpA patients from India on low dose, on demand IFX therapy, have both the trough IFX and ATI correlate significantly with the measures of disease activity. Therefore, these may be used in addition to clinical activity scores for a more cost effective on demand IFX therapy in SpA patients, especially in an expense constrained country like India.

**AB0684** CLINICAL RESPONSE AND RADIOGRAPHIC PROGRESSION IN ANKYLOSING SPONDYLITIS PATIENTS UNDER ANTI-TNF THERAPY: IMPACT OF HIP INVOLVEMENT

A.Y. Shimabuco, F.M. Milanze, J.C.B. Moraes, G.V. Perico, C.R. Gonçalves, M.G. Waisberg, P.D. Sampaio-barros, C.O.S. Saad, *Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo, São Paulo; 1Unidade Radiológica Criciúma, Criciuma, Brazil*

**Background:** Hip involvement is considered an important prognostic factor associated with radiographic progression in ankylosing spondylitis (AS) patients. However, there are no studies regarding hip involvement impact on clinical response and radiographic progression in AS patients under anti-TNF therapy.

**Objectives:** Compare clinical and radiographic progression in AS patients receiving anti-TNF therapy with and without moderate-severe hip involvement.

**Methods:** Forty-seven AS patients referred to receive anti-TNF treatment were included and classified according to baseline hip involvement based on Bath Ankylosing Spondylitis Radiology Hip Index (BASRI-Hip); none-minimal hip disease (hip grade <3) or moderate-severe disease (hip grade ≥3). Demographic data, presence of HLA-B27, extra-articular involvement, DMARD and NSAID use, clinical and laboratory disease parameters (BASDAI, BASMI, BASFI, ASQoL, mSASSS and inflammatory markers) were assessed at baseline and two years after anti-TNF treatment.

**Results:** Thirty-four (72.3%) patients were classified as none-minimal hip disease and 13 (27.7%) as moderate-severe hip involvement. Both groups were similar at baseline considering age, HLA-B27, extra-articular involvement and comedication use. Laboratorial markers (ESR, CRP) and disease parameters (BASDAI, BASMI, BASFI, ASQoL, mSASSS and inflammatory markers) showed no difference at baseline. Moderate-severe group had longer disease (10.0±7.6 vs. 4.9±3.3, P=0.002) and lower BASMI (3.8±2.4 vs. 6.5±2.5, P=0.002) and ASQoL (13.7±4.6 vs. 9.9±4.9, P=0.007). After two-years of anti-TNF therapy, both groups presented similar BASDAI response (delta BASDAI, p=0.134; final BASDAI, p=0.324) and an increase in mSASSS (13.6±18.3 vs. 16.1±19.4, P=0.02), despite similar delta BASDAI and final BASDAI.

**Conclusions:** Our study provides evidence that hip involvement did not impact on clinical response in AS patients under anti-TNF therapy but may have an effect on radiographic progression of these patients.
SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENTS IN WORK PRODUCTIVITY AND HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS: LONG-TERM RESULTS FROM MEASURE 1 AND MEASURE 2

A. Deodhar, P.G. Conaghan, V. Strand, A. Boonen, G. Ferraccioli, F. Van den Bosch, V. Bhosekar, B. Porter, K. Gandhi, S. Jugil, Oregon Health & Science University, Portland, Oregon, United States; University of Leeds, Leeds, United Kingdom; Stanford University School of Medicine, Palo Alto, CA, United States; Maastro Cancer Centre, Maastricht, Netherlands; Catholic University of the Sacred Heart, Rome, Italy; Ghent University Hospital, Ghent, Belgium; Novartis Pharmaceuticals Corporation, East Hanover, United States; Novartis Pharma AG, Basel, Switzerland

Background: Patients (pts) with ankylosing spondylitis (AS) experience significant restrictions in work productivity and health-related quality of life (HRQoL). Secukinumab (SEC) demonstrated rapid improvements in signs, symptoms and physical functioning in pts with AS.

Objectives: To assess whether the beneficial effects of SEC on AS signs and symptoms were reflected in improvements in work productivity and HRQoL in the overall population and in TNF inhibitor (TNF)-naive pts and pts with an inadequate response or intolerance to TNF inhibitors (TNF-IR) for up to 52 weeks (wks) in MEASURE 2 and 104 wks in MEASURE 1.

Methods: 371 and 219 pts were randomized to SEC or placebo (PBO) in MEASURE 1 (10 mg/kg IV followed by 150 or 75 mg SC) and MEASURE 2 (150 or 75 mg SC). At Wk 16, PBO pts were re-randomized to SEC 150 or 75 mg SC (PBO pts with ASAS20 response at Wk 16 were switched to SEC at Wk 24 in MEASURE 1). Productivity was measured using the Work Productivity and Activity Impairment-General Health (WPAI-GH) questionnaire, which includes questions to assess absenteeism, presenteeism and overall work productivity and health-related quality of life (HRQoL).

Results: At baseline (BL), 77 of 125 and 45 of 72 randomized pts were employed and working in the SEC-groups in MEASURE 1 and 2, respectively. Improvements in all WPAI domains were observed with SEC in the overall, TNF-naïve and TNF-IR populations at Wk 16 in both studies, and effects were generally sustained through Wks 52 and 104 (Table). In MEASURE 1, activity impairment in the overall population was improved by 49% and 44%, respectively, and was significantly improved by 45% from BL at Wk 104. Improvements were 51%/49% in TNF-naïve and 42%/19% in TNF-IR pts, respectively. In MEASURE 2, activity impairment and work productivity improved by 43% and 40% vs BL, respectively, at Wk 52; improvements in activity impairment/work productivity in TNF-naïve and TNF-IR pts were 49%/34% and 32%/16%, respectively. Similar responses were seen in the other WPAI scores across both studies. Early improvements in ASQol were sustained through Wk 104 in MEASURE 1 and Wk 52 in MEASURE 2. At Wk 104 of MEASURE 1, ASQol scores had improved by 48% vs BL with SEC; improvements were 50%/37% in TNF-naïve and TNF-IR pts, respectively.

Conclusions: SEC provides sustained improvements in work productivity and ASQol for up to 104 wks among AS pts, regardless of prior TNF exposure.

DOI: 10.1136/annrheumdis-2017-eular.1856
STATEMENTS

The asAS NSAID index. 1 year after baseline — 9 (13.8%) pts started treatment with anti-TNF because of high activity of the disease and absence of effect from 2 NSAIDs. 2 years after baseline number of pts with anti-TNF equal - 15 (23.0%).

Results: Compared with baseline characteristic after 2 years have significantly reduced disease activity and increased the number of asAS partial remission (PR) in patients with axSpA (Table 2).

There were no statistical differences between the frequency of NSAIDs intake and early axSpA disease activity (Table 2).

Conclusions: Long reception of NSAIDs in patients with early axSpA reduces disease activity; however, the receive frequency does not affect the activity of the disease.

Disclosure of Interest: None declared

AB0689 METABOLIC SYNDROME IN ANKYLOSING SPONDYLITIS AND THE EFFECT OF ANTI-TNF THERAPY

F. Atenzi 1, L. Gianfrancesco 2, I.F. Masala 3, S. Bongiovanni 1, L. Boccassini 1, P. Sarzi-Puttini 1, M. Turri 1, 1 Rheumatology Unit, L.Sacco University Hospital; 2 Cardiology Unit, Department of Biomedical Sciences for Health, IRCCS Galeazzi Orthopedic Institute, Milan; 3 Orthopedic and Trauma, Santissima Trinità Hospital, Cagliari, Italy

Background: Metabolic syndrome (MeS) is a cluster of cardiovascular (CV) risk factors (obesity, dyslipidemia, hypertension, alterations in glucose metabolism, and insulin resistance) whose prevalence is increasing particularly in developed countries. In comparison with the general population, patients with ankylosing spondylitis (AS) are at increased risk of cardiovascular (CV) disease, which is one of the main causes of mortality among them.

Objectives: The aim of this study was to identify the relationship between MeS and disease activity in AS patients, and evaluate the effect of anti-tumour necrosis factor (TNF) therapy.

Methods: The study involved 30 outpatients who met the New York diagnostic criteria for AS: 14 males and 16 females; mean age 53.07±10.73 years; mean disease duration 5.03±2.07 years. All of the patients were being treated with DMARDs and anti-inflammatory drugs, but none had received any biological agents or steroids at baseline. The patients underwent laboratory tests (lipid profile and glucose levels), a clinical and standard echocardiographic examination, carotid ultrasonography (including the assessment of intima-media thickness and pulse wave velocity), and speckle tracking echocardiography (STE) of the left ventricle (LV) using Philips CLAB software to evaluate their CV risk profiles. Functional impairment and disease activity were assessed using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Bath Ankylosing Spondylitis Functional Index (BASFI). All of the patients were evaluated at baseline and after 12 months of anti-TNF treatment. The data were statistically analyzed using non-parametric chi-squared and McNemar tests, and the Wilcoxon-Mann-Whitney test.

Results: Before starting anti-TNF therapy, the cohort was divided into two groups: those with MeS (25%) and those without. The patients with MeS higher BASDAI scores (chi-squared test: 4.85; p=0.03). After 12 months of follow-up, there was a statistically significant improvement in global functional impairment (QoL) in both groups: from a baseline median of 19.94 (IQR 18.66–20.78) to a median of 21.46 (IQR 20.37–22.69) (p=0.02) in the non-MeS group, and from a baseline median of 18.88 (IQR 16.00–19.35) to 19.54 (IQR 18.21–19.98) (p=0.04) in the MeS group. No other changes in CV parameters were observed. The improvement in BASDAI scores was greater in the MeS group, but the difference was not statistically significant. The prevalence of MeS decreased after 12 months of anti-TNF therapy, although the McNemar test showed that the decrease was of borderline significance (p=0.048).

Conclusions: AS patients affected by MeS. The effects of anti-TNF drugs on MeS are still controversial, but our findings suggest that they improve CV markers such as GLS as well as disease activity. The main limitation of this study is its small sample size and short follow-up; further studies are required in order to clarify the influence of MeS on clinical therapeutic outcomes.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.1792
Background: The regulatory phase III trial supporting the approval of biosimilar infliximab (BOW015) in India included only rheumatoid arthritis patients. Consequent-ly, there is paucity of data on the effectiveness of BOW015 in Ankylosing Spondylitis (AS).

1,2,3 Hence, we decided to objectively quantify the effectiveness and safety of BOW015 in AS patients.

Objectives: To determine safety, efficacy and tolerability of BOW015 in Indian AS patients.

Methods: We retrospectively collected data from seven centres to get a comprehensive picture of the Indian population. The protocol along with data collection form was designed by the investigators and ethics committee approval was obtained. Biologic naïve patients diagnosed with AS as per Assessment of SpondyloArthritis International Society criteria who were having six months of follow up data during January-November 2016 were included in the study. Percentage of patients achieving major clinical improvement (Ankylosing Spondylitis Disease Activity Score C-reactive protein (ASDAS-CR) ≥2.1 from the baseline to six months of follow up) was the primary variable. Secondary variables included: clinical improvement criteria (ASDAS-CR ≤1.1 from the baseline to six months of follow up), change in ASDAS-CRP, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), CRP and Erythrocyte Sedimentation Rate (ESR) from the baseline to six months. Variables were reported as mean ± Standard Deviation (SD), absolute change in variable were reported along with their Confidence Interval (CI) and data was analyzed using Statistical Package for the Social Science V.22.

Results: A total of 68 patients treated with BOW015 having follow up data for six months were analyzed. Mean age of patients was 32.63±11.73 (SD) years. BASDAI, ASDAS-CRP, ESR and CRP which continued till the end of six months. There was an absolute change of -2.54 (95% CI -1.92, -3.17) in BASDAI and -1.77 (95% CI -1.43, -2.11) in ASDAS-CRP right from first follow up corresponding to post 1st dose visit which was statistically significant (see Table-1). This trend was observed in the subsequent visits in BASDAI, ASDAS-CRP, ESR and CRP which continued till the end of six months. One patient developed pulmonary tuberculosis and marginally elevated liver enzymes were seen in two patients.

Conclusions: BOW015 showed significant improvement in ASDAS-CRP and BASDAI in patients with AS on a six month follow up period and the clinical benefits were apparent as early as first dose of BOW015.

DOSE TAPERING OF INFIXIMAB IN PATIENTS WITH SPONDYLOARTHROPATHIES

M. Correzeau, J.C. Nieto, C.M. González, A. López, R. González, C. Saenz, L. García-Montoya, F.J.L. Longo, L. Monteagudo, Rheumatology Department, Hospital General Universitario Gregorio Marañon, Madrid, Spain

Background: Infliximab have proven to be effective in spondyloarthritis. Previous studies suggest that patients in clinical remission may benefit from dose reduction or pharmacological tapering without relapse.

Objectives: To study the evolution of clinical activity and physical function in patients with spondyloarthritis, ankylosing spondylitis (AS) and psoriatic arthritis (PsA) under Infliximab (IFX) tapering strategy.

Methods: This is a prospective single-centre observational study of patients diagnosed with AS and PsA treated with IFX (5 mg/kg/infusion) between January 1, 2012 and December 31, 2015. We included patients who achieved clinical remission or low activity index (expressed with BASDAI and BASFI) and decided to lower the dose of 5 mg/kg/infusion, maintaining the periodicity of the treatment in each patient. Demographic data (age, gender, time with IFX) daily activities, physical activity (BASDAI and BASFI) and laboratory data (ESR and CRP) were collected at the baseline visit prior to tapering, at the next infusion following dose reduction and the last infusion (between November 1st 2014 and December 31st, 2016).

Results: We included 18 patients (16 men) on IFX treatment with EA (16) or axial APs (2). The medians of age and time of evolution were 50.79 years (41.8–55.1) and 9.5 years (7.2–11.9), respectively. Table 1 shows the clinical and laboratory data obtained at the baseline visit, the next infusion and the last infusion. Fourteen patients (87.9%) continued with the dose of 4 mg/kg/infusion and are maintained in clinical remission. Four patients returned to the dose of 5 mg/kg/infusion due to loss of efficacy at dose reduction, with a mean follow-up of 17.6 months (17.0–19.1). Clinical remission was again achieved in 4 patients, although one of them changed biological therapy due to loss of efficacy of IFX after 3 infusions with 5 mg/kg/infusion.

Conclusions: In our patients with spondyloarthritis dose reduction of IFX was well tolerated and safe, maintaining the clinical response measured by BASDAI and BASFI. In 3 out of 4 patients who worsened upon dose reduction, the 5 mg/kg/infusion dose recovered clinical remission.

IMPACT OF THE BASELINE BATH ANKYLOSING SPONDYLITIS RADIOLOGY HIP INDEX ON THE STRUCTURAL HIP JOINT PROGRESSION AFTER TNFα BLOCKING THERAPY IN SPONDYLOARTHROPATHIES PATIENTS

K. Maatallah 1, M. Sahli 1, I. Mahmoud 2, W. Hamidi 3, O. Saidane 2, M. Kechri 1, R. Tekaya 1, L. Abdelmoula 4, 1Rheumatology, Kassab university hospital; 2Rheumatology, Charles Nicolle university hospital, Tunis, Tunisia

Background: One of the major goals of treatment of spondyloarthritides (SpA) is to prevent, slow the radiographic damage. The TNFα inhibitors – Infliximab have proven to be effective in spondyloarthritis. Previous studies suggest that patients in clinical remission may benefit from dose reduction or pharmacological tapering without relapse.

Objectives: To compare, in real-life settings, the retention rates of the initial anti-TNF therapy between 2001 and 2015. Nevertheless, the randomized studies were of short duration and included a selected population that differed from patients treated in daily practice.

Methods: To compare, in real-life settings, the retention rates of the initial anti-TNF therapy between 2001 and 2015. Nevertheless, the randomized studies were of short duration and included a selected population that differed from patients treated in daily practice.

conditions like ankylosing spondylitis (AS). Despite good treatment options such as tumor necrosis factor alpha (TNFα) inhibitors in AS, it is seen that patients have applied for CAM use for many reasons including local regulatory funding requirements, potential risks and accessibility of biological treatments. Few studies have examined the frequency of CAM use, and associations between demographic and disease-related factors in it in AS.

**Objectives:** To investigate the CAM usage of patients with AS and to determine the associated factors.

**Methods:** Total of 123 patients with AS, who were being followed in a tertiary rheumatology outpatient clinic, were included to the study. The demographic and clinical characteristics along with the behaviors about the CAM usage of the patients agreeing to participate were recorded to the “Patient Assessment Form”. The activity of the disease were determined with doctor global assessment (numeric visual analog scale (nVAS); 0–10), and Routine Assessment of Patient Index Data (RAPID)-3 score. The treatment adherence of the patients was assessed with the Morisky Green Levine Scale.

**Results:** One hundred eleven patients (%90.2) were male, and mean age was 36.5±8.8 years. The mean disease duration and mean delay in diagnosis were 10.9±6.4, and 3.7±3.9 years, respectively. The mean RAPIDS score, doctor and patient global assessment were, 9.9±5.3, 2.8±1.9, and 4.6±2.7, respectively. While 79 patients (%64.2) were on anti-TNF treatment, 76 patients were receiving NSAIDs, and 35 patients (%28.5) reported an adverse event related with the treatment. Forty-five patients (%36.6) reported to use any CAM (previous or current) (Table1). The reasons reported by the patients for the usage of CAM were: for disease activity – Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), for functionality – Bath Ankylosing Spondylitis Functional Mobility Index (BASMI), and for depression – Beck depression Inventory (BDI). All patients were evaluated before treatment and at 3 months.

**Results:** The demographic characteristics of the patients were compared and there was no significant difference between the groups. The improvements in all parameters were better in both groups receiving exercise and anti-TNF therapy than in the control group after treatment compared with baseline. The Anti-TNF + GPR exercise therapy resulted in greater improvements than the anti TNF+ conventional exercise therapy in pain, and mobility parameters.

**Conclusions:** Anti-TNF therapy and exercise were efficient in both groups on improving pain, disease activity, fatigue, sleep quality, and depression. However, the improvements in pain and mobility were greater in the active AS patients with GPR exercise method. Therefore motivated patients should be encouraged to perform this exercise program.

**EFFECTIVE DRUG AND SURVIVAL OF ANTI-TUMOUR NECROSIS FACTOR-ALPHA THERAPIES IN PATIENTS WITH SPONDYLO-ARTHRITIS: ANALYSIS FROM THE THAI RHEUMATIC DISEASE PRIOR AUTHORIZATION (RDPA) REGISTER**

P. Chiochanwisawajik 1, W. Katchamart 1, P. Chevasirakul 1, P. Narongroeknavin 2, W. Loutreroeno 3, M. Osin 4 on behalf of the Thai Rheumatism Association.

**Objectives:** To evaluate the long-term efficacy and safety of the first TNFi in real-life practice and to identify the risk factors related to drug discontinuation in Thai patients with SpA from the RDPA registry.

**Methods:** Patients who fulfilled the 1984 Modified New York criteria for ankylosing spondylitis (AS), CASPAR criteria or Moll and Wright criteria for psoriatic arthritis (PsA) and the European Spondyloarthropathy Study Group Criteria for Modified Amor criteria for undifferentiated SpA (uSpA), and were prescribed the first TNFi between December 2009 and October 2014 in the RDPA registry were enrolled. Baseline demographic and clinical data were retrieved. A Cox proportional hazard model was used to identify the factors associated with discontinuation. The P-value of <0.05, two-sided was considered statistically significant.

**Results:** Of the 142 patients included, 97 had AS, 41 had PsA, and 4 had uSpA. Most AS patients were male (54.6%) with mean (SD) age of 44.6 (10.6) years, median (IQR) delay in diagnosis 6.5 (5.6, 8.2) [from a 10-cm visual analog scale (VAS)], and median baseline patient global assessment (bPGA) was 7.2 (6.0, 9.8) [from a 10-cm visual analog scale (VAS)]. For PsA patients, patients were female (68.3%) with mean age of 52.6 (SD 12.2) years, median (IQR) delay in diagnosis 6.6 (5.8, 7.4, 9.7) years in patients active axial involvement and median baseline number of joint involvement was 13.5 (IQR 8.5, 6, 18.3) joints per patient with active peripheral joint involvement. The Efficacy of the TNFi treatment was good and it was increased over time in AS and PsA patients (figure 1). During the 5-year follow-up, AS, PsA, and uSpA patients had comparable discontinuation rate of their first TNFi treatment [25% (26%) in AS, 14% (34%) in PsA, and 1% (25%) in uSpA; P=0.82]. In univariate analysis, leflunomide use, and bFGF use -3 comparing to >-6 (from a 10-cm VAS) were associated with the discontinuation of TNFi in AS patients with hazard ratio (HR) (95% CI) of 2.56 (1.13, 5.81) and 8.59 (1.82, 40.65), respectively. For the patients with PsA, only infliximab use was associated with TNFi discontinuation with HR of 4.79 (95% CI 1.33, 17.20) in univariate analysis. The reason for TNFi discontinuation were good response (38%), serious adverse effects (SAE) (30%), non-adherence (20%), and lack of efficacy (13%). Among SAE, 58% was infectious causes (57% tuberculosis and 43% non-mycobacterium infections). The others were non-infectious causes.

**EFFECTS OF GLOBAL POSTURAL REEDUCATION EXERCISE AND ANTI-TNF TREATMENTS ON DISEASE ACTIVITY, FATIGUE, MOBILITY, SLEEP QUALITY AND DEPRESSION IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS (PROSPECTIVE-CONTROLLED TRIAL)**

N.H. Coksevim, D. Durmus, O. Kuru, Physical Therapy and Rehabilitation, 19 Mayis University Medical Faculty, Samsun, Turkey

**Background:** Ankylosing spondylitis (AS) is chronic inflammatory disease that affects primarily the spine and the sacroiliac joints. ASAS/EULAR guidelines describe regular exercise as the cornerstone of non-pharmacological treatment and non-pharmacological treatments including non-steroidal anti-inflammatory drugs as first-line therapy, and a tumour necrosis factor (TNF) alpha inhibitor (anti-TNFα) as second-line medication in patients with persistently high disease activity despite conventional pharmacological treatment in patients with AS.

**Objectives:** The purpose of this study was to investigate the effects of combination therapy with global postural reeducation exercise (GPR) and Anti-TNF treatments on pain, disease activity, mobility, fatigue, sleep quality, and depression in patients with active AS.

**Methods:** 60 active AS patients who meet the criteria of Modified New York and/or AS ASAS axial spondyloarthropathy were included in the study. Patients were divided into 3 groups. The first group was given anti-TNF therapy plus GPR exercise program. The 2nd group was given anti-TNF and conventional exercise therapy. The 3rd group was given routine exercise program along with their existing treatments (NSAIDs and/or SLZ). Following inventories are used for clinical evaluation: for disease activity – Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), for functionality – Bath Ankylosing Spondylitis Functional Index (BASFI), for mobility – lumbar Schober, chest expansion, hand-finger to floor distance, for fatigue – fatigue Multidimensional Assessment Questionaire (MAF), for sleep quality – Pittsburgh sleep quality index (PSQI), for depression

**AB0701** THE REAL-LIFE USE OF GOLIMUMAB IN PATIENTS WITH IMMUNE-MEDIATED RHEUMATIC DISEASES: ONE YEAR RESULTS OF THE GO-PRACTICE STUDY

R.-M. Filpo 1, F. Tubach 1, G. Ouaniche 2, P. Goupille 3, E. Lespesailles 4, N. Gouyette 5, B. Fautrel 6, J. Ouaniche 7, P. Goupille 8, E. Lespesailles 9, F. Berenbaum 10

**Background:** The GO-PRACTICE study was initiated to describe the use of Golimumab (GLM), a human anti-TNFα monoclonal antibody, in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) in French clinical practice.

**Methods:** Observational, multicenter, prospective, national study. Adult patients with RA, PsA and AS were included consecutively after GLM decision for treatment. The primary outcome was the M0-M4 change of VAS-F. The secondary outcomes included: 1) the M0-M4 change of VAS-M; 2) the proportion of patients with a 50/100 change of VAS-F; 3) the proportion of patients with a 50/100 change of VAS-M; 4) the proportion of patients with a 25/100 change of HAQ.

**Results:** A total of 754 patients (134 sites) were included between January 2015 and March 2016. Most of them had AS (64%), and 22% and 13% had RA and PsA, respectively. Mean age was 46±13 years and 61% were female. Almost 37% had received prior biotherapy. Nearly all patients (99%) were prescribed GLM as 50 mg-monthly injections. GLM was mostly co-prescribed with other anti-rheumatic treatments (84%). Of the 163 patients with available data at strictly 1-year, 56.4% were still treated with GLM; (61.8% in biotherapy-naïve patients); the persistence rate was similar across the three groups. The Kaplan-Meier duration curves of GLM are presented in figure 1. The main reason for GLM discontinuation was primary non-response, reported in 42% of patients. Among patients who continued GLM treatment, a meaningful improvement in disease activity was observed at 1-year in 71.9% of RA, 63.2% of PsA and 68.0% of AS patients. Patients-reported outcomes, including pain and functional disability, also showed improvement.

**Conclusions:** In real-life practice in France, GLM was prescribed according to recommendations in terms of dosage and therapeutic strategy. One-year interim analysis, performed in one third of the cohort, suggests that GLM treatment is associated with clinical improvements leading to persistence of treatment. These results need to be confirmed in the final overall analysis planned in 2018. 

**AB0702** IMPROVEMENT OF FATIGUE IN PATIENTS WITH SPONDYLOARTHRITIS TREATED WITH ANTI-TNF THERAPY: PROSPECTIVE STUDY IN A REAL-LIFE SETTING

**Background:** Besides randomized controlled trials evaluating biologic agents on fatigue, the impact of anti-TNF therapy on this crucial symptom has been poorly assessed in a real-life setting.

**Objectives:** To assess the early effect of etanercept (ETN) on fatigue-related outcomes in spondyloarthopathies (SpA) patients in a real-life setting.

**Methods:** This prospective study included patients with active SpA fulfilling ASAS axial or peripheral criteria, requiring an anti-TNF. All patients were treated with ETN 50mg weekly. BASDAI, BASFI, functional assessment of chronic illness therapy-fatigue (FACIT-F) (0 maximum and 52 the minimum of fatigue) and visual analogic scale of fatigue (VAS-F) (0 the minimum -100 maximum of fatigue) were assessed at inclusion at the time of ETN beginning (M0) and 4±1 months later (M4).

**Results:** The primary outcome was the M0-M4 change of VAS-F. The secondary outcomes were: i) the M0-M4 change of FACIT-F; ii) the frequency of patients who met improvement according to FACIT-F (defined as the minimal clinically important difference of FACIT-F corresponding to a 4-points decrease). To determine whether fatigue change was related to disease activity improvement, a correlation between M0-M4 changes of BASDAI and VAS-F or FACIT-F was determined.

**Conclusions:** This real-life study investigating the early effect of etanercept therapy on fatigue in SpA patients showed that fatigue (according to VAS-F) significantly improved while effect on FACIT-F was less pronounced. This improvement was explained, in part, by disease activity improvement.

**AB0703** IMPACT OF ANTI-TNF AGENTS ON PATIENT-REPORTED OUTCOMES IN SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW OF THE LITERATURE AND META-ANALYSIS

S. Lacaix 1, A. Constantin 1,2, A. Cantagrel 1,2, T. Barthele 3, A. Ryusse-Witrand 1, Y. Degboe 1,2, F. Rheumatology Center. Hospital Pierre Paul Riquet, Toulouse University Hospital; 2CPTP, INSERM UMR 1043, Toulouse; 3Rheumatology Department, Hop Acronim, Bordeaux University Hospital, Bordeaux; 4Pharmacovaepidemiologie, Evaluation de l'utilisation et du risque medicament, INSEEM UMR 1027, Toulouse, France

**Background:** Disability, alteration in quality of life and fatigue are frequently reported in spondyloarthritis (SpA). Anti-TNF demonstrated clinical efficacy in SpA. However efficacy on patient-reported outcomes (PROs) may differ from medical assessment.

**Objectives:** To assess the impact of anti-TNF on quality of life, disability and fatigue reported by SpA patients.

**Methods:** Design: systematic review and meta-analysis of the literature. Data sources: two authors (SL and YD) independently screened PubMed-Medline, Cochrane library and EMBASE databases until November 2016. Key words: (“Patient reported” OR “quality of life” OR fatigue OR FACIT) AND (spondyloarthritis OR “psoriatic arthritis” OR “ankylosing spondylitis”) AND (anti-TNF OR certolizumab OR etanercept OR adalimumab OR infliximab OR golimumab).

**Articles selection:** randomized controlled trials (RCTs), published in English, assessing efficacy of anti-TNF on PROs, in ankylosing spondylitis (AS), psoriatic arthritis (PsA) or SpA according to the ASAS criteria. Data collected: fatigue assessed by FACIT score, quality of life assessed by Short Form 36 (SF36) mental and physical component or by Health Assessment Questionnary Disability Index (HAQ). Data analysis: Article quality was evaluated by the Jadad scale. For SF36 and HAQ outcomes, pooled variations at 12 and 24 weeks were computed by meta-analysis. Heterogeneity was measured by I² index.

**Results:** Of the 604 articles identified, 37 references were eligible for systematic review and 13 for meta-analysis. Our systematic review identified 10 RCTs concerning AS, 20 concerning PsA and 7 concerning axial SpA. However due to the heterogeneity in available statistical data, references eligible for meta-analysis were mainly related to PsA.

HAQ assessment was available for a meta-analysis in 8 studies. HAQ was significantly improved at 12 and 24 weeks with anti-TNF. The impact on HAQ variation at week 24 was -0.29 points [95% CI: -0.37, -0.22]. Heterogeneity was important (I² = 57%; see figure).

Ten studieswere eligible for a meta-analysis of anti-TNF effect on SF36 mental form. An improvement was observed at 12 and 24 weeks, although superior at 24 weeks. The effect at week 24 was 2.78 [95% CI: 1.87 - 3.68], without heterogeneity (I² = 0%; see figure).
Twelve studies were eligible for a meta-analysis of anti-TNF effect on SF36 physical form. We observed a similar and significant improvement at 12 and 24 weeks. The effect at week 24 was 6.74 [95% CI: 5.34 – 8.13], with an important heterogeneity (I² = 84%; see figure). Fatigue was evaluated in 3 studies. Adalimumab induced a significant improvement in FACIT score at 12 and 24 weeks in one study. Two studies using different scores (Fatigue Assessment Scale, BASDAI fatigue item) to assess cetolizumab effect highlighted similar findings: an early improvement in fatigue at week 12, remaining significant and stable at week 24.

Conclusions: Anti-TNFs agents significantly improve disability, quality of life and fatigue in patients with PsA.

Acknowledgements: France pharmaceutical company provided logistic support by organizing a meta-analysis methods workshop, but played no further role in the project.

AB0704 HIP ARTHROPLASTY IN PATIENTS WITH ANKYLOSING SPONDYLITIS: CLINICAL AND FUNCTIONAL EFFICIENCY

S. Lapshina1, I. Akhtyamov2, I. Gilmutdinov2, L. Myasoutova1, 1Kazan State Medical University; 2Republic Clinical Hospital, Kazan, Russian Federation

Objectives: To evaluate the results of the hip joint replacement in patients with SpA under the dynamic supervision of a rheumatologist and orthopedist within the first year after the operation.

Methods: As part of special program for rheumatology patients hip endoprosthesis was done in 12 patients (mean age - 44±15.3 years) with SpA, 8 of them with ankylosing spondylitis (AS) and 4 with psoriatic arthritis (PsA). Duration of the disease - 13±7.9 years, positive for HLA B27 in 9 (75%) patients. High activity for AS-DAS was at 58.3% of the patients. Took NSAIDs at the time of the operation - 11 (91.6%) patients, salsalazine 5 (41.6%), methotrexate - 2 (16.7%). 1 (8.3%) patient received etanercept, 1 (8.3%) patient - infliximab. Dynamic observation of rheumatologist and orthopedist was carried out before, just after surgery, after 6 months, 1 year and 2 years, with the assessment of VAS, BASDAI, ASDAS, BASFI.

Results: The reduction of pain intensity on the VAS was observed in the first month after the surgery (47.3±18.6 mm), initially it was 74.0±24.1 mm, 42.5±9 mm after 6 months (p<0.05), after 12 months - up to 22.5±19.9 mm (p<0.05). ASDAS significantly (p<0.05) reduced from 2.9±0.01 to 1.6±0.35 - in 6 months and 1.26±0.88 - 12 months after operation; BASDAI: from 6.2±3.91 to 2.7±2.20 - 6 months, 2.6±1.53 at 1 year follow-up. BASFI index before surgery - 5.4±5.29, 6 months - 2.7±2.31, 1 year - 2.3±2.60 points. No complications after surgery were registered.

Conclusions: Hip joint endoprosthesis in patients with SpA is effective not only in improving functional ability and pain relief, but also a reduction of disease activity. Dynamic rheumatologist observation in perioperative period leads to positive dynamics in relation to the activity of SpA and quality of life of patients during the first year after surgery.

AB0705 CONTINUED EFFECTIVENESS OF A BIOSIMILAR ADALUMAB IN PATIENTS WITH ANKYLOSING SPONDYLITIS AFTER STOPPAGE OF INITIAL TREATMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS

S. Bandyopadhyay1, A. Ray2, R.N. Sarkar2, S. Dash1, S. Mondal1, 1Medicine, Apollo Gleneagles Hospital; 2Medicine, Fortis Hospital, Kolkata, India

Background: Adalimumab, an anti TNF-α agent, has been proven to be safe and effective in treatment of ankylosing spondylitis (AS). A biosimilar adalimumab was approved for use by Indian regulators in 2014. It is a ‘first in market’ of the reference adalimumab in terms of purity, potency, safety and clinical efficacy. In the absence of availability of adalimumab in India, this biosimilar adalimumab currently serves as an accessible, cost-effective option for treatment of AS patients.

Objectives: This retrospective analysis evaluates effectiveness of biosimilar adalimumab (bADA), in terms of disease activity, safety and outcomes in real-life Indian AS patients treated for initial 24 weeks and then followed for next 24 weeks off biologic treatment.

Methods: Medical records of AS patients with Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional Index (BASFI) >4, who were prescribed bADA therapy between January to December 2015 were analysed. For patients, who stopped bADA treatment after 24 weeks, standard AS outcome-measurement scores including ESR, CRP, BASDAI, BASFI, and Health Assessment Questionnaire (HAQ) at baseline, week 24 and at week 48 were measured to evaluate ongoing efficacy, were compared using paired Student’s T-test. Patients were allowed to continue methotrexate and salazopyrin as part of routine medical care.

Results: During the study period, 52 AS patients were prescribed bADA 40 mg every 2 weeks. Of these patients, 10 (19.2%) patients had stopped treatment after 6 months, were considered for this analysis. Mean age for this group was 36.5±71.08 years; 10 females. At the end of 24 weeks' treatment, there were significant reductions in levels of inflammatory markers ESR, CRP, as well as in BASDAI, BASFI and HAQ scores. Eight patients continued to receive methotrexate and 8 patients sulfasalazine as concomitant medications. After week 48 (24 weeks post stoppage), BASDAI and BASFI scores did not deteriorate despite discontinuation of bADA treatment. The patients' HAQ scores were also indicative of similar trends of continuing improved health status post therapy.

Data presented as Mean±standard deviation. *p = not significant for any parameter when compared for changes from week 24 to week 48. **p=0.006 as compared to week 24 for rise in ESR during the bADA free period.

Conclusions: Biosimilar adalimumab therapy was effective in treating AS patients. The disease activity and health assessment scores continued to remain stable with no worsening after the stoppage of treatment for 6 months, indicating a post-therapy effectiveness in these patients with no reported adverse event.

AB0706 ANKYLOSING SPONDYLITIS PATIENTS WITH UVEITIS HAD A HIGHER ADALUMAB RETENTION RATE: HUR-BIO REAL LIFE RESULTS

B. Armagan1, A. Sarı1, A. Erden2, L. Kılıç1, D.C. Guven2, T. Pashayev2, E. Bilgin 1, C. Simsek2, E.C. Erdat2, O. Karadag1, A. Akdoğan1, S. Apras Bilgen1, S. Kiraz1, I. Ertenli 1, U. Kalyoncu1, 1Hacettepe University, Department of Internal Medicine, Division of Rheumatology; 2Department of Internal Medicine Hacettepe University, Ankara, Turkey

Background: Retention of biological drugs in inflammatory arthritis may be affected by many different obvious and unknown factors. It is also important to explore the characteristic or disease features in ankylosing spondylitis (AS), retention rate of biological drugs may be related with extra-articular presentation of AS such as uveitis, as well.

Objectives: The objective of this study was to assess whether uveitis affected retention of adalimumab in AS patients in our single center biological cohort.

Methods: Hacettepe University Biological registry is single-center biological registry since 2005. HURBIO had 2165 spondyloarthritids patients of which 1190 patients had AS according to NY criteria. Until now, in 510 of 1190 patients had used adalimumab and 350 of 510 patients had available for uveitis. Patients

None declared

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.3996
were assessed for demographic characteristics, disease duration, HLA-B27, DMARD and biological usage, biological switch ratio. Baseline disease activity was assessed with BASDAI, BASFI VAS (pain, fatigue and patients global assessment), ESR and CRP. Patients were compared according to having uveitis or not. Retention rate of adalimumab assessed by Kaplan-Meier survival analysis. For routine practice, adalimumab could be considered for not. Our biological cohort supported that AS patients with uveitis had better survival. For routine practice, adalimumab could be considered for AS patients with uveitis.

Conclusions: Determination of possible risk factors for retention of TNFi drugs is one of the treatment option for uveitis whether uveitis related with SpA or not. Our biological cohort supported that AS patients with uveitis had better adalimumab survival. For routine practice, adalimumab could be considered for AS patients with uveitis.

COMPARATIVE EFFECTIVENESS OF SECUKINUMAB AND GOLIMAB IN ANKYLosing SPONDYLITIS ASSESSED BY MATCHING-ADJUSTED INDIRECT COMPARISON USING PIVOTAL PHASE 3 CLINICAL TRIAL DATA

W. Maksymowycz1, E. Choy2, Y. Yazici3, J. Walsh4, H. Thom5, C. Kalyvas6, T. Fox7, K. Gandhi8, S. Jugi9, University of Alberta, Edmonton, Canada; 2University of Cardiff, Cardiff, United Kingdom; 3New York University School of Medicine, New York; 4University of Utah, Salt Lake City, United States; 5University of Bristol, Bristol, United Kingdom; 6Mapi Group, Houten, Netherlands; 7Novartis Pharma AG, Basel, Switzerland; 8Novartis Pharmaceuticals Corporation, East Hanover, United States

Background: No data are available from head-to-head RCTs between secukinumab 150 mg (SEC; an anti-IL-17A) and golimumab 50 mg (GOL; a TNFi) in patients with active ankylosing spondylitis (AS). Matching-Adjusted Indirect Comparison (MAIC) can be used to estimate comparative effectiveness and enables treatment outcomes to be compared across effectively balanced trial populations. MAIC is an established method in health technology assessments and NICE have published guidance on appropriate methodology, and especially for assessing imbalances in observed covariates between trials.

Objectives: To assess the comparative effectiveness of SEC and GOL up to week 24 using MAIC with pooled individual patient data (IPD) from the RCTs MEASURE 1 (M1) and MEASURE 2 (M2) and published aggregate data from the RCT GO-RAISE.

Methods: Pooled M1 and M2 data were used to maximize the effective sample size (ESS) for SEC. IPD from the SEC arms of M1 and M2 (n=197) were weighted to match the published baseline characteristics of the GOL arm of GO-RAISE (n=138). Placebo arms were matched in the same way; placebo-comparisons were possible only until week 16 because patients could receive active treatment from this time onwards. Logistic regression was used to determine weights for age, sex, BASFI, disease duration, CRP and previous TNFi therapy. Recalculated outcomes from M1 and M2 (SEC, ESS=102; placebo, ESS=81) were compared with data from GO-RAISE (GOL, n=138; placebo, n=78). Pairwise comparisons – reported as odds ratios (ORs [95% CIs]) – were performed for ASAS 20, ASAS 40 and ASAS PR responses at nearest-equivalent time points across trials: week 12 (SEC)/14 (GOL), week 14 (GOL)/16 (SEC) and week 24 (SEC and GOL). Non-responder imputation (NRI) was available for all binary outcome data. Strict thresholds were avoided when interpreting p values, in line with American Statistical Association 2016 guidance.

Results: There was no evidence of differences in ASAS 20 and ASAS 40 responses between SEC and GOL at weeks 12/14 and 14/16 (both placebo-adjusted). At week 24, non-placebo-adjusted ASAS 20 and ASAS 40 responses using NRI were higher with SEC than GOL (OR [95% CI]: 1.58 [0.93–2.69], p=0.089 and 1.58 [0.94–2.64], p=0.089, respectively). There was no evidence of differences in ASAS PR responses between SEC and GOL at weeks 12/14, 14/16 and 24. A sensitivity analysis conducted after adding BASDAI score to the matching parameters yielded similar results.

Conclusions: There was no evidence of differences in ASAS responses between SEC and GOL in placebo-adjusted analyses. In non-placebo-adjusted analyses, SEC showed higher ASAS 20 and ASAS 40 responses than GOL at week 24.

AB0708 TRANSITION FROM ONGOING INFlixIMAB REFERENCE PRODUCT TO ITS BIOSIMILAR: CAN WE TALK ABOUT A FAILURE?

W. Akrout1, A. Bosyco1, R. Levet-Labry1, E. Gazeix-Fontaine2, M. Paul1, P. Claudepierre1, 1Clinical Pharmacy Department; 2Rheumatology Department, Henri Mondor University Hospital AP-HF; Créteil, France

Background: Some recent publications support the fact that there is no clinically meaningful difference between infliximab biosimilar and the originator in naïve patients, but sole a few of them actually assessed the transition itself. Since May 2016, according to the European guidelines, the French Health Authorities have allowed interchangeability between a biotherapy reference product and its biosimilar. According to the last studies focusing on the safety and efficacy issues, avoiding the transition to biosimilar looks no longer justified.

Objectives: This work aimed to understand to which extent the use of infliximab biosimilar may result in the failure of the switch strategy in spondyloarthritis patients.

Methods: This is a retrospective study conducted from June to December 2016, according to the European guidelines. The French Health Authorities have allowed interchangeability between a biotherapy reference product and its biosimilar.
2016. Only were included the adult patients with rheumatoid arthritis (RA), spondyloarthritis (SpA) or psoriatic arthritis (PsA) having accepted the transition from Infliximab reference product (IFXR) to its biosimilar (IFX B). For SpA patients, transition monitoring was based on the end-of-dose “wearing off” (WO) phenomenon assessment before and after the switch, disease activity score BASDAI and also the inflammatory marker CRP. Transition was considered as unsuccessful after 2 IFX® infusions with patient complain. In this case, the drug level was determined using ELISA before switching back to IFX®, and any spacing infusions because a concomitant health disorder was sought.

Results: Of the 99 patients treated with IFX® for more than 2 years, 91% (90/99) infusions because a concomitant health disorder was sought. The level was determined using ELISA before switching back to IFX®, and any spacing infusions because a concomitant health disorder was sought. Only were included the adult patients with rheumatoid arthritis (RA), spondyloarthritis (SpA) or psoriatic arthritis (PsA). Fourteen patients (12 SpA, 2 RA) didn’t reach the 3rd IFX® administration. SpA patients reported the occurrence of arthralgia (12/12) and a partial (8/12) or total (4/12) efficacy loss. Only 5 patients reported a 2 point-increase or more regarding the BASDAI score, and only 3 patients had an increase in the CRP level (in Table 1). Except for P1, the efficacy loss was associated in each case with WO phenomenon already reported before the transition (8/12) or undetectable IFX® level (3/12). For these 3 last patients, the IFX® drug administration rate was increased by at least 2 weeks than usual because of a concomitant infection.

Table 1: SpA patients discontinued IFX® outcomes

</tbody>
</table>

Conclusions: This observational study showed a transition failure rate at 16% (76/99) in global, which reached 23% (12/53) if limited to SpA. All SpA patients with supposed transition failure reported either a disease escape beforehand or a concomitant infection requiring to spacing infusions. In order to complete these results, an anti-IFX antibodies monitoring is in progress to so highlight any IFX activity loss. Any failure observed with the transition would be actually more complex than the presumably inefficacy of the biosimilar IFX® especially for SpA patients. So, it seems difficult to assess robustly the inefficacy of the transition to IFX® in SpA patients only according to patient complain. References:

Spondyloarthritis - clinical aspects (other than treatment)

**AB0709 THE RELATIONSHIPS BETWEEN THORACIC REGION INVOLVEMENT AND FUNCTIONS OF UPPER EXTREMITY, SCAPULAR KINEMATICS IN PATIENTS WITH ANKYLOSING SPONDYLITIS: PILOT STUDY**

O. Mete1, D. Oskay1, A. Tufan2

1. Department of Medicine, Gazi University, Ankara, Turkey
2. Department of Rehabilitation Medicine, Gazi University, Ankara, Turkey

Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease that mainly affects the axial skeleton. As the disease progresses, increased thoracic kyphosis can be seen in these patients. Because of increase in thoracic kyphosis, the orientation of the scapula on the thorax and thus the functions of upper extremity may change.

Objectives: The aim of the study is to investigate the relationships between thoracic region involvement and functions of upper extremity, scapular kinematics in patients with AS.

Methods: Fifteen (15) patients with AS and eleven (11) healthy control were participated in the study. Thoracic kyphosis angle and shoulder range of motions were assessed by using digital inclinometer, scapular and shoulder muscle strength were assessed by using digital dynamometer. Three dimensional (3D) scapular kinematics were assessed by using electromagnetic tracking system, disability level of upper extremity was assessed by Turkish Version of Disability of Arm, Shoulder and Hand Questionnaire (DASH-T). Spearman correlation coefficient, Pearson correlation coefficient, Mann-Whitney U Test and Independent Sample T-Test were used for statistical analysis.

Results: DASH-T, thoracic kyphosis angle, shoulder abduction, internal rotation, external rotation of dominant side, shoulder abduction, internal rotation of non-dominant side, anterior deltoid, middle deltoid, serratus anterior, downward trapezius muscle strengths of dominant and non-dominant side, upward rotation of scapula during 30.60.90 degrees humeroracohal elevations at sagittal plane, and anterior deltoid, middle deltoid, serratus anterior, muscle strength of dominant and non-dominant side showed significantly differences between two groups. Thoracic kyphosis angle showed correlations with DASH-T (p<0.05, r=0.619), shoulder flexion, abduction, internal rotation, external rotation of dominant side (p<0.05, r=0.687), middle deltoid (p<0.05, r=0.657), p<0.05, r=0.599) and shoulder flexion, abduction, internal rotation of non-dominant side (p<0.05, r=0.858). P<0.05, r=0.805), (p<0.05, r=0.791), (p<0.05, r=0.691), (p<0.05, r=0.877). (p<0.05, r=0.796), (p<0.05, r=0.884), (p<0.05, r=0.724), (p<0.05, r=0.673). Correlations between thoracic kyphosis angle and anterior tilt of scapula during 90 degree humeroracohal elevations at sagittal plane of dominant side were obtained (p<0.05, r=0.522).

Conclusions: Scapulohumoral joint biomechanics and functions of upper extremity were affected by kyphotic posture in patients with AS. One of the most important causes of biomechanical impairment in AS patients is the deterioration of scapular kinematics with kyphosis. For preventing functional impairment, treatment programs should be supplemented with scapular kinetic exercises.

**AB0710 REVIEW OF PREGNANCY OUTCOMES IN SPONDYLOARTHROPATHY IN A UNIVERSITY TEACHING HOSPITAL**

A. Shajpal1, M. Khare2, A. Moomty3, 1. Obstetrics; 2. Rheumatology, University Hospitals of Leicester, Leicester, United Kingdom

Background: Spondyloarthropathy (SpA) is a chronic inflammatory condition of the spine affecting mainly the male population however the incidence amongst the female population is increasing. The peak incidence of SpA is in the reproductive age group. There has been a lack of focus on pregnancy in SpA as compared to other autoimmune condition such as Lupus and Rheumatoid arthritis, but this is changing. There is a paucity of information (1) on fertility and pregnancy outcomes in this condition compared to other diseases and this may lead to inequality in healthcare delivery.

Objectives:

• To review the pregnancy outcomes in women with SpA in our unit
• To review ankylosing spondylitis activity during pregnancy
• To improve the quality of care in this group of patients by developing local pathways and appropriate MDT involvement

Methods: This is a retrospective case review of pregnancies in women with SpA booked at a large tertiary teaching hospital over three years between January 2014 and December 2016. We have an annual delivery rate of 11,000 maternities. The maternity electronic database and clinic diaries were used to identify the cases. A standardised proforma was used to collect and collate the data for demographics, pre pregnancy counselling, disease activity and pregnancy outcome.

Results: Six pregnancies were identified in the study period. All patients were under the care of a Rheumatologist. The maternal age range was between 28 and 35 years. The BMI ranged between18 and 37. Ethnicity included 5 caucasian and one Asian woman. Five women had previous pregnancies and one was in her first pregnancy. Two of the multiparous women had previously delivered by caesarean section. Three of the six women suffered from anxiety and/or depression and one had antiphospholipid syndrome. Two of the patients were not on any medcations at the time of pregnancy and didn’t require any during pregnancy. Four women needed various analgesics and one patient was on sulfasalazine but stopped this at 5 weeks’ gestation. NSAIDs was stopped in 3 women after confirmation of pregnancy. One patient who was on Anti TNF therapy discontinued the drug preconception. We observed 50% attended specialist maternal-fetal medicine and anaesthetic services. One patient saw a physiotherapist and accessed hydrotherapy during pregnancy.

Two of six patients delivered preterm (<37 weeks) and 4 delivered at term (>37 weeks). Of the preterm deliveries, 1 went into spontaneous, labour not related to disease flare and the other was delivered electively for fetal concerns. All the women delivered by caesarean section. One was planned as an elective caesarean for maternal request due to difficulty abducting legs. All the remaining caesarean deliveries were for obstetric indications not related to SpA.

Conclusions: This small observational case series did not highlight any worsening SpA disease activity or poor pregnancy outcome. Further larger studies are required. However a care pathway for managing this group of patients would help to standardise the care during pregnancy. A multidisciplinary approach is essential to optimise the quality of care for these patients.
AB0711 REVIEW OF MANAGEMENT OF HLA B27 POSITIVE UVEITIS PATIENT ATTENDING A TERTIARY HOSPITAL – HOW GOOD ARE WE?

B Kapoor1, K Periyasamy1, M Babington1, A Moorthy1, B. Kapoor1

Objectives:

• To assess the ophthalmologist practice in evaluating patients with AAU for inflammatory back pain or other Rheumatological diagnoses.
• To identify the number of HLA B27 requests made for uveitis patients.
• To identify the referral rate of HLA B27 uveitis patients to Rheumatologists for evaluation.

Methods:

We conducted a retrospective pilot study to assess all patients with AAU presenting over a period of one-week to our busy teaching hospital eye casualty which serves over one million population. All patients with iritis were identified from eye casualty records and medical case notes were obtained. A standard proforma was designed and piloted with few case notes initially. Modified proforma was subsequently used to collect the data which was collated and analysed using EXCEL spread sheet.

Results:

A total of 62 patients (n=62) with AAU presented to eye casualty over a one-week period. Case notes of 49 patients could be procured. Majority of the patients were Caucasians (n=35) while the rest were Asians (n=12) and blacks (n=2). Sex ratio was nearly equal with 25 patients being males and the rest were females. Most of our patients’ age ranged between 20 to 60 years. 60% patients had a history of recurrent iritis. Out of these 9 patients had bilateral uveitis and 14 were unilateral. In 6 patients, the laterality was not documented. A history for spondyloarthropathy was elicited in only 14 patients by the ophthalmologist at the time of initial assessment. Out of these 14 patients inflammatory back pain history was positive in 10 patients. Only 17 out of 62 (27%) patients had HLA B27 checked and it was noted to be positive in 5. Among the 5 HLA B27 positive patients 2 patients were referred to rheumatology whereas 2 patients were already under rheumatologist.

Conclusions: We observed that there is a clear lack of understanding in eliciting effective rheumatology history in patients with recurrent anterior uveitis and requesting HLA B27 appropriately. Therefore, a need for a clear pathway for managing patients presenting with recurrent uveitis and HLA B27 positivity for evaluation of Inflammatory back pain. Clear local guidelines and pathway need to be developed to provide effective care. Good communication between the Ophthalmologist and Rheumatologist is key in early diagnosis and effective management of this deforming condition.

AB0712 CLINICAL CHARACTERISTICS OF SPONDYLARTHROPATHIES (SPA) WITH AND WITHOUT PERIPHERAL ENTEHESITIS – DATA FROM THE DESIR COHORT

V. Nadon 1, A. Molto 2, A. Ethcheto2, L. Bessette 2, L. Michel 2, P. Claudepierre 2, D. Wendling 5, C. Tkaczyk 2, B. Harauzi 1, M. Dougados 2, 1 Inserm 789; 2Rheumatology, Hôpital Cochin, Paris, France; 3CHUL, Quebec, Canada; 4Hôpital Henri Mondor, Créteil; 5CHRU, Besançon, France; 1Janssen, Montreal, Canada.

Background: Peripheral enthesitis, mostly in the lower limbs, is a major feature of spondylarthropathies. Its prevalence is highly variable depending on the population studied, estimated between 10% and 70%. The probability to develop a peripheral enthesitis over time and the factors associated with it are mostly unknown.

Objectives: The aims of the present study were: 1) To describe the prevalence and characteristics of peripheral enthesitis in early axial SpA population, at the inclusion in the DESIR cohort; 2) to estimate the incidence of peripheral enthesitis over time; 3) to determine the factors associated with the presence of peripheral enthesitis.

Methods: We used data from the DESIR cohort, a prospective multi-center, longitudinal French cohort of 708 patients with inflammatory back pain suggestive of early axial SpA (~3 years since axial symptoms onset). We performed a descriptive analysis to evaluate the prevalence and characteristics of the peripheral enthesitis at time of inclusion (location, number of entheses, and mean time between first entheses and axial symptoms). We also estimated the incidence of peripheral entheses over a follow up period of 80 months, using Kaplan-Meier curves. Finally, we determined the baseline characteristics associated with the presence of a peripheral enthesis by multivariable analysis (logistic regression, including the variables significantly associated in the univariable analysis).

Results: At inclusion, 399 patients (56.4%) had peripheral enthesis in their past medical history. The locations were mainly the plantar fascia (212/395, 53.7%) and the Achilles tendon (152/395, 38.5%). Seventy-seven (19.4%) of these patients developed peripheral enthesis before their axial symptoms, with a mean time interval of 773 days. During the 5-year follow-up period, 109/708 (15.4%) patients developed new peripheral enthesic symptoms, resulting in 504/708 (71.2%) patients who had presented with at least one episode of peripheral enthesitis at 5 years. Variables associated to peripheral enthesitis according to the univariable analysis were: older age, male gender, HLA B27 positivity, MRI sacroiliitis, Modified NY criteria fulfilled, presence of either anterior chest wall pain, peripheral arthritis, dactylitis or psoarisis, high BASDAI, BASFI or mean score ASAS-NSAID. Only the history of anterior chest wall pain and of peripheral arthritis were significantly and independently associated with the presence of peripheral enthesis in the multivariable analysis (Odds Ratio (OR) = 1.6 [95% Confidence interval 1.6–2.3], and OR=2.1 [1.4–3.0], respectively)

Conclusions: This prospective study highlights the high prevalence of peripheral enthesitis in early axial SpA and stresses the importance of researching any signs and symptoms of enthesitis, especially in those patients with anterior chest wall pain and peripheral arthritis.

AB0713 UVEITIS SECONDARY TO SPONDYLARTHROPATHIES IN AN OCULAR INFLAMMATION INTERDISCIPLINARY UNIT

D. Peiteado 1, A. Pieren 1, A. Schlinker 2, V. Hidalgo 2, C. Millán 1, E. De Miguel 1, A. Balóa 1, 1Rheumatology; 2Ophthalmology, Hospital Universitario la Paz, Madrid, Spain

Objectives: To describe the characteristics of ocular involvement in spondyloarthropathies in an ocular inflammation interdisciplinary unit.

Methods: This descriptive study include the patients with uveitis secondary to spondyloarthropathy or inflammatory bowel disease (IBD) treated by the rheumatologist from January 2012 to December 2016 in an ocular inflammation multidisciplinary unit. Demographic characteristics, aetiology, ocular involvement pattern, and systemic therapy data were collected and analysed.

Results: From 276 patients evaluated by the rheumatologist, 111 (40.2%) were uveitis secondary to systemic inflammatory diseases. Within this group, the uveitis
associated with spondyloarthritis (including also IBD) were the most frequent (68 patients, 61%). Focusing on this group, 57.4% were male with a mean age of 49±15.8 years. 73.5% were HLAB27 positive and 76% had radiologic sacroiliitis.

In 24 patients (35.3%) the diagnosis of spondyloarthritis was made after the anamnesis in the uveitis unit. The diagnosis was already known in the other cases. The spondyloarthritis subtypes are described in the table.

According to the anatomical distribution, 95.6% were anterior uveitis (AU), followed by the intermediate and posterior ones (1.5% both), 85.3% has unilateral involvement and 10.3% bilateral. Relapsing acute AU was the most frequent pattern (73.5%), followed by non-relapsing acute AU (16.2%) and chronic AU (7.4%).

27 patients (35.3%) required treatment with DMARD to achieve uveitis control. The most commonly used drugs were salazopyrine (7 patients), methotrexate (6 patients), mycophenolate (1), and in another 6 patients anti-TNF treatment was started or the previous dose of the biological was adjusted. The visual acuity (VA) was not perfect (VA<1 in both eyes) in 35% in the first collected visit. 19 patients had cataract, and 19 (13%) had ocular hypertension. Only 1 patient had bilateral ciliary macroedema. Follow-up data were available for 43 patients and VA was stable in 47%, worsening in 23% and improving in 30% (median follow-up time 23 months, IQR: 6–41).

Conclusions: Our work confirms that in spondyloarthritis the most frequent pattern of ocular involvement is relapsing acute AU. Spondyloarthritis diagnosis was made at the uveitis unit in 35% of patients. More than one-third of patients required systemic therapy for ocular involvement control. Thirty-five percent of the patients had a reduced VA, remaining stable or improving in most, during the follow-up.

AB0714 DIFFERENTIATING CHARACTERISTICS IN PATIENTS WITH SPONDYLOARTHRITIS WHO HAVE RECEIVED DIFFERENTS ANTI-TNF THERAPIES
E. Moral1, C. Plasencia1, D. Pascual Salcedo2, C. Tornero1, P. Bogas1, V. Navarro3, A. Villalba1, D. Peiteado1, I. Monjo1, A. Balsa1, I. Rheumatology; 2 Immunology, la Paz University Hospital, Madrid, Spain
Background: The term spondyloarthritis (SpA) encompass a group of chronic inflammatory disease with predominant axial involvement. Anti-TNF therapy (AT) has collected a high patient visit. From 19 patients has cataract, and 19 (13%) had ocular hypertension. Only 1 patient had bilateral ciliary macroedema. Follow-up data were available for 43 patients and VA was stable in 47%, worsening in 23% and improving in 30% (median follow-up time 23 months, IQR: 6–41).

Conclusions: Our work confirms that in spondyloarthritis the most frequent pattern of ocular involvement is relapsing acute AU. Spondyloarthritis diagnosis was made at the uveitis unit in 35% of patients. More than one-third of patients required systemic therapy for ocular involvement control. Thirty-five percent of the patients had a reduced VA, remaining stable or improving in most, during the follow-up.

AB0715 DIFFERENCES IN THE CO-MORBIDITIES DESCRIBED FROM SPONDYLOARTHRITIS PATIENTS WITH OR WITHOUT CONCOMITANT FIBROMYALGIA
E. Roussou, M. Karela, A. Georgiou. Rheumatology, Barking, Havering and Redbridge University Hospitals NHS Trust, London, United Kingdom
Objectives: To assess the differences in the occurrence of co-morbidities from cardiovascular, respiratory, renal/urological and Central nervous systems (CNS) between patients with spondyloarthritis (SpA) not having headache as presenting symptom and those having headache as presenting symptom.

Methods: Data obtained through a questionnaire from 776 patients seen in clinic with SpA was analysed with reference to headache as symptom at presentation. From the total 776 patients 13 patients did not record an answer to the question and were hence excluded. The remaining 763 patients were divided in 2 groups: Those having headache at presentation (n=117) considered having sFM, and those not having headache at presentation (n=656).

24% of the nonresp-AT were ADA + at drug discontinuation, while only 0.7% of the AT- (resp-AT) were ADA + (p=0.001) at last visit.

Conclusions: In our cohort of patients with axial SpA, a significant improvement in BASDAI, ASDAS and ASDAS after 6 months of treatment is associated with a lower frequency of drop-out of the first AT. Moreover a lower BMI, DMARDS at baseline and absence of ADA determine a better response to AT treatment.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.6566
The data of patients with sFM were compared with the data of patients who did not report headache as a presentation symptom therefore not having FM with regards to age, disease duration, delay in diagnosis, disease activity (BASDAI) functional ability (BASFI), ESR, CRP and associated comorbidities from cardiovascular, respiratory, renal/urinary, and CNS systems. Central nervous system was evaluated by symptoms of dizziness and numbness. Independent sample T test was used to explore differences between the 2 groups and confidence intervals obtained.

Results: Table shows demographics and disease characteristics as well as differences between SpA patients presenting with headache (indicating secondary FM), and those not presenting with headache. A greater proportion of patients with SpA and headache (sFM) report cardiovascular and CNS co-morbidities. There was no significant difference noted in the respiratory or renal/urological co-morbidities amongst the 2 sub-groups.

Conclusions: A significantly higher proportion of patients described cardiovascular and CNS co-morbidities in the sFM group of SpA. No significant difference was noted in the 2 sub-groups with regards to the respiratory or renal systems.

AB0716 PREVALENCE OF STRUCTURAL LESIONS TYPICAL FOR AXIAL SPONDYLOARTHRITIS IN YOUNG MILITARY RECRUTS BEFORE AND AFTER MECHANICAL STRESS

G. Verkas1,2, M. de Hooge2, T. Renson2, P. Carron1,2, S. De Mits3, G. Souverijns1, D. Elewaut1,2, F. Van den Bosch1,2. 1Department of Rheumatology, Ghent University Hospital; 2IBB Inflammation Research Centre; 3Department of Rehabilitation Sciences and Physical Therapy, Ghent University, Gent; 4Department of Radiology, Jessa Ziekenhuis, Hasselt, Belgium

Background: Magnetic resonance imaging (MRI) has become the imaging modality of choice in early SpA. Not only has this imaging technique proven useful in the identification of inflammatory lesions on T2 FS/T2R sequences, also structural lesions such as erosions, sclerosis, fat infiltration and ankylosis can be seen on T1 sequences. There is still ongoing debate concerning the possible inclusion of any structural lesion in the definition of a positive MRI in order to improve specificity. However, erosions and fat infiltration have also been found in respectively more than 10% and 17% of non-SpA patients on MRI of the sacroiliac joints. [1]

Objectives: To evaluate the presence of structural lesions on MRI of the sacroiliac joints (MRI-SIJ) in young, asymptomatic subjects.

Methods: Twenty-five military recruits volunteered to perform a MRI-SIJ before and after 6 weeks of physical training, of which 22 recruits underwent imaging at both time points. The MRIs were scored for structural lesions by 3 trained readers MdH, GV and TR, blinded for time sequence and clinical findings. Regarding the number of lesions a consensus was made by agreement of 2 out of 3 readers.

Results: At baseline, structural lesions were present in 36.4% (8/22) of subjects of which 5 subjects presented with at least 1 erosion, one subject with sclerosis and 3 subjects presented fatty lesions. This increased to 50% subjects (11/22) with structural lesions on MRI-SIJ after 6 weeks of mechanical stress, of which 8 subjects with at least 1 erosion, one subject with sclerosis and 3 subjects presented fatty lesions (P=0.453). The change scores for sclerosis, erosions and fatty lesions were respectively 0.0 (±0.0), 0.2 (±0.1) and 0.3 (±0.2). None of the subjects displayed ankylosis. The lesion distribution is visualized in Table1.

Table 1. Number of structural lesions in young military recruits before and after intensive training

AB0717 CONDUCTION DISTURBANCES IN A GROUP OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS

H.S. Park1, A. Laiz1, C. Alonso2, A. García-Guillén1, M. MILLIAN2, B. Magallares1, P. Moya1, I. Castelvi1, C. Díaz-Torres1, J.M. De Liobet1. 1Rheumatology; 2Cardiology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

Background: Cardiac conduction disturbances are known to be one of the many extra-articular manifestations of Ankylosing Spondilitis but not as well related to axial spondyloarthropathies.

Objectives: Description of conduction disturbances found in a group of patients with Axial Spondyloarthropathy (AxSpa) that met ASAS criteria.

Methods: Clinical and demographic variables of 78 patients with AxSpa were registered. It included cardiovascular risk factors as well as cardiovascular adverse events. All of them had a routine electrocardiogram done which were analyzed by a cardiologist.

Results: 48 of the 78 patients were men, with a mean age of 61 with standard deviation (SD) of 14. The mean time of evolution of the disease was 23 years (SD ±16). HLA-B27 was prevalent in 54 (69.2%). The sacroiliitis was found in radiologic examination of 72 (92.2%), and 6 (7.7%) of them presented edema in magnetic resonance imaging. Other clinical traits were: 43 (55.1%) peripheric arthritis 43, 8 (10.3%) dactylitis, 33 (42.3%) enthesitis, 16 uvulitis (20.5%), 2 (2.6%) inflammatory bowel disease and psoriasis 34 (43.3%). The following cardiovascular risk factors were registered: 25 (32%) smokers, 42 (53%) hypertension, 32 (41%) dislipemia, 9 (12%) diabetes, 9 (12%) hyperuricemia and 20 (26%) obesity. 14 patients had structural cardiac (11 ischemic cardiopathy and 3 aortic valvulopathy). The electrocardiographic register showed conduction disorders in 20 patients (25.6%). The details of these findings are specified in table 1.

AB0718 PREVALENCE OF RISK FACTORS FOR FRACTURES IN AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW

J. Ramírez García1, R. Curbelo2, J.C. Nieto3, S. Castañeda4, L. Carmona2. 1Rheumatology, Hospital Clinic, Barcelona; 2Instituto de Salud Musculosqueletica; 3Rheumatology, Hospital U.G. Gregorio Marañón; 4Rheumatology, Hospital de la Princesa, Madrid, Spain

Background: Spinal fractures occur more than expected in axial spondyloarthritides (AxSp). However, it is not totally clear whether fracture risk depends solely on biomechanical problems of the spondyloarthritic spine or whether the prevalence of risk factors for fracture is larger than expected in these patients.

Objectives: To describe the prevalence of risk factors for osteoporotic fractures (both axial and peripheral) in AxSp.

Methods: A systematic literature search was conducted. Medline, Embase and Cochrane Library databases were searched with a sensitive strategy including type of study and synonyms of AxSp. All contemporary cross sectional studies or baseline results from representative cohorts of AxSp published between January 2006 and 2016 were selected for detailed review. Only studies that fulfilled a minimum quality for survey data were included. Data on bone mineral density, prevalence of osteoporosis, and risk factor for fractures in AxSp patients were collected.

Results: After screening 3597 titles and abstracts, only 43 studies (34 cross-sectional, 3 prospective and 6 retrospective) were reviewed in detail. Of these, 20 studies compared AxSp patients with a control group, either healthy individuals (17 studies) or subjects with other diseases (6 studies). Reported prevalence of osteoporosis varied from 2% to 39.6%. Alcohol intake (58–61%), use of corticosteroids (11.7–87%), and 25-OH vitamin D deficit (25–76%) were unexpectedly high in AxSp patients. All other factors were within expected frequencies for a not too old population.

Conclusions: Our systematic review found that alcohol intake, steroid use and 25-OH vitamin D deficit should be taken into account when assessing comorbidity in AxSp in order to avoid excess fractures.

AB0719 BASELINE CHARACTERISTIC OF NEWLY DIAGNOSED PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE SINGLE CENTRE LITHUANIAN COHORT

J. Sabaliauskienė1, A. Baranauskaitė2, 1Rheumatology, 2University of Health Sciences, Kaunas, Lithuania

Background: The prevalence rates for spondyloarthropathies has been investigated in an epidemiological study in Lithuania (1), but no studies are analysing the demographics, clinical characteristics of SpA in Lithuania. Changes in spondyloarthritides (SpA) concept and application of the new criteria for classification should improve spondyloarthritides diagnostic standards in routine clinical practice.

Objectives: To assess demographics and clinical manifestations of firstly diagnosed axial spondyloarthritides, to compare arkyloising spondylitis (AS) with non-radiographic axial spondyloarthritides (nr-axSpA) using standardized clinical assessment tools.

Methods: In September 2014 our centre began to collect a cohort of patients with newly diagnosed axial spondyloarthritides, according to ASAS criteria. Statistical analysis was performed with SPSS 20.0. A p<0.05 was considered statistically significant.

Results: 97 patients (60 men, 37 women) have been included. All of them (100%) suffered from chronic back pain. Inflammatory back pain (according to ASAS criteria) was present in 77%, 34 (35,1%) patients already had definite radiographic changes in the sacroiliac joints (SIJ), therefore based on modified New York criteria was diagnosed. The mean age at first visit was similar: 35.5±15.7 (AS) versus 33.5±14.0 (nr-axSpA). BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) was significantly less in AS group (mean 106.6 months in AS versus 44.8 months in nr-axSpA). The prevalence of HLA-B27 was similar: 74.6% vs 91.2% for nr-axSpA and AS, respectively. There were more males in AS group (76.5% vs 54.0%, p<0.05). The frequency of clinical features (peripheral arthritis, dactylitis) and extra-articular manifestations (enthesitis, uveitis, psoriasis, inflammatory bowel disease, preceding infection) was similar between the two subgroups (p>0.05).

Mobility was slightly more impaired in AS patients, but it did not reach a significant level.

No differences in the level of global pain, patient’s global assessment were found. BASDAI did not show the significant difference between AS and nr-axSpA (mean 4.5±2.1 vs 3.9±2.0), as well CRP (mean CRP 17.3±19.0 vs 17.5±17.0), due to the fact that ESR.

Conclusions: Diagnosis of axial SpA in Lithuania remains delayed. The proportion of patients with AS among newly diagnosed axial SpA is high. There are more women in the nr-axSpA group. Both groups do not differ regarding clinical features, disease activity.

AB0720 CHARACTERISTICS OF TUNISIEN SPONDYLOARTHRITIS PATIENTS WITH HIP DISEASE

K. Maatallah1, F. Essafi1, I. Mahmoud2, K. Ben Abdelghani3, O. Saidane2, 1Rheumatology; 2Lithuanian University of Health Sciences, Kaunas, Lithuania

Background: spondyloarthritides (SpA) is characterized by inflammation of spine and sacroiliac joints. Hip involvement is the most frequent extra spinal arthritic manifestation of SpA and may lead to a worse functional outcome.

Objectives: The objective of this study was to assess clinical, biological and radiological characteristics of SpA patients with hip disease.

Methods: This is a transversal multicenter study, including SpA patients (satisfying ASAS criteria2009) with hip disease. Demographic, clinical, radiographic, and laboratory data were collected and analyzed. Radiographic forms of hip disease were assessed according to Netter classification (early, condensing, destructive, and synostosante forms). Radiographic severity was assessed by the modified Stokes Ankylosing Spondylitis Spine Score (mSASSS) and BASRI (Bath Ankylosing Spondylitis Radiologic Index).

Methods: Patients with hip disease were enrolled. In all patients, X-ray of both hips was performed. The presence of mSASSS and BASRI were calculated.

Results: Ninety-five patients were evaluated (77men). The mean age was 41.53±1.97 years. The median age at disease onset was 26.23±10.29 years. The mean disease duration was 6.48 years. 46% of patients were smoker. HLA-B27 was positive in 50% of cases. A peripheral joint involvement was found in 33% of cases. Extra-articular manifestation was seen in 57% of patients: uveoprosis (16 patients), uveitis (15 patients), psoriasis (10 patients), chronic inflammatory bowel disease (12 patients). 5% of patients had bilateral hip involvement and 147 hips were evaluated. The median BASDAI and BASFI scores were respectively 5.4 and 5.5.

The mean index of severity for osteoarthritis for the hip (ISH) was 12.24 (±6.84). Patients had an early form of hip disease in 22% of cases. Condensing form was in 3% of cases, combined forms in 22% of cases and destructive form in 53% of cases. The mean mSASSS score was 15.34±16.22.

Conclusions: Our finding confirm previous observation that clinical and radiological hip involvement is associated with a more severe disease with a high activity and pronounced functional impairments.

AB0721 THE EVALUATION OF ULTRASONOGRAPHIC AND CLINICAL ENTHESOPATHY IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES

E. Suleyman1, H. Harman2, K. Nas3, 1Division of Rheumatology and Immunology, Department of Physical Medicine and Rehabilitation, Sakarya University, Faculty of Medicine, Sakarya; 2Rheumatology Clinic, Bolu Izzet Bayraslı State Hospital, Bolu, Turkey

Background: Enthesitis is considered as the primary anatomical lesion in spondyloarthropathy (SpA) but it can be seen in other rheumatic diseases. Its locations and clinical relationships have not been studied well in the literature.

Objectives: We aimed to investigate the frequency of ultrasonographic, clinical enthesopathy and the relationship between enthesopathy and disease activity, functional status in patients with rheumatoid arthritis (RA) and axial SpA.

Methods: Thirty three axial SpA, 21 RA patients and 30 healthy subjects were included in the study. The clinical and functional evaluations relied on the BASDAI, BASFI, ASQoL, DAS28, and HAQ, and on aVAS for enthesal pain, as well as on the RMDQ. Knee, ankle and elbow were examined with US bilaterally in 172 joint regions.

Results: The physical examination scores for enthesis were 1.97±2.68, 2.43±1.80, 0.23±0.12 in axial SpA, RA and healthy subjects, respectively. There was a significant difference between axial SpA and RA about enthesitis physical examination scores (p=0.123). A statistically significant difference was not found between axial SpA and RA in quadriceps tendon enthesis and distal patellar ligament enthesis according to MASEI index (MASEI 3.45, p=0.993, p=0.124, p=0.652). Other MASEI enthesis scores were statistically higher in axial SpA group than RA and healthy subjects (p<0.008). Positive correlations were found between BASDAI scores and enthesis pyhsical examination scores, MASEI total scores (p=0.739, p=0.0001, p=0.516, p=0.002).

Conclusions: Ultrasonographic enthesis was associated with impaired quality of life in axial SpA. MASEI 1 and 2 was specific enthesal regions in MASEI index for axial SpA. Different from RA, the calcaneal enthesis region for clinical investigation and ultrasonographic enthesisopathy should be focused on in axial SpA.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.6834
Results: 92 primary care practices were randomized. 679 patients participated (64% women, mean age 36.2 years (SD7.5) and median CLBP duration 9 years (IQR 4–15 years). 333 patients were randomized to the intervention group, both groups had similar characteristics at baseline. Sixty percent of participants had a positive referral rule. RMDQ scores are shown in table 1. Sub scores are shown for patients with a positive outcome of the referral rule (PRP) and a negative outcome of the referral rule (NRR). The change in RMDQ score after 4 months in the intervention group was -0.74 (95% confidence interval (CI) -1.31 – -0.18) and in the control group -0.46 (95% CI -0.98 – 0.05). There was no significant difference between groups.

Conclusions: Compared with usual care, use of the CaFASpA referral rule in CLBP patients in a primary care setting did not significantly impact disability in these patients, 4 months after a referral advice was made. Results after 12 and 24 months should be awaited before definitive conclusions about the impact of the CaFASpA referral rule for axSpA in CLBP patients can be made.

Carmona 19, 1 Rheumatology, HU Gregorio Marañón; 2 InMuse, Madrid; 3 Rheumatology, HU Monte Naranco, Oviedo; 4 Rheumatology, HU Reina Sofia, Córdoba; 5 Rheumatology, HU la Princesa, IIS-IP, Madrid; 6 Rheumatology, HU Clinic i Provincial, Barcelona; 7 Rheumatology, H U Can Misses, Ibiza; 8 Rheumatology, HU 12 de Octubre, Madrid; 9 Rheumatology, H U de Plasencia, Plasencia; 10 Internal Medicine, HU la Princesa, IIS-IP; 11 Cardiology; 12 Gastroenterology, HU la Paz; 13 Psychology, UCJC, Madrid; 14 Centro de Salud Ciudadanos, Getafe; 15 Centro de Salud Alcobendas, Alcobendas, Spain

Background: The management of comorbidity in patients with axial spondyloarthritis (AxSpA) needs improvement; the implementation of clinical practice guidelines is still deficient and heterogeneous.

Objectives: To prioritise comorbidities in AxSpA and to elaborate practical aids for their identification and follow-up.

Methods: A multidisciplinary panel [10 rheumatologists (6 experts in AxSpA), 2 family doctors, 1 internist, 1 cardiologist, 1 gastroenterologist, 1 psychologist and 3 methodologists] prioritised, in a discussion group, a list of comorbidities based on frequency and impact. Each comorbidity was discussed largely and systematically. A list of items was prioritised, in a discussion group, a list of comorbidities based on frequency and impact. Each comorbidity was discussed largely and systematically. A list of items was prioritised, in a discussion group, a list of comorbidities based on frequency and impact. Each comorbidity was discussed largely and systematically.

Conclusions: These checklists are intended to facilitate the systematic evaluation of co-morbidity associated with AxSpA, thus allowing an earlier detection and better control and management of these patients by the rheumatologist.

AB0725 USING A REDUCED JOINT COUNT IN MEASURING DISEASE ACTIVITY IN PSORIATIC ARTHRITIS, IS IT LEGIT?

M. Vis1, K. Wervers2, I. Tchetverikov3, A. Gerards 4, M. Koek5, C. Appels6, K. Wervers2, I. Tchetverikov3, A. Gerards 4, M. Kok5, C. Appels6.

Newly diagnosed PsA patients were included in the Dutch Early Methods:

Objectives: To evaluate the effect of using a 28, 44 or 66/68 joint count on Minimal Disease Activity (MDA).

Methods: Newly diagnosed PsA patients were included in the Dutch Early south-west Psoriatic Arthritis Registry (DEPAR) study between August 2013 and January 2017. Joint scores at baseline and 6 months were calculated using a 28, 44 and 66/68 joint count. Consequently MDA was calculated using each of these joint counts. MDA is defined as minimal disease activity in 5 out of 7 domains (swollen joints, tender joints, PASI, patient vas pain, patient vas global, HAQ, emotional state).

Results: In total, 413 patients were included into the study, of which 320 had reached 6 months follow-up at the time of this abstract. Half of the patients were male (49%), and mean age was 50 years (SD 13.8).

The percentage of patients with at least one involved joint (swollen or tender) at baseline decreased from 91% using the 66/68 score to 86% with 44 joints and then to 80% with a 28 joint count (Table 1). At 6 months these scores were 66% 63% and finally 56% respectively for the 66/68, 44 and 28 joint count. After 6 months, 96 patients (30%) had achieved MDA using the original 66/68 joint count. Using a 28 joint count, 10 more patients (10% of the MDA population) were classified as having achieved MDA.

Table 1. Joint scores and MDA at baseline (n=421) and 6 months (n=320) using 66/68, 44 and 28 joint counts in a population of newly diagnosed PsA patients

<table>
<thead>
<tr>

<td>28</td>
<td>28</td>
</tr>
<tr>
<td>MDA (%)</td>
<td>56 (14)</td>
<td>65 (16)</td>
</tr>
</tbody>
</table>

Conclusions: Using reduced joint counts in PsA misclassifies around 10% of patients as having no joint involvement. It also misclassifies about 10% of the MDA population of having achieved MDA while they have not. Full 66/68 joint counts remain recommended for measuring disease activity in PsA.

AB0726 SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

M. Ismael, A. Mosallam, M. Abdelaziz, A. Moshrif, Rheumatology, Faculty of Medicine, Al Azhar University, Assiut, Egypt

Background: Systemic inflammatory response of various autoimmune diseases has been reported as a cause of accelerated atherosclerosis which is a risk factor for cardiovascular complications.

Objectives: This study aimed to evaluate atherosclerosis in patients with ankylosing spondylitis (AS) and its relation to disease activity.

Methods: The study was carried out on thirty AS patients, who fulfilled the modified New York criteria. Thirty apparently healthy normal volunteers, age and sex matched served as control. Complete History taking, General and systemic examination, Body mass index (BMI), Bath AS disease activity index (BASDAI), Bath AS functional index (BASFI), lipid profile, inflammatory markers and serum glucose level were done. Based on BASADI score, patients were then classified to active and inactive groups comprised 11 patients (37%) and 19 patients (63%) respectively. Carotid intima-media thickness (CIMT) was measured using real-time gray-scale sonography. The intima-media thickness (IMT) of common carotid artery, carotid bulb and internal carotid artery was determined.

Results: 25 males (83.3%) and 5 females (16.7%) with mean age 39.1±12.38, their mean disease duration 13.13±8.03 while controls were 21 males (70%) and 9 females (30%) with mean age 39.7±12.6.

While IMT was found significantly increased in patients (0.87±0.49) versus controls (0.5±0.12) (P<0.001), there was no significant difference regarding the presence of plaques and there was no stenosis found in cases or controls. No significant difference was found between active and inactive cases as regard to components of lipid profile. The mean IMT in active and inactive cases was 0.76±0.11 and 0.72±0.17 respectively with no significant difference, we found no significant correlation between IMT and different disease scores, ESR or CRP.

Conclusions: AS patients have a higher risk for developing atherosclerosis. IMT of common carotid artery could be added as a further investigation for detection and follow up of atherosclerosis in AS patients.

RHEUMATIC MANIFESTATIONS OF INFLAMMATORY BOWEL DISEASES, STUDY FROM MIDDLE EAST

M. Hammoudet1, S. Alkaibit1, M. Sharma1, E. Al-Sayed1, P. Chandrat2, M. Elbadri1, S. Hammoudet1, N. Abu Na@yahoo2, 1Medicine; 2Research center, HMC; 3Research center, Weill Cornell College-Qatar, Doha, Qatar

Background: Musculoskeletal symptoms accompanying the diagnoses of Inflammatory bowel diseases (IBD), are seen in 6-46% of cases.

Objectives: The goal of this study is to examine the prevalence of rheumatic manifestations among patients diagnosed with IBD.

Methods: Between 1/2/2015 and 30/7/2016 all consecutive IBD patients were approached. A total of 127 adult patients signed the consent form. The diagnosis and the clinical course of inflammatory bowel disease (IBD) of Crohn’s or Colitis (UC) had to be confirmed by a colonoscopy and histopathology. Patients were then interviewed and examined by one of two expert rheumatologists. A set of questions were used, complete rheumatological examination, X-rays of the lumbosacral and SI joints, and HLA-B27 test were done.

Results: Among our sample; 66% were Arabs and 34% are Asians. 58.3% were males, 52% fell in the age category of 30–49 years, 83.1% were married, 25.6% had a graduate degree, 36.5% had a history of smoking, and 15.2% had a family history of IBD.

In our study, it was seen that 36.9% had Crohn’s disease, and 64% had ulcerative colitis.

Any type of rheumatic manifestations were present in 57.5% with no significant differences between the the two types of IBD diseases (p>0.05).

The majority of these patients had peripheral manifestations (arthritis, arthralgia, enthesitis) (43.3%), while only 3.1% had axial alone, and 11% had both types. Among those with peripheral manifestations; 7.2% had type 1 arthritis (Psoriatic), while 1.4% had type 2 arthritis (Polyarticular).

There were no significant differences between the two types of IBD diseases in regards to the presence of peripheral manifestations (p>0.05).

However, the two diseases were significantly different in the presence of axial manifestations as more people with Crohn’s have axial manifestations. Combined with Ulcerative colitis (12.3%). Those with Crohn’s had more people with rheumatic manifestations 4–7 years before the diagnosis of IBD. HLA-B27 was positive in 5 patients with Crohn’s and 2 with ulcerative colitis.

Logistic regression analysis of the data did not reveal any significant predictor or potential risk (type of IBD, gender, age group, BMI, smoking, family history, duration or extent) for the development of musculoskeletal manifestations in our patients.

Conclusions: In this study of musculoskeletal manifestations of patients with IBD from the Middle East 57.7% of them have any rheumatic manifestations. Peripheral manifestations occurred in 43%, axial alone in 3.1%, axial and peripheral manifestations in 11.5%, type 1 arthritis in 7.2% and type II in 1.4%. More patients from the Middle East 57.7% of them have any rheumatic manifestations. Peripheral manifestations in our patients.

Disclosure of Interest: None declared.

SPONDYLOARTHRITIDES AND ITS RESPONSE TO ANTI-RHEUMATIC DRUGS

N. Ronsard1, I. Hokstad2, G. Deyab3, D. Greco1, S. Agewali4, S. Avila5, J.E. Whist6, F. Bennini7, I. Høiland8,9, 1Department of Food and Drug, University of Parma, Parma, Italy; 2Lillehammer Hospital for Rheumatic Diseases; 3Department of Medical Biochemistry, Innlandet Hospital Trust, Lillehammer; 4Oslo University Hospital, Ullevål; 5Institute of Clinical Sciences, University of Oslo, Oslo; 6Department of Medicine; 7Innlandet Hospital Trust, Lillehammer, Norway; 8Department of Medicine, Brigham and Women’s Hospital; 9Harvard Medical School, Boston, United States

Background: Spondyloarthritis is associated to accelerated atherosclerosis, possibly due to chronic inflammation and lipid metabolism disturbances. Circulating lipoprotein function may be more important than concentration. In particular, cholesterol efflux capacity (CEC) of high density lipoproteins (HDL) opposes foam cell formation and cholesterol esterification, which in turn represents a cardiovascular risk.

Objectives: Our aim was to compare CEC and CLI in patients with ankylosing spondylitis (AS) and psoriatic arthritis (PsA). We also aimed to evaluate CEC and CLI modulation upon anti-rheumatic therapy and their relationship to lipid profile levels.

Methods: Patients with AS (n=24) and PsA (n=36) were from the observational PSARA study. Treatment was: anti-TNF agents for AS; MTX alone or in combination with an anti-TNF agent for PsA.

Results: Serum was drawn before, after 6 weeks and after 6 months of anti-rheumatic therapy to measure CEC with a validated cell model (radioisotopic technique to measure % cholesterol efflux on total cell cholesterol) and CLI with a macrophage model and fluorometric measurement of cell cholesterol.

Conclusions: At baseline serum LDL and total cholesterol were higher in PsA than in AS patients. LDL, total cholesterol and HDL increased after treatment in AS, but not in PsA. In AS, CEC increased after 6 weeks of treatment (4.9±0.3 vs. 5.5±0.3, 95% CI: −1.09 to −0.03, p<0.05), in parallel with HDL serum levels. In PsA, CEC did not differ between any of the time points.

Cqc did not change with treatment in AS nor in PsA, but was overall higher in PsA than in AS patients. Despite the LDL serum level increase in AS, after 6 months of treatment the difference between CLC in PsA and AS was the most significant (34.0±1.8 in PsA vs 27.8±1.5 in AS, CI 95%: 3.28 to 6.67, p<0.05). In addition, after 6 months of therapy the correlation of CLC with LDL levels, present before treatment, was lost in the AS group. In the PsA group CLI did not correlate with LDL serum levels at any time point.

BENEFITS OF ADDITIONAL SPINAL MAGNETIC RESONANCE IMAGING COMPARED TO SACROLIAC JOINTS IMAGING ALONE IN THE DIAGNOSIS OF Spondylarthropathy

N. Ahmad1, A. Khan1, P. Yoon2, J. Kitchen1. 1Department of Rheumatology; 2Department of Radiology, Royal Berkshire NHS Foundation Trust, Reading, United Kingdom

Background: Axial spondyloarthritis (AxSpA) is a chronic inflammatory condition predominantly involving the axial skeleton including the spine and sacroiliac joints. Magnetic resonance imaging (MRI) demonstrates inflammation and structural changes in patients with both ankylosing spondylitis and non-radiographic (nrAxSpA) forms of SpA and has become widely used in diagnosing SpA.

Objectives: To determine the additional diagnostic benefit of including limited spine MRI in the whole spine imaging with SU MRI to SU MRI alone in patients with suspected SpA.

Methods: MRI scans performed for suspected SpA over twelve months from November 2015 to November 2016 were reviewed retrospectively (n=203).

Results: MRI scans from 203 patients with suspected SpA were reviewed. 81 (40%) were male and 122 (60%) were female. The age range was 13 to 78 years (mean ±41). 130 (64%) were less than 45 years of age. 157/203 (77%) patients had inflammatory changes involving both SpA and Spine and 4/43 (9%) had spinal inflammatory changes only with normal SIJs (Table 1). In these four patients the sacro-iliacum spine was involved. In HLA-B27 positive patients (n=46), 25 (54%) had a positive MRI.

Conclusions: The majority of patients with SpA can have their diagnosis confirmed on SU MRI. However a proportion of patients (9%) had spinal changes only. Additional spinal MRI has been shown to increase the diagnostic yield for axial spondyloarthritis in our cohort.

References:
In AS, CEC improved significantly during anti-TNF therapy, probably due to increase in anti-atherogenic HDL. Despite the LDL increase associated with the anti-TNF therapy in AS patients, CLC stayed constant, standing against a hypothetical pro-atherogenic effect of such LDL increase. These data may be useful for atherosclerosis prevention and treatment with tailored strategies for AS and PsA patients.

AB0731 OVERCOMING THE PROBLEMS OF UNTRANSLATABILITY: A MOBILE PHONE APPLICATION IN THE EXAMPLE OF TURKİSH VERSION OF BASDAI

Y. Özmen1, E. Mammadov1, Y. Yağıcıkaya1, A. U. Oral1, Z. Ertürk1, Ü. G. Gazel1, S. Kaymaz1, A. Aksoy1, F. Alibaz-Öner1, N. İnanç1, H. Direskeneli1, A. Gökduman2, P. Atagunduz1,1 Rheumatology, Marmara University Faculty of Medicine, Istanbul; 2Plexus Information Technologies Inc., Ankara, Turkey.

Background: Patient-reported outcomes (PROs) are important in monitoring and making treatment decisions. Recently, we reported that the translation of “tender points” in the fourth question of the Turkish version of BASDAI was not correctly understood, and replacing this question with an enthesis examination (BASDAI-Q4) decreased the score (ΔBASDAI-Q4:p<0.0001, 95CI:0.54–1.44).

Objectives: We report here the results of an investigator initiated clinical trial using a self-developed mobile phone application (MPA) to overcome the problem of untranslability.

Methods: Out of 135 invited 95 axSpA patients participated. Initially, BASDAI self-report forms (BSRF) were administered. Thereafter, patients were randomized into two groups and completed a second set of BSRF after using the MPA with embedded videos defining terms and grading for each domain. Group B completed a second set of BSRF under guidance of an inexperienced family physician (FP). A third set of BSRFs were completed by Group B with the same FP after going through the MPA. Afterwards, an enthesis examination (EE) was performed by a blinded rheumatologist and patients graded enthesis pain between 0–10. Standard Q4 was replaced with the EE scoring (BASDAI-Q4). Patients older than 45 years of age were excluded.

Results: Fifth three male (%55.7) and 42 female (%44.3) patients, with a mean age ±SD at the onset of the disease was 41.3±12.4 years. Non-radiographical axial disease (21.1%) 12 years (SD=8.7) were studied. Sixty-four and 31 patients were randomized to Groups A and B, respectively. Nine patients reported the Q4 as “not understood.” 32 patients had no enthesis on EE, but of those only 21 scored “0” for Q4 during the unassisted PRO. Eleven reporting no enthesis had so on EE.In Group A, 9 patients reported enthesis after MPA assistance and four had enthesis at the final EE. Nineteen patients had no enthesis on physical examination, but of those only 12 scored “0” for Q4 during the unassisted PRO, and an additional nine scored “0” for Q4 after MPA assistance. Six out of seven patients reporting no enthesis, but with enthesis on EE reported enthesis after MPA assistance. In Group B, scoring for Q4 was similar after both the unassisted- and FP’s first assistance PRO. Out of four “not understood” responders for Q4, two reported enthesis after the second assistance of FP and both had enthesis at the final EE. Six patients had no enthesis on EE, but one scored “0” for Q4 during the unassisted PRO, and an additional two scored “0” for Q4 after second FP assistance. Two out of four patients reporting no enthesis, but with enthesis on EE, reported enthesis after second FP assistance. Mean BASDAI was significantly higher in both groups than BASDAI-Q4 (Group A:3.97±1.95 vs. 2.84±1.98, p<0.0001, 95% CI:0.58–1.52; Group B:3.91±0.25 vs. 2.98±2.25, p<0.0001, 95% CI:0.48–1.31). In both groups, MPA, both patients, and FPs resulted in more reliable overall BASDAI scores with BASDAI-Q4 as the gold standard (Group A:3.05±2.25 vs. 2.84±1.98, p=0.081, 95% CI:0.71–1.45; Group B:3.21±1.87 vs. 2.98±2.25, p=0.075, 95% CI:0.01–1.63).

Conclusions: Mobile applications may improve the quality of collected data in cases of untranslatability even in previously validated PROs.

AB0732 SPONDYLOARTHRITIS IN THE DEMOCRATIC REPUBLIC OF CONGO

P. Lebughe1, K. de Vlam2, R. Westhovens3, J.-J. Malemba1, M. Mbuyi-Muamba1, J.-J. Malemba1, 1Rheumatology, University Hospital of Kinshasa, Kinshasa, Congo, The Democratic Republic of the; 2Rheumatology, Department of Development and Regeneration, Skeletal Biology and Engineering Research Center, Division of Rheumatology, University Hospitals Leuven, Leuven, Belgium

Background: While spondyloarthritis (SpA) is intensively studied in the Western world, data are scarce in sub-Saharan Africa.

Objectives: To determine the spectrum of SpA in outpatients with rheumatological complaints attending two rheumatology practices in Kinshasa, Democratic Republic of Congo.

Methods: A descriptive cross-sectional study over six months (December 1st, 2010 until May 31th, 2011). We included consecutive patients attending to the two rheumatology practices of Kinshasa; diagnosis was based on the Amor or the ESSG criteria, and a clinical evaluation by a rheumatologist. Sacroiliac joint radiographic lesions were scored with the modified New York criteria. BASDAI and BASFI were evaluated in axial SpA.

Results: One hundred five patients (10.7%) were diagnosed among 984 rheumatologic outpatients with a sex ratio (male to female) of 1.4. The average age at the onset of the disease was 41.3±12.4 years. Non-radiographical axial spondyloarthritis was the most frequent subtype (49.8%) followed by reactive arthritis (25.0%). Other subtypes were: ankylosing spondylitis (1.02%), psoriatic arthritis (0.1%), SAPHO syndrome (0.1%) and IBD associated arthritis (0.1%). Mean BASDAI and BASFI in axial SpA were 42.7±100 and 46.4±100 respectively.

Conclusions: These data may be useful for atherosclerosis prevention and treatment with CBD and CoA clinical trials.

AB0733 ASSOCIATIONS OF SERUM OSTEOPROTEGERIN AND IL-18 CONCENTRATIONS WITH CARDIOVASCULAR RISK IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS PATIENTS

E. Kontny1, K. Bonek2, P. Gluszko2, 1Department of Pathophysiology and Immunology, 2Department of Rheumatology, National Institute of Geniatrics, Rheumatology and Rehabilitation, Warsaw, Poland

Background: Inflammatory spondyloarthropathies (SpAs), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) are associated with cardiovascular (CV) disorders. In both diseases cytokines of IL-17/IL-23 axis are thought to play a pathogenic role. PsA, but not AS, is usually preceded by psoriasis, suggesting contribution of skin inflammation-related cytokines to disease manifestation and CV risk.

Objectives: To search in AS and PsA patients for the association between CV risk and serum concentrations of select cytokines, i.e. of IL-17/A23 axis, IL-18 and osteoprotegerin (OPG) with skin and cardiovascular (CVD) pathogenesis, respectively.

Methods: Twenty patients with AS (15M/5F) and 18 patients with PsA (10M/8F) of similar age (meansSD: 42±7 vs 46±10 years) and disease duration (6.5±10 vs 6.1±7 years) were evaluated. A group of 38 sex and age-matched healthy volunteers was used as a control. Routine laboratory tests, i.e. measurement of serum C-reactive protein (CRP) concentrations were performed. Clinical data, including evaluation of disease activity by ASDAScore and BASDAI indices, calculation of SCORE (Systemic Coronary Risk Evaluation) index and atherogenic index (AI=total cholesterol/HDL) were collected. Serum concentrations of IL-17A, IL-21, IL-23, IL-27, IL-18 and OPG were measured by specific commercially available enzyme-linked immunosorbent assays (ELISA) and were expressed in pg/ml. The Mann-Whitney U-test was applied for intergroup comparison, and correlation was assessed using a Spearman’s Rank two-tailed test (R value is shown).

Results: Compared with control, total group of SpAs patients was characterized by significantly elevated serum concentrations of OPG (1757±852 vs 464±100 pg/ml), IL-18 (273±235 vs 164±195 pg/ml) and IL-21 (68±127 vs 20±49 pg/ml). Interestingly, while up-regulation of OPG (1517±387) and IL-18 (324±291)
EVALUATION OF CARDIOVASCULAR RISK PROFILES IN A POPULATION OF PATIENTS WITH ANKYLOSING SPONDYLITIS: A CROSS-SECTIONAL STUDY

1Unit of Research “Molecular Bases of Human Diseases”, 12ES17, Stax Medicine University Biochemistry laboratory Habib Bourguiba Hospital; 2Hedi Chaker Hospital; 3Laboratory Habib Bourguiba Hospital, Sfax, Tunisia

Background: ankylosing spondylitis (AS), like the other chronic inflammatory rheumatic diseases, is considered to have higher cardiovascular (CV) risk (1). The pathogenesis is not clearly defined.

Objectives: assess the early biological markers of atherosclerosis in Tunisian patients with AS compared with healthy controls and evaluate the relationship between systemic Coronary Risk Evaluation (SCORE) for CV-related mortality and biological markers (2).

Methods: This was a cross-sectional study conducted since June 2015 until October 2016 including patients with AS in the South of Tunisia and matched controls with sex, age group, body mass index (BMI) and smoking. Patients diagnosed with AS should fulfill the modified New York criteria. For patients and controls, we measured total cholesterol (TC), high density lipoprotein (HDL) cholesterol, triglycerides, apolipoprotein (Apo) AI, ApoB, lipoprotein (a) [Lp(a)] and C-Reactive Protein (CRP). Low-density lipoprotein (LDL) cholesterol was calculated with the Friedewald formula. SCORE was calculated through the use of sex, age, systolic pressure, smoking and TC. Comparisons were performed using two sample t-tests for parametric values and Wilcoxon Mann-Whitney Test for non-parametric values. Correlation analyses were performed with Spearman rank.

Results: Overall 85 patients with AS and 79 controls were included. The mean age was (43.81±14.29 vs 44,27±14 years). The sex ratio (M/F) was 2/1 and the age was (43.81±14.29 vs 44,27±14 years). The sex ratio (M/F) was 2/1 and the age was (43.81±14.29 vs 44,27±14 years). The sex ratio (M/F) was 2/1 and the age was (43.81±14.29 vs 44,27±14 years).

Conclusions: Risk factors of CV disease in AS patients are similar to markers of vascular pathology and traditional cardiovascular disease risk. In addition, we showed that CRP is significantly higher in AS patients than in controls.

Disclosure of Interest: Supported by the NIHRG, Warsaw, Poland (grants No S/16 and S/2).

AB0735 EVALUATION OF PSYCHOLOGICAL STATE OF PATIENTS WITH ANKYLOSING SPONDYLITIS: REGIONAL REGISTRY AS A TOOL FOR IMPROVEMENT OF MANAGEMENT

S. Lapshina, D. Abdulganiev, L. Myasoutova. Kazan State Medical University, Kazan, Russian Federation

Background: According to modern conception “T2T” a patient with ankylosing spondylitis (AS) takes an active part in the disease treatment that determines the importance of his psychological state.

Objectives: To evaluate interconnection between the psychological state of the patient with AS and the disease course.

Methods: Within the regional registry which is a part of epidemiological study of clinical diversity of AS in Russian population, 40 patients (32 males and 8 females) at the age of 21 to 56 years (average age 40.3±10.0) were examined. The average disease duration on the day of examination was 12.7±9.9 years, BASDAI - 5.4±1.8, BASFI – 5.3±4.2, Functional status (range of motion) was determined by applanation tonometry by SphygmoCor, Australia. For statistical analysis we used Mann-Whitney criteria and Spirmen correlation method. The study was based on GCP principles.

Results: A total of 17 (42.5%) patients had anxiety and depression: moderate – 15 (88.2%), severe – 2 (11.8%) responders. With the disease duration of less than 5 years propensity for depression and anxiety was noted by 6 out of 11 (54.5%) patients, 5 to 10 years – 2 out of 12 (16.7%), more than 10 years – 9 out of 17 (52.9%).

Conclusions: Among the patients without limitation of motion (BASFI) anxiety and depression was revealed in 2 out of 11 (18,2%), with moderate limitation –6 out of 18 (33,3%), with severe limitation –9 out of 11 (81.8%) patients. According to BASMI 1 out of 2 patients without limitation of motion had anxiety and depression, 6 out of 19 (31,5%) – with moderate limitation and 10 out of 19 (52.6%) with severe limitation. The direct correlation was revealed between EQ-5D score and BASFI (r=0.996) and between EQ-5D and BASDAI (r=0.855), concurrently such correlation was also revealed between BASMI and BASDAI (r=0.803).

AB0736 THE DATA OF CENTRAL AORTIC PRESSURE AND PULSE WAVE VELOCITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS

T. Aksenova 1, 2, N. Ivashhenko 1, 2, S. Tsarenko 1, V. Gorbunov 1, P. Gromov 2, Therapy, Chita State Medical Academy; 2The hospital within the Russian Railroad Network, Chita, Russian Federation

Background: Pulse Wave Velocity (PWV) is the main determinant of arterial stiffness. In recent years the increased arterial stiffness in Ankylosing Spondylitis was shown [1]. The most of investigations of arterial stiffness in ankylosing spondylitis were performed on the treatment by anti TNF-therapy [2]. However, today this issue has not been adequately studied.

Objectives: To evaluate the data of central aortic pressure and PWV and their relationship with Ankylosing Spondylitis.

Methods: 49 patients with Ankylosing Spondylitis aged between 19 and 60 (mean age 39.6±10.6) were examined. This group (group 1) included 38 men, 11 woman. Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP) was 3.1±0.55. Duration of Ankylosing Spondylitis was from 0.5 to 20 years (mean 5.8±4.76 years). X-ray stage sacroiliac joints (according Modified New York Criteria) was 2.9±1.42. The control group included 33 healthy individuals. The groups were similar in age and sex. 10 patients with ankylosing spondylitis have history of arterial hypotenison, however, at the time of inclusion in this study their blood pressure was stabilized. The groups did not differ by office blood pressure parameters and heart rate. Indicators of central aortic pressure and PWV were determined by applanation tonometry by SphygmoCor, Australia. For statistical analysis we used Mann-Whitney criteria and Sperm correlation method.

The study was based on GCP principles.

Results: Increased levels of central systolic blood pressure (118.0±14.02 vs 111.1±10.2, p=0.0001), mean blood pressure (80.2±11.86 vs 78.1±7.3, p=0.001) were determined in patients with Ankylosing Spondylitis.

Conclusions: Increased levels of central systolic blood pressure, central diastolic blood pressure, central mean pressure were determined in patients with Ankylosing Spondylitis. The relationship between clinical data, X-ray stage and PWV was demonstrated.

Psoriatic arthritis

AA AMYLOIDOSIS IN RHEUMATOID ARTHRITIS AND IN PSORIATIC ARTHRITIS – A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 173 PATIENTS

Á. Ápáthy 1, M. Bél 2. 1Department of Rheumatology, St. Margaret Clinic Budapest; 2Department of Pathology, Hospital of the Order of the Brothers of Saint John of God, Budapest, Hungary

Background: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA), like all chronic autoimmune arthritides, may be complicated by AA amyloidosis (rAA).

Objectives: The aim of this study was to determine the prevalence and extent of AA in RA and PsA patients, and to appraise the extent of amyloid A deposits in various organs.

Methods: At the National Institute of Rheumatology 11860 patients died between 1968 and 1998; among them 161 patients with RA and 12 with PsA. All of them were autopsied. RA and PsA were diagnosed clinically according to the criteria of 1987 and 1998; among them 161 patients with RA and 12 with PsA. All of them were autopsied.

Results: The prevalence (in %) and the average extent of amyloid A deposits (absolute value) in various organs of RA and PsA patients are summarized in Table 1.

Conclusions: Based on the nearly same 0.585 versus 0.668, significantly not different: p<0.198 average amount of amyloid A deposits/patient, the immune processes (producing amyloid A deposit) of our RA and PsA patients may be similar.

The more prominent amyloid deposition in the lungs of RA patients (in contrast to PsA patients) may be associated with more frequent and pronounced pulmonary complications of RA (vasculitis, interstitial pneumonitis and fibrosis, etc.), than by PsA.

Extreme severe amyloid deposition in the skin of PsA patients may be due to local factors, namely severe systemic dystrophic changes of the skin in psoriasis.
MHAQ RESPONSE AMONG PATIENTS WITH PSORIATIC ARTHRITIS INITIATING A TNFI

A. Ogdie 1, L. Palmer 2, D. Solomon 3, A. Kavanagh 4, J. Greenberg 2,5, J. Curtis 6, L. Harrold 2,5, J. Kremer 2,5, P. Mease 7, 1University of Pennsylvania, Philadelphia, PA; 2Corona Research Foundation, Albany, NY; 3Brigham and Women’s Hospital, Boston, MA; 4University of California San Diego, San Diego, CA; 5New York University, New York, NY; 6University of Alabama, Birmingham, AL; 7University of Massachusetts, Worcester, MA; 8Swedish Medical Center, Seattle, WA, United States

Background: Improved functional ability is among the most relevant outcomes for patients with psoriatic arthritis (PsA). The modified health assessment questionnaire (mHAQ) is one of the most commonly used patient reported outcome measures used in PsA and addresses the domains of disability and physical function.

Objectives: We examined the change in mHAQ over one year among patients with PsA initiating a TNFI and examined predictors of a clinically meaningful improvement in disability and physical function, as measured by the mHAQ.

Methods: Patients with PsA enrolled in the Corona Registry between 2005–2013 were followed from initiation of a TNFI (etanercept, adalimumab, infliximab, certolizumab, or golimumab) to the visit closest to 12 months. Patients were required to have at least three tender or swollen joints for inclusion for this study (this is not an inclusion criteria for Corrons). The mHAQ within six months prior to TNFI initiation was included, and at least one follow up visit 5–13 months after TNFI initiation with mHAQ. The mean change in mHAQ score was the change in percentile of 0.35 or more in the mHAQ score, the minimal clinically important improvement in PsA2. Predictors of mHAQ response were measured in the six months before TNFI initiation. Covariates with p-value <0.10 in univariable logistic regression models and -10% missing values were included in a multivariable model and removed individually until all remaining variables were significant (p<0.05).

Results: Among 1742 TNFI initiations, 721 initiations (623 patients) met inclusion criteria. Mean age at initiation was 51.5 years (SD 12.3), 56% were female, mean PsA duration was 5 years (IQR 2–11), and median baseline mHAQ was 0.375 (IQR 0.125–0.875). The mean change in mHAQ was -0.086 (SD 0.38) and median change in mHAQ was 0 (IQR: -0.25 to 0.125); 23% had a mHAQ decrease of 0.35 or more. In univariable models, college education and being married or partnered were inversely associated with mHAQ response (baseline decrease of 0.35 of more. In univariable models, college education and being married or partnered were inversely associated with mHAQ response (baseline decrease of 0.35 or more). In multivariable models and -10% missing values were included in a multivariable model and removed individually until all remaining variables were significant (p<0.05).

Conclusions: A clinically meaningful change in mHAQ occurred in 23% of patients and was strongly associated with age and baseline mHAQ score. In this real world population, there was little change in mHAQ scores over one year, despite treatment with TNFis and other biologics. These analyses are limited by the mHAQ score in patients with PsA. Despite having at least 3 tender and 3 swollen joints, many patients in this cohort had a low mHAQ at baseline which did not allow for sufficient change to meet the MCII.

OBJECTIVES: The aims of this study were to culturally adapt the questionnaire for Portugal, and evaluate its reliability and validity in patients with PsA.

Methods: The original UK English version of PsAQoL was translated into Portuguese by a bilingual translation panel. An independent lay panel reviewed the instrument’s item phrasing to ensure appropriateness in colloquial European Portuguese. Structured cognitive debriefing interviews were conducted with ten PsA patients to assess the acceptability, the understanding and the redundancy of ambiguity of the questionnaire. The Portuguese PsAQoL was subsequently applied to PsA patients followed at the Rheumatology Department of Centro Hospitalar do Baixo Vouga, E.P.E. To assess reproducibility, thirty patients with PsA completed the Portuguese PsAQoL on two occasions, two weeks apart. A larger sample was recruited to determine internal consistency and construct validity. Descriptive statistical analysis was used to characterize the data. The Nottingham Health Profile (NHP) was used as a comparator instrument.

Results: Translation and adaptation were successful. The validation sample included 104 patients, 67% of whom were men. Their median age was 50.2 (SD=12.1) yrs and most were married. Cronbach’s alpha for the Portuguese version of the PsAQoL was 0.91 and the test-retest reliability 0.92, indicating that the measure has good internal consistency and produces low random measurement error. The PsAQoL could distinguish between groups of patients defined by self-reported general health status, self-reported severity of PsA and fibromyalgia. Differences in arthritis did not influence PsAQoL scores. There was a positive correlation between the total score of ApAQoL and each of the dimensions of the NHP.

Conclusions: The Portuguese version on the PsAQoL was found to be relevant, understandable and easy to complete, reliable and valid. It should be considered for use in clinical practice and research settings to assess PsA-specific QoL.

While Tumor Necrosis Factor inhibitors (TNFi) are effective agents for PsA, the relationship between early treatment and patient reported outcomes in a real world setting has not been reported previously.

**Objectives:** To assess whether timely treatment with TNFi leads to better improvement in quality of life outcomes than delayed treatment.

**Methods:** This was a retrospective analysis of patients with PsA and/or Psoriasis (PsO) using TNFi with or without methotrexate, and who had a minimum of 2 visits at the Center of Excellence for Psoriasis and Psoriatic Arthritis at our university. Detailed demographic and clinical characteristics of this cohort have been published previously\(^1\). Demographics, quality of life measures (e.g. Routine Assessment of Patient Index Data – RAPID3; Psoriasis Quality of Life – PqOQ12. Short Form 12 – SF-12), and clinical data (percent of body surface area involved with PsO – BSA%) were collected from patient-reported questionnaires and electronic medical records. Only those patients who had a chronological overlap of treatment exposure and QoL measures such as RAPID3, SF-12 and PqOQ were included. To ascertain treatment effects, a mixed-effects model was fitted to estimate the effect of each QoL outcome of a patient separately. Then, for all estimated trends of an outcome, a linear regression model was employed to explore the association between the magnitude of estimated trends and timeliness of TNFi treatments.

**Results:** The quality of life measures were not affected by how early after the disease onset TNFi treatment was started (in other words, no statistically significant associations between the effectiveness of TNFi treatment and disease duration) for RAPID3 (p=0.285), SF-12 (p=0.674), or BSA (p=0.078). For PqOQ, there was a significant association between the trend of treatment effects and timeliness of treatment. A day of delay into treatment was reached in a reduction of 4.4x10^-6/day in the trend of PqOQ scores (p=0.007).

**Conclusions:** In this sample of PsA & PsO patients, timing of starting TNFi in patients with PsA had significant impact on improvements in the PqOQ, but not other quality of life measures such as RAPID3, SF-12 and BSA. A relatively short treatment history might have led to the negative correlations.

AB0746 PRELIMINARY RESULTS OF A TWO-YEAR FOLLOW UP OF SUBCLINICAL Atherosclerosis IN PATIENTS WITH PSORiATiC ArTHRiTS

C. Vergara-Dangond¹, M. Robustillo-Villarino¹, V. Núñez-Monje¹, M. Aguilar-Zamora¹, L. Montolivo-Chiva¹, E. Valls-Pascual¹, A. Ybáñez-García¹, A. Martínez-Ferrer¹, J.J. Alegría-Sancho¹. ¹Rheumatology; ²Hospital Universitario Dr. Peset, Valencia, Spain

Background: Psoriatic arthritis (PsA) is a disease associated with an increased cardiovascular (CV) risk, due to early atherosclerosis, which is comparable to a rheumatoid arthritis population. However, there is a lack of studies that evaluate the progression of subclinical atherosclerosis over a year in these patients.

Objectives: To explore the progression of the vascular damage by different techniques in patients with PsA and the factors related with these changes.

Methods: Pre-post study with analytical components. 44 patients with PsA (CASPAR criteria) and peripheral joint involvement of more than one year since diagnosis were consecutively included. We gathered demographic (age, gender, BMI), clinical (traditional CV risk factors, previous CV event), and analytical variables (atherogenic index, GFR [MDRD], fibrinogen, glycated hemoglobin, CRP, ESP, ultrasensitive CRP, apolipoprotein A1 ratio) and baseline CV risk was estimated with SCORE tool. Other variables were collected retrospectively from patients electronic medical record. The extracranial branches of carotid artery were explored by ultrasonography (US) using an Esaote MyLab70XVG with a 7–12 MHz linear transducer and an automated program measuring intima-media thickness (IMT) through radiofrequency (RFQIMT), and the presence of atheroma plaques, as per the Mannheim consensus, was registered. Pulse wave velocity (PWV) was determined, as an arterial stiffness marker, by a validated MobileOCTraphy device.

Patients were followed during a 2-year period between may 2015 until december 2016. All of the tests were repeated after 2 years. Statistical analysis was performed using SPSS 17.0 software.

Results: We analyzed 38 patients, excluding those with high CV risk (previous CV event, diabetes, hypertension, dyslipidemia, smoking, age ≥60 years). At baseline, the mean and median of age was 59.2 and 60.5 years (39–88), respectively, mostly women (65.8%). The median BMI was 28 (17–35). 28.9% were smokers and 36.8% had hypertension. 26.3% received glucocorticoids, 57.9% NSAIDs, 64.2% DMARDs and 31.6% biologic therapies. The median SCORE, ESP and MDA28 were 5.8mg/L (1–19.1), 7mmHg (23–28) and 2.17 (1.24–3.7), respectively. The median SCORE was 1 (0–7), the PWV was 8 m/s (5.6–13.5) and basal IMT was 728 (462–1087); the presence of atheroma plaques was detected in 35.1% of the patients.

After 2 years, plaque appearance was seen in 15% more of patients, as well as worsening of PWV and IMT in 38.9% of patients, respectively. These changes were not significant. No patient developed a CV event. In the bivariate analysis, PWV progression at 2 years related with advanced age, female gender, higher CV risk factors, and smoking. It demonstrated that CZP treatment inhibits radiographic progression over 96 weeks (wk).

It demonstrated that CZP treatment inhibits radiographic progression over 96 weeks (wk).

Objectives: We report the long-term effect of CZP treatment on radiographic progression in pts with PsA over 4 years.

Methods: The RAPID-Psa phase 3 trial was double-blind and placebo-controlled to Wk4, dose-blind to Wk48, and open-label (OL) to Wk216. Pts had active PsA and had failed ≥1 DMARD. Pts randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose at Wk0, 2, 4) continued their assigned dose in the OL period. Radiographs taken at baseline (BL), and at Wk96, 168, 216, were read in a single reading campaign using the modified Total Sharp Score (mTSS) for PsA by 2 readers, blinded to patient information and time point sequence. The mean of the scores of the 2 readers was used. Outcomes reported are the least squares (LS) mean mTSS score, change from BL (CFB) in mTSS score, and the percentage of pts assessed for radiographic damage who achieved mTSS non-progression (defined either as CFB in mTSS score <0.5 or <0), for all Wk60 CZP-treated pts, irrespective of dose regimen. mTSS score and CFB were estimated using Mixed Model Repeated Measures (MMRM) estimates; proportions of pts with radiographic non-progression are presented as observed cases.

Results: 409 PsA pts were randomized, of whom 273 received CZP from Wk0. The LS mean BL mTSS score was 16.0 and there was little increase from BL in mTSS score to Wk216 (Table). Amongst those who completed the study to Wk216, the majority of CZP-treated pts achieved radiographic non-progression to Wk216, both with non-progression defined as CFB in mTSS score <0.5 or <0 (Table). The change in LS mean mTSS score over time for Wk0 CZP-treated pts was consistently low throughout the trial: 0.14 (95% CI: 0.02–0.26) per 48 wks from BL to Wk96, and 0.18 (95% CI: 0.08–0.28) per 48 wks from Wk96 to Wk216.

Table: mTSS score and radiographic non-progression to Wk216 for patients treated with CZP from Week 0

Conclusions: There was little radiographic progression in CZP-treated PsA pts, as measured by mTSS, throughout the 4-year RAPID-Psa trial.
**AB0748**  HYPERURICEMIA IN PSORIATIC ARTHRITIS: A NEW LOOK AS A RISK FACTOR FOR CARDIOVASCULAR EVENTS

**D.S. Bulbulov**, Altay State Medical University, Barnaul, Russian Federation

**Background:** According to various authors, the prevalence of hyperuricemia in patients with psoriatic arthritis is higher than the general population. This is consistent with the total patient population. Thus, seronegative spondyloarthritis patients, as it is known, possess a higher incidence of cardiovascular mortality than the population in general, in particular due to life-threatening cardiac arrhythmias.

**Objectives:** To study the effect of hyperuricemia on the development of ventricular extrasystole in patients with psoriatic arthritis and the interrelation of uric acid levels and gradation of ventricular extrasystole.

**Methods:** The study involved patients with psoriatic arthritis, confirmed by CASPAR criteria (2006), n=59. The average age – 57.15±11.12 years. All patients underwent the study, including record of cardiac contractility and treadmill test. Inclusion criteria - the presence of psoriatic arthritis for the period of at least one year, uric acid levels over 360 mmol/l for women and more than 420 mmol/l for men. The exclusion criteria included the presence of coronary heart disease, myocardial contractility disorders and decreased ejection fraction according to Simpson less than 55%. For all patients was recorded Holter ECG for the period of 24 hours on an outpatient basis. The level of uric acid was measured by means of the standard method of biochemical analyzer.

**Results:** The prevalence of ventricular extrasystole in patients with psoriatic arthritis and age are shown in Table 1. Moreover, there has been discovered a direct correlation of medium strength between the uric acid levels and frequency and Lown-Wolf gradation of ventricular extrasystole (Table 1).

</table>

**Conclusions:** 1. Hyperuricemia in patients with psoriatic arthritis by exclusion of cardiogenic causes of cardiac extrasystole is an independent risk factor for ventricular extrasystole.

2. The level of hyperuricemia correlates directly with the Lown-Wolf gradation of ventricular extrasystole.

**AB0749**  AXIS INVOLVEMENT IN THE RUSSIAN COHORT OF EARLY PERIPHERAL PSORIATIC ARTHRITIS PATIENTS AND ITS ASSOCIATION WITH ARTHRITIS ACTIVITY, PATIENT’S ASSESSMENT AND SEVERITY OF SKIN LESION

**Background:** The association of axial involvement with peripheral arthritis activity and skin lesion severity in early psoriatic arthritis (ePsA) patients (pts) has not been studied properly.

**Objectives:** To study the prevalence of axial involvement detected by magnetic resonance imaging (MRI) and X-ray of sacroiliac joints (SJs) and its correlation with peripheral arthritis activity and skin lesion severity in peripheral ePsA pts.

**Methods:** 79 pts (M/F–42 /37) with peripheral ePsA criteria (NCT02065713) were included; mean age 36.5±10.9 yrs, disease duration 12.1±10.1 mo., disease activity index (DAS28) 8.8±1.7, patient’s pain VAS 55.0±17.9, patient’s global disease activity VAS 56.9±17.1, C-RP16.1 [8.6; 31.0] mg/l, ESR 22.5±19.2 mm/h. All pts were examined by an independent reader. Radiographic sacroiliitis (R-SI) was defined at 2 grade changes, at least in one SIJ, while definite radiographic sacroiliitis (MRI-SI) was evaluated by an independent reader. Radiographic sacroiliitis (MRI-SI) was considered according to New York criteria (unilateral grade ≥3 or bilateral grade >2). Skin lesion area was measured according to BSA. BSA ≥10% was defined as extensive.

**Results:** IBP was found in 58 out of 89 (65.1%) pts, 35 (60.3%) of them had short-term (episodic) IBP, and 23 (39.7%) pts had long-term IBP. MRI-SI was observed in 28 out of 79 (35.4%) pts. R-SI was determined in 42 out of 89 (47.2%) pts, while dR-SI was found in 27 out of 89 (30.3%) pts. 34 (38.2%) pts were HLA-B27 positive. In pts having IBP disease activity measured by DAS28 was 4.5±1.6. An association was detected between the presence of MRI-SI and activity of peripheral arthritis by DAS28 (r=0.25; p=0.03). Correlation was detected between the presence of MRI-SI and the value of patient’s global disease activity (r=0.23; p=0.047) as well as patient’s pain (r=0.31; p=0.007).

**AB0750**  THE GO-DACT PROTOCOL: A RANDOMIZED CONTROLLED TRIAL TO COMPARE THE EFFICACY OF GOLUIMAB IN COMBINATION WITH METHOTREXATE (MTX) VERSUS MTX MONOTHERAPY, IN IMPROVING DACTYLITIS AND ENETHESIS, IN MTX NAIVE PSORIATIC ARTHRITIS PATIENTS

E_Vieira-Sousa 1, H. Canhão 2, J.E. Fonseca 1 on behalf of GO-DACT research team. 1Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa and Rheumatology Department, Hospital de Santa Maria, Lisbon, Portugal, 2Academic Medical Centre, CEDOC, NOVA Medical School, Universidade Nova de Lisboa, Lisbon, Portugal

**Background:** Dactylitis is a hallmark manifestation of psoriatic arthritis (PsA) and a key feature for PsA diagnosis. Active dactylitis is associated with a higher risk of erosions and can severely impact function. The therapeutic strategies for dactylitis are however largely empirical, with a profound absence of knowledge regarding efficacy, as primary endpoint, and impact on disease progression. The use of biologic disease modifying anti-rheumatic drugs (DMARDs) in patients with dactylitis, refractory to non-steroidal anti-inflammatory drugs (NSAIDs) or local corticosteroids, is recommended by EULAR guidelines, over the use of conventional DMARDs, based in the scarcity of evidence and properly designed studies in this field.

**Methods:** GO-DACT is an investigator initiated ongoing multicentric trial, involving 13 national Rheumatology departments. Patients older than 18 years, with the diagnosis of PsA and active dactylitis (tenderness score ≥1), refractory to NSAIDs for <3 months, were included. Patients were randomized on a 1:1 ratio, to either MTX in combination with golimumab or placebo, for a period of 24 weeks. The primary aim of this trial is to determine differences of efficacy between the two treatment arms, in improving dactylitis (and enthesis), as assessed by the dactylitis severity score (DSS) at 24 weeks. Key secondary outcomes include: Leeds dactylitis index (LDI), Leeds enthesis index (LEI), joint counts, psoriasis area and severity index (PASI) and nail psoriasis severity index (NAPSI), health assessment questionnaire (HAQ), Dermatology life quality index (DLQI) and composite indexes for disease activity. The effect of treatment arms, on different tissue compartments, will be assessed by contrast-enhanced magnetic resonance imaging (MRI), with high resolution images for dactylitis, at baseline and 24 weeks.

**Results:** The results from GO-DACT are expected to have implications in clinical practice, bringing robust and valid data for the definition of dactylitis treatment stratification and algorithm GO-DACT will also contribute to understand dactylitis pathogenesis through the assessment of treatment efficacy, namely in distinct tissue compartments as defined by MRI. https://www.clinicaltrials.gov (NCT02065713)

**AB0751**  THE DIFFERENCES AND SIMILARITIES BETWEEN PATIENTS AND PHYSICIAN GLOBAL ASSESSMENT IN PATIENTS WITH PSORIATIC ARTHRITIS

K. Nas 1, E. Kılıç 2, R. Cevik 3, A.Z. Daglı 3, G. Kilic 4, S. Sag 1, A. Kamanli 1, I. Tekeoglu 1. 1Division of Rheumatology and Immunology, Dept of PM&R, Sakarya University Faculty of Medicine, Sakarya, Turkey; 2Rheumatology Department, State Hospital, Afyon; 3Division of Rheumatology, Dept of PM&R, Dicle University Faculty of Medicine, Diyarbakir; 4Dept. of PM&R, Akyon Kocatepe University Faculty of Medicine, Akyon, Turkey

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with psoriasis, axial involvement, enthesis, dactylitis and uveitis. The differences and similarities between patient’s global assessment (PGA) and physician’s global assessment (PhGA) were not assessed clearly in PsA.

**Objectives:** The aim of this study was to assess differences and similarities between patient’s and physician’s perspective of global assessment in patients with PsA.
AB0752  CONSENSUS STATEMENT ON THE USE OF METHOTREXATE IN PSORIATIC ARTHRITIS PATIENTS

J. Tornero 1, E. Loza 1, D.D. Cañete 1, 2, E. Loza 3, J. Cañete 1, 2

1Rheumatology, Hospital de Guadalajara, Guadalajara; 2Instituto de Salud Musculosquelénetica, IMUsM, Madrid; 3Rheumatology, Hospital de l'IDLAPS, Barcelona, Spain

Background: Methotrexate (MTX) is the cornerstone in rheumatic diseases, including psoriatic arthritis (PsA), but the complexity of PsA and the paucity of randomised controlled studies and strategic trials need a clear analysis.

Objectives: To develop recommendations for the management of MTX in PsA (musculoskeletal manifestations) based on best evidence and experience.

Methods: The coordinators formulated 14 questions about MTX use (indications, efficacy, safety) in patients with PsA. A systematic literature review was performed to answer these questions. Using this information, inclusion and exclusion criteria were established as well as the search strategies (Medline, Embase and the Cochrane Library), that were designed by an expert librarian. Two different reviewers selected the articles, first by title and abstract, then by detailed review, and collected data independently. Evidence tables were produced. With this evidence the coordinators proposed 12 preliminary recommendations that will be discussed and voted in a nominal group of expert meeting. The level of evidence and grade of recommendation will be defined using the Oxford Centre for Evidence Based Medicine. Agreement will be stabilised if at least 80% of the experts voted yes (yes/no).

Results: A total of 12 preliminary recommendations on the use of MTX in PsA were proposed (see table).

Conclusions: This document aims to help to answer usual clinical questions and facilitate decision making when treating PsA patients with MTX.

AB0753  ARTERIAL STIFFNESS INCREASE IN THE EARLY PHASE OF ARTHROPATHY RELATED TO PSORIATIC ARTHRITIS IS NOT FURTHER MODIFIED BY STABLE PROLONGED RETENTION OF A MINIMAL DISEASE ACTIVITY CONDITION

F. Fiscetti, F. Bozzo, M. Rovina, G. Simon, M. Bardelli, R. Carretta. University of Trieste, Italy, Trieste, Italy

Background: Increased large arteries wall stiffness (AS) is a well known independent morbidity and mortality cardiovascular risk factor, not only related to hypertension and diabetest, but also induced by long standing systemic inflammation, as observed in inflammatory rheumatic or gut chronic diseases. Psoriatic arthritis (PsA) was also shown to increase cardiovascular morbidity, but this observation was commonly related with the associated occurrence of long term arthritis, disease activity and CV traditional risk factors

Objectives: To assess whether in a selected group of PsA patients, affected by recent onset (4–12 months) arthritis, not suffering from CV disease risk factors, evidence could be obtained of an early alteration of arterial wall function as expressed by an increased arterial pulse wave velocity (aPWV) and secondary reduced tonometric subendocardial viability ratio (tSEVR).

Further, we evaluated if a 18 months (Mth) treatment with synthetic disease modifying antirheumatic drugs (sDMARD) other than cyclosporine, leading to a demonstrable target of clinical “minimal disease activity”(MDA) could modify such possible modifications

Methods: Conclusive data were obtained in a selected group of 12 PsA patients (PsA disease criteria classification JCA 2010; M/F 6/6; mean age 50.8; range 40-70) not suffering from axial spondylitis who firstly underwent (without any previous treatment) aPWV measurement (PulsePen, Diatecne Srl, Milan) and tSEVR calculation, and then were re-evaluated for the same calculations after a 18 mth time of sDMARD treatment. Each of the PsA Pts had a 3–4 Mth follow up and showed to reach the target of stable MDA (with also ultrasound confirmed remission of active synovitis) after a 4–8 Mth treatment. Before treatment, the group of PsA Pts was compared with an age, body weight, CV parameters and risk factors–matched control group of voluntary 22 healthy subjects (M/F 11/11; mean age, 51.3; range, 41–87).

Results: Before any treatment, aPWV was higher in the group of patients with PsA than in control subjects (median, 8.667 m/s vs 6.963 m/s, p<0.02) while tSEVR was decreased (median, 1.44 vs 1.50, p<0.05). Aortic PWV was not modified after the sDMARD treatment (median m/s, before=8.691, after=8.691, p=0.55), despite statistically significant improvements of the disease activity scores (DAS28; modified CDAI; DAPSA) as well as cutaneous PASI, and stable retention of a MDA condition. A direct correlation (Spearman rank) between aPWV and DAS28 (rho=0.70; p-value=0.04), BASDAI (rho=0.77; p-value=0.01), and RA 28 Score (rho=0.66; p-value=0.005) was found, not instead between aPWV and ESR or CRP. Pts with PsA, at the end of the follow up, had increased levels of systolic (134,1±14,3 vs 122±11,2, p<0.05) and diastolic (82±7,4 vs 73,5±6,6, p<0.05) blood pressure, with unmodified heart rate.

Conclusions: Early onset of PsA seems to be associated with already established and stable increase of AS. Sub-clinical previous inflammation and length of psoriatic disease could be addressed as possible causes

COMPARISON OF COMPOSITE INDICES TAILORED FOR PRIMARY EFFICACY AND SAFETY OF ADALIMUMAB IN NAIL PSORIASIS vs PsA

AB0754

COMPARISON OF COMPOSITE INDICES TAILORED FOR PRIMARY EFFICACY AND SAFETY OF ADALIMUMAB IN NAIL PSORIASIS vs PsA

FM. Perrotta, A. De Socio, E. Lubrano. Medicina e scienze della salute, Università degli studi del Molise, Campobasso, Italy

Background: Remission or low disease activity should be the target of therapy in chronic inflammatory arthritis as well as in Psoriatic arthritis (PsA). In a complex disease such as PsA, several methods are available to define remission that comprise the assessment of different clinical features.

Objectives: The aim of this study was to compare the composite indices tailored for PsA in both patients treated with csDMARDs and bDMARDs.

Methods: Adult PsA patients classified with CASPAR criteria and with >6 months follow up treated with first csDMARDs and bDMARDs were consecutively enrolled in our recent clinic. To assess disease activity, composite indices tailored for PsA namely DAPSA, cDAPSA, PASDAS, MDA (5/7) and MDA (7/7) were used. DAPSA and cDAPSA score ≤4, MDA 7/7 and PASDAS ≤1.9 identified remission while MDA 5/7 and PASDAS ≤3.2 the minimal disease activity and inactive disease criterion

Results: One hundred nine PsA patients were enrolled. Of this, 79 patients were in stable treatment with bDMARDs and 30 with csDMARDs. Overall, 28 (25.6%), 23 (21.1%), 19 (17.4%), 54 (49.5%), 13 (11.9%) and 35 (32.1%) PsA patients were in cDAPSA remission, DAPSA remission, MDA 7/7, MDA 5/7, PASDAS ≤1.9 and PASDAS ≤3.2. Patients in bDMARDs had a significantly low median DAPSA, cDAPSA, PASDAS and PASDAS score than patients treated with csDMARDs (table 1). Overall, the concordance between the ratios ranging from slight to good.

Conclusions: PsA patients in bDMARD are more likely to reach a status of MDA and remission in respect to csDMARDs. PASDAS ≤1.9 and MDA 7/7 seem to be stringent remission criteria.

DEPRESSON AND ANXIETY MAY CONTRIBUTE TO HIGHER DISEASE ACTIVITY AND WORSE QUALITY OF LIFE IN PSORIATIC ARTHRITIS

F. Farkas 1, N. Ikum 1, A. Szentpetery 1, B. Kirby 2, O. FitzGerald 1. 1Department of Rheumatology; 2Department of Dermatology, St. Vincent’s University Hospital, Dublin, Ireland, Dublin, Ireland

Background: Psoriatic arthritis (PsA) is a heterogeneous disease with variable types of joint involvement, extra-articular features, including skin psoriasis, and with well-known comorbidities such as depression and anxiety. Composite Psoriatic Disease Activity Index (CPDAI) adequately assesses disease activity in this complex condition. To date, no study has evaluated the relationship between depression/anxiety scores and CPDAI in PsA.

Objectives: The aim of this study was to compare 1) depression/anxiety scores; 2) physician-assessed and patient-reported outcome measures (PROMs) between patients with CPDAI≤4 suggesting low disease activity versus with CPDAI>4 reflecting moderate or severe disease activity in PsA.

Methods: PsA patients fulfilling the CASPAR criteria were recruited. Patients underwent musculoskeletal and skin assessments (TCJ68, SJUC66, Leeds enthesitis index, dactylitis digit score and PASI) and they have completed questionnaires on physical function and health-related quality of life (HAQ, PsAQoL, DLQI; EQ-SD, BASDAI, BASFI, ASQoL, Braf-NRS, pain and general health VAS). Patients were assessed for depression/anxiety using the Hospital Anxiety and Depression Scale (HADS-A and HADS-D) and Penn State Worry Questionnaire (PSWQ). Data were analyzed using Mann Whitney, Chi-square tests and linear regression model.

Results: 100 PsA patients were recruited; 57 presented with CPDAI≤4 (age 52.7±9.46 years) and 43 with CPDAI>4 (age 52±11.82 years). Patients with CPDAI>4 had significantly higher TCJ68 (p<0.001), Leeds enthesitis index (p<0.015) and significantly worse HAQ, BASDAI and ASQol scores. There was no significant difference in other items of CPDAI between the two groups. Patients with CPDAI>4 had significantly higher HADS-D, HADS-A and PSWQ scores (p<0.001; p<0.001, respectively) and significantly worse PROMs, including PsAQoL, EQ-SD score, BASFI, Braf-NRS, pain and general health VAS (Table 1). Multiple regression analysis revealed significant relationship between PsAQoL, BASFI and CPDAI (B=0.311, p=0.0093; B=0.568, p<0.0001, respectively).

Conclusions: This is the first study assessing the relationship between depression/anxiety and CPDAI in PsA. We have found significantly higher HADS-D, HADS-A, PSWQ scores and worse PROMs in patients with CPDAI>4 compared to those with CPDAI≤4. Based on our results there is significant relationship between depression/anxiety, physical function, quality of life and disease activity in psoriatic arthritis.

AB0756

PRIMARY EFFICACY AND SAFETY OF ADALIMUMAB IN NAIL PSORIASIS FROM THE FIRST 26 WEEKS OF A PHASE-3, RANDOMIZED, PLACEBO-CONTROLLED TRIAL WITH SUBANALYSIS IN PATIENTS WITH AND WITHOUT PSORIATIC ARTHRITIS

B.E. Elewski 1, P.A. Rich 1, F. Behrens 2, G. Guillen 2, Z. Geng 2, O. Reyes Serven 1, 1University of Alabama at Birmingham, School of Medicine, Birmingham; 2Oregon Health and Science University Hospital, Portland, United States; 3Goethe University Medical Center, Frankfurt, Germany; 4Hôpital la Mètairie, Service de Dermatologie, CHU Poitiers, France; 5AbbVie Inc., North Chicago, United States

Background: Psoriatic arthritis (PsA) disease burden for patients (pts) with psoriasis (Ps) and concomitant fingernail Ps plus psoriatic arthritis (PsA) is higher compared with pts with Ps alone.

Objectives: We report safety and efficacy of originator adalimumab (ADA) in pts with fingernail Ps, and also for pts with or without concomitant PsA.

Methods: Results are reported from the double-blind PBO-controlled, Period A in which 217 pts with moderate to severe plaque Ps and fingernail Ps were included and randomized 1:1 to receive 40 mg ADA every other week (eow) from wk 1 (initial 80 mg dose at wk 0), or matching PBO, for 26 wks. The primary endpoints were the proportion of pts with ≥75% improvement in modified Nails Ps Severity Index (mNAPSI 75) and the proportion of pts with Physician’s Global Assessment of Fingernail Psoriasis (PAGA-F) of (clear) or (minimal) (1) with ≥2 grade reduction from baseline (primary in US only; for regulatory purposes). Missing data were handled by multiple imputation. Safety was assessed using treatment-emergent adverse events (AEs).

Results: Of the 217 randomized pts (108 PBO, 109 ADA), 84.3% were male; mean age (SD) was 46.7 years (17.8); 66% completed 26 wks of treatment, or early escaped to Period B according to protocol. Both primary endpoints were met: total fingernail mNAPSI 75 was achieved by 3.4% PBO vs 46.6% ADA (p<0.001), and PAGA-F 0 or 1 with ≥2 grades improvement was achieved by 6.9% vs 48.9% (p<0.001). At baseline, 28.6% had PsA (29.6% PBO, 27.5% ADA) with mean

impact of disease activity on physical function and health-related quality of life in patients with psoriatic arthritis

K. Nas1, G. Kiliç2, R. Çevik3, A. Z. Dagil1, E. Kılıç1, S. Sag1, E. Uerkermkaz1, A. Kamar1, I. Tekesoglu1, Department of Rheumatology and Immunology, Sakarya University Faculty of Medicine, Sakarya; Department of Physical Medicine and Rehabilitation, Sakarya University Faculty of Medicine, Sakarya; Physical Medicine and Rehabilitation, Afyon Kocatepe University Faculty of Medicine, Afyon; Division of Rheumatology, Department of Physical Medicine and Rehabilitation, Dicle University Faculty of Medicine, Diyarbakir; Rheumatology Clinic, Afyonkarahisar State Hospital, Afyon; Department of Biostatistics, Sakarya University Faculty of Medicine, Sakarya, Turkey

Background: Psoriatic arthritis (PsA) is a chronic progressive inflammatory disease characterized by peripheral arthritis, dactylitis, axial joint involvement and enthesitis. Disease consequences such as chronic pain, severe joint damage and fatigue may adversely affect on patient’s physical function and health-related quality of life (QoL) to perform daily activities.

Objectives: The aim of this study was to investigate the potential relationship between physical function and health-related QoL and disease activity measures in patients with PsA.

Methods: For all participating patients, quality of life, functional and disease activity measures were measured by different ways: Nottingham Health Profile (NHP), psoriatic arthritis quality of life (PsQoL), Antirheumatic Drugs Survey, Health Assessment Questionnaire (HAQ), BASFI, VAS pain, BASDAI, and ESR. CRP. Patients with PsA were discriminated into low and high disease activity (NHP), psoriatic arthritis quality of life (PsAQoL), Ankylosing Spondylitis Quality of Life (ASQoL) and Disease Activity Score 28 (DAS28). Baseline measurements of disease activity and health-related QoL were performed in all patients. Disease activity measures were found correlated with all important QoL measurements including NHP, SF36, PsQoL, HAQ and ASQoL. In patients with PsA, high disease activity may lead to severe impairments in daily activities and influence on participation in society.

Conclusions: Psoriatic arthritis has a major impact on patients’ lives. Variable disease activity measurements were found correlated with all important QoL measurements including NHP, SF36, PsQoL, HAQ and ASQoL. In patients with PsA, high disease activity may lead to severe impairments in daily activities and influence on participation in society.

AB0760 EFFICACY OF USTEKINUMAB IN A COHORT OF PATIENTS AFFECTED BY PSORIATIC ARTHRITIS IN REAL-LIFE

Background: Psoriatic arthritis (PsA) is a chronic inflammatory joint disease, that can be treated effectively with synthetic disease modifying anti-rheumatic drugs (DMARDs) and biological agents. Ustekinumab is a monoclonal antibody that inhibits IL-12 and 23 that has recently demonstrated efficacy and safety for the treatment of patients with PsA in the PSUMMIT 1 and PSUMMIT 2 studies.

Objectives: To evaluate the efficacy of Ustekinumab in our patients with psoriatic arthritis with peripheral involvement in clinical practice conditions.

Methods: Descriptive, prospective, longitudinal and open study including patients diagnosed with psoriatic arthritis with peripheral involvement. All patients were given ustekinumab at an initial dose of 45 mg administered subcutaneously followed, by another dose 4 weeks later then every 12 weeks. Clinical scores (DAS28, MASES, Pain Vas, Clinicians Vas) were assessed and CRP was measured at baseline and after 6 months of treatment.

Results: 52 patients were included, 25 were female (48.1%) and 27 male (51.9%). They had a mean age of 46.9±11.39 years, a disease duration of 5.03±5.08 years, and moderate disease activity (DAS 28 of 3.95±0.87), the number of tender and swollen joints were 6.24±4.9 and 2.82±2.36, respectively. The patients had received an average of 1.42±1.75 biological therapies previously. Ustekinumab was prescribed as a first line treatment in 42.3% of patients, 19% after failure of a TNF inhibitor and 38% of patients had received 2 or more biological therapies previously. Ustekinumab was administered alone in 51% of the patients, 36.5% in combination with methotrexate and 11.5% in combination with leflunomide. 23.1% of the patients had dactylitis and 36.5% had enthesitis (mean MASES 1.31±0.86). At 6 months of treatment, there were improvements in the number of tender and swollen joints (mean NAD 4.84±6.4 and NAT 2±4 at 6 months, respectively) and MASES index (mean at 6 months, 0.35±0.96). 15 patients completed at least 6 months of treatment. Improvements in DAS28-CRP scores were observed at 6 months of treatment (3.26±1.62), with a mean DAS28 change after 6 months (ΔDAS28) of -0.65±1.88. At month 6, 71.4% of the patients had low disease activity, and 35.7% were in clinical remission according to the DAS28 index.

Conclusions: Ustekinumab is effective in patients with psoriatic arthritis with peripheral involvement in routine clinical practice.

AB0761 THE BIOLOGIC THERAPY USE FOR ENTEHISIS AS A PREDICTOR OF PSORIATIC ARTHRITIS IN PSORIATIC PATIENTS

I. Litovenchenko1, O. Golovenchenko2, 1Medical Clinical Investigational Center of Medical Center “Health Clinic”, Medical Center Health Clinic; 2Medical Clinical Investigational Center of Medical Center “Health Clinic”, Medical Center “Health Clinic”, Vinnytsia, Ukraine

Background: According to ACR data 15–20% patients (PTN) with psoriasis are developed with psoriatic arthritis (PsA). Herewith the enthesitis (ETS) as usual is the first signs of PsA manifestations. It is usually asymptomatic at the beginning of the disease. However it is successfully diagnosed with Doppler ultrasound (DU). In average, it takes about 2 years from beginning of the disease till diagnosis PsA is established. PsA treatment is low effective with DMARD, and middle effective with biologic therapy. Wherein no treatment restores the articular changes that have occurred. Thus the actual is to find some resolution to the effective therapy for PTN with psoriasis and also to identify the factors preceding the development of the PsA.

Objectives: Consider the application of biologic therapy before the articular changes in PTN with psoriasis and predictors of psoriatic arthritis.

Methods: Observed 82 PTN with pustular psoriasis without clinical manifestations of PsA. A physical examination (including PASI), a series of laboratory tests (hematology, CRP, RF, anti -icp, HLA-B27, uric acid), DU to identify the PsA, its activity, as well as to the exclusion of other types of arthritides were used.

Results: 3.7% PTN were diagnosed with PsA with articular changes. 23.1% PTN were founded with enthesitis. The remaining 73.2% PTN had no signs of enthesitis during physical examination and DU. PTN with enthesis were divided into 2 groups. I – 47% PTN (22% of them had clinical manifestations of enthesis; the average group PASI= 42.4±8.2) received a 52-weeks course of ustekinumab (45 mg administered subcutaneously initially and 4 weeks later, followed by 45 mg administered subcutaneously every 12 weeks), II group – 53% people (20% PTN had clinical manifestations of enthesis; the average group PASI= 43.6±9.0) did not receive biological therapy, but only standart treatment for psoriasis. After 1 year follow-up after completion of the treatment course – 11% PTN from group I developed PsA with articular changes. From the group II in 80% PTN developed PsA with articular changes. The average group I PASI= 7.6±1.5; the average group PASI= 6.2±1.3. (p < 0.05)

Conclusions: Thus, the ustekinumab use in pustular psoriasis with enthesitis possibly may be reasonable and will hinder the development of PsA. Ustekinumab is also high effective for the improving of the psoriasis skin symptoms. DU is the high effective diagnostic method for detecting enthesitis without clinical manifestations. Frequency of screening DU in PTN with psoriasis, for the early detection of enthesis is the perspective for further study.

Disclosure of Interest: None declared
Methods: There was no statistically significant difference between groups in terms of hypertension, LDL levels, and smoking status (p=0.775, p=0.228, p=0.136 respectively). PsA patients had higher BMI scores (p=0.03). Insulin levels and HOMA-IR scores were significantly higher among PsA patients compared to controls (p=0.001, p=0.005). There was a statistically significant difference between groups in terms of PTX 3 (p<0.001). PTX 3 was significantly correlated with HOMA-IR and cIMT (r=0.243 p=0.043 and r=0.421 p=0.001 respectively). However, no correlation between PTX 3 and disease activity parameters such as ESR, CRP, SJC, TJC, and VAS-pain was detected (p=0.824, 0.662, 0.922, 0.924, 0.410 respectively). There was no significant difference in terms of PTX 3 levels between PsA patients on biologic treatment or other treatment strategies (p=0.27).

Conclusions: Elevated levels of PTX 3 may be associated with cardiovascular involvement in PsA patients independent from the disease activity. This marker might be used for risk prediction for CMD or may represent a target for new therapies.

AB0763 USTEKINUMAB FOR THE TREATMENT OF PSORIATIC ARTHRITIS – RESULTS OF THE FIRST INTERIM ANALYSIS OF THE NON-INTERVENTIONAL STUDY SUSTAIN

Objectives: SUSTAIN is a prospective, multi-center non-interventional study in Germany to observe long term efficacy and safety, quality of life and further patient reported outcomes in patients with active psoriatic arthritis under treatment with Ustekinumab in routine clinical care.

Methods: In this study treatment with Ustekinumab is according to the label (Stelara®). It is planned to observe 400 patients at 75 centers for 160 weeks with documentation intervals at week 0 and then every 12 weeks. Besides demographic data, the following data will be documented: Amount of swollen and tender joints, joint entheses, skin symptoms (BASI and PASI), patient reported outcomes concerning disease activity and pain, Health Assessment Questionnaire (HAQ), quality of life (SF-12), sleep quality (VAS), satisfaction with therapy of patient and physician, safety (adverse events [AE]/serious adverse events [SAE]), pharmacoeconomic aspects, number of patients with “Minimal Disease Activity” (MDA), number of patients with MDA at week 28 and 52.

Results: Overall, there have been 189 patients (56% women) at 59 centers documented after 11 months. At week 4 154 patients and at week 16 112 patients. At baseline, the patients had a mean age of 56 years (29–85), body weight 87 kg (50–147), BMI 30 (19–47), showed arthritis at small (68.8%) and/or big (51.3%) joints, skeletal involvement (19%), enthesitis (13.2%). The number of tender joints improved from a mean of 8.6 (CI 95% 7.1/10.2) to 4.7 (3.1/6.3) at week 16, number of swollen joints from 3.4 (2.6/4.2) to 1.4 (0.9/1.9). The patient reported global disease activity (0–100) decreased from 55.1 to 38.6 at week 16. Further improvements were documented for enthesitis, PASA, EAP, RA, and pain. Efficacy of the therapy with Ustekinumab after 16 weeks was assessed as “very good” by 32.3% and as “good” by 44.8% of the treating physicians and by 34% and 40.2%, respectively, of the patients. In total, 60 adverse events were reported, of which four were serious. All in all safety of therapy with Ustekinumab after 16 weeks was assessed as “very good” by 51% and as “good” by 49% by the treating physicians, and by 55% and 37%, respectively, of the patients.

Conclusions: The non-interventional study SUSTAIN showed relevant improvements with elevated treatment satisfaction and good safety in patients with active psoriatic arthritis after 16 weeks under real world condition.

AB0764 MALIGNANCY AND SERIOUS INFECTIONS AMONG PSORIATIC ARTHRITIS PATIENTS TREATED WITH BIOLOGICAL DRUGS IN A REGIONAL REGISTRY IN THE NORTHWEST OF SPAIN

J. Pinto-Tasende 1, F.J. Maceiras-Pan 2, L. Guerra-Vazquez 3, L. Fernandez-Dominguez 4, J.A. Mosquera-Martinez 2, C. Garcia-Porrúa 6

1INI-BIC-Rheumatology, Complejo Hospitalario Universitario A Coruña, A Coruña, 2Rheumatology, Complejo Hospitalario Universitario de Vigo, Vigo, 3Rheumatology, Complejo Hospitalario Universitario de Ferrol, Ferrol, 4Rheumatology, Complejo Hospitalario Universitario de Ourense, Ourense, 5Rheumatology, Complejo Hospitalario Universitario de Pontevedra, Pontevedra; 6Rheumatology, Hospital Universitario de Lugo, Lugo, Spain

Background: Biological treatments have provided new opportunities for disease control for patients with psoriatic arthritis. However, it is important to evaluate their safety, since they expose them to an increased risk of developing malignant and serious infections.

Objectives: To examine the rate of solid tumors and serious infections among patients diagnosed with psoriatic arthritis (PsA) treated with biological drugs (BD) in 2011–2015.

Methods: We included all PsA patients (CASPAR criteria) under treatment with BD followed in our regional registry (reference population 2.055.000) between January 2011 and December 2015. In order to capture the incidence of new malignancy we excluded patients with a prior history of malignancy. Medical records were fulfilled for patients and were recorded solid tumors diagnosed (date of diagnosis and histology information) and all serious infections (requiring hospitalization or intravenous antibiotics) in this time period. Incidence rates (IRs) were calculated per 1000 Person-year (py). We used for this analysis sex, age, disease duration, current BD with or without current CMDR associated. Continuous variables were reported as mean ± standard deviation (SD). Categorical variables were reported as percentages and frequencies. Differences were considered statistically significant if p<0.05 (two-tailed).

Results: Among 604 patients 329 (54.5%) of whom were men, with a mean age of 53.3±12.6 years and a time since the diagnosis of PsA of 12.4±8.7 years. There were 14 cancers diagnosed during treatment (2.3%), with an IR of 0.48 cases per 1000 patient-years. Patients who at this time had a higher age had a higher IR, 63.4±10.0 years vs 53.1±12.6, than those who did not develop disease (p=0.010). Etaercept was the most used (42%) and no differences were observed among BDs (p=0.214) or between naïve and non-naïve to BD (p=0.384). Current CMDR associated (56.2%) did not differences in tumors (p=0.429). Prostate tumor was the most frequent (21.4%). There were 42 had serious infection (6.2%), with an IR of 13.9 cases per 1000 patient-years, and was more common in men (4.7% vs 8.8%, p=0.049). Severe infections were more frequent in patients non-naïve to BD (10.4% vs 5.4%, p=0.026). Pneumonia (28.6%), varicella-zoster virus infection (16.6%), osteosarcoma (14.3%) were more frequent. Latent tuberculosis infection was positive in 133 patients (22.0%) and 3 developed tuberculosis.

Conclusions: Patients older than 60 years with psoriatic arthritis treated with BDs had a higher incidence of tumor development. Most of patients were men and prostate tumor was the most frequent. Pneumonia was the most frequent serious infection and non-naïve to BD patients had a higher IR of serious infections.

Objectives: To explore the relationship between DAPSA states and function, health-related quality of life and PROs, and the individual DAPSA components in the different states in pts treated with secukinumab through 104 wks using pooled post-hoc analysis.

Methods: FUTURE 2 study design has been reported. DAPSA was derived as sum of five core components: tender joint and swollen joint counts (TJC 68, SJC 66), pt global assessment (PiGA) and pain (PP) assessed by a 10cm VAS, and PROs DAPSA states were determined by remission - REM: <4, MDA: ≤14, LDA: >14 and ≤28, high disease activity (HDA): >28. Means±SD of each core component of DAPSA were analysed at Wks 16, 24, 52 and 104 using observed data. The relationship between HAQ-DI, SF-36 PCS and MCS, PsAQoL, DLQI and FACIT - Fatigue with DAPSA states was assessed in the pooled treatment arms at each time point using a mixed-effect model for repeated measures (MMRM) analyses.

Results: Baseline characteristics were similar across treatment groups. DAPSA scores at baseline (mean±SD) were 42±17.4, 46±21.4 and 44±25.3 in the secukinumab 300mg, 150mg and placebo groups, respectively. Mean scores of each component by DAPSA states at Wk 16 were shown in table and were sustained through Wk 104. Significant differences were observed among secukinumab treated pts between REM vs. HDA and LDA vs. HDA states for PRO scores through Wk104 (Figure).

Conclusions: In pts treated with secukinumab 300 or 150mg, the five individual components related to DAPSA REM were <1 in contrast with other disease states and were sustained through Wk 104. DAPSA REM was associated with significantly greater improvement in physical function, health-related quality of life and fatigue indicating that it is an important target to be achieved and sustained in PsA pts.

AB0766 SECUKINUMAB PROVIDES SUSTAINED REMISSION AND LOW DISEASE ACTIVITY RELATED TO DISEASE ACTIVITY INDEX FOR PSORIATIC ARTHRITIS (DAPSA): 2 YEAR RESULTS FROM THE FUTURE 2 STUDY

Introduction: Secukinumab, a fully human anti-interleukin-17A monoclonal antibody, significantly improved American College of Rheumatology responses vs. placebo at Week (Wk) 24 that were sustained through Wk 104 in active PsA patients (pts) in the FUTURE 2 study1. This post-hoc exploratory analysis assessed DAPSA states through Wk 104.

Methods: In total, 397 active PsA pts were randomised to subcutaneous (s.c) secukinumab (300, 150 or 75mg) or placebo at baseline and Wks 1, 2, 3 and 4, and every 4 wks (q4w) thereafter. Placebo pts were re-randomised to secukinumab 300 or 150mg s.c q4w from Wk 16 or 24, depending on Wk 16 clinical response. DAPSA was derived as the sum of five variables: tender joint and swollen joint counts (TJC 68 and SJC 66); pt global assessment and pain assessed on a 10cm visual analogue scale; and C-reactive protein levels (mg/dl) with validated cut-off to indicate remission (REM) or low disease activity (LDA).

Objectives: To explore the relationship between DAPSA states and function, health-related quality of life and fatigue indicating that it is an important target to be achieved and sustained in PsA pts.

Results: Baseline demographics and clinical characteristics were similar across treatment groups and previously reported. DAPSA score at baseline (mean [SD]) was 42.0 (17.4), 46.8 (24.3) and 44.9 (25.3) in the secukinumab 300mg, 150mg and placebo groups, respectively. In the overall population, at Wk 16, REM was achieved in 14/97 (14.4%) with secukinumab 300mg and 10/100 (10%) with secukinumab 150mg vs. placebo 4/87 (4.6%); LDA in 27/97 (27.8%) and 34/100 (34%) vs. 12/87 (13.8%), respectively. REM or LDA were sustained through Wk 104 with secukinumab 300 and 150mg (55/84 [65.5%; REM + LDA] and 41/77 [53.2%; REM + LDA], respectively). The proportion of pts achieving each DAPSA state at Wks 16 and 104 by anti-TNF status (anti–TNF-naïve vs. inadequate response/intolerance to these agents [anti–TNF-IR]) and time since first PsA diagnosis (<2 vs. >2 years) using observed data. Only data for secukinumab 300 and 150mg (approved doses) are reported.

Conclusions: In pts treated with secukinumab 300 or 150mg, the five individual components related to DAPSA REM were <1 in contrast with other disease states and were sustained through Wk 104. DAPSA REM was associated with significantly greater improvement in physical function, health-related quality of life and fatigue indicating that it is an important target to be achieved and sustained in PsA pts.
IL-17-22-23 PATHWAYS IN PSORIATIC ARTHRITIS AND PSORIASIS

K. Nas 1, R. Cevik 2, I. Yildiz 2, J. Rech 3, G. Schett 4, Division of Rheumatology and Immunology, Department of Physical Medicine and Rehabilitation, Sakarya University, Faculty of Medicine, Sakarya; 2Division of Rheumatology, Department of Rheumatology, University Hospital, Münster, Germany; 3Department of Biostatistics, Dick, University, Faculty of Medicine, Diyarbakir, Turkey; 4Department of Internal Medicine and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

Background: Psoriatic arthritis (PsA) is an immune-mediated chronic inflammatory rheumatoLOGY-associated with psoriasis. T helper 17 pathway has been shown to play an important role in PsA.

Objectives: In this study, we aimed to investigate concentrations of TH17 pathway cytokines such as IL-17, IL-22 and IL-23 in psoriasis (PsO) with/and without structural bone damage and psoriatic arthritis (PsA), and their relationship with disease activity and clinical findings.

Methods: A total number of 74 patients, 24 patients with PsA (mean age 57.5±11.37; 13 women, 11 men) and 25 patients with PsO and structural bone damage (mean age 49±13.92; 11 women, 14 men) and 25 patients with PsO and no structural bone damage (mean age 41±16.77; 7 women, 18 men), were recruited from the Department Internal Medicine 3 of the University of Erlangen-Nuremberg. Both PsO and PsA patients were evaluated according to the CASPAR criteria.

Results: Demographic and disease specific variables were recorded. Bone architecture of the metacarpal heads I and II were assessed by high-resolution peripheral quantitative computed tomography (HR-pQCT, XtremeCT, Scanco, Switzerland). Disease activity was assessed with Disease Activity Score (DAS28). Psoriatic skin and nail disease activity were measured by the PASI.

Results: The ages of the patients in the three groups were similar. IL-17A concentrations were significantly different between the groups (p<0.001). However, we found there was no difference between PsA and PsO groups. Serum levels of IL-17A were significantly correlated to patient pain of VAS (r=0.318, p=0.06), VAS patient global assessment (r=0.272, p=0.021), DAS28 (r=0.394, p=0.001) and PASI (r=0.519, p=0.000) in PsO and PsA. PASI score were also positively correlated with IL23 (r=0.286, p=0.015) and S100A8 (r=0.288, p=0.011).

Conclusions: IL-17A seems to play an important role in development of PsA and bone damage in PsO. This role should be elucidated by further and larger clinical studies.

AB0768 SONOGRAPHIC SIGNS OF ENTHESITIS IN ESTABLISHED PSORIATIC ARTHRITIS AND HEALTHY VOLUNTEERS

K. Wervers 1, I. Herrings 1, J.J. Luime 1, M. Moed 1, I. Tchetverikov 2, A.H. Gerards 3, J.M.W. Hazes 1, M. Vis 1, Rheumatology, Erasmus MC, Rotterdam; 2Rheumatology, Albert Schweitzer Hospital, Dordrecht; 3Rheumatology, Vlietland Hospital, Schiedam, Netherlands

Background: Previous research in our group showed that sonographic signs of enthesitis are present in early and established PsA, but in young healthy volunteers as well. The Madrid Sonographic Enthesitis Index (MASEI) was only able to differentiate between patients and healthy volunteers after excluding knee and ankle joints.

Methods: A total number of 84 established PsA patients and 25 healthy volunteers aged 35–55 years were enrolled. Both PsO and PsA patients were evaluated according to the Classification Criteria for Psoriatic Arthritis (CASPAR) for the diagnosis of psoriatic arthritis (PsA), not all patients with PsA are seronegative. Measurement of anti-cyclic citrullinated peptides (ACPAs) is a useful key test for rheumatoid arthritis and PsA; however, the prevalence of ACPA in patients with PsA is unclear.

Objectives: We analyzed the clinical features of RF- or ACPA-seropositive patients with PsA in comparison with seronegative patients with PsA using the ISLAND registry (UMIN00002492).

Methods: One hundred patients with psoriasis referred from dermatologists for assessment of synovitis or enthesitis from July 2015 to August 2016 were enrolled. PsA was diagnosed by CASPAR, and synovitis or enthesitis was confirmed by ultrasound assessment. Factors compared between seropositive and seronegative patients included age, sex, smoking, use of disease-modifying antirheumatic drugs, prevalence of enthesopathy, eye symptoms, duration between skin onset and musculoskeletal onset, psoriasis area severity index, composite psoriatic disease activity (CPDAI), psoriatic arthritis screening and evaluation (PASE), disease activity score-28 (DAS-28), and laboratory data.

Results: In total, 52 patients had PsA and 48 patients had psoriasis without any musculoskeletal manifestations. Significant differences were observed in the age at onset of psoriasis (37.4 vs. 47.9 years, respectively; p<0.01) and several clinical parameters (CPDAI: 14.60 vs. 4.55, respectively; p<0.01; PASE: 50.8 vs. 32.0, respectively; p<0.01; DAS28 <3.7 vs. > 3.7, respectively; p<0.009). ACPA positivity was observed in 15.9% of patients with PsA and in 0.0% of patients with psoriasis (p<0.04). Among 44 of the 52 patients with PsA whose ACPA data were available, the duration from skin onset to joint onset was shorter in the 7 ACPA-positive patients (43±32.8 months) than in the 37 ACPA-negative patients (147±115.6 months), although the difference was not statistically significant (p=0.30). There were no statistically significant differences in the PASE, DAS-28, C-reactive protein concentration, or matrix metalloproteinase-3 concentration. The differences between RF positive and negative patients were not also statistically significant.

All data are presented as mean ± standard deviation or median [range] unless otherwise indicated.

Conclusions: Among the patients with PsA in this series, ACPA positivity occurred in 15.9% and RF positivity occurred in 12.8%. Seropositive patients with PsA tended to have a shorter duration between skin onset and joint onset compared with RF-negative patients, although the prevalence of ACPA in patients with PsA is unclear.

(median 12 (IQR 7.25–17) vs. 7.5 (5–9), P < 0.001), while the original MASEI did not differ significantly (Table 1). Confluent PD over a larger area was only seen in 8% of the established PsA patients. Structural damage on ultrasound was more pronounced in the patients compared to the healthy volunteers. Number of PD locations and PD score did not distinguish the two groups.

CHANGE OF PSORIATIC ARTHRITIS IMPACT OF DISEASE (PSAID12) QUESTIONNAIRE RELATED TO CHANGE IN DISEASE ACTIVITY IN EARLY PSORIATIC ARTHRITIS

K. Wervers1, J.J. Luime1, I. Tchetverikov2, A.H. Gerards3, M.R. Kok4, C.W.Y. Appels5, W. van der Graaff6, J.H.L.M. van Groenendaell7, L.-A. Korswagen8, J.J. Veris-van Dieren9, J.M.W. Hazes1, M. Vis1 on behalf of Cicero. 1Rheumatology, Erasmus MC, Rotterdam; 2Rheumatology, Albert Schweitzer Hospital, Dordrecht; 3Rheumatology, Vlietland Hospital, Schiedam; 4Rheumatology, Maastricht Hospital, Rotterdam; 5Radiology, Maastricht University Medical Center, Maastricht; 6Rheumatology, Rivas Hospital, Gorinchem; 7Rheumatology, Reumazorg Zuid West Nederland, Roosendaal; 8Rheumatology, Sint Franciscus Gasthuis, Rotterdam; 9Rheumatology, Reumazorg Zuid West Nederland, Gothen, Netherlands.

Background: The Psoriatic Arthritis Impact of Disease 12-item questionnaire (PSAID12) has been developed to measure impact of Psoriatic Arthritis (PsA) for purposes of monitoring and clinical management. Although validated in patients with longstanding disease, data on validity and sensitivity to change in early PsA is lacking.

Objectives: We aim to relate change in disease activity to change in PsAID12 score in early PsA and evaluate which PsAID domains are more likely to change.

Methods: Patients with a new diagnosis of PsA were included in the Dutch southwest Early Psoriatic Arthritis cohort (DEPAR). For this analysis, patients that have PsAID12 (range 0–10) and Composite Psoriatic Disease Activity Index (CPDAI) (range 0–15) data at two consecutive visits (i.e. 3 months apart) within the first year were included. In case multiple periods per patients were available, the first time period was chosen. The change in PsAID is compared to the change in disease activity over this period, measured with the CPDAI using Spearman’s correlation coefficient. Change in score on individual domains of the PsAID was analysed in subgroups of patients that perceived improvement in health and those that perceived worsening. The SF-36 question on self-perceived change in health was used to determine these subgroups.

Results: 143 unique patients had at least one period with two PsAID and CPDAI measures (67 from baseline-3 months, 25 6–9 months and 25 9–12 months). Mean age was 51 (SD 13.7) and 70 (49%) were male. The initial median PsAID was 3.35 (IQR 1.4–5.1) and the subsequent score was 2.25 (0.95–4.8 with a mean delta of 0.52 (P < 0.01). Median first CPDAI score was 4 (2–7) and 3 (1–5) for the second with a mean delta of 0.45 (P < 0.05). The difference in CPDAI score was significantly but moderately correlated with the difference in CPDAI (Spearman’s rho 0.267, P=0.0013). 58 patients (41%) report a better health status compared to 3 months ago. Figure 1 shows that patients with self-perceived improvement of health have the highest improvement in pain and only domains of skin problems and embarrassment/shame did not improve significantly. Patients reporting worsening of health (n=29) only have significantly lower scores in fatigue, discomfort and social domains.

Conclusions: Improvement in CPDAI disease activity is significantly but moderately associated with improvement in PsAID score, with the biggest improvement in the pain domain in patients with a self-reported improvement of health.

AB0771

SAFETY AND EFFICACY OF APREMILAST THROUGH 104 WEEKS IN PATIENTS WITH MODERATE TO SEVERE PSORIASIS WHO CONTINUE ON APREMILAST OR SWITCH FROM ETANERCEPT TREATMENT IN THE LIBERATE STUDY

K. Reich1, M. Goodfield2, L. Green3, K. Nogales4, R. Chen5, E. Levi4, R.G.B. Langley5, 1Dermatologikum Hamburg, Hamburg, Germany; 2Leeds General Infirmary, Leeds, United Kingdom; 3George Washington University School of Medicine, Washington, DC; 4Celgene Corporation, Summit, United States; 5Dalhousie University, Halifax, Canada.

Background: Many patients (pts) with chronic plaque psoriasis exhibit nail and scalp involvement that can markedly affect quality of life and be difficult to treat.

Objectives: The phase 3b LIBERATE (Evaluation in a Placebo-Controlled Study of Oral Apremilast and Etanercept in Plaque Psoriasis) study (NCT01690299) evaluated the efficacy and safety of apremilast or etanercept vs. placebo in biologic-naive pts with moderate to severe plaque psoriasis. Efficacy assessments included effects on preexisting nail and scalp disease and skin lesions.

Methods: In this double-blind, double-dummy study, pts were randomized (1:1:1) to placebo (PBO), apremilast 30 mg BID (APR), or etanercept 50 mg QW (ETN) through Week 16; thereafter, all pts switched to or continued APR (PBO/APR, ETN/APR, APR/APRR) through Week 104. The primary end point was achievement of a ≥75% reduction from baseline in Psoriasis Area and Severity Index (PASI) score (PASI-75) at Week 16 with APR vs. PBO; the secondary end point was PASI-75 achievement at Week 16 with ETN vs. PBO. Physician assessments were also conducted for overall disease activity (static Physician’s Global Assessment [sPGA]; scalp disease area and severity Physician Global Assessment [ScPGA], limited to patients with score ≥3 at baseline, indicating moderate to very severe scalp disease); and nail disease (Nail Psoriasis Severity Index [NAPSI], limited to patients with active disease [NAPSI ≥1] in the target nail at baseline). Responses were assessed at Week 104 using the last-observation-carried-forward (LOCF) methodology.

Results: The APR extension phase (Weeks 16 to 104) included 226 pts (PBO/APR n=73; APR/APR n=74; ETN/APR n=79). At Week 16, PASI-75 scores were significantly better for both APR and ETN; long-term treatment with APR maintained both PASI-75 and sPGA ≥3 or 1 response levels (Table). Improvements were seen in nail and scalp disease at Week 16, and responses continued to improve with APR treatment over 104 weeks and in pts who switched from ETN to APR (Table). ScPGA 0 or 1 was achieved by 50.0% to 59.2% of pts across treatment arms, and mean percent improvement from baseline PASI NAPSI score ranged from −48.6% to −51.1% (Table); the proportion of pts achieving NAPSI-50 response ranged from 48.6% to 65.2%. Adverse events (AEs) occurring in ≥5% of pts during Weeks 0 to 16 were diarrhea, nausea, nasopharyngitis, upper respiratory tract infection, and headache; long-term assessment by exposure-adjusted incidence rates [EIR] 100 pt-yrs showed no increase with longer-term APR exposure. No increase in EIR/100 pt-yrs of serious AEs occurred during the APR extension phase (3.45 to 5.49, across groups) vs. Weeks 0 to 16 (PBO 0.0; ETN 7.91; APR 12.57). Changes in laboratory parameters were infrequent and transient; EIR/100 pt-yrs remained low across groups through 104 weeks.

Conclusions: APR demonstrated efficacy through Week 104 in pts who continued APR and pts who switched from PBO or ETN to APR at Week 16. The AE profile remained consistent with prolonged APR exposure, and no new safety or tolerability issues were observed through Week 104 in pts with moderate to severe plaque psoriasis.
AB0772 SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENT IN FUNCTION, QUALITY OF LIFE AND FATIGUE OVER 2 YEARS IN PATIENTS WHO ACHIEVED LOW DISEASE ACTIVITY RELATED TO PSORIATIC ARTHRITIS DISEASE ACTIVITY SCORE (PASDAS)

L.C. Coates1,2, T.K. Kvien3, P. Nash4, L. Gossec5, V. Strand6, L. Pricop7, L. Rasouliyan8, K. Ding9, S. Jugl9, C. Gaillez9 on behalf of the FUTURE 2 study group.

1University of Leeds; 2Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; 3Diakonhjemmet Hospital, Oslo, Norway; 4University of Queensland, Brisbane, Australia; 5UPMC Universitè Paris 06, Paris, France; 6University of Medicine, Palo Alto; 7Novartis Pharmaceuticals Corporation, East Hanover, United States; 8RTI Health Solutions, Barcelona, Spain; 9Novartis Pharma AG, Basel, Switzerland

Background: PASDAS is a composite index measuring disease activity in psoriatic arthropits (PsA), well correlated with HAQ and health related quality of life.

Objectives: To report the impact of secukinumab on individual core components of PASDAS and its relationship with function, quality of life and fatigue of PsA patients achieved PASDAS low disease activity (LDA) vs. high disease activity (HDA) through Week 104 using post-hoc analysis from FUTURE 2 trial.

Methods: 297 pts with active PsA were randomised to s.c. secukinumab (300, 150, or 75mg) or placebo in FUTURE 2 study. PASDAS is derived from physician’s global VAS, pts global VAS, SF-36 PCS, tender and swollen joints (TJC68 and SJC66), Leeds enthesitis count, dactylitis count and CRP level and has cut-points for HDA (≥3.2) and remission (REM ≤1.9). PASDAS was assessed at Wks 16, 52 and 104 and reported as observed using non-mutually exclusive categories at group level. Additionally, the SF-36 PCS, SF-36 MCS, HAQ-DI, FACIT-Fatigue, PsAQoL, and DLQI were assessed by PASDAS LDA and HDA at Wks 16, 52 and 104 using MMRM analyses.

Results: PASDAS component among pts reaching LDA and HDA at Wk 16 for each treatment group are shown in table and were similar at Wk 104. Secukinumab treated pts achieving PASDAS LDA had significantly greater improvements in function, physical and mental health quality of life and fatigue compared to HDA through Wk 104 (Figures).

Conclusions: In pts treated with secukinumab, the most improved individual components with PASDAS LDA were related to dactylitis, enthesitis, SF36-PCS, Physician global VAS and SJC at Wk 16 and Wk 104. PASDAS LDA was associated with better improvement in function, quality of life and fatigue than HDA confirming the importance to reach stringent target in a PsA pts with PsA associated with better improvement in function, quality of life and fatigue than

**AB0773** EFFECTIVENESS OF GOLIMUMAB IN TNF-INHIBITOR PREVALENCE, CLINICAL AND RADIOGRAPHIC UNDERESTIMATED AXIAL AND ENTHESIAL INVOLVEMENT IN

1 Državni Univerzitet Novi Pazar, Departman za biomedicinske nauke, Novi Pazar; 2 Ambulatorio Reumatologia, Ospedale di Mesagne, Mesagne, Italy; 3 Državni Univerzitet Novi Pazar, Departman za biomedicinske nauke, Novi Pazar; 4 Institute Niska Banja, Nis, Serbia

**Background:** In real-life world settings, failure of a first TNF-inhibitor (TNFi) put rheumatologists against a crossroad to choose a further TNFi or a biologic drug with a different mechanism of action. 

**Objectives:** Aim of this study was to assess effectiveness of golimumab (GOL) as second line drug after failure of a first TNFi as treatment of patients affected with rheumatoid arthritis (RA), psoriatic arthritis (PsA), or axial-spondyloarthritis (AxSpA).

**Methods:** GOAREL is a prospective cohort of patients starting GOL in community-based care rheumatology centers in Apulia (south Italy) since 2013. Of 494, we selected 368 patients (RA n.73, PsA n.168, and AxSpA n.127) commencing GOL as first ever biological (n.206, 55%) or second treatment (n.161, 44%) after inadequate response to a first TNFi (adalimumab (ADA, n.51), etanercept (ETA, n.81), or infliximab (IFX, n.29). Three patients failing certolizumab were excluded. Primary endpoint was to compare the drug retention rate of biological naïve and TNFi inadequate responders (TNFi-IR) patients on treatment with GOL. In addition, drug retention of second line GOL patients according to the fires TNFi was assessed. Drug survival was estimated by Kaplan-Meier life table analysis. Estimates hazard ratios (HRs) of 2-years drug discontinuation adjusted for demographics, type of disease, disease characteristics, body mass index, co-therapy with glucocorticoids or methotrexate, and prior TNFi were computed by backward selection Cox-regression model.

**Results:** 2-year drug survival on GOL of naïve and TNFi-IR patients was not significantly different (Figure 1). Mean survival time was 20.0 months (95% CI 18.9–21.0) for naïve and 20.4 months (95% CI 19.3–21.6) for TNFi-IR patients. Likewise, drug retention rates on GOL of TNFi-IR patients subdivided by previous TNFi was not significantly different and similar to naïve patients (Figure 1). Mean survival time was 19.0 months (95% CI 16.7–21.4) for prior-ADA, 20.5 months (95% CI 19.9–22.1) for prior-ETA, and 22.0 months (95% CI 19.6–24.3) for prior-IFX. Multiple Cox-regression model showed gender female as the only independent factor positively associated to the risk of GOL discontinuation (HR 2.5, 95% CI 1.5–4.2, p 0.0001).

**Conclusions:** In real-life setting effectiveness of GOL seems to be similar in naïve or TNFi-IR patients with RA, PsA, and AxSpa. Furthermore, clinical outcomes were not influenced by the previous TNFi.

**Disclosure of Interest:** None declared

**AB0777** UNDERESTIMATED AXIAL AND ENTHESIAL INVOLVEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS IN A RUSSIAN RHEUMATOLOGICAL DAILY PRACTICE: COMPARED WITH RHEUMATOLOGICAL PRACTICE

M. Chamurtseva, E. Loginoa, T. Kostateva, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Psoriatic arthritis (PsA) is frequently underdiagnosed by dermatologists due to its heterogeneous clinical manifestations such as peripheral arthritis, dactylitis, spondylitis and enthesitis. For the correct early diagnosis, choice of treatment and for better outcomes proper evaluation of all symptoms is required. 

**Objectives:** To compare the definition of the main clinical symptoms of PsA by dermatologists and rheumatologists in daily clinical practice.

**Methods:** 103 pts (male-47/female-56) with different forms of plaque psoriasis (PsO), mean age 44±13.69 years (yrs.), mean psoriasis duration 10.7±10.2 yrs., mean PASI 5.05±1.23 were included. In rheumatological clinic, all pts completed a PEST questionnaire and underwent clinical evaluation by a dermatologists in order to identify the main clinical symptoms of PsA such as peripheral arthritis, dactylitis, spondylitis and enthesitis. Later all pts were subsequently evaluated by dermatologists to confirm/exclude the diagnosis of PsA based on CASPAR criteria and underwent standard clinical examination to identify the same symptoms - peripheral arthritis, dactylitis, spondylitis (based on inflammatory back pain (IBP) ASAS criteria) and enthesitis (based on Leeds Enthesial Index (LEI) plus Plantar Fascia (PF)), Mtm%, t-test were performed. All p<0.05 were considered to indicate statistical significance. 

**Results:** 61 out of 103 pts with PsO (59.2%) had PsA based on rheumatological evaluation and CASPSSR criteria. Dermatologists diagnosed peripheral arthritis in significantly less cases compared to rheumatologists: in 15 (24.6%) and in 35 (57.4%) out of 61 pts (p<0.001) accordingly. No significant difference was seen in clinical evaluation of dactylitis by dermatologists or rheumatologists - in 37 (60.7%) and in 40 (65.6%) out of 61 pts accordingly (p=0.32). Heel pain was noted by dermatologists in 32 out of 61 pts (52.5%) according to PEST questionnaire. Dermatologists could not find enthesis according to LEI. Rheumatological examination based on LEI scale identified lateral epicondyles in 11 out of 61 pts (18%), enthesis of medial femoral condyles in 8 out of 61 pts (13.1%), enthesis of Achilles tendon insertions – in 25 out of 61 pts (41%). Enthesitis of PF were observed in 15 out of 61 pts (24.6%). Dermatologists noted back pain using PEST questionnaire in 30 out of 61 pts (49.2%). IBP based on ASAS criteria was not detected by a dermatologists in any case. In these 30 pts having back pain IBP was diagnosed by a rheumatologists in 21 (70%) cases; and in the rest 9 out of 30 pts (30%) mechanical back pain was observed. On the basis of clinical examination tendinitis was not noted by dermatologists, while rheumatologists found hand tendinitis in 13 out of 61 pts (21.3%).

**Conclusions:** Peripheral arthritis, axial and enthesis involvement were underestimated by dermatologists using PEST screening questionnaire, because it does not cover these symptoms in detail. ASAS criteria for IBP and standard enthesitis assessment should be implemented into Russian rheumatological clinical practice. To improve early PsA diagnosis in rheumatological practice, interdisciplinary educational training programmes and collaboration with rheumatologists are needed.

**Disclosure of Interest:** None declared

THE EFFECT OF PREGNANCY ON DISEASE ACTIVITY OUTCOMES IN PSORIATIC ARTHRITIS PATIENTS

M. Berman1, D. Paran1, D. Dizam2, J. Wollman1, D. Levartovsky1, O. Elkayam1,2, Rheumatology, Tel Aviv Sourasky Medical Center, Tel Aviv; 2Rheumatology, Carmel Medical Center, Haifa, Israel

Background: Psoriatic arthritis often affects patients at a childbearing age. The relationship between pregnancy and psoriatic arthritis, in terms of pregnancy outcomes and its effect on disease activity, has not been well studied

Objectives: To evaluate the effect of pregnancy on disease activity in psoriatic arthritis.

Methods: A retrospective review of files of female patients followed at Psoriatic arthritis clinic at the Tel Aviv Medical center was performed, patients with at least 1 pregnancy during follow up and one visit during or soon after pregnancy were included. A review of files was performed which included the follow-up: age, disease duration, pattern of PsA, disease activity before and during and after pregnancy, record of treatment, including IA injections. Postpartum period was defined as up to 1 year after pregnancy. PsA activity was defined as follow: no disease activity (no active synovitis), mild disease (up to 1 joint involved), moderate to severe disease (more than 2 joints involved). The follow-up during and after pregnancy was classified as: improvement, worsening or stable.

Results: 25 PsA women and 35 pregnancies were identified. 33 resulted in live healthy babies. One pregnancy was interrupted on week 23, so partial follow up was available. The mean age at pregnancy was 32.5 years. Table 1 summarizes statistical disease activity before, throughout pregnancy and during the postpartum period in the whole group. No significant change in disease activity was noticed throughout pregnancy while significant proportion of patients flared at postpartum. Before 21 pregnancies patients were treated with biologic agents. In 15, biologic treatment was discontinued close to pregnancy or during flared at postpartum. Before 21 pregnancies patients were treated with biologic agents. In 10, biologic treatment was discontinued close to pregnancy or during flared at postpartum. Before 21 pregnancies patients were treated with biologic agents. In 10, biologic treatment was discontinued close to pregnancy or during flared at postpartum.

Conclusions: Patients with PsA definitively flare after pregnancy. Our results suggest that stopping treatment with biologic agents before pregnancy is associated with flare during pregnancy and the postpartum period. It seems that in terms of PsA disease activity, it may be recommended to continue treatment with biologic agents throughout pregnancy.

CHARACTERISTICS OF AMYLOID A DEPOSITION IN PSORIATIC ARTHRITIS AND IN RHEUMATOID ARTHRITIS – A COMPARATIVE POSTMORTEM CLINICOPATHOLOGIC STUDY OF 161 RHEUMATOID AND 12 PSORIATIC ARTHRITIS PATIENTS

M. Bély1, Á. Apáthy2. 1Department of Pathology, Policlinic of the Order of the Brothers of Saint John of God, 2Department of Rheumatology, St. Margaret Clinic Budapest, Budapest, Hungary

Background: The aim of this study was to determine the prevalence and extent of amyloid A deposition on different tissue structures in various organs of rheumatoid arthritis (RA) and psoriatic arthritis (PsA) patients.

Methods: AAs was detected in 34 (21.1%) females; 29, average age: 64.3 years, range: 63–32, onset of RA: 48.6, average disease duration: 14.8 years) of 161 RA, and in 2 (16%) female: 2 average age: 57.5 years, range: 63–52, onset of PsA: 47.5, average disease duration: 11.0 years) of 12 PsA patients.

RA and PsA were diagnosed clinically according to the criteria of the American College of Rheumatology (ACR) [1,2].

Amyloid deposits on different tissue structures [arteriolar, small artery, medium size artery, venule, small vein, medium size vein, interstitial collagen fiber, reticulin fiber] were evaluated, using these "global assessment" by the patient (PaGl) and by the physician (PhGl). The agreement and interplay between PaGl and PhGl are not well clarified in patients with PsA, however.

Disclosures: None declared

DOI: 10.1136/annrheumdis-2017-eular.1221

PATIENT AND PHYSICIAN GLOBAL ASSESSMENTS ARE POORLY CONNECTED IN INDIVIDUAL PATIENTS WITH PSORIATIC ARTHRITIS AND ONLY POORLY EXPLAINED BY OTHER CLINICAL MARKERS OF DISEASE ACTIVITY

E.M. Egamose1,2, O.R. Mordsen1,2, 1Department of Rheumatology, Copenhagen University Hospital Rigshospitalet Gentofte, Hellerup; 2The DANBIO registry, Copenhagen University Hospital Rigshospitalet Glostrup, Glosstrup, Denmark

Background: Assessment of disease activity is important in the evaluation and monitoring of patients with psoriatic arthritis (PsA) in clinical care and research. As there is no single "gold standard" variable for assessment of disease activity several markers of disease activity are used, among these "global assessment" by the patient (PaGl) and by the physician (PhGl). The agreement and interplay between PaGl and PhGl are not well clarified in patients with PsA, however.

Objectives: The objective of the study was to examine associations on the group level and agreements on the individual patient level between PaGl and PhGl as scored on visual analogue scales (VAS) in the daily clinic by patients with active PsA and their rheumatologists.

Methods: Traditional disease activity data on 76 PaA patients with active disease planned to initiate biological treatment were extracted from the Danish DANBIO registry. Data comprised swollen joint count (SJC), tender joint count (TJC), CRP, patient and physician global assessment (PaGl and PhGl) and pain (VAS), HAQ-DI and DAS28-CRP (4v). Parametric statistics was used. The predictability of PaGl and PhGl, respectively, by all other disease markers mentioned and by age and sex was examined using stepwise multiple regression analysis. Agreement between the VAS scores was expressed as the bias (mean difference between intra-individual scores) and the 95% lower and upper limits of agreement (lLoA;ULoA) according to the Bland-Altman method.

Results: The prevalence and extent of amyloid A deposits on different tissue structures were compared by Student (Welch) t-probe.

Conclusions: The difference between average prevalence (£0.388) and average amount (£0.444) of amyloid A deposits in structures and PsA patients was not significant.

Disclosure of Interest: None declared

vs. PSo, PaSo was in general scored considerably higher than PSo. The two scores were poorly correlated not only on the individual level but also on group level with no systematic differences between the scores. PaSo was best predicted by pain, and PSo by SCJ reflecting patients and physicians diverging attitudes to the importance of the different disease manifestations. The findings highlight the challenge of understanding and dealing with discrepancies between assessments and attitudes by physicians and patients.

</table>

Background: Psoriatic arthritis (PsA) has various clinical manifestations. The therapeutic response of patients may be affected by epidemiological parameters such as body mass index (BMI), disease duration, sex and the choice of therapy. Objectives: To illustrate clinical manifestations of psoriatic arthritis to assess the impact of epidemiological features and treatment choice on therapeutic response.

Methods: We retrospectively studied 411 patients diagnosed with PsA and we recorded the clinical manifestations of the disease. Data of 254 out of 411 patients were analyzed to examine the possible effect of BMI, disease activity, sex and treatment choice on therapeutic response. Patients were followed up at predefined time points (baseline, 12 weeks, 24 weeks, 48 and 240 weeks after initiation of treatment). The therapy response was assessed using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), disease activity score-28 (DAS) - C-Reactive Protein (CRP), DAS28-erythrocyte sedimentation rate (ESR) and Health Assessment Questionnaire (HAQ). Patients were categorized in three groups: patients treated with biological synthetic disease modifying anti-rheumatic drugs (DMARDs) (anti-tumor necrosis factor alpha (TNFα) agents), patients treated with synthetic DMARDs and combined therapy (biological and synthetic DMARDs).

Results: The interval between psoriasis and PsA in women is shorter (<p=0.041). PsA presented predominantly as asymmetric oligoarthritis (41.6%), followed by symmetric polyarthritis (24.5%). Arthritis of distal phalangeal joints was established in 3.14%, while 4.37% shown only enthesitis or dactylitis. Axial involvement was recorded in 26.27%. Twenty-eight patients had only axial disease and 60% had peripheral joint involvement. 23/411 patients (5.60%) had eye involvement, 8/411 (1.95%) and 6/411 (1.46%) had involvement of the urogenital and gastrointestinal system, respectively. Eleven patients had pulmonary fibrosis. In the subgroup analysis of 254 patients, disease duration was positively correlated in all time points (<p=0.005) with all disease activity scores. Statistical significant difference with respect to gender was observed for DAS28-CRP (3.93–2.96, 3.54–2.64 p<0.001) and DAS28-ESR (3.37–2.82 p=0.001, 3.06–2.26 p=0.023) at 12 and 24 wks respectively. More specifically women showed higher disease activity than males the first 6 months after treatment. BMI was not significantly correlated with the disease activity. Treatment with biological DMARD showed a statistically significant difference in all disease activity scores early in the disease course (<p=0.05) in comparison with those receiving conventional DMARD. After the first 12 wks all disease activity scores were rather stable with no differences between the treatment groups.

Conclusions: PsA manifests predominantly as asymmetric oligoarthritis. Extraarticular manifestations are less frequent. Higher disease duration was associated with higher disease activity. Women early on disease course had higher DAS-28 scores. Treatment with biological DMARD showed better response in PsA patients compared with synthetic early in the disease course. However, after the first 12 wks there were no significant differences in treatment response with respect to treatment choice.

Background: Achieving sustained clinical response to biologics is part of treat-to-target recommendations in psoriatic arthritis (PsA) and is aimed at optimising treatment goals.1

Objectives: To evaluate patient (pt)-level secukinumab data and report the likelihood of improving, sustaining or worsening of American College of Rheumatology (ACR) response and disease status (disease activity score 28 based on C-reactive protein [DAS28-CRP]) from Week (Wk) 24 to 104 in pts with active PsA from the FUTURE 2 trial.2,3

Methods: The findings of the FUTURE 2 trial through Wk 104 have been previously reported.3 Post-hoc shift analyses were performed on ACR response between Wks 24 and 104 for subgroups of secukinumab-treated pts, based on their higher response rate at an earlier time point in 1 out of 4 categories (ACR non-responders [NR], ACR20, 50 or 70) by evaluating whether the response improved, sustained or worsened at a later time point using exclusive categories and as observed analyses. Similar shift analysis on DAS28-CRP derived criteria were performed in 4 exclusive categories extrapolated from rheumatoid arthritis: high, moderate, low disease activity (HDA, MDA, LDA) or remission (REM) only.4

Results: In total, 86/100 (86%) and 76/100 (76%) pts in the secukinumab 300 and 150mg groups, respectively, completed the 104-wk treatment. Of which, 73/70 and 81/75 pts in secukinumab 300/150mg were eligible for ACR and DAS28-CRP shift analysis, respectively, from Wk 24 to 104. Baseline demographics and clinical characteristics were balanced across the two dose groups.2,3 Most secukinumab-treated pts who achieved at least an ACR20, 50 or 70 response and Psoriasis Area and Severity Index (PASI) 75 or 90 response at Wk 24, improved or sustained their response at Wk 104 (Figure, data not shown for PASI response). Similarly, a majority of pts who were in the MDA, LDA or REM category at Wk 24 sustained or improved their disease status related to DAS28-CRP score at Wk 104 (Figure).

Figure: Shift analysis in ACR and DAS28-CRP responses from Week 24 to 104

Conclusions: In this post-hoc analysis, a majority of secukinumab-treated pts who achieved at least ACR20 and PASI 75 response or at least MDA at Wk 24 sustained or improved their ACR and PASI responses or sustained or reduced their disease status at Wk 104. Numerically higher sustained response and LDA or REM rate was observed for secukinumab 300mg, thereby extending the sustainability of response and lowering the disease activity that has been previously reported at group level.2,3

AB0781 PSORIATIC ARTHRITIS IN PSORIASIS PATIENTS: RESULTS OF A FRENCH SURVEY

P. Claudepierre1, P. Richebe2, S. Benkhalifa3, D. Sid Mohand4, B. Charles5, Y. Braults5, M. Lahaia5, 1Department of Rheumatology, Université Paris Est Créteil, Chenevier-Mondor Hospital, Créteil; 2Department of Rheumatology, Université Paris Est Créteil, Chenevier-Mondor Hospital; 3Pfizer; 4France Psoriasis, Paris; 5Private dermatology practice, Biarritz, France

Background: Early detection of psoriatic arthritis (PsA) in patients with skin psoriasis (Pso) is critical to reduce the risk of joint damage, disability, and comorbidities. However, PsA is mostly underdiagnosed in patients with Pso. Objectives: first to compare characteristics of patients with Pso without PsA with those of patients with Pso and PsA, then to compare patients with PsA and potential but undiagnosed PsA (puPsA) to the other patients.

Methods: 817 patients completed an online questionnaire published by the French Psoriasis Patients Association, including multiple-choice questions regarding in particular past and current symptoms. For analysis, a first comparison was performed between patients with Pso without known PsA and patients with PsA and PuPsA, then between patients with symptoms suggestive of PsA (puPsA group), i.e., patients with past or current joint or back pain accompanied by waking up at night and/or morning stiffness, with PsA patients on the one hand, and with patients without known PsA and without symptoms suggestive of puPsA, on the other hand.

Results: 746 patients reported having Pso of which 192 (25.7%) had also PsA. Among the 554 patients without known PsA, 190 (34.3%) had symptoms suggestive of PsA, 101 (18.2%) had rheumatologic symptoms without suggestive of PsA, and 263 (47.5%) had no rheumatologic symptoms. The comparison, in multivariate analysis, between patients with Pso and PsA and patients with Pso without known PsA showed significant differences (p<0.05): Pso and PsA patients had more often current bone or joint pain at any time (OR=7.8), joint pain during the day (OR = 2.45), stiff back or joints on waking (OR=1.77), painful and swollen fingers and toes (OR=3.15), past joint pain during the day (OR=3.05), and drug in tablet form (OR=2.07), biotherapy alone (OR=0.45) or with DMARDs (OR=16.06); conversely they had less often guttate psoriasis (OR=0.54). Results of the multivariate analysis comparing patients with puPsA to the other patients are shown in Tables 1 and 2 (comparison with patients with Pso and PuPsA in Table 1; comparison with patients with Pso without known PsA in Table 2).

Conclusions: That survey on Pso patients showed that a fourth of them also had PsA, but more importantly that about another fourth had puPsA, highlighting the underdiagnosis of PsA. It suggests that presence of fatigue and nail changes might raise suspicion of PsA in Pso patients.

AB0782 PSORIATIC ARTHRITIS EARLY ULTRASONOGRAPHIC CHANGES IN PATIENTS WITH PSORIASIS AND NAIL PSORIASIS: A COMPARATIVE STUDY WITH SUBJECTS WITHOUT PSORIASIS

P. Rodriguez Henriquez1, M.L. Cardenas-Hernandez2, L. Lammoglia-Ordiales3, L.T. Becerril-Mendoza4, R.M. Lacy-Niebla5, 1Rheumatology; 2Dermatology. Hospital General Dr. Manuel Gea González; 3Rheumatology, Hospital Juárez de Mexico, Mexico, Mexico

Background: Psoriatic Arthritis (PsA) has a prevalence of 30% amongst Psoriasis (Ps) patients. However in patients with ungual Ps the prevalence has been reported in up to 68% of cases. In musculoskeletal ultrasound (MSUS) studies the lesion most frequently reported is enthesis followed by synovitis in early PsA patients.

Objectives: To determine the presence of psoriatic arthritis early ultrasonographic changes in patients with psoriasis, nail psoriasis, and subjects without psoriasis.

Methods: Analytic, comparative, prospective and transversal study, in which patients with psoriasis, nail psoriasis, and subjects without psoriasis paired by age, were recruited. Each group underwent a skin and joint checkup, which included demographic data, comorbidities, psoriasis severity and joint signs and symptoms. The ultrasonographic evaluation consisted in a gray scale detection and classification according to severity scales, of synovitis, enthesis, synovial effusion and bone erosions in the distal interphalangeal joints of both hands.

Results: A total of 16 patients, 8 with psoriasis and 8 with nail psoriasis, as well as 9 subjects without psoriasis, were recruited. The psoriasis group included mostly men (87.5%), unlike the subjects without psoriasis (44.4%) and the nail psoriasis group (37.5%) (p=0.09). The mean age for the study population was 55.16 ± 8.09 years. There was no statistical significance between groups (p=0.430). The greatest prevalence of comorbidities was found in both groups with psoriasis. The mean time of disease duration in the nail psoriasis group was 20.12 ± 14.54 years, vs 13.37 ± 14.45 years in the psoriasis group (p=0.247). Synovitis was found in 100% of patients in the psoriasis group, vs 37.5% in the nail psoriasis group, and 62.5% in the subjects without psoriasis group (p=0.028). No enthesitis was observed in any group.

Conclusions: Synovitis was more frequent than enthesis in our population as an ultrasonographic finding of psoriatic arthritis. No association was found between other variables with synovitis, such as age, sex, disease duration and comorbidities.

AB0783 THE RELATIONSHIP BETWEEN THE DEGREE OF SKIN INVOLVEMENT AND JOINT ACTIVITY IN PATIENTS WITH PSA: EXPERIENCE FROM THE CORRONA REGISTRY

Objectives: To characterize the relationship between skin severity and joint activity in patients with comorbid PsA and PsO at enrollment.

Methods: Data from the U.S. Corrona PsA/spondyloarthritis (PsA/SpA) registry were obtained from the period 3/21/2013–9/30/2016. Inclusion criteria included a diagnosis of PsA, a history of PsO, and age greater than 18 years. PsA patients were evaluated for skin severity as defined by Body Surface Area (BSA) and joint activity as defined by the level of clinical disease activity index (CDAI). Patient characteristics, including current and prior PsA medication use, were obtained during the enrollment visit. We evaluated the relationship between skin severity (BSA) and joint activity (CDAI) with multi-variable linear regression.

Results: 1,542 patients met inclusion criteria: 52.9% were women with mean (SD) age 53.7 (13.2) years, with median 9.0 years PsA disease duration, and 71 (4.6%) with fibromyalgia. 266 (18%) patients were on DMARD therapy, 430 (29%)
on csDMARDs only. 616 (42%) were on first line biologic/targeted synthetic (ts)DMARD therapy, and 172 (12%) were on second line biologic/tsDMARD therapy. The relationship between skin severity and joint activity was statistically significant ($p<0.0001$) with a correlation of $0.183$. Results were similar when adjusting separately for treatment and for duration of PsA and PsO. Greater age, female gender, higher dactylitis count, not achievement of MDA, higher HAQ, and patient reported pain and fatigue affected the relationship.

**Conclusions:** The relationship between skin severity and joint activity is statistically significant and varies by age, gender, MDA, HAQ, and patient reported pain and fatigue. This suggests degree of skin involvement is important to take into account when evaluating PsA patients.

Teng9, J. Wollenhaupt9. 6Medical Center and University of Washington School of Medicine, Seattle, United States; 2Toronto Western Research Institute, Toronto, Canada; 3Hospital Clínico Universitario, Santiago, Spain; 4Monash University, CabriniHealth, Melbourne, Australia; 5University of California, San Diego, School of Medicine, La Jolla, United States; 6University of Orléans, Orléans, France; 7University of Erlangen-Nuremberg, Erlangen, Germany; 8Celgene Corporation, Summit, New Jersey; 9Schön Klinik Hamburg Elbek, Hamburg, Germany.

**Background:** Dactylitis and enthesitis are common disease manifestations encountered in nearly 10–30% of patients with psoriatic arthritis (PsA). Previous clinical trial data suggests that anti-tumor necrosis factor (aTNF) is effective in controlling dactylitis and enthesitis among PsA patients, however there are limited data in real world studies.

**Objectives:** To evaluate the effectiveness of aTNFs on dactylitis and enthesitis in patients with PsA enrolled in Corrona, a large US observational cohort of patients with PsA and spondyloarthritis.

**Methods:** Adult PsA patients who initiated or were currently on an aTNF at recruitment (definition) between 3/2013–9/2016 and had a 12 month follow-up visit were included. Dactylitis was defined as a non-zero total dactylitis score on a scale 0–20 and enthesitis was defined by a non-zero score on the SPARRC enthesitis index, 0–16. The primary outcome was change in dactylitis and enthesitis scores at 12 months from baseline. Descriptive analysis of patient characteristics at baseline was examined and change in outcomes was evaluated using t-tests.

**Results:** There were 28 patients with dactylitis and 77 patients with enthesitis who met the inclusion criteria. Patients with dactylitis and enthesitis had a mean (SD): age of 49.2 (11.5) years, body mass index of 30.8 (6.6) and 31.4 (7.6), disease duration of 9.3 (9.1) and 8.1 (7.7) years, and 28.6% and 45.5% were on methotrexate combination therapy respectively. Patients had a mean clinical disease activity index of 15.1 in both groups, 40.0% and 17.1% were in minimal disease activity, mean (SD): body surface area was 4.4 (4.4) and 5.2 (2.6) and mean APACHE II score was 31.1 (28.5) and 43.3 (27.5) on a visual analogue scale (VAS) of 0–100, and more than 80% and 90% of patients had some morning stiffness in the dactylitis and enthesitis groups, respectively. At 12 months from baseline, there were significant improvements in both dactylitis and enthesitis scores in patients with PsA treated with aTNF (Table).

**Table:** Primary outcomes in PsA patients on aTNF at 12 months from baseline

**Conclusions:** In this clinical registry, aTNF therapy significantly improved both dactylitis and enthesitis at 12 months. Further evaluation of secondary outcomes and larger studies with comparator cohorts will further validate the effectiveness of aTNFs in improving the outcomes in PsA patients.

**AB0785**

**CONSISTENT SAFETY PROFILE WITH UP TO 4 YEARS OF APREMILAST TREATMENT: ANALYSIS OF DATA FROM 1493 PATIENTS WITH PSORIATIC ARTHRITIS IN 3 LARGE, PHASE III, LONG-TERM STUDIES**

**Background:** Apremilast (APR), an oral phosphodiesterase 4 inhibitor, regulates immune activity in psoriatic arthritis (PsA) patients. Safety data were pooled from the phase 3 PALACE 1, 2, and 3 studies.

**Objectives:** Evaluate the long-term safety of APR treatment for up to 4 years in patients with active PsA despite prior conventional DMARDs and/or biologics.

**Methods:** Patients were randomized at baseline (1:1:1 to placebo, APR) to 30 mg bid (APR30), or 40 mg bid (APR40). PBO patients were re-randomized to take into account when evaluating PsA patients.

**Conclusions:** aTNF therapy significantly improved both dactylitis and enthesitis at 12 months. Further evaluation of secondary outcomes and larger studies with comparator cohorts will further validate the effectiveness of aTNFs in improving the outcomes in PsA patients.
to APR30 or APR20 at Week 16 (early escape) or Week 24. Double-blind APR treatment continued to Week 52; patients could continue APR during an open-label, long-term treatment phase for up to 5 years. Visits in years 2, 3, and 4 were scheduled at 13-week intervals. Safety was assessed at each visit throughout the study, and results are summarized here by exposure.

At least one PROM of 1494 patients were randomly selected and reviewed: 1 dose of study medication (PBO: n=495; APR30: n=497; APR20: n=501). At the 4-year data cut, the numbers of patients receiving APR30 and APR20 in each exposure period were 1441 in Weeks 0 to ≤52, 1028 in Weeks >52 to ≤104, 865 in Weeks >104 to ≤156, and 767 in Weeks >156 to ≤208. During the 0- to ≤52-week APR-exposure period, adverse events (AEs) occurring in >5% of APR30-exposed patients were diarrhea, nausea, headache, upper respiratory tract infection, and nasopharyngitis (Table). Most diarrhea and nausea AEs were reported within the first 2 weeks of treatment and usually resolved within 4 weeks; the frequency of gastroenterological AEs was higher with longer APR30 exposure. The frequency of other common AEs either decreased or remained stable with prolonged exposure (Table). Most AEs were mild/moderate in severity. During Weeks >156 to ≤208 of APR exposure, the discontinuation rate due to AEs was 1.7% with APR30, and the rate of serious AEs (SAEs) was 7.0%, consistent with earlier periods; most SAEs occurred in 1 patient each case. Rates were very low for major cardiac events, malignant neoplasms, and serious opportunistic infections, comparable to the first year of treatment. Rates of depression remained very low in Weeks >156 to ≤208. Marked laboratory abnormalities were infrequent, and most returned to baseline with continued treatment.

Conclusions: APR30 demonstrated a favorable safety profile and was well tolerated for up to 208 weeks, marked by the lack of accumulation of immunosuppression or need for specific laboratory monitoring. The incidence of AEs remained stable or decreased with long-term exposure to APR30.

AB0786 SYSTEMATIC REVIEW OF MEASUREMENT PROPERTIES OF PATIENT REPORTED OUTCOME MEASURES IN PSORIATIC ARTHRITIS: A GRAPPA-OMERACT INITIATIVE

P. Heijgaard 1,2, L. Klokker 1, A.-M. Orba 1, K. Holmsted 1, E.M. Bartels 1, Y.Y. Leung 3, N. Goel 2, M. de Wit 2, D. Gladman 2, P. Mease 2, L. Dreyer 1, L.E. Kristensen 1, O. FitzGerald 2, W. Tillett 2, L. Gossese 2, P. Hellwell 2, V. Strand 2, A. Ogde 2, C. Terwee 2, R. Christensen 2 on behalf of the GRAPPA-OMERACT PsA Core Set Working Group. The Parkiner Institute, Frederiksenborg and Bisbjerg Hospital, Copenhagen, Denmark, Frederiksberg, Denmark; 2GRAPPA-OMERACT PsA Core Set Working Group, International organisation.

Background: An updated psoriatic arthritis (PsA) core domain set (COS) for randomized controlled trials (RCTs) was endorsed at the Outcome Measures in Rheumatology (OMERACT) meeting in 2016 and reflects the patient and physician perspectives [1].

Objectives: To synthesise the evidence on measurement properties of Patient Reported Outcome Measures (PROMs) in PsA in order to contribute to the development of a PsA core outcome measurement set (COMS) for RCTs according to the OMERACT Filter 2.0 Framework.

Methods: A systematic literature search was performed in EMBASE, MEDLINE and PsycINFO to identify studies published in English on PROM measurement properties in PsA. Two independent reviewers rated the quality of studies according to CONSORT-based Standards for the selection of health Measurement Instruments. [3] Extracted data on measurement properties and performed a qualitative evidence synthesis.

Results: Of 4703 identified references, 162 were read in full-text and 44 included in the systematic review (SR). Thirty-nine instruments, consisting of one or more scales, were analysed. PROMs measuring core set domains with at least fair quality evidence for good validity and reliability (and without evidence for inadequate measurement properties) were: Stockerau Activity Score for PsA (German) for the Musculoskeletal Disease Activity domain; the Psoriatic Symptom Inventory for Skin Disease Activity; the 36-Item Short Form Health Survey Physical Function scale and to a lesser extent the Health Assessment Questionnaire Disability Index and Bath Ankylosing Spondylitis Functional Index for Physical Function; the Psoriatic Arthritis Quality of Life Questionnaire, the Psoriatic Arthritis Impact of Disease questionnaire and VITACORA-19 (Spanish) for Health related Quality of Life/Life Impact; the Functional Assessment of Chronic Illness Therapy-Fatigue Scale for Fatigue, and the Social Role Participation Questionnaire for Participation. Evidence for content validity was lacking for most of these PROMs.

Conclusions: At least one PROM with some evidence for good validity and reliability was available for five out of eight inner circle domains of the PsA COS. Lack of content validity evidence constitutes a critical barrier for application to the PsA COS per the OMERACT Filter 2.0 Instrument Selection Algorithm [2]. This SR serves as a guide for additional research to increase knowledge of PROM measurement properties in PsA followed by stakeholder consensus for developing a PsA COMS.

AB0787 STUDY OF SERUM SCLEROSTIN LEVELS IN ASSOCIATION WITH ENTHESIAL ULTRASONOGRAPHY IN EGYPTIAN PSORIATIC ARTHRITIS PATIENTS

R. Elmallah 1, E. El Attar 1, D. Farrag 1, D. Samaha 2 on behalf of responsibility for part of clinical measuring of sclerostin level. 1 Rheumatology & Rehabilitation; 2Clinical & Chemical Pathology, Faculty of Medicine Ain Shams University, Cairo, Egypt

Background: Psoriatic arthritis (PsA) is characterized by focal bone erosions and new bone formation, suggesting an uncoupling of osteoblast–osteoclast homeostasis [1]. Serum sclerostin is a protein inhibitor of wnt signalling pathway of bone formation implicated in the suppression of bone repair in inflammatory arthritis. The role of sclerostin in osteoimmunology and inflammatory arthritis is still controversial [2].

Objectives: This study aimed at measuring serum sclerostin in psoriatic arthritis men and to correlate its levels with disease activity scores, ultrasonographic findings and bone mineral density in those patients.

Methods: This study included 30 male patients diagnosed with Psoriatic arthritis (PsA), 15 healthy age and sex matched volunteers as control group. Patients disease activity index measured. Clinical assessment by Leed’s enthesis Index (LEI) [3], Spinal manifestations scored according to Bath Ankylosing Spondylitis Activity Index [4]. Serum sclerostin measured using enzyme linked immunosorbent assay. Ultrasonography of enthesis at Leeds enthesis sites [5] and dual energy x-ray absorbiometry (DEXA) at the lumbar spine.

Results: The study included 30 PsA male patients with a mean age of 43.3±8.33 mean, body mass index (BMI) of 26.87±2.63 and 15 healthy age and sex matched

Figure 1. Ultrasonograpic longitudinal scan of the tendoachilles showing hypoechogenic area of edema & power Doppler signal at insertion.
controls with a mean age of 42.12±7.22 mean BMI of 25.87±3.51 with an
unsignificant difference between the two groups.
Serum sclerostin level significantly higher in PsA patients compared to controls
with a mean of (0.64 and 0.37ng/ml) respectively, positive significant correlation
with patients’ age, disease activity scores, ultrasonographic findings of inflam-
mation and damage at the enthesis as well as negative correlation with
activity of adjacent bone. Thus, a positive though non-significant correlation detected between
serum sclerostin and Leoids clinical enthesis index (LEI) and CRP.

Conclusions: sclerostin plays important role in pathogenesis of psoriatic arthritis and
associated with bone damage either systemic or localized. Further studies for the effect of treatment on serum sclerostin, ultrasonographic and bone mineral
density findings is recommended

AB0789 THE PSORIATIC ARTHRITIS PATIENT’S JOURNEY: SPECIAL EMPHASIS ON DIAGNOSIS AND TREATMENT DELAYS

Background: A delay in diagnosis and treatment of Psoriatic Arthritis (PsA) is associated with increased disability and damage in the long term. There is currently scarce data available about diagnosis delay, referrals delays, and time to first treatment in patients with PsA in developing countries.

Objectives: To describe the journey of patients with psoriatic arthritis, with special emphasis on diagnosis and treatment delays.

Methods: All patients with PsA registered in the Rheumatology Unit data base (between 2000–2016), with complete data, were included. Electronic medical records were manually revised, and the following data were obtained: date of first visit to a Dermatologist due to Psoriasis (PsO) symptoms, date of PsO diagnosis, date and type of first musculoskeletal symptom, specialty of physician seen at first visit for musculoskeletal symptoms, date of PsA diagnosis, date and reason for prescription of first Disease Modifying anti-Rheumatic Drug (DMARD). Predictive outcome variable was mean lag time between first musculoskeletal symptom and diagnosis of PsA. Other variables calculated were: mean lag time between first musculoskeletal symptom and first physician encounter because of those symptoms, mean lag time to first DMARD and mean lag time between PsO diagnosis and PsA diagnosis. Variables associated with a delay in PsA diagnosis (more than one year delay) were analyzed in multivariable analysis (logistic regression).

Results: 93 patients were included, mean age 60.8 years (SD: 15.3), 61% males. Mean age at time of PsA diagnosis was 52 years (SD: 14.8). The most common musculoskeletal symptom was arthralgia (46%), followed by arthritis (37%), enthesitis (6%), low back pain (6%), and dactylitis (4%). Mean lag time between first musculoskeletal symptoms and visit to a physician because of those symptoms was 16.8 months (SD: 44.4) (median: 1.92 (IQR: 0.35–11.6). In Only 33% of the cases the first specialist seen was a Rheumatologist. Mean lag time between first musculoskeletal symptom and diagnosis of PsA was 19.2 (SD: 28.8) months (Median: 7.2 (IQR: 2.4–21.6 months). In 90 patients (97%), the diagnosis of PsO preceded the diagnosis of PsA, a mean time of 15.1 years (SD: 14.4). 83 patients (89%) received traditional DMARDS, 82% because of diagnosis, more symptoms, with a mean lag time between PsA diagnosis and initiation of DMARDS of 11.4 months (SD: 31.2) (Median: 0.48 (IQR: 0–4.3) months). Forty-three patients (46.2%) had a delay on PsA diagnosis equal or greater than 1 year.

Conclusions: Mean time between symptoms’ onset and PsA diagnosis was relatively short. However, a delay greater that one year was observed in almost half of patients. As none of the variables studied was associated with a delay equal or greater than 1 year in PsA diagnosis.

AB0790 HYPERURICEMIA IN PSORIATIC ARTHRITIS: PREVALENCE AND ASSOCIATED FACTORS
T. Gudu, A. Peltea, A. Balanescu, V. Bojincu, D. Opris, D. Predeteaun, R. Ionescu. Rheumatology, St Maria Hospital, UMF Carol Davila, Bucharest, Bucharest, Romania

Background: Hyperuricemia is frequent in psoriatic arthritis (PsA) and it seems to be related to metabolic syndrome rather than to extensive psoriatic skin disease [1].
**AB0791 HIGH PREVALENCE OF METABOLIC DISORDERS AND OBESITY IN PSORIATIC ARTHRITIS COMPARED TO PSORIASIS ALLONE: A RETROSPECTIVE DERMATOLOGICAL CLINIC-BASED STUDY**

N. Batkaeva, T. Kortosova, E. Batkaev. Department of dermatology, RUODN University, Y.A. Nasonov research Institute of Rheumatology, Moscow, Russian Federation.

**Background:** An association between increased adiposity, obesity (ObS), and psoriasis has emerged. In addition to obesity, patients with psoriasis are more likely to have metabolic syndrome.

**Objectives:** To evaluate the prevalence of endocrine diseases, nutritional and metabolic disorder (ENMD) comorbidity in patients (pts) with PsA and Psoriasis (PsO) patients without arthritis in the dermatological hospital cohort.

**Methods:** 889 pts (Male-516/Female-329) with moderate-to-severe plaque PsO, mean age 50.4±17.6 years, mean PsO duration 21.5±14.7 were included. PsO pts with Endocrine, nutritional and metabolic diseases (E00-E90) (ENMD), including Disorders of thyroid gland (E00-E07), Obesity and other hyperalimentation (E65-E68), Diabetes mellitus (E10-E14) (DM) were identified in the hospital Database reporting and coding by International Statistical Classification of Disease and Related Health Problems (ICD-10) between 2010 - 2015 years. Mzm, t-test, χ² (%), were calculated. All p<0.05 were considered to indicate statistical significance.

**Results:** 302 out of 889 pts (33.9%) had PsA and 587 out of 889 pts (66.1%) had PsO alone. PsA pts were older than PsO pts – 55.3±15.7 and 50.4±17.6 (p<0.001). 155 out of 889 pts (17.4%) had ENMD. In PsA pts ENMD were found in significantly more cases than in PsO pts – in 76 out of 302 pts (25.2%) and in 79 out of 587 pts (13.5%) accordingly (χ²=18.986, df=2, p<0.0001). In PsA pts ENMD coding as E00-E07 were found in significantly more cases than in PsO pts – in 25 out of 302 pts (8.3%) and in 23 out of 587 pts (3.9%) accordingly (χ²=7.421, df=2, p=0.00645). Obs coding as E65-E88 were found in significantly more cases in PsA pts compared to PsO pts - in 54 out of 302 pts (17.9%) and in 64 out of 587 pts (10.9%) accordingly (χ²=8.4354, df=2, p=0.00368).

**Conclusions:** ENMD comorbidities are common for PsA and PsO without arthritis pts. Obs and disorders of thyroid gland were found in significantly more cases in PsA pts compared to PsO pts. Obesity and PsA are an unhealthy combination. Obesity may represent an additive cardio-metabolic risk factor in PsA subjects. High frequency of ENMD in PsA than PsO could be due to share inflammation pathways with insulin resistance and age. Patients with more severe psoriasis are at higher odds of endocrine, nutritional and metabolic diseases compared with those with mild psoriasis.

**AB0792 CURRENT STATUS AND UNMET NEEDS IN THE MANAGEMENT OF PSORIATIC ARTHRITIS WITH CONVENTIONAL SYNTHETIC AND BIOLOGICAL DISEASE MODIFYING ANTI-RHEUMATIC DRUGS: TAIWANESE NATIONWIDE PHYSICIANS’ PERSPECTIVES**

T.-H. Li1, C.-C. Lai2, C.-Y.Tsai2. Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Chiayi Branch, Taichung Veteran General Hospital, Chiayi City; Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei Veteran General Hospital, Taipei City, Taiwan.

**Background:** Psoriatic arthritis (PsA) contributes to enormous burden of disease and thus early correct diagnosis and adequate therapeutic management are essential for physicians in practice; however, there have been several studies highlighting the inadequate diagnosis and suboptimal therapies for PsA worldwide and physicians generally report difficulties in managing psoriasis.

**Objectives:** To analyze the real-world clinical practice of PsA in Taiwan, and assess physicians’ adopted methods and difficulties of diagnosis, therapeutic consideration and strategy, in addition to rationales for biologic agents and unmet needs.

**Methods:** A nationwide cross-sectional observational study in Taiwan was conducted by means of the face-to-face in depth interviews with the 80 physicians, composed of 50 rheumatologists and 30 dermatologists, from November 2014 to January 2015.

**Results:** The major adopted diagnostic examinations for PsA are arthritis performance, psoriasis and nail dystrophy, roentgenological studies, personal and family history; however, more dermatologists rely on RF for initial diagnosis (p<0.05). The difficulties for diagnosis, considerations on therapeutic management and current prescription were reported and displayed some interdisciplinary difference. Rationales for biological agent selection were investigated and physicians generally favored etanercept in terms of milder symptoms or more conservative treatment. The main unmet needs for current biologic therapies for PsA included the aspects of better efficacy, safety, sustainability and oral administration.

**Conclusions:** The nationwide study is the first survey for real-world clinical practice of PsA in Asia and provides detailed messages about the diagnostic difficulties and therapeutic consideration, especially rationally and unmet needs on current biologic therapies, which may offer possible directions for new drug development. We also made interdisciplinary comparison, hence in order to improve comprehensive care.

**AB0793 EFFICACY OF IVEKIZUMAB IMPROVING SF-36 SCORES IN BIOLOGICAL DAMAR-NAIVE PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM A PHASE 3 STUDY (SPIRIT-P1)**

V. Strand1, A.B. Gottlieb2, T.K. Kvien3, A. Naegel4, C.-Y Lin4, Q. Benichou4, J. Britt4, Stanford University School of Medicine, Palo Alto; 2 New York Medical College, Valhalla, United States; 3 Diakonhjemmet Hospital, Oslo, Norway; 4 Eli Lilly and Company, Indianapolis, United States.

**Background:** In a phase 3 randomized controlled trial (RCT), ixekizumab (IXE), a high affinity mAb that selectively targets interleukin-17A, significantly improved signs and symptoms of psoriatic arthritis (PsA) and health status vs placebo (PBO)1.

**Objectives:** To evaluate the efficacy of IXE improving patient (pt)-reported health status, assessed by Short Form Survey (SF-36) physical and mental component summary (PCS and MCS) and domain scores.

**Methods:** In phase 3 RCT (SPIRIT-P1; NCT01695239), DMBARD-naive pts with active PsA (N=417) randomly received IXE 80 mg either once every 4 weeks (Q4W) or 2 Wks (Q2W) after a 160 mg starting dose, or 40 mg adalimumab (ADA) Q2W, or PBO. Health status was assessed by SF-36 at baseline, Wk 12, and Wk 24. Treatment comparisons were by mixed model for repeated measures for continuous data and logistic regression for categorical data. Missing values were imputed by nonresponder imputation.

**Results:** Baseline SF-36 scores were similar across treatment groups. At Wk 24, significant improvements were observed with ADA and IXEQ2W for PCS, and 5/8 domains (PF, RP, BP, GH, and RE), and with IXEQ4W for PCS and 6/8 domains (except VT and MH) (Figure) (post hoc for individual domains). In pts with baseline scores < A/G norms, significant improvements vs PBO were observed with ADA and IXEQ4W for PCS, MCS, and 5/8 domain scores (PF, RP, pf=0.001).

EFFECT OF TOFACITINIB ON PATIENT-REPORTED OUTCOMES IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM TWO PHASE 3 STUDIES

1Division of Immunology/Rheumatology, Stanford University, Palo Alto, CA, United States; 2UZ Leuven, Leuven, Belgium; 3Unidad Reumatológica Las Americas S.C.P., Mérida, Venezuela; 4Swedish Medical Center and University of Washington, Seattle, WA, United States; 5Department of Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada; 6Pfizer Inc, Collegeville, PA; 7Pfizer Inc, Groton, CT; 8Pfizer Inc, New York, NY, United States.

Background: Tofacitinib is an oral Janus kinase inhibitor under investigation for active psoriatic arthritis (PsA). The safety and efficacy of tofacitinib (5 mg twice daily), administered orally in addition to conventional synthetic disease-modifying antirheumatic drug and/or phototherapy, in patients with active PsA has been investigated in two Phase 3 randomised controlled trials (RCTs: OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]).

Objectives: To evaluate patient-reported outcomes (PROs) in patients (pts) with active PsA enrolled in OPAL Broaden (N=392) and OPAL Beyond (N=384). OPAL Beyond pts had an inadequate response (IR) to one previous synthetic disease-modifying antirheumatic drug and were naïve to tumour necrosis factor inhibitors (TNF) whilst OPAL Beyond pts had an IR to one TNF.

Methods: Pts were randomised to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, placebo (PBO)→ tofacitinib 5 mg BID, PBO→ tofacitinib 10 mg BID and, in OPAL Broaden, also to adalimumab 40 mg subcutaneously every 2 weeks (active comparator). Pts receiving PBO advanced to either tofacitinib 5 mg BID or 10 mg BID at month 3 (M3) in both RCTs. Least squares mean changes from baseline in PtGA and Arthritis Pain (VAS) were compared to PBO at M3 (p<0.05). SF-36 normative values were similar between tofacitinib and adalimumab.

Results: Pts with active PsA in OPAL Broaden and OPAL Beyond RCTs receiving tofacitinib 5 mg and 10 mg BID reported improved PROs compared with PBO (Table 1). Greater improvements in PtGA and Arthritis Pain were observed earlier as Week 2 through M3 with both tofacitinib doses compared with PBO in both studies (p<0.05). Greater improvements were also reported in SF-36 Physical Component Summary, Dermatology Life Quality Index (DLQI) and Ankylosing Spondylitis Quality of Life (ASQOL) questionnaires. Nominal p values are reported without adjustment for multiple comparisons.

Conclusions: Pts with active PsA enrolled in OPAL Broaden (N=392) and OPAL Beyond (N=384) had greater improvements in PROs with tofacitinib compared with PBO.

Table 1. Percentage of patients with SF-36 scores ≥ normative values at week 24 (n) among the patients reporting SF-36 scores > normative values at baseline (N) (nonresponder imputation)

Osteoarthritis and comorbidity: association between mental features and cytokine levels

E. Trifonova, O. Sazonova, E. Zonova. Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: Studies of mental health in patients with osteoarthritis (OA) are topical at the present time. This applies especially to OA patients with such comorbidity as obesity, metabolic syndrome (MS) and type 2 diabetes mellitus (T2DM). Psychological features, quality of life (QoL) and depression degree also can be linked with immunopathogenesis of OA with obesity, MS, T2DM.

Objectives: To explore the mental health in knee OA patients with obesity, MS and T2DM and to estimate association between psychological and immunological features.

Methods: Patients (n=128) with bilateral knee OA according to ACR criteria were divided into four groups. Group 1 (n=17) had obesity, group 2 (n=17) had MS, group 3 (n=56) had T2DM and group 4 (n=38) had only knee OA without concomitant diseases. Patients with OA and obesity were characterized by low values of mental health (SF-MH) (median (Me) 52; interquartile range (IQR) 25–52.3; p=0.02). Serum cytokines levels were not different by groups knee OA patients with comorbidity and group knee OA patients without comorbidities. During comparative analysis, we found many statistically significant differences in PROs compared with PBO at M3 that were maintained throughout both RCTs.

The predictive role of interleukine 6 and 10 in impairment of mental health in patients with knee osteoarthritis and uncontrolled type 2 diabetes mellitus

E. Trifonova, O. Sazonova, E. Zonova. Novosibirsk State Medical University, Novosibirsk, Russian Federation

Background: The influence of different interleukins on development and progression of osteoarthritis (OA) has been proved. However, there is lack of data on relationship between mental health and immunological features in OA patient with type 2 diabetes mellitus (T2DM).

Objectives: To estimate the relationship between mental health and the proinflammatory serum cytokine levels in patients with knee OA and T2DM depending on glycemic control.

Methods: A study was performed on 45 persons who had bilateral knee OA according to the ACR criteria and T2DM. Then patients were divided into two groups according to the compensation degree T2DM taking into account glycemic control. Group 1 (n=26) and Group 2 (n=19) had controlled T2DM. Group 2 (n=19) had uncontrolled T2DM. All patients were comparable by age, sex and duration of OA. Serum cytokine levels (IL-1β, IL-6, IL-10, IL-18, NO, and adipokines (adiponectin, leptin) using ELISA were measured. Blood glucose level was also estimated. The parameters of QoL, mental health, depression degree and coping strategies to overcome pain were measured by short form 36 (SF-36); Knee injury and Osteoarthritis Outcome Score –(KOOS) and with patient health questionnaire-9 (PHQ-9), Coping Strategy Questionnaire (CSQ). We used U-Mann-Whitney test to detect differences between selected groups. Correlation was assessed using Spearman correlation coefficient (rs).

Results: Patients with OA and uncontrolled T2DM had significant low values of role limitations due to emotional problems (SF-RE) (median (Me) 38; interquartile range (IQR) 25–52.5; p=0.02). Serum cytokines levels were not different between studied groups. Correlation analysis identified the relationships between parameters of mental health and serum cytokine levels in OA patients with uncontrolled T2DM. Certain data are presented (Table).

Conclusions: It follows from these results mental and immunological parameters of OA patients with uncontrolled T2DM can be linked. Such interleukins as IL-6 and IL-10 may play a role of potential biomarkers of mental impairment in this category of patients. This data should be verified by larger studies and may allow in future to develop programs of treatment and rehabilitation of OA patients with uncontrolled T2DM within personalized medicine.

LONG TERM PROSPECTIVE MULTICENTER RANDOMIZED PLACEBO-CONTROLLED STUDY OF HYALURONIC ACID IN SMALL JOINTS OSTEOARTHRITIS (SJOA)

E. Tsytsova, E. Nasonov, M. Kramarenko, A. Ivanyuk, A. Foteeva, O. Polikarpova

Objectives: To investigate the efficacy and tolerability of amtolmetin guacil (AMG; Niselat®, Dr. Reddy’s Laboratories Ltd, India) versus previous therapy with nonsteroidal anti-inflammatory drugs (NSAID) in patients with knee osteoarthritis (OA) in terms of pain and functional activity. Methods: The open-label observational study included 220 patients aged 30–65 years who suffered from knee OA and intense pain during NSAID intake and had symptoms of dyspepsia in the absence of contraindications to the use of AMG. Among the comorbidities that occurred in 68% of the patients, there was a preponderance of hypertension (42%), lower extremity varicose veins (6.4%), and diabetes mellitus (6%). Treatment efficacy was evaluated using three domains of the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) including pain, physical function, and patient’s global assessment.

Results: AMG had a marked analgesic effect confirmed by 40% or more pain reduction at 72.5% of the patients. The high analgesic effect of AMG was confirmed by a statistically significant (p<0.001) reduction in the WOMAC index (pain and stiffness) and by an increase in functional activity. There was a significant decrease in painless and painful signs of dyspepsia, as well as positive changes in the measures “overall assessment of dyspepsia severity” (p<0.001) and “satisfaction with treatment”. Overall assessment of AMG tolerability was only positive: excellent (33%), good (56%), and satisfactory (11%). There were no serious adverse events (AE). AE were graded as moderate and mild in 8 and 82% of cases, respectively. AE were recorded in 7.7% of the patients.

Conclusions: The findings suggest that AMG offers good prospects for knee OA treatment.

DECREASED RATIO OF TIMP1/MMP-9 IS ASSOCIATED WITH HIGHER PAIN SENSITIVITY IN A SUBSET OF OSTEOARTHRITIC PATIENTS WITH LOW MECHANISTIC TARGET OF RAPAMICIN GENE EXPRESSION IN THE PERIPHERAL BLOOD

E. V. Tchetina, G. Jones, F. Cicuttini et al.

Objectives: To confirm that a lower ratio of TIMP1/MMP-9 is associated with increased pain perception in osteoarthritis patients. Methods: A total of 855 patients suffering from knee osteoarthritis were evaluated and divided into two groups based on the ratio of TIMP1/MMP-9. Results: The patients with the lowest ratio of TIMP1/MMP-9 had a significantly higher pain perception during movements and a higher percentage of patients with high pain sensitivity (p<0.001).

Conclusions: The results suggest that a lower ratio of TIMP1/MMP-9 is associated with increased pain perception in knee osteoarthritis patients.

Disclosure of Interest: None declared

KNEE OSTEOARTHRITIS PATIENTS’ USE OF AND COMPLIANCE TO AN ORTHOTIC INTERVENTIONS

E. Mauricio, M. Sliepen, D. Rosenbaum, Universitätsklinikum Münster, Münster, Germany

Background: Knee osteoarthritis (KOA) is the most common form of arthritis with an estimated lifetime prevalence of 44.7% (1). The use of orthotic devices (knee braces, insoles, wedged shoes) is a generally accepted conservative therapy for KOA patients (2). However, it is suggested that their effectiveness is detrimentally affected by poor patient compliance due to discomfort while wearing these devices (3).

Objectives: The aim of this study is to objectively establish the compliance to an orthotic intervention using a thermal sensor (TS) and comparing it to patients’ self-reported wear time.

Methods: Ten medial KOA patients (mean±SD age 57.6±13.4 years, BMI 27.3±3.2 kg/m²), clinically diagnosed according to the ACR Guidelines, were recruited for this study. A small, light-weight TS with the size of an average lithium battery (0.5°C resolution) was placed in a newly developed ankle-foot-orthosis (AFO) that patients were asked to wear as often as possible during a period of six weeks. The TS measured the temperature every 5 minutes for 4 weeks. Patients rated the comfort of the orthosis during the first visit using a scale from 1 to 5 (1 being the most comfortable).

Results: The patients reported during these six weeks how many hours per day they had worn the orthosis and rated which amount of pain they felt each day (from 0=no pain to 10=most painful). To determine the patients’ compliance, the AFO wear time, derived from the TS, was compared to the wear time per day recorded in the patients’ diaries. The threshold to differentiate the wear
and non-wear times was set at 25°C. Timeframes during which the temperature rose above 25°C were classified as wear time. A Wilcoxon signed-rank test was performed between the different wear times and Spearman’s correlations between pain, comfort and wear time were determined.

**Results:** On average, patients wore the device for 143±80 h according to the form they filled out, whereas the TS measured only 83±36 h, leading to an overestimation of 72%. Patients reported an average pain level of 3±1.4 during the six weeks period and the AFO’s comfort was rated with 1.9±0.3. Statistical differences were found between the wear time reported by the patients and the wear time derived from the TS (p=0.005). Additionally, a significant correlation between the AFO comfort and the wear time derived from the TS was found (r = −0.81; p=0.001). No significant correlation was found between pain and wear time.

**Conclusions:** As can be expected, patients who found the AFO more comfortable were the ones who wore the orthosis for longer periods. The wear time recorded by the TS was significantly lower compared to the self-reports. This might be due to a social desire bias, overestimating the amount of hours of wearing the AFO as we asked the patients to wear it as often as possible. Secondly, patients might have trouble to accurately recall the amount of wear hours, thereby inducing an overestimation of wear time. As the reliability of self-reported measures seems to be questionable, such data should be interpreted with care.

**EFFECTS OF DIETARY MAGNESIUM SUPPLEMENTATION AND INTRA-ARTICULAR MgSO4 INJECTION ON EXPERIMENTAL OSTEOARTHRITIS AND POTENTIAL MOLECULAR MECHANISMS BY MRNA AND lncRNA EXPRESSION PROFILES SCREENING**

G. Lei1, C. Zeng1, H. Li1, J. Wei2, T. Yang1, B. Wise3, X. Ding1, Y. Zhang1, Y. Yang1, Z. Deng1, J. Li1, Y. Cui1. 1Department of Orthopaedics; 2Health Management Center, Xiangya Hospital of Central South University, Changsha, Hunan Province, China; 3Department of Internal Medicine and Department of Orthopaedics, University of California, Davis School of Medicine, Sacramento, CA, Division of Rheumatology, Department of Internal Medicine, Rush University Medical Center, Chicago, IL, United States; 4International Medical Center, Xiangya Hospital, Central South University, Changsha, Hunan Province, China

**Background:** Epidemiological studies of ours and other groups have reported an inverse association between dietary and serum Mg with knee radiographic osteoarthritis (OA) [1–4].

**Objectives:** To investigate the effects of dietary magnesium supplementation and intra-articular MgSO4 on the development of experimental rat osteoarthritis, and explore the underlying potential molecular mechanisms by mRNA and IncRNA expression profiles screening.

**Methods:** Rat osteoarthritis model was induced by surgery. Articular cartilage damage was evaluated by modified Mankin score system after intervention of dietary magnesium supplementation or intra-articular MgSO4 injection. Microarray was performed to reveal alteration of expression profiles of mRNA and IncRNA after intervention of MgSO4 on human osteoarthritis chondrocytes. Bioinformatics analyses including gene ontology analysis, pathway analysis, target gene predictions and network analysis were used.

**Results:** Comparing with normal diet, dietary Mg supplementation showed significantly ameliorated cartilage damage at the medial femoral condyle, lateral tibial plateau and medial tibial plateau (P<0.05), and approaching significance at the lateral femoral condyle (P=0.06). All four locations exhibited mitigated cartilage damage in the intra-articular MgSO4 group compared with intra-articular saline (P<0.05). 1767 IncRNAs and 2558 mRNAs were upregulated while 994 IncRNAs and 1512 mRNAs were downregulated in chondrocytes with intervention of 50mM MgSO4 compared with control group (fold change >2.0). The top 6 IncRNAs which showed the largest difference were ENST00000429530.1, ENST00000425914.2, ENST00000561231.1, ENST00000560962.1, ENST00000419881.1, ENST00000419881.2. Bioinformatics analyses indicated that the differentially expressed IncRNA target genes of chondrocyte after intervention of 50mM MgSO4 are enriched in negative regulation of phosphatidylinositol 3-kinase signaling.

**Conclusions:** Both dietary magnesium supplementation and intra-articular MgSO4 injection may exert cartilage protective effects by causing widespread changes in the profile of IncRNAs and mRNAs of chondrocytes.

**DOES INTRA-ARTICULAR INJECTION OF PLATELET-RICH PLASMA PROVIDE CLINICALLY PREFERABLE OUTCOMES IN THE KNEE OSTEOARTHRITIS? A DOUBLE-BLIND, RANDOMIZED CONTROLLED PILOT STUDY**

J. Moghimi1,2, R. Ghorbani1, H. Beiki1. 1Social Determinants of Health Research Center; 2Department of Internal Medicine, Semnan university of medical sciences, Semnan, Iran, Islamic Republic of

**Background:** Knee osteoarthritis (OA) symptoms Improvements with platelet-
Background: This double-blind randomized controlled trial, 34 patients with knee OA grade 2 or 3, from March 2013 to February 2016 were selected. Participants were randomly assigned one knee as the case and other knee was considered as control to receive three injections of either PRP or placebo. The administering doctor, and the patients were blinded to group allocation. Outcomes included safety and recruitment data, 100 mm the EuroQol-visual analogue scales (EQ-VAS), the international knee documentation committee (IKDC), the Western Ontario and McMaster Universities Arthritis Index (WOMAC) and the Tegner Activity Score (TAS) at six and three months.

Results: Twenty four (100%) participants met the inclusion criteria. No treatment-related major adverse events were reported. The PRP group demonstrated significant improvements at all follow up time points in the WOMAC (3 months: p=0.017; 6 months: p=0.029, ETA=0.601). For the PRP group, the 11.47 mm reduction in EQ-VAS at 6 months (p=0.040) and the 7.35 mm at 3 months (p=0.035) was statistically significant improvement from baseline. The PRP group also significantly improved IKDC (p=0.039, ETA =0.619) and TAS (p=0.028, ETA =0.641) at three months. The placebo group showed improvements on only the IKDC Function at 3 months (p=0.019, ETA =0.591). There were no significant between-group differences for any of the self-reported measures at either time-point.

Conclusions: The study provides proof-of-concept evidence about the safety and feasibility of intra-articular injections of PRP necessary to appraise a larger clinical trial knee OA. Our preliminary findings also suggest PRP improves self-reported symptom severity, sports activity, and function in daily living activities, however no between-group differences were found. PRP may provide an effective and safe novel treatment for knee OA.

AB0804 SINGLE-NUCLEOTIDE POLYMORPHISM (SNP) RS143383 GROWTH AND DIFFERENTIATION FACTOR 5 (GDF5) IN KNEE OSTEOARTHRITIS IN EGYPTIAN POPULATION

M. Hassani 1, N.A. Mohamed 2, S.A. Mahran 1, 1 Rheumatology Department; 2Medical Biochemistry, Assuit University, assuit, Egypt

Background: Osteoarthritis (OA), is an age-related common polygenic disease characterized by the thinning and loss of the articular cartilage in synovial joints such as knees. The etiology and pathogenesis of OA is largely unknown, the single-nucleotide polymorphism (SNP) rs143383 (C/T) influencing OA susceptibility across a range of ethnic groups.

Objectives: The present study investigated to identify the association of polymorphism in GDF5 gene with osteoarthritis in Egyptian population.

Methods: This Cross sectional study of 100 male ≥40 years that fulfilled American College of Rheumatology (ACR) for Knee OA and 100 controls recruited from the outpatient clinic of Department of Rheumatology, Assuit university, Egypt. Clinical symptoms were assessed with WOMAC index and VAS for knee pain. The severity of disease was determined by radiological grades (Kellgren Lawren). Body Mass Index (BMI) was recorded. DNA isolation and genotype analysis the method of (Southam et al, 2007) was followed for determining the GDF5 gene (T/c; rs143383) polymorphism. Amplification was performed.

Results: There were weak but significant associations present between the GDF5 polymorphism and knee OA at the allele level (C vs. T: 0.85, 95% CI =0.79–0.93) and genotype level (CC vs. CT: 0.72; CT vs. TT: 0.81; CC/CT vs. TT: 0.83; CC vs. CT/TT: 0.78) in the overall population. A stronger significant association was observed for CC vs. CT/TT (p=0.03, P<0.001) in comparison with other models.

In males we identified a second polymorphism, located in the 3’-UTR of GDF5, that influenced allelic expression of the gene independent of rs143383.

Conclusions: GDF5 is an OA susceptibility gene with association between the GDF5 polymorphism and clinical symptoms of knee OA in Egyptian population.

Tornú, Buenos Aires, Argentina; 12 Facultad de Medicina, Universidad Francisco Marroquin; 13Facultad de Medicina, Universidad Francisco Marroquin, Ciudad de Guatemala, Guatemala, 14Centro Clínico la Isabela, Carabobo, Venezuela, Bolivarian Republic Of; 15 Universidad Peruana de Ciencias Aplicadas; 16 Universidad Nacional Mayor de San Marcos, Peru, Peru; 17 Universidad Estadual de Campinas, Brasil, Brazil; 18 Institute of Urology, Valencia; 19 Complejo Hospitalario Universitario ‘Ruiz y Paz’, Ciudad Bolivar; 20 Unidad de Investigaciones Reumatológicas. Clínica Félix Boada, Caracas, Venezuela, Bolivarian Republic Of; 21 Division of Rheumatology, The Warren Alpert School of Medicine, Providence, United States; 22 Universidad de la Sabana, Barranquilla, Colombia; 23 Hospital Pirovano, Buenos Aires, Argentina

Background: This consensus derives from a previous study of Demographic and Clinical Characteristics by the PANLAR OA study group, reporting significant results in terms of handling these patients and in which it were evident the need of reaching an agreement in the management of hand, hip and knee OA in Latin America (2).

Objectives: The aim is to update the recommendations for the treatment of knee, hip and knee OA by agreeing on key propositions relating to the management of hand, hip and knee OA, identifying and critically appraising research evidence for the effectiveness of the treatments and by generating recommendations based on the available evidence and expert opinion.

Methods: Recommendations were developed by a group of 40 specialists made up of rheumatologists and members of other medical disciplines. A systematic review of articles, meta-analyses and guidelines for the management of hand, hip and knee OA published from 2008 and January 2014 was done. The level of evidence and strength of recommendation were classified according to the Jadad scale (3). The level of agreement was established through a Delphi technique.

Results: Both ‘strong’ and ‘conditional’ recommendations are given for management of hand, hip and knee OA and non-pharmacological, pharmacological and surgical modalities of treatment are presented according to the different levels of agreement.

Conclusions: These recommendations are based on the consensus of clinical experts from a wide range of disciplines considering the available evidence, while balancing the benefits and risks of non-pharmacological, pharmacological and surgical treatment modalities. It is hoped that these recommendations will be utilized by healthcare providers involved in the management of patients with hand, hip and knee OA.

AB0806 THE EFFECT OF REPETITIVE ACTIVE RANGE OF MOTION VERSUS CONTINUOUS PASSIVE MOTION ON EARLY FUNCTIONAL OUTCOMES AFTER PRIMARY TOTAL KNEE REPLACEMENT

M. Erduran 1, M. Eymir 2, B. Unver 2, 1Faculty of Medicine Surgery Medicine Department of Orthopaedics and Traumatology, Dokuz Eylül University, İzmir, Turkey; 2School of Physical Therapy and Rehabilitation, Dokuz Eylül University, İzmir, Turkey, İzmir, Turkey

Background: Continuous passive motion (CPM) is a common procedure in total knee replacement (TKR), but its effectiveness is controversial at early stage after TKR. Some studies have claimed that CPM promoting rapid postoperative recovery and the range of motion (ROM), However, some studies have demonstrated that CPM have any benefit on ROM, length stay of hospital and postoperative recovery (1, 2). Some studies have demonstrated that CPM improves the range of motion (ROM), however there is not any study that compared the effect of repetitive active range of motion (AROM) vs. CPM on early functional outcomes after TKR.

Objectives: The aim of this study was to compare the effect of AROM vs. CPM on early functional outcomes after TKR.

Methods: The study group consisted of 71 patients, who underwent primary TKR because of arthrosis were consecutively allocated to a AROM group (n=40, with
Validity of the Quadriceps Angle Measurement in Patients with Varus Knee Osteoarthritis: Compare the Goniometric and Photogrammetry Method to Radiography Method

M. Erduran 1, M. Eymir 2, B. Üner 3, N. Demirkiran 1. 1Faculty of Medicine Surgery Medicine Department of Orthopaedics and Traumatology, Dokuz Eylul University, Izmir, Turkey; 2School of Physical Therapy and Rehabilitation, Dokuz Eylul University, Izmir, Turkey; 3Department of Orthopaedics and Traumatology, Dokuz Eylül University, Izmir, Turkey, Izmir, Turkey

Background: Various measurement methods have been defined to assess the alignment of the lower extremities. The Q-angle measurement is reported to be associated with knee injury and patellofemoral dysfunction. The Q-angle has been assessed using radiographic scans, goniometry and photogrammetry methods in supine and standing positions. The radiography method is accepted to be the most accurate and valid measurement technique in measurement the Q-angle. But as a result of being expensive and time-consuming, this invasive method is not mostly preferred in research and clinics. The goniometric measurement of the Q-angle is practical because it is simple, requires inexpensive equipment (only a goniometer), and can be applied in a short time. Photogrammetry measurement technique is also an advantageous method for reducing measurement errors caused by goniometers and reduction of investigator errors.

Objectives: The aim of the present study, was to compare the clinical assessment of the Q-angle (goniometric and photogrammetric measurement methods) to a radiological assessment using radiograph (criterion validity) in patients with varus knee osteoarthritis.

Methods: The study group consisted of 15 (median age 68.6±11.9 years) patients with unilateral and bilateral varus knee osteoarthritis. Q-angle measurements were assessed on both lower extremities with three different goniometric methods (goniometric measurement method in standing position with quadriceps muscle relaxed; goniometric measurement method in supine position with quadriceps muscle relaxed; and contracted) using a 360° universal goniometer. After the goniometric measurements, photographs were taken with quadriceps muscle relaxed in standing position. For radiographic assessment, we used patients’ lower extremity scanograms, which had been determined to obtain the Q-angle (radiographic assessment). The goniometric and photogrammetry measurements were statistically analyzed using paired t-test.

Results: There was a good correlation between the radiographic assessment and photogrammetric measurement (r=0.623, p<0.001). Also a good correlation was observed between radiographic assessment and goniometric measurement (in standing position with quadriceps muscle relaxed; in supine position with quadriceps muscle relaxed and contracted) (r=0.676, p=0.001, r=0.616, p=0.0005; r=0.676, p<0.001, respectively).

Conclusions: According to our result, the photogrammetric measurement and the goniometric measurement appear to be valid alternatives to the radiographic measurement for determining the Q-angle. These alternative measures might be used by clinicians and researchers to measure the Q-angle of patients with varus knee osteoarthrosis in orthopaedic clinics.

Comparing the Effects of Physical Therapy and Non-steroidal Anti-inflammatory Treatment on Sleep Quality, Quality of Life and Clinical Status in Knee Osteoarthritis

M. Sezgin 1, E. Eşildal 1, H. Ankaralı 2, G. Sahin 1. 1Department of Physical Medicine and Rehabilitation, Mersin University Medical Faculty; 2Department of Biostatistics and Medical Informatics, Duzce University Medical Faculty, Duzce, Turkey

Objectives: We aimed to compare the effectiveness of physical therapy (PT) and non-steroidal anti-inflammatory drug (NSAID) therapy on sleep quality, quality of life and clinical status in patients with knee osteoarthritis (OA).

Methods: Demographic characteristics of the participants were recorded. MOS sleep scale, Nottingham Health Profile (NHP) and Western Ontario & McMaster Universities Osteoarthritis Index (WOMAC) were used to evaluate sleep quality, quality of life and clinical status of patients before and after the treatment. All patients were divided into two groups as PT (57 patients) and NSAID (43 groups). The patients in the drug group were administered oral ketoprofen (50 mg/daily), and the patients in the PT group were administered five times a week, total 15 seances hot-pack, ultrasound and transcutaneous electrical nerve stimulation therapy.

Results: Demographic characteristics, MOS sleep scale and NHP were similar at baseline in both groups (p>0.05). WOAMC pain, stiffness, and physical function scores before treatment were significantly poorer in the PT group than the NSAID group (p<0.05). There were statistically significant improvements on the MOS sleep scale (except snoring subscore, p=0.05, table 1), NHP (except social isolation, p=0.209) and WOMAC pain, stiffness, physical function and total scores of both groups after treatments (p<0.05). Improvement was also similar when both groups were compared after the treatment (p>0.05). After the two treatment, significantly side effect was not observed.

Conclusions: PT and NSAID therapy has good effectiveness on sleep quality, quality of life and clinical status in knee OA.

Fall Risk and Related Factors in Knee Osteoarthrosis

M. Aikan Melikoglu 1, A. Kal 1. 1Rheumatology; 2Physical Medicine and Rehabilitation, Atatürk University Faculty of Medicine, Erzurum, Turkey

Background: Balance, as a complex task, may be affected in knee osteoarthrosis (KO) and this may cause fall instability and fall risk.

Objectives: The aim of this study was to determine the fall risk in patients with KOA with an objective computerized technique and to evaluate the potential risk factors for falls in these patients.

Methods: Patients with KOA and controls were included in this cross-sectional study. Gender, age, and body mass index (BMI) were recorded. Pain was evaluated with a visual analog scale (VAS). The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) was used to assess the patients and the Falls Efficacy Scale International (FES-I) was used for the evaluation of fall efficacy. Knee radiographs were recorded with the Kellgren–Lawrence grading scale. Fall risk analysis was performed by using the Tetrax Interactive Balance System, which is a computerized posturography device.

Results: One hundred patients with KOA and 30 controls were included. The age, gender, and BMI scores were similar between the groups. FES-I scores were significantly higher than in the controls (p<0.000). Using a computerized system, significantly higher fall risk results (p<0.000) and significantly low, moderate, and high fall risk distribution were recorded in the cases than in the controls (p<0.000). Fall risk was significantly related to age, pain, and the WOMAC scores of the patients.
Conclusions: Using an objective computerized technique, our study demonstrated a higher fall risk in patients with KIA than in healthy individuals. This higher risk was shown even in the early radiographic phases of the disease related to age, pain, and dysfunction. An understanding of factors on postural control seems to be critical in successful fall prevention in these patients.

AB0810 CORRELATION BETWEEN KNEE EXTENSOR MUSCLE STRENGTH AND GAIT ENDURANCE AFTER TOTAL KNEE ARTHROPLASTY

M.J. Suh, B.R. Kim. Jeju National University Hospital, Jeju, Korea, Republic Of

Objectives: This study was undertaken to identify the relationship of objective physical performance and gait endurance after 1 month after total knee arthroplasty.

Methods: One-hundred ninety-five patients (32 males and 163 females; average age 72.6±6.1 years) who underwent a primary total knee arthroplasty (TKA). Patients completed 6-minute walk test (6MWT) to assess gait endurance. Additional physical performance test including timed up and go (TUG) test, timed Stair Climbing Test (SCT), instrumental gait analysis for spatio-temporal parameters, and isometric knee flexor and extensor strength of the surgical and nonsurgical knees 1 month after TKA were measured. To evaluate self-reported physical function, self-reported disease-specific physical performance measured by using the Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) and self-reported quality of life measured by using EuroQOL five dimensions (EQ-SD) questionnaire. Visual analog scale (VAS) of post-operative knee pain was recorded each patient.

Results: In the bivariate analyses, the postoperative gait endurance had a significant positive correlation with the postoperative gait speed (r=0.48, p<0.001), cadence (r=0.40, p<0.001), stride length (r=0.58, p<0.001), postoperative peak torque (PT) extensor of non-surgical knee (r=0.49, p<0.001), postoperative peak torque (PT) flexor of non-surgical knee (r=0.34, p<0.001), EQSD (r=0.33, p<0.001) and a significant negative correlation with TUG (r=-0.46, p<0.001), SCT-ascent (r=-0.63, p<0.001), SCT-descent (r=-0.68, p<0.001), WOMAC pain score (r=-0.29, p<0.001), WOMAC stiffness score (r=-0.35, p<0.001), WOMAC function score (r=-0.43, p<0.001).

In the linear regression analyses, the postoperative Visual analog scale VAS (β=0.41, p<0.0001), peak torque (PT) extensor of surgical knee (β=0.56, p<0.001) and peak torque (PT) extensor of non-surgical knee (β=0.77, p<0.001) were factors predictive of the postoperative 6MWT.

AB0811 HYALURONIC ACID INTRA-ARTICULAR INJECTION VERSUS ORAL ATORVASTATIN IN THE TREATMENT OF KNEE OSTEOARTHRITIS

M. Jokae, Z. Marfeizi, K. Hashemzadeh, H. Zarei. Mashhad University of Medical Sciences, Mashhad, Iran, Islamic Republic Of

Background: Osteoarthritis is a degenerative joint disorder of articular cartilage and is the most common type of arthritis in the elderly. Some studies have suggested that Hyaluronic acid and atorvastatin may have a role in the treatment of osteoarthritis.

Objectives: The purpose of the present study was to investigate and compare the potential effects of Hyaluronic acid and Atorvastatin on the symptoms of knee osteoarthritis.

Methods: We conducted a randomized, controlled trial in patients with knee osteoarthritis. Eligible patients were those who met the ACR criteria of primary knee osteoarthritis, radiologically ascertained grade I or II of knee osteoarthritis on the Kellgren-Lawrence scale, had a pain score (maximum 100) and age 50–70 years. Patients were not eligible if they had secondary osteoarthritis, systemic disease like diabetes, history of inflammatory arthritis, severe knee deformity (varus or valgus >50 degree), history of coagulopathy, severe cardiovascular disease, and active infections. Patients were enrolled from outpatient clinic of Imam Reza Hospital, Mashhad, Iran. We divided them randomly into two groups; Group 1 (n=35) received intra-articular Hyaluronic acid each week for three weeks, and group 2 (n=35) received oral atorvastatin 40 mg/day orally for six months. Symptoms were assessed by the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) at baseline and every month up to 6 months.

Results: Twenty eight patients (40%) were male and 42 patients (60%) were female. There was not a significant difference between 2 groups regarding sex (P=0.626). Mean age of patients was 57.9±1.1 years. Groups mean age did not differ significantly (P=0.710). The pain and function scores were significantly decreased only in the Hyaluronic acid group in the second month (P<0.001). There was not any significant improvement in any group in the next months (figure 1).

Conclusions: Intra articular Hyaluronic acid improved the pain and function of patients with knee osteoarthritis in the second months after injection. Atorvastatin did not have any effect on the knee osteoarthritis symptoms during 6 months.

AB0812 DIFFERENTIATED APPROACH TO THE TREATMENT OF OSTEOARTHRITIS WITH COMORBIDITIES

Background: A significant prevalence of osteoarthritis (OA), the most disability joint disease in the world, which is important in the search for the new treatment. Analysis of modern therapy of OA was the reason for research efficacy of NSAIDs and SYSADOA on biochemical, inflammatory and immunological signs in the treatment of OA.

Objectives: Differentiated approach to the treatment of OA depending of presence of hyperuricemia.

Methods: 176 patients (144 women, 32 men) was examined, aged (59.7±10.86 years with confirmed radiographic OA according to Kellgren and Lawrence scale. Division into groups was performed depending on treatment. For 14 days group 1 (n=30) received nimesulide 100 mg twice daily, and group 2 (n=30) - meloxicam after surgery. It may be possible to predict with good accuracy for postoperative gait speed. In addition, these results could be of importance in determining effective rehabilitation strategies focusing on resistance training for improvement of gait speed early after TKA.

PROPOSAL FOR THE CONSTITUTION IMPLEMENTATION AND MEDICAL SHIFT OF THE TIBIAL ARTICULAR SURFACE SHOULD BE TAKEN INTO ACCOUNT FOR ONE FACTOR OF MEDIAL OSTEARTHRITIS OF THE KNEE

P. Nagamine, Center of Artificial Joint and Rheumatism, Fukukowa Tokukushiku Medical Center, Kasuga, Japan

Background: Varus knee is one factor of medial osteoarthritis of the knee. According to the concept of the constitutional varus\(^1\), the bone growth disturbance at the growth plate in the medial proximal metaphysis of the tibia results in proximal tibia vara. In this situation, the tibia is bent at the proximal metaphysis and the tibial surface (TAS) may be shifted medially. The medial shift of the TAS will increase the mechanical loading in the medial side of the knee. The medial shift of TAS will also influence the value of the Hip-knee-ankle (HKA) angle because the tibial plafond that is the end point of the mechanical axis (MA) of the tibia will shift medially. The purpose of this study was to assess the extent of the medial shift of TAS in knees with medial osteoarthritis, and to assess the effect of this medial shift of TAS on the value of HKA angle.

Objectives: The purpose of this study was to assess the extent of the medial shift of TAS in knees with medial osteoarthritis, and to assess the effect of this medial shift of TAS on the value of HKA angle.

Methods: This study consists of 116 knees with medial osteoarthritis. The mean age was 75.3 years old. The mean standing femorotibial angle (FTA: lateral angle between femoral and tibial anatomical axes) was 183.6°. The anatomical axis (AA) was the central line of the femoral and the tibial shaft. On the anteroposterior view radiograph of the tibia, AA, MA and tibial plateau tangent were drawn. MA is the line between the center of the tibial spine notch and the center of the tibial plafond. Two angle parameters and two distance parameters were measured.

Results: Those angle between AA and MA (Angle AA-MA) (the value was positive when MA located medial to AA), angle between the tibial plateau tangent and the line perpendicular to AA (Angle plateau) were calculated. The distance between AA and the tibial spines notch on the tibial plateau (Distance AA-MA) (the value was positive when Point M located medial to AA), and the length of MA were calculated.

Conclusion: The knee angle underestimated varus deformity, the more the tibial articular surface shifted medially. The maximum Distance AA-MA was 16.1mm. In this case, HKA angle underestimated varus deformity up to 3°.

AB0815 PREVALENCE OF DORSAL AND LUMBAR VERTEBRAL OSTEOARTHRITIS IN WOMEN OVER 50 YEARS OF AGE EVALUATED USING THE LANE RADIOGRAPHIC SCORE IN FIVE LATIN-AMERICAN COUNTRIES

S.M. Carrillo 1, D.X. Xibillé 2, E. Granados-Sandoval 3, D. Cureli-Quiroz 4, E. Denova-Gutiérez 4, M.G. Olivera-Soto 4, P. Clark 4, 1 Rheumatology, Hospital Regional 1ro de Octubre ISSSTE, CDMX; 2SEC - Investigación, Servicios de Salud de Morelos, Cuernavaca; 3Radiology Unit, Hospital Regional 1ro de Octubre ISSSTE; 4Unidad de Epidemiología Clinica, Hospital Infantil Federico Gómez Facultad de Medicina UNAM; 5Unidad de Investigación, Colegio Mexicano de Reumatología, CDMX, Mexico

Background: Osteoarthritis is the most common musculoskeletal disease worldwide. Spinal osteoarthritis (OA) is a frequent cause of back pain and disability in patients over 60. The frequency of radiographically-evident dorsal and lumbar OA in Latin America is unknown.

Objectives: To determine the prevalence of dorsal and lumbar vertebral OA in a database-driven random sample of women 50 years of age and older from the Latin-American Vertebral Osteoporosis Study (LAVOS) in 5 LA countries (México, Brazil, Argentina, Colombia and Puerto Rico).

Methods: Lumbar and Dorsal X-rays were performed by a standardized protocol and analyzed independently by two trained radiologists and a general practitioner using the Lane score to establish diagnosis and degree of vertebral OA severity. Inter and intra observer agreement was determined to be k = 0.6.

Conclusion: As OA severity increases, so does the prevalence of OA.

AB0816 COMPREHENSIVE ANALYSIS OF A NEW CHEMICAL COMPOUND FOR THE TREATMENT OF OSTEOARTHRITIS BY A PROTEOOMIC APPROACH IN HUMAN CHONDROCYTES

S. Cheleschi 1, V. Calamia 2, M. Fernandez-Moreno 3, Á. De Palma 1, M. Galeazzl 1, M. Anzini 4, A. Fioravanti 1, F.J. Blanco 5

Department of Medicine, Surgery and Neuroscience, Rheumatology Unit, University of Siena, Policlinico le Scotte, Siena, Italy; 2Servicio de Reumatología, Grupo de Proteómica; 3Servicio de Reumatología, Grupo de Proteómica y Genómica, INIBIC-Hospital Universitario A Coruña, A Coruña, Spain; 4Servicio de Biotecnología, Chemistry and Pharmacy. Universidad di Siena, Siena, Italy; 5Servicio de Reumatología, Grupo de Proteómica y Genómica, INIBIC-Hospital Universitario A Coruña, A Coruña, Spain

Background: Selective cyclooxygenase (COX)-2 inhibitors were developed to prevent NSAID-gastro-intestinal adverse effects. VA692, a new hydroxyethyl selective COX-2 inhibitor, showed anti-inflammatory, anti-necroitive and chondroprotective properties. Proteomics is being applied for the study of drug mode of action, toxicity and to identify new drug targets.

Objectives: The aim of this study was to analyze the anti-inflammatory effect of VA692, in comparison with celecoxib. By iTRAQ methodology, we quantitatively analyzed the different expressed profiles in T/C-28a2 cell line treated with the studied drugs in presence of IL-1β.

Methods: Human T/C-28a2 chondrocytes cell line were generated by Goldring group. Human articular cartilage was obtained from femoral heads of five OA patients. Cells were incubated with VA692 and celecoxib (1, 0.5 and 0.05 μM) in presence of Interleukin (IL)-1β (5ng/ml) for 48h. The expression of inflammatory cytokines and anti-oxidative enzymes was evaluated by quantitative qRT-PCR, PGE2 release by ELISA, and apoptosis and ROS production by flow cytometry. T/C-28a2 cell line was also processed to carry out western blot tests and finally employed for the iTRAQ analysis. Statistical analysis was performed by ANOVA and Bonferroni multiple comparison tests.

Results: IL-1β-stimulated chondrocytes showed a significant increase (p < 0.001) of COX-2, IL-1β, IL-6, IL-8, superoxide dismutase (SOD)-2 and catalase (CAT) expression, as well as IL-1β-induced overexpression, as well as IL-1β-induced overexpression. The tested drugs significantly counteracted the effect of IL-1β, with a better modulation by VA692 1μM in T/C-28a2 cell line (p < 0.01 for COX-2, IL-1β, IL-8, CAT; p < 0.001 for IL-6, SOD-2). Regarding apoptosis and ROS production, the new drug was able to significantly reduce (p < 0.05) their increase induced by IL-1β (p < 0.05). Proteomic analysis led to identification of 797 proteins in T/C28a2 cell line, 123 of which were significantly modulated by VA692 in presence of IL-1β (p < 0.001), and 34 by IL-1β alone (p < 0.05). 22 proteins were commonly modulated in both groups, thus indicating that 101 proteins were regulated by VA692 in a specific manner. Among the proteins down-regulated by VA692, some with structural function were detected as responsible for the counteraction cell death (the shock proteins) and glycolytic enzymes. Proteins involved in calcium metabolism and in ribosome biogenesis resulted up-regulated instead, as well as SOD-2 as confirmed by western blot analysis.

Conclusions: Our data demonstrated the anti-inflammatory effect of VA692, suggesting also its anti-apoptotic and anti-oxidant role. The proteomic profile showed that VA692 induced not only an anti-inflammatory effect in chondrocytes but, interestingly, this compound also seemed to regulate their anabolic response.

AB0818 IMPROVING CARE FOR PATIENTS WITH OSTEOARTHRITIS IN FIVE EUROPEAN COUNTRIES: THE JIGSAW-E PATIENT PANEL

S. Blackburn 1, J. Meesters 2, M. De Witt 2, L. Campbell 2, G. Rhodes 1, D. Schiphof 1, V. Vliet Vlieland 2, S. Bierma-Zeinstra 4, N. Østerås 5, S. Pais 6, E. Roos 7, N. Evans 1, K. Dziedzic 1, Keele University, Keele, United Kingdom; 2Leiden University Medical Center (LUMC), Leiden; 3VU University Medical Center, Amsterdam; 4Erainghjoed University Medical Centre Rotterdam, Rotterdam, Netherlands; 5Diakonhjemmet Hospital, Oslo, Norway; 6University of Algarve, Algarve, Portugal; 7University of Southern Denmark, Odense, Denmark

Background: EULAR guidelines for osteoarthritis (OA) endorse high quality care and support to self-manage with core recommended treatments such as exercise, weight loss and the provision of written information and education. An EU-funded project, Joint Implementation of Guidelines for oSteoArthritis in Western Europe (JIGSAW-E), aims to improve the management of OA across five European countries (UK, Netherlands, Norway, Denmark, Portugal) by implementing an intervention to enhance the OA consultation. Coordinated, cross-border Patient and Public Involvement and Engagement (PPIE), working in active partnership with the project team, is an essential component of JIGSAW-E.

Objectives: To describe the PPIE in the JIGSAW-E project.

Methods: A two-day international workshop established the JIGSAW-E Patient Panel to act as the voice of patients and the public in the project and to co-develop clear information and resources for patients. Panel members meet regularly with the project teams in each country. The Patient Panel is coordinated and supported by dedicated PPIE teams in the UK and Netherlands.

Results: The JIGSAW-E Patient Panel consists of Patient Champions and patient representatives from newly established or existing patient groups in each of the five countries. The Patient Champions form a core group of seven patient representatives who work closely with the Patient Panel and the JIGSAW-E team. PPIE activities have included:

- On 3 Patient Champions sit on the JIGSAW-E project steering committee.
- In the Netherlands, Patient Panel members substantially contributed to the translation and cultural adaptation of a guidebook for patients with OA. This process will continue as JIGSAW-E is rolled out in each of the five countries.
- Patient Panel members in the UK have helped refine an OA Quality Indicator questionnaire for use in JIGSAW-E.

A glossary of terms has been developed to support the involvement of Patient Panel members throughout the project.

Conclusions: Effective and meaningful PPIE is a central component to delivery and success of raising awareness and implementing the OA management
recommendations on a national level. The Patient Panel represents a step forward in international collaboration of PPIE within implementation projects. The Patient Panel is producing culturally appropriate and relevant information and resources for patients in five European countries. Future activities may include the development of patient stories to support increased adoption of JIGSAW-E, providing the patient perspective during training of health care professionals, and the digitisation of patient resources into Smartphone or tablet Apps.

AB0819 PERSONALIZED ARTICULATING JOINT DISTRACTION FOR TREATMENT OF TIBIOFEMORAL OSTEOARTHRITIS: CLINICAL FEASIBILITY
T. Struij1, R.J. Custers2, N.J. Bessellink1, J.E. Jaspers3, A.K. Marijnissen1, F.P. Liefker1, S.C. Mastbergen1, 1Rheumatology & Clinical Immunology; 2Orthopedics; 3Medical Technology & Clinical Physics, University Medical Center Utrecht, Utrecht, Netherlands

Background: Osteoarthritis (OA) patients encounter progressive pain and functional disabilities, including joint stiffness, due to degeneration of the joint tissues. For knee OA, the most prevalent form, available treatment strategies are limited in number and focus primarily on minimizing the functional disability, inflammation, and pain in a conservative manner since still no unambiguously proven effective disease modifying approaches are available. Progress in the development of joint sparing procedures however, has demonstrated the regenerative capacity of the osteoarthritic joint and with that the delay for conventional last resort therapy such as total knee arthroplasty (TKA). Knee Joint Distraction (K JD) is a joint preserving procedure that can postpone knee arthroplasty in case of knee osteoarthritis for over 5 years [1]. Distraction is applied with an external fixator for 6–8 weeks.

Objectives: To reduce the burden on patients during treatment originating from a restriction in joint flexion during KJD, we evaluated an articulating frame. A personalized articulating KJD-device was developed, biomechanically tested, and technical feasibility was evaluated in cadaveric legs. Reproduction of joint specific motion was demonstrated and articulating KJD was concluded to be technically feasible. In this study, clinical feasibility was tested in 3 patients.

Methods: Patients received rigid knee joint distraction treatment in general practice. After 2–4 weeks, the frame was removed in the outpatient clinic and the joint was flexed in a continuous passive motion (CPM) device until 30° flexion was reached, or motion became painful. Subsequently, the articulating frame was attached to the bone pins (figure 1), followed by computerized personalization of the hinge from a non-invasive motion measurement. After assembling the custom parts, weight-bearing and non-weight-bearing radiographs were taken at 0, 15, and 30° flexion for joint space width measurements. Finally, the articulating device was replaced by the rigid frame and treatment was continued according to clinical practice.

Results: For none of the three patients, the articulating distractor could be personalized. In the first patient, 15° flexion was achieved on the CPM, but pin positions did not allow for positioning of the frame. In the other patients, 8° and 15° flexion was measured, which was too little motion for the custom software to generate personalized hinge parts. Pain at the pin sites during motion was reported by all patients.

Figure 1. The articulating frame assembled to the bone pins and bone pin clamps as used for rigid joint distraction in clinical practice, and previous to measurement of joint-specific motion and customization of joint specific hinge parts.

Conclusions: Despite confirmation of joint-specific articulating distraction on cadaveric legs, clinical feasibility could not be demonstrated, mainly due to painful motion of soft tissues along the bone pins.

AB0819 IS INCREASING THE TREND OF PRIMARY TOTAL HIP ARTHROPLASTIES FOR THE PATIENTS WITH OSTEOARTHRITIS, BUT DECREASING THE RATE OF WOMEN IN SUPER-AGING AREA OF JAPAN IN LAST TWELVE YEARS?
Y. Takahiko1, K. Sasaki1, H. Oki1, Y. Nagamura1, A. Narita1, J. Ito1, H. Kawaji2, M. Ishi2, M. Takagi1, 1Department of Orthopaedic Surgery, Yamagata University Faculty of Medicine; 2Department of Orthopaedic Surgery, Yamagata Saisei Hospital, Yamagata, Japan

Background: Elderly people over 65 year-old have increased year by year in many countries [1]. Because their rate was from 19.5% at 2004 to 26.8% at 2015 in Japan and 50.8% at 2015 in our super-aging area, the numbers of total joint arthroplasties have increased too [2]. In fact, the numbers of total hip arthroplasty predicted increasing from six hundred fifty-six thousand cases at 2010 to one million three hundred seventy-six thousand cases at 2020 in USA [3]. The rate of total joint arthroplasty, including primary total hip arthroplasty, may reflect trends in management and health outcomes of elderly people with osteoarthritis (OA) in our super-aging area of Japan [4].

Objectives: The aim of this study was to analyze the trend of primary total hip arthroplasties for the patients with OA in our institutes in the last twelve years.

Methods: We surveyed the number and rate of orthopaedic surgeries and primary total hip arthroplasties in our two institutes from 2004 to 2015.

Results: We had 19,862 cases of orthopaedic surgeries, including 3,782 primary total hip arthroplasties in the last twelve years. They have increased year by year (r=0.92, p<0.05, Fig. 1). Mean age was 64.5 old-year (62.4–66.8) in last twelve years, had become older year by year (r=0.78, p<0.05, Fig. 1). Mean age was 64.5 old-year (62.4–66.8) in last twelve years, and related to total numbers of orthopaedic surgeries in our super-aging area of Japan [4]. Mean rate of female was 87% (85–91) in last twelve years, had gradually decreased year by year (r=-0.68, p<0.05), 91% at 2004 vs 85% at 2015.

Conclusions: The rate of total joint arthroplasties including primary total hip arthroplasty increased year by year, and related to total numbers of orthopaedic surgeries in our super-aging area of Japan. Mean age at receiving primary total hip arthroplasty was older annually but mean rate of women had gradually decreased year by year. Although majority of OA hip consist of female which have secondary dysplastic acetabulum in our country, it might increase gradually the patients of man with OA hip in super-aging time in Japan.

AB0820  FREQUENCY OF OSTEOPOROSIS AND ASSOCIATED RISK FACTORS IN MEXICAN PATIENTS WITH RHEUMATOID ARTHRITIS

A.N. Rangel-Botello 1,2, A. Gallegos-Posada 2, F. Jasso-Avila 2, D. Ramos-Bello 1,2, C. Villa-Calderón 3, M.U. Martínez-Martínez 1,2, C. Abud-Mendoza 1,2, 1Rheumatology, Hospital Central Dr. Ignacio Morones Prieto; 2Faculty of Medicine, Autonomous University of San Luis Potosí, San Luis Potosí; 3Faculty of Medicine, Autonomous University of Aguascalientes, Aguascalientes, Mexico

Background: The risk of osteoporosis in patients with rheumatoid arthritis (RA) is of particular interest as it can be associated with genetic and environmental factors. The frequency of generalized osteoporosis in different studies is variable.

Objectives: The aim of the study was to investigate the frequency of osteoporosis as well as to describe the risk factors in RA population.

Methods: Retrospective study, including patients with RA who had at least 2 densitometries in their follow up. We collected demographic characteristics, use of glucocorticoids (GC), other medications and antibody profile. Variables were compared between groups with or without osteoporosis. The frequency of osteoporosis was calculated according to the T-score and logistic regression was performed to explore the association of osteoporosis and relevant variables. Statistical analysis was performed using R software version 3.2.1. Baseline characteristics were compared between groups of patients (osteoporosis in the lumbar spine, femoral neck and hip) defined according to the T-score results. We used x2 or Fisher test for categorical variables as appropriate and Wilcoxon test for continuous variables. A logistic regression model was used to explore the relationship between osteoporosis and variables that could contribute as risk factors.

Results: One hundred and five patients were included, 96.2% were women, RA evolution of 7 (ICR 8) years. The frequency of osteoporosis was: lumbar spine 55.2%, hip 12%, and femoral neck 25.7%. Patients with lumbar spine osteoporosis had higher age (62 vs 58 years, p=0.13), lower weight (57 vs 63.8 kg, p=0.00004) and higher FRAX scores (26.5 vs 11.5, p=0.004; 8.5 vs 2.4, p=0.02). The associated risk factors were: weight (OR 1.09, 95% IC 1.03–1.15, p=0.001), GC use (OR 4.36, 95% IC 1.00–18.89, p=0.049), menopause (OR 22.78, 95% IC 2.73–190.12, p=0.003). There was no association with disease activity.

Conclusions: High rates of osteoporosis were found in patients with RA and the risk factors in RA population.

AB0822  CLINICAL FEATURES AND PREDICTIVE FACTORS OF ORAL BISPHOSPHONATE-RELATED OSTEONECROSIS OF THE JAW: AN ANALYSIS OF 8 CASES IN A SINGLE INSTITUTION

A. Suzuki 1, M. Yoshida 1, M. Mori 2, Y. Sakamoto 3, 1Department of Rheumatology; 2Department of Pathology; 3Department of Oral Surgery, Mitsu Memorial Hospital, Tokyo, Japan

Background: Oral bisphosphonates (BPs) have been increasingly prescribed for the treatment of and prophylaxis for osteoporosis over the past decade. More than 190 million prescriptions for oral BPs have been dispensed worldwide, and, thus, the number of patients that develop oral BP-related osteonecrosis of the jaw (BRONJ) is expected to increase in the future. Although previous studies have investigated oral BRONJ, predictive factors have not yet been identified [1].

Objectives: The aim of the present study was to clarify the clinical features and predictive factors of oral BRONJ.

Methods: We included 8 patients who had taken oral BPs and were diagnosed with BRONJ at Mitsui Memorial Hospital (Tokyo, Japan) between 2011 and 2016. The following details were collected for each patient from a review of medical charts: sex, age, type of BP used, duration of BP administration, co-morbidities, laboratory values at presentation including hemoglobin, albumin, and serum creatinine values, clinical stage of the lesion, site affected, and pathological findings. Laboratory values of patients with BRONJ were compared with those of 242 patients (as a control group) who were prescribed BPs in October 2016 at our hospital. The Mann-Whitney U-test and chi-squared test were used for statistical comparisons between the oral BRONJ and control groups. Risk factors for BRONJ were assessed using multivariate analyses with a logistic regression analysis. All analyses were performed using SPSS ver. 21.

Results: The mean age and female ratio in the oral BRONJ and control groups were 64 years and 80%, and 71±12.7 years and 66.1%, respectively (p=0.26, p=0.61). The mean interval between the initiation of BP therapy and a confirmed diagnosis was 45.9±35.5 months. Seven patients had lesions in the mandibular bones and alveolus and were used in six cases. Oral BPs were administered to three patients with rheumatoid arthritis or multiple sclerosis, all of whom were given a maintenance dose of corticosteroids. The remaining three out of 5 oral BP users developed BRONJ after dental extraction. Regarding laboratory results, serum albumin values were significantly lower in the oral BRONJ group than in the control group (3.7±0.3 g/dl and 4.2±0.4 g/dl, respectively, p<0.01). Serum hemoglobin levels were slightly lower in the oral BRONJ group than in the control group (11.3±1.3 g/dl and 12.4±1.7 g/dl, respectively, p<0.06). A multiple logistic regression analysis identified serum albumin levels as the only significant predictive factor for oral BRONJ (OR=0.14; 95% CI 0.03–0.71, p<0.05). A pathological examination was available in six patients, with Actinomyces being identified as the causative agent in five of them.

Conclusions: Oral BRONJ mainly developed in patients with long-term corticosteroid use for an underlying illness or those who underwent dental extraction, and hypoaalbuminemia was the only laboratory marker identified as a predictive factor for BRONJ.
EVALUATION OF OSTEOPOROSIS AND FRACTURES IN PATIENTS WITH DIABETES MELLITUS TYPE 2: RESULTS OF A 5-YEAR FOLLOW-UP

V.L. Masenko 1, A.N. Kokov 1, S.E. Semenov 1, T.A. Raskina 2, O.L. Barbashin 1, 1Federal State Budgetary Scientific Institution Research Institute for Complex Issues of Cardiovascular Diseases; 2Kemerovo state medical academy of Federal Agency of Healthcare and Social Development, Kemerovo, Russian Federation

Background: The treatment of Osteoporosis is difficult to monitor and so usually incomplete resulting in inadequate response.

Objectives: To evaluate the minimum period of treatment required with Bisphosphonates and Parathyroid hormone in order to see a significant change in serial Bone Mineral Density analysis (BMD).

Methods: Low BMD patients were subjected to yearly infusion of Zoledronic Acid 5mg (ZA) verses daily Subcutaneous injections of Teriparatide 20 μg (PTH). A single center pixel beam body densitometer was used to measure serial BMD at baseline and yearly. Average BMD measures from the Spine L2, L3 and L4 (BS) and Total Hip (BH) were evaluated. The percentage change in the mean BS and BH readings was calculated to look for the least significant change (LSC) in the density scores.

Results: Significant change of 4.65% was seen (LSC=2.6%)2 in the Spine in the PTH group after one year of treatment while it took two years in the ZA group for a 2.77% change. There was no significant change (LSC=0.6%) in both groups in the BH. A p<0.05 was considered statistically significant. The finding is summarized in Table 1.

Table 1

COMPARISON OF THE CAPABILITY OF RADIAL BONE MINERAL DENSITY AND CALCEANAL QUANTITATIVE ULTRASOUND VARIABLES IN THE IDENTIFICATION OF MEN WITH OSTEOPOROSIS

A. Oral, D. Sindel, A. Yaliman, S. Ashghari Kalebar, S. Esmaeilzadeh. Physical Medicine and Rehabilitation, Istanbul University Istanbul Faculty of Medicine, Istanbul, Turkey

Background: Bone mineral density (BMD) as measured by dual-energy X-ray absorptiometry (DXA) is considered the gold standard for the management of osteoporosis. Recently, quantitative ultrasound (QUS), which is easy to use, inexpensive, portable, does not use ionizing radiation, and has also been shown to provide information about bone quality and to predict fracture risk, has gained growing interest in this area.

Objectives: The aim of this study was to compare the capability of one-third radius (33% radius) DXA BMD measurements and calcaneal QUS (cQUS) variables for identifying axial osteoporosis as measured by DXA in men.

Methods: Axial BMD measurements at the lumbar spine and at the hip (femoral neck and total hip), 1/3 radius BMD of the non-dominant forearm were made using DXA and cQUS variables at both sides as measured twice were obtained in 179 men aged between 24 and 85 years. Osteoporosis was defined based on the WHO criteria in men aged 50 and over, a man having been considered as osteoporotic in the presence of a T-score <−2.5 in any of the axial regions measured.

For defining axial osteoporosis or BMD below the expected range for age, Z-scores were used which were younger than the age of 50 years. Receiver operating characteristic (ROC) analysis was used to assess the osteoporosis identification capability of measurements.

Results: The areas under ROC curves (AUCs) for 1/3 radius BMD, its T-score, the lowest means (as calculated as the mean of the two calcaneal QUS measurements for each heel) of quantitative ultrasound index (QUI), QUI T-score, broadband ultrasound attenuation (BUA), speed of sound (SOS), and estimated heel BMD (eBMD) for identifying axial osteoporosis or BMD below the expected range were found as 0.755, 0.767, 0.760, 0.717, 0.768, and 0.764 (p < 0.001 for all), respectively.

Conclusions: In conclusion, AUCs pointed to similar for QUI, QUI T-score, and eBMD or even better for (SOS) osteoporosis discriminative capability of cQUS variables in comparison to radial DXA BMD variables. These findings may have implications that cQUS variables, particularly SOS, may be used for the identification of osteoporosis in men whose axial BMD cannot be measured by DXA due to certain circumstances as well as in circumstances where DXA is not available.

AB0828

MAJOR RISK FACTORS OF OSTEOPOROSIS IN RA FEMALE PATIENTS WITH NORMAL MENSTRUAL CYCLE

E.A. Taskina, L.I. Aksheeva, I.S. Dydykina, M.M. Podvorotova, A.V. Smirnov, S.I. Glukhova, E.L. Nasonov. V.A. Nasonov Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

Background: Only postmenopausal women were in the researcher’s focus in the majority of publications on osteoporosis (OP) risk factors (RF) in RA female patients (pts). Meanwhile the data on OP RF in menstruating women presented in the rare available papers are not consistent.

Objectives: To identify the major OP RF in RA female pts with normal menstrual cycle.

Methods: 51 RA pts (based on ACR criteria) female pts with normal menstrual cycle aged 20 to 51 years (mean age 41±1.7 years) were examined. The following info was included in each individual pts’ files: anthropometric parameters, social and demographic data, case history, clinical examination and lab findings, traditional OP RF, pts’ joint status, comorbidity status, pain intensity assessments and VAS evaluation of pts’ general health status. Axial bone mineral density (BMD) was measured with DXA scan using Z-score calculator. Based on the OP status all pts were divided into 2 groups:pts with OP – 16 (31.4%), and pts without OP – 35 (68.6%).

Results: Comparative analyses of the groups showed that: OP pts were younger (31±10 vs 42±8.5 years, p=0.02), Disease duration was comparable in both groups. Clinical manifestations of inflammation activity (mean DAS 28 score and hsCRP) were statistically significantly more pronounced in the OP group vs the pts without OP (4.9±1.1 vs 4.19±1.06, p=0.049; 27.8 (10.8–45.5) vs 7.4 (1.4–27.7) mg/L, p=0.02, respectively). High DAS 28 (50 vs 20-6%, RR=2.43, 95% CI 1.07–5.53, p<0.03) scores were more often documented in the OP pts. Pronounced feet and hand bone destruction based on the radiographic findings was documented in the majority of pts in both groups, although in the OP pts the joint space narrowing counts (97 (62.5–121) vs 73.5 (53–87), p=0.02) and the total Sharp score (98 (64.5–183) vs 89.0 (63–112), p=0.03) were statistically significantly lower in the OP pts. The mean of the following major OP RF in the RA female pts were more pronounced: bone loss (83.1 vs 37.1%, RR=2.19, 95% CI 1.34–3.57, p=0.004), as well as GCs -pulse therapy (56.3 vs 25.7%, RR=2.18, 95% CI 1.08–4.45, p=0.04), had higher GCs cumulative dose (18.8 (8.1–30.7) vs 6.4 (0.8–14.1), p<0.01), higher GC daily dose at the time of examination (8.8 (6.3–10) vs 5 (3.8–6.3)mg/day, p=0.01) and higher average daily dose in the previous year (8.8 (5–10) vs 3.8 (2.5–6.3)mg/day, p=0.01) versus the pts without OP. Analysis of traditional RF (low body weight/BMI, long immobilization periods, smoking, family history of OP and others) showed no difference between the two groups. Discriminant analysis revealed the following major OP RF in the RA female pts were more pronounced: RA activity (based on the Das 28 score) and GCs dose at the time of examination (given GCs therapy lasts ≥3 months). Meanwhile the patient’s body weight and age at the onset of RA were identified as protective factors for BMD. Based on the abovementioned risk and protective factors and the derived coefficients the authors designed a formula allowing to predict of OP in female RA pts before menopause with high accuracy (area under the ROC-curve=0.833). The model accuracy is 85.1%.

Conclusions: RA activity and GCs dose (GCs therapy duration ≥3 months) were identified as the major OP RF in young RA female pts before menopause, thus adequate and timely therapy aimed at obtaining RA control and achieving remission should be considered as key OP prevention strategy.

BONE METABOLISM IN LIVER TRANSPLANT PATIENTS TWO-YEAR STUDY. INFUENCE OF MEDICAL INTERVENTION PRIOR TO SURGERY AND ANTIRESORPTIVE TREATMENT

E. Labrador Sánchez1, E. Grau García1, K. Arevalo Ruales1, J.F. Fragio Gil1, R. González Mazzario1, C. Alcalá Escandell1, I. Cánovas Olmos1, I. Chalmeta Verdoso2, C.M. Feced Olmos1, I. González Puig1, J. Iovra Cortes1, I. Martínez Cordellat1, C. Najera Herranz1, R. Negueroles Albueix1, J.E. Oller Rodríguez1, F.M. Ortiz-Sanjuan1, E. Vicens Bernabeu1, A. Villota Bello1, V. Forner Ferrer1, D. Hervás Marín1, D. Moya Najera1, A. Moya Herranz1, J.A. Román Iovra1,2,1 Rheumatology department, HUP La Fe; 2Medical School, UCV;2 Biostatistic Unit, IIS la Fe; 4Health and Sport Group, UV; 5 Hepatology Department, HUP La Fe, Valencia, Spain

Background: Osteoporosis is a frequent complication in patients with chronic liver diseases, mainly in advanced stages or with evidence of cholestasis. During the first few months after liver transplant (LT) it seems that there is an accelerated bone mass loss and greater fracture risk.

Objectives: To study the antiresorptive treatment effect in bone metabolism in patients undergoing LT and to evaluate whether medical intervention prior to LT decreases the risk of osteoporosis.

Methods: We recruited patients from the LT Protocol of Osteoporotic Risk Assessement. The patients were evaluated 3–4 months before surgery, shortly after transplant (month 0) and 6–12–18–24 months after surgery. Data of bone metabolism biomarkers, densitometric values and antiresorptive treatment was collected. Biostatistical analysis with R (3.3.2.) was performed.

Results: We selected 163 LT patients of which 86 completed 24 months follow-up. From the total cohort, 77.8% were men and the mean age at transplantation 54.5±9.4 years old. 92.6% of patients were supplemented with vitamin D after surgery and 19.6% initiated antiresorptive treatment. We observed that 25-OH Vitamin D, PTH, beta-CTX and P1NP levels were corrected through the follow-up. T-score during the first year of follow-up decreased slightly and at 24 months the tendency was towards increase. This pattern was stronger in lumbar spine (t-score -1.48±1.34 after surgery and -1.28±1.06 at 24 months). Statistical analysis showed that antiresorptive treatment significantly influence lumbar and hip densitometric values (P<0.001 and P<0.001 respectively) as well as P1NP levels (P<0.003 and P<0.012 respectively). Moreover, obesity (P<0.004), as well as beta-CTX (P<0.029) and 25-OH Vitamin D (P<0.024) standardization improved hip densitometric values. Finally, LT patients evaluated before surgery showed better lumbar densitometric values than those evaluated after the transplant (P<0.007).
Conclusions: We observed 25-OH/vitamin D levels and bone metabolism biomarkers correlation during the first two years after LT. Medical intervention prior to LT as well as antiresorptive treatment seem to play a decisive role in bone mineral density improvement.

AB0830 BONE MINERAL DENSITY IN MULTIPLE MYELOMA: 39 CASES

Z. Saoussen, H. Mouannas, A. Arfa, M. Jguirim, B. Ismaiel, M. Touzi, N. Bergaoui. Rheumatology department of Monastir University Hospital, Monastir, Tunisia

Background: In multiple myeloma (MM), osteolysis affects more than 80% of patients. This leads to bone pain, pathological fractures and hypercalcemia. These lesions result from the hyperactivation of osteoclast activity and decreased osteoblasts one. The real impact of this osteolysis on bone mineral density remains largely understudied. To the best of our knowledge the impact of MM on bone mineralization was studied worldwide only for 6 times where our study is the second biggest one.

Objectives: The aim of the study was to evaluate bone mineralization in the patients with multiple myeloma according to the criteria of diagnostic (IMWG: International Myeloma Working Group 2014, during a period of 5 years (2011–2016).

Methods: This is a transverse and descriptive study. The bone mineral density was measured by dual-energy X-ray absorptiometry with Lunar Prodigy in spine (L2-L4) and femoral neck.

Results: Thirty-nine patients were collected. The average age was 63±10 years [50 years, 86 years] upon them 26 men and 13 women. The sex-ratio is equal to 2. 18 patients were smoking (35%), 9 of them had diabetes and only 2 were alcoholic (6%). The Body Mass Index (BMI) average was 29 kg/m². Only one case was underweight (3%). The reason of seeking health carewas poor general state in 14 cases (49%), bone pain in 22 cases (78%), 5 cases among them of generalized bone pain (23%) and 12 cases of rachialgia (4.5%) and only 4 cases of pathological fracture in stage II. The distribution of patients into staging proceeding according to the Durie and Salmon Classification was as follows: 25 cases (84%) in stage III, 3 cases (10%) in stage II, 2 cases (7%) in stage I, and 27 cases (90%) Type A and 3 cases (10%) type B. The average of the monosonal score was 34/G [2.5G, 88G]. The heavy chains antibodies were IgG type in 19 cases (84%), IgA type in 7 cases (24%), IgM type in only one case (4%) and IgD type in only one case (4%). The light chains were kappa type in 19 cases (84%) and Lambda type in 11 cases (37%). The ISS score was equal to 1 in 6 cases (23%), equal to 2 in 13 cases (44%) and equal to 3 in 8 cases (30%). The average bone mass in the spine was 0.99/±.254/cm² [0.63/cm²; 1.89/cm²] and in the femoral neck 0.86/±.254g/cm² [0.63/cm²; 1.89/cm²]. The average of the Z-score in the spine was -0.76/±1.89 [4.4; 5.7] and in the femur -0.42/±0.962 [2.8; 1.4]. The mean T-score in the spine was -1.62/±2.025 [-4.9; 5.6] and in the level of the femur -1.57/±1.178 [-3.7; 1]. There was a decrease of bone mineral density noticed in 15 patients (39%) in at least one place (T-score more than 2.5 SD below normal of young healthy persons. Seventeen patients (58%) were candidates for autogenous bone graft. They had induction chemotherapy (Dexamethasone-thalidomide). Others were treated by MPT protocol (Prednisone-Thalidomide-Dexamethasone) in 8 cases (28%), CDT protocol (Cyclophosphamide-Thalidomide-Dexamethasone) in one case (4%) and MP protocol (Melphalan -Prednisone) for the remaining (10%).

Conclusions: BMD analysis suggests that MM is associated with systemic bone disease with progressive loss of bone mass at both the spinal and lumbar levels. In order to better study the impact of multiple myeloma and chemotherapy on bone densitometry, a densitometry control about 5 years is favorable.

AB0831 FRAX SCORE: AN INTERESTING WAY FOR GASTROENTEROLOGISTS TO ASSESS FRACTURE RISK IN PATIENTS WITH LONG-TERM PROTON PUMP INHIBITORS

H. Romdhane 1, M. Cheikh 1, K. Abdelghani 2, R. Ennailer 1, N. Bel Hadj 1, A. Laser 1. 1Gastroenterology and hepatology, 2Rheumatology, Mongi Slim Hospital, TUNIS, Tunisia

Background: Proton pump inhibitors (PPI) are widespread nowadays. Recent concerns have emerged about possible bone complications of long-term use of PPIs, such as low bone mineral density (BMD) and an increased risk of fractures. Proton pump inhibitors (PPI) are effective in many indications. Nevertheless, some serious adverse effects associated with prolonged exposure, including a fracture risk, have occurred. This could be explained by two main mechanisms: decreased absorption of calcium secondary to decreased gastric acidity and inhibition of proton pump of osteoclasts reducing bone resorption.

Methods: We studied 52 patients. Those who have been taking PPI for at least one year. In all patients, we specified the indication and duration of PPI. We then looked for the main personal or family risk factors for osteoporosis. Bone mineral density (BMD) was performed in all patients and Frax score was calculated for those older than 40 years.

Objectives: The aim of our study was to evaluate the usefulness in our practice of this score in patients under long-term PPI.

Results: We included 52 patients. The mean age was 49.5 years old. The male-female ratio M/F was 0.48. At least three risk factors were found in more than 50% of the population. The calculated daily calcium intake was insufficient in 94% of the patients. The mean duration of PPIs intake was 45 months. The most frequent indication was gastro esophageal reflux disease (76%). The PPI prescription was appropriate in 94% of the cases. The prevalence of osteopenia and osteoporosis was respectively 52% and 19%. The predictive factors of low BMD were an age ≥50 years old (p<0.03), the menopause (p<0.0001), a calcium intake ≤550 mg/day (p<0.003), and a PPI use duration ≥30 months (p<0.006). The multivariate study could not be undertaken because of co linearity of the factors.

Conclusions: The long term PPI use is associated to the risk of bone complications, especially among patients at risk for osteoporosis. It seems reasonable to be more vigilant in prescribing PPIs and use lowest effective dose for patients with appropriate indications, and to screen these complications if necessary.

AB0833 BONE MINERAL DENSITY IN TUNISIAN PATIENTS WITH AUTOIMMUNE HEPATITIS

M. Cheikh, H. Romdhane, H. Bennejma, R. Ennailer, N. Bel Hadj. Gastroenterology and hepatology, Mongi Slim Hospital, TUNIS, Tunisia

Background: Bone loss in autoimmune hepatitis (AIH) is scanty and conflicting. The pathogenic mechanisms are not completely elucidated.

Objectives: This study aimed to assess the prevalence and risk factors for bone loss in patients with AIH.

Methods: Bone mineral density (BMD) using X-ray absorptiometry at both lumbar spine and femoral neck sites was measured in patients with AIH. Were excluded patients with diseases disturbing the bone density. Osteopenia was considered if T-score < -1.5 DS and osteoporosis if T-score < -2.5 DS.
Results: Twenty eight patients were enrolled in the study. They were 19 women (sex-ratio M/F=0.6), with a mean age of 54 years [extremes: 13 - 73 years]. Most patients had type 1 AIH (89.2%). Seventeen patients were diagnosed at stage of cirrhosis (60.7%). Associated auto-immune manifestations were observed in 42.8% of cases. Overlap syndrome with primary biliary cirrhosis was noted in 20.7% of cases. A total of 27.9% of patients were on steroid treatment and 24.26% of patients were on steroid treatment for more than 6 months. BMD was low in 9 patients (32%) as follow: osteopenia in 6 cases and osteoporosis in 3 cases. There was a correlation between bone loss and use of steroid treatment but it wasn’t statistically significant (p=0.07).

Conclusions: In our series, the prevalence of bone loss in AIH is high (45%). This data suggest that bone status should be assessed routinely in patients with AIH, especially in those on steroid treatment.

AB0834 RISK FACTORS FOR DECREASED BONE MINERAL DENSITY IN INFLAMMATORY BOWEL DISEASE IN A TUNISIAN COHORT

H. Romdhane 1, M. Cheikh 1, K. Abdelghani 2, R. Ennaifer 1, N. Bel Hadj 1, A. Lastar 2, 1Gastroenterology and hepatology; 2Rheumatology, Mongi Slim Hospital, Tunis, Tunisia

Background: Patients with inflammatory bowel disease (IBD) are at risk for metabolic bone disease. Many studies have identified various risk factors but most of them have involved western patients.

Objectives: The aim of this study was to investigate the prevalence and the risk factors for metabolic bone disease in Tunisian IBD patients.

Methods: Retrospective study including patients with IBD admitted in our department between January 2011 and December 2015. Demographic and clinical characteristics of patients were analysed. Bone mineral density of the femoral neck, total femur and lumbar spine was quantified by dual-energy X-ray absorptiometry.

Results: Among 82 patients followed for IBD (70.7% with Crohn’s disease; 29.3% with Ulcerative colitis), a bone densitometry was performed in 56% of cases (n=46). 16 patients have osteopenia and 7 had osteoporosis, as assessed by T-score. Variance analysis showed that Crohn’s disease in particular ileal disease, high steroid dose and the presence of extra-intestinal manifestations were significantly associated with a low bone mineral density (all p<0.05). In the other hand, IBD duration since diagnosis, sex, tabagism were not associated with bone loss.

In multivariate regression analysis, risk factors for decreased bone mineral density were IBD duration since diagnosis, high steroid dose, ileal crohn’s disease and extra-intestinal manifestations.

Conclusions: In our Tunisian cohort of IBD patients, Crohn’s disease, high steroid dose and extra-intestinal manifestations were associated with increased risk for metabolic bone disease. High risk patients should be identified and appropriate therapies should be started early to improve long term quality of life.

AB0835 DENOSUMAB AS A FIRST CHOICE DRUG FOR GLUCOCORTICOID INDUCED OSTEOPOROSIS TREATMENT INSTEAD OF BISPHOSPHONATE

I. Yoshii 1, T. Chijuwa 2, 1Orthopaedic Surgery, Yoshii Hospital, Shimanto City; 2Rheumatology, Kochi Memorial Hospital, Kochi, Japan

Background: Glucocorticoid induced osteoporosis (GIO) is serious problem for raising risk of bone fragile fracture. In general, first choice drug for GIO is bisphosphonate (BPH), however, denosumab (dMAB), a monoclonal antibody of receptor activator of nuclear factor kappa-B ligand, is closed up as an alternative selection for GIO recently.

Objectives: The aim of this study is to evaluate effectiveness of dMAB in bone mineral density (BMD) for GIO treatment compared to BPH.

Methods: In this study, all patients who had been glucocorticoid steroid (GCs) have been administered for more than three months, who met indication criteria for GIO what was determined by the Japanese Society for Bone and Mineral Research in 2014, that is matrix calculated in adding points of past fracture history, age, dosage of GCs, and BMD value (1), were enrolled. Before March 2013, data was lacking, so patients who have been administrated GCs after April 2013 were picked up. Patients BMD at GCs administration, at 6 months after initial treatment, if drug was changed, also at 6 months after second treatment, for minimum lumbar spine (LS), femoral neck (FN), and greater trochanter (GT) were measured with dual-energy X-ray absorptiometry (DEXA). Patients were classified by drug for initial treatment and second drug if administrated. Patients age, initial, average, and total dose of GCs, term length of administration, and BMD and its gain for each chance were compared with Mann-Whitney U-test and Student’s paired T-test.

Results: 149 patients in whom 48 with no drug administrated (N), 24 for BPH naive and continued (BB), 22 for BPH naive and changed to dMAB (BD), 21 for dMAB naive and continued (DD), 34 for dMAB naive and changed to BPH (DB) were counted. In these, sex distribution was 26 for men and 123 for women. Underlying disease for administration of GCs were rheumatoid arthritis for 114, polymyalgia rheumatica for 12, idiopathic thrombocytopenic purpura for 9, systemic lupus erythematosus for 6, and others for 8. For groups, age at baseline, initial, average, and total dose, and term length of administration of GCs demonstrated no significant difference between any pairs of the groups. BMD at baseline for Group N demonstrated significant greater per-cent of young adult mean (%YAM) than Group DD (p<0.01) in all parts, yet greater than the other groups but not statistically significant. In Group N, BMD had significantly decreased from the baseline to 6 months later in all parts (p<0.01). In the other groups, BMD had shown gain at 6 months after drug administration in all part, however, in Group DB showed mean %YAM loss for GT after first and second drug administration compared to Group BD had shown %YAM loss after first but gain after second drug for FN (Table 1).

Conclusions: From these results, dMAB is effective role in raising BMD for GIO as a initial drug, and a second drug even after inadequate response to BPH. dMAB could be possible to be chosen as a first choice drug for GIO treatment.

AB0836 PERFORMANCE OF QUANTITATIVE ULTRASOUND AND SIX OSTEOPOOROSIS RISK INDEXES IN MENOPAUSAL WOMEN: VALIDATION AND COMPARATIVE EVALUATION STUDY

1Rheumatology Department, Military Hospital; 2Chemistry-Biochemistry Department, Faculty of Medicine and Pharmacy, Ibn Zohr University, Agadir; 3Rheumatology Department, Military Hospital Avicenne, Marrakech, Morocco

Background: A number of questionnaire-based systems and the use of portable quantitative ultrasound scanners (QUS) have been devised in an attempt to produce a cost-effective method of screening for osteoporosis.

Objectives: to assess the sensitivity and specificity of different techniques and their ability to act as screening tools in relation to dual energy X-ray absorptiometry (DXA).

Methods: 295 white menopausal women aged over 60 were enrolled. Each subject completed a standardized questionnaire which permits the measure of six osteoporosis indexes and had bone mineral density (BMD) measured using QUS and DXA. Sensitivity and specificity of the different techniques in relation to DXA were plotted as receiver-operator characteristic (ROC) curves at DXA T-score total hip ≤ -2.5 (osteoporosis).

Results: BUA sensitivity and specificity values were respectively 76.8% and 51.2% at the total hip. The optimal cut-off T-score for QUS was -2 at the total hip. The osteoporosis self-assessment tool (OST) provided consistently the highest AUC (0.80) among the clinical tools and had the best sensitivity and specificity balance (90.2% vs.44.5%). OST negative likelihood ratio was 0.22.

Conclusions: OST (based only on the weight and the age) performed slightly better than QUS and other risk questionnaires in predicting low BMD at the total hip.

AB0837 BONE METABOLISM AND OSTEOPOROSIS RISK FACTORS ANALYSIS IN SPINAL CORD INJURY PATIENTS AT TWELVE MONTHS FOLLOW UP

I. Martinez Cordelias 1, F. Torralba Collados 2, C. Grao Castellote 3, E. Grau Garcia 1, V. Forges Ferrer 2, E. Labrador Sanchez 1, K. Arvelo Ruales 1, J. Frago Gil 1, R. Gonzalez Mazair 1, C. Alcaraz Escandel 1, I. Cinclota Verdejo 1, C. Feced Olmos 1, L. Gonzalez Puig 1, J. Ivorra Cortés 1, R. Negueroles Albuixec 1, J.E. Oller Rodríguez 1, F. Ortiz Sanjuán 1, E. Bernabeu Vicens 1, C. Nájera Herranz 1, I. Cánovas Olmos 1, J.A. Román Ivorra 1.

1Orthopaedic Surgery, Yoshii Hospital, Shimanto City; 2Chemistry-Biochemistry Department, Faculty of Medicine and Pharmacy, Ibn Zohr University, Agadir; 3Rheumatology Department, Military Hospital Avicenne, Marrakech, Morocco

Background: The spinal cord injury associated with the immobilization of the
patient leads to a decrease in bone mass. The bone loss greater is observed in the 6 months after the spinal cord injury, and stabilizing between 12–16 months after the same. The incidence of fractures oscillates between 1.5% and 6%.

**Objectives:** To assess bone metabolism and bone fracture incidence in SCI patients.

**Methods:** Prospective study of SCI patients from the Spinal Cord Injury Unit of La Fe Hospital. In all cases densitometry, x-ray image, bone metabolism biomarkers and clinical evaluation have been performed according protocol. Statistical techniques was carried out using R software 3.2.3, using mixed linear regression models.

**Results:** We studied 40 patients with SCI, 54% of them men and 46% women, with a mean age of 59.5 years (57.3–63.5). The 58% of patients showed thoracic injuries, 48.6% paraparesis and 46.7% presented level C in Asia scale. The baseline study was performed in 100% of patients (n=40), 65% in month 6 (n=26), 30% in month 12, and in 25.5% in month 18 (n=9). The 32.4% of patients received supplementation with calcium and vitamin D at month 0, 66.7% at month 6 and 100% at month 12.

In month 6, the 11.1% was treated with antiresorptive drugs. An increase in vitamin D values can be observed in the population with follow-up (values of 16.82 in month 0 to 39.33 in month 12), justified by the supplementation, and there is an increase in Calcium and a decrease in phosphorus values.

There was also a decrease in PTH levels in month 12 (32.3) compared to month 0 (34.08), as well as a decrease in bctx levels. Probably related to the increase of vitamin D intake.

Despite a decrease in the densitometric parameters at month 6, a slight recovery was observed in bone mineral density at month 12. No bone fractures were seen during Follow-up in none of the patients.

Results from biochemical markers and densitometry are showed in the table below.

### Conclusions:
A high percentage of our patients with spinal cord injury has a vitamin D deficiency. In addition, the lower values are associated with cases where the mobility limitation is higher. As patients increase vitamin D values, a decrease in the bctx and PTH parameters is observed.

No fractures were detected during follow-up.

**EPIDEMIOLOGY AND ANALYSIS OF FALLS IN PATIENTS DURING BALNEOTHERAPY IN DANUBIUS HEALTH SPA PIESTANY**

I. Rybar, V. Kolinoka, T. Zimanova, R. Gaspar. Department of Rheumatology, National Institute of Rheumatic Diseases; Department of Physiotherapy, Danubius Health Spa, Piestany, Slovakia

**Background:** Patients falls in hospitals are frequent and undesirable complications that may lead to negative outcomes such as injuries, prolonged hospitalization and legal liability.

**Objectives:** To investigate the incidence and characteristics of patients hospitalized in the Health Spa Piestany.

**Methods:** Prospective analysis of falls in the group of in-patients of health spa during a year since 01.01.2015 to 31.12.2015.

**Results:** Overall there were hospitalized in the health spa 25 774 in-patients. The mean age of patients was 64,02±13,16 years. There were women - 15 301, mean age (63.81±11.57) years and men 10 473, with mean age (64.43±9.22) years. Falls were confirmed in 131 patients (women 94, mean age 68.55±12.02 years and men 37 males, mean age 70.39±7.82 years. Fractures have been confirmed in 19 patients, all of them non-vertebral. The ankle distortion were in 11 patients and lacerated wounds in 10 patients. There were collapse status in 8 and commotoe cerebri in 1 patient. Spa therapy had to be discontinued only in 5 from 131 patients due to falls. The annual incidence of falls reached 5,08 cases/1000 patients.

**THE EFFICACY AND SAFETY OF DENOSUMAB LOCAL EXPERIENCE**

J. Al-Saleh, N. Salah, A.S. Hasan, M. Mohamad, F.A. ElBadawi, M. Khamasha. Rheumatology Department, Dubai Hospital, Dubai, United Arab Emirates

**Background:** Denosumab was introduce to the United Arab Emirates Market in 2013. Given the limited experience in using Denosumab in the region we have explored it efficacy and safety in daily practice.

**Objectives:** To assess the efficacy and safety of Denosumab in our practice.

**Methods:** Inclusion criteria: All patients received Denosumab in a dose of 60mg every six months. Underwent DEXA scan in Dubai Health Authority. Exclusion from analysis: Other Doses of Denosumab, who received less than 3 doses, and those with no follow up DXA scan. Outcome measures: 1) Efficacy: Proposed Criteria for Assessing Clinical Response [1,2], a) “inadequate”: incident fracture and significant BMD decrease. b) “possible inadequate”: incident fracture or Significant BMD decrease. c) “appropriate”: no fracture and stability or increase in BMD. 2) Safety: Reviewing the medical records and conduct patients interview for occurrence of the following adverse events. Statistical analysis: Descriptive statistical analysis, Graphpad Prism 6 was used.

**Results:** 143 patient identified. Out 139 patients 86 were eligible for analysis (See table 1). At baseline 39% had normal vitamin D level, 57% had insufficiency and 4% had deficiency. 20 of 86 did not undergo repeated DXA scan. 9% had osteoporia and 91% had osteoporosis before initiating Denosumab in comparison 8% had normal bone mineral density, 45% had osteopenia and 47% post four injections of Denosumab. Table 2 summarize the comparison between the responders and non-responders. There was a significant positive correlation in the increase in bone mineral density among the responders at the femoral neck and the lumbar spine. (r=0.56, 95% confidence interval: 0.31–0.74, P-value <0.0001)

AB0840 LOCAL FRACTURE LIASON SERVICE (FLS): PRELIMINARY RESULTS

J. Rosas 1, C. Cano 1, M. Lorente 1, A. Pons 1, E. Salas 1, T. Linares 2, M. Hernández 2, J.M. Senabre-Gallego 1, M. Marco-Mingot 4, J.D. Alvarado 2, G. Santos-Soler 1, H. Arcos 1, A. García 1, J. Hernández 2, J.J. Jiménez 2, X. Barber 2, C. López 2, M.D. López 2, A.M. Molinó 2, B. Statti 2, M. Sanchis-Seila 5 on behalf of FLS-HMB and AIRE-MB Groups. 1Rheumatology Department; 2Traumatology Department; 3Radiology Department; 4Laboratory Department, Hospital Marina Baixa, Villajoyosa (Alicante); 5CIO, Universidad Miguel Hernández, Elche, Spain.

Background: Hip fracture has great impact on morbi-mortality, but a large percentage of patients do not receive treatment.

Objectives: To know the characteristics of patients with hip fracture and its evolution in the first 6 months.

Methods: A prospective, 6-month follow-up study of patients over 60 years old admitted for hip fracture, evaluated in a local FLS. At 3 months after discharge, patients are evaluated for: epidemiological data, fracture income (days of admission, prior and discharge of osteoporosis (OP) drugs, general biochemistry and vitamin D), OP records and possible diseases or osteoporizing drugs, lumbar spine and hip Bone densitometry (BMD) lateral dorsal and lumbar spine radiology and the treatment was decided. The electronic history before and after the fracture were reviewed.

Results: Of 152 patients >60 years old, admitted in 2016 due hip fracture, 77 (51%) were during the first 6 months. However, radiology or BMD data were not available for 30 (39%) patients, 16 (21%) for death and 14 (18%) for loss of follow-up. Mean BMI was 26.02±6.2. The mean age of menopause was 49±5 years. 1% of the patients received corticosteroids and 2% of patients an osteoporosis disease (COPD) was found. Mean time of admission was 7.57±2.51 days. In 3% of the patients, before the fracture were receiving OP treatment, which continued to discharge. The mean level of calcium, phosphorous and alkaline phosphatase was normal. However, the mean level of 25OH vitamin D was 13.55±8.63 nm (range: 12 to 25 ng/ml).

In 11 of the 27 (41%) patients, in whom radiology was available, the presence of vertebral fracture was demonstrated. The mean T-score for lumbar BMD was 1.8±1.65 DE (32%; the result was normal, 36% osteopenia, 32% OP), femoral neck 2.5±0.77 DE (27%; osteopenia, 77% OP) and in total hip: 2.5±0.86 DE (56%; osteopenia and 44% OP). In 100% of patients evaluated in Rheumatology, initiated treatment for OP: zolodronate: 40%; alendronate: 20%, denosumab: 25%; PTH: 15%.

Conclusions: In patients with hip fracture: 1) Mortality is high (21%), in the first 6 months after fracture, 2) The prevalence of vertebral fracture is 40%. 3) It is accompanied by very low blood levels of vitamin D. 4) In a high percentage the result of BMD is normal or osteopenia. 5) A minimum number of patients receive specific treatment for osteoporosis after fracture. 6) Evaluation in a FLS, ensures the evaluation and treatment of patients.

AB0841 MEDICAL AND SOCIAL CONSEQUENCES IN HIP FRACTURES DEPENDING ON THE METHOD OF TREATMENT

J.V. Averkieva, T. Raskina. State Medical University Kemerovo, Kemerovo, Russian Federation

Background: medical and social significance of osteoporosis is determined by its consequences - fractures of the vertebrae and the bones of the peripheral skeleton. Osteoporosis is one of the high rates of mortality and disability among older adults.

Purpose: to follow basic health and social consequences among the surviving patients with hip fractures aged 50 years or older at 6, 24 months.

Objectives: The study included 432 patients (328 women and 104 men) with hip fracture and accompanying osteoporosis. The study assessed the risk factors and the impact of treatment on the consequences of osteoporosis fractures.

Methods: Surgical treatment was performed in 171 (40.04%) patients, conservative - 34 (7.8%) (p<0.0001). After 24 months from the time of the fracture using surgical treatment, restoration of function was observed in 72 (57.6%) and 32 (27.35%) patients who received surgical and conservative treatment, respectively (χ2=4.62, p=0.031).

Conclusions: the obtained during this study data suggest that the immediate and long-term consequences in patients with a fracture of the proximal femur depends on the method of treatment. Surgical treatment is the method of choice for the treatment of patients with this type of fracture.

AB0842 SARCOPEania AND OSTEOPOROSIS IN PATiENTS WITH RHEUMATOID ARTHRiTHiS

K. Amirov, Medical Radiology, Tashkent Institute for Postgraduate Medical Education, Tashkent, Uzbekistan.

Background: Musculoskeletal disorders in RA are characterized by lesions of the peripheral joints, the development of local and systemic osteoporosis (OP), as well as a decrease in muscle mass and strength, which are currently being considered within the framework associated with chronic diseases syndrome and are accompanied by cachexia and sarcopenia.

Objectives: To determine the prevalence and the relationship between sarcopenia and OP in patients with RA.

Methods: 156 RA patients were examined, of whom 83 postmenopausal women (mean age 61.7 years) and 73 males (mean age, 59 years). The control group consisted of 35 healthy subjects matched for age and sex. Exclusion criteria were: other rheumatic and endocrine diseases, severe somatic diseases, cancers, etc. The states of bone mineral density (BMD) at the lumbar spine (L-1-L-4) and femoral bone were assessed by dual-energy X-ray absorptiometry (DXA).

Results: Most RA patients (83% women and 83% men) were decreased in BMD of osteoporosis (OP) level. BMD were negatively correlated with radiographic stage of RA, the DAS 28 and HAQ. IPC also revealed significant correlations with laboratory parameters such as creatinine, total protein, albumin, rheumatoid factor, and 1,25 (OH) D. Investigation of body composition showed a statistically significant reduction ITM RA patients compared to the control group, with no differences between the groups for fat mass. Sarcopenia had 25% of women and 55% men with RA, whereas the control groups, 8.7% and 0%, respectively. The majority of patients of both sexes sarcopenia observed on the background of the normal range of body fat index. Status of TM in patients with RA was statistically significant (p<0.05) associated with femoral BMD and lumbar spine (r=0.3), BMI (r=0.5), force compression (r=0.4) RA radiographic stage (r=0.4), indicators of total protein (r=0.5).

Conclusions: Patients with RA, together with OP/sarcopenia have a significant reduction in muscle (lean) mass. Sarcopenia in patients with RA was observed in the majority of men (55%) and 25% of women, significantly more than the control groups. Implementation of the DRA with the program “whole body” will allow to identify not only bone, but also muscle loss in RA patients, which will help to intensify targeted therapy.

AB0843 RELATIONSHIP BETWEEN THE HISTOLOGICAL CLASSIFICATION OF MARSH AND THE AFFECTATION OF THE BONE METABOLISM IN PATIENTS WITH A RECENT DIAGNOSIS OF CELIAC DISEASE

L. López 1, M. Larrea 2, A. Erra 1. 1Rheumatology; 2Gastroenterology, Hospital San Rafael, Barcelona, Spain

Background: Celiac disease is a chronic autoimmune pathology that affects people with genetic predisposition, caused by a permanent intolerance to gluten. Its prevalence has been estimated at around 1% but about 30% of patients are diagnosed after age 60. Its diagnosis is made through clinical data, serological markers, study of duodenal biopsy (BD) and response to the gluten-free diet. The histological study (Marsh classification) remains the gold standard to the diagnosis and allows classification of the disease in 4 types: grade I (less histological lesion) of Marsh and the bone metabolism in patients with a recent diagnosis of celiac disease.

Objectives: To evaluate if there is a relation between the histological classification of Marsh and the bone metabolism in patients with a recent diagnosis of celiac disease.

Methods: Prospective study, which included all patients with a recent diagnosis of celiac disease by the Digestive Service during the period 2014–2016. This diagnosis was made through a clinical, serological (anti-transglutaminase IgA, anti-endomysium IgA), histological BD and genetic study (HLA DG2 and HLA DQB). All patients underwent a study of phospho–calcium metabolism including: calcium, phosphatemia, vitamin D, PTH, alkaline phosphatases, 24-hour calciuria and a densitometric study (BMD). We present the inclusion data of these patients.
Results: 15 patients were included: 11 women and 4 men, with a mean age of 42.2 years (SD±16). The genetic study was performed in 12 patients: 75% were positive for HLA DQ2 and 25% for HLA DQB. The determination of antibodies was positive in 12 patients (73%) and negative in 3 (18%). These 3 were positive for the genetic study (2 HLA DQ2 and 1 HLA DQB). The study of BD showed: type I in 4 patients; Type IIa in 2 patients; Type IIb in 6 patients; Type IIIC in 3 patients. BMD showed normal values in 33%, osteopenia in 47% and osteoporosis (OP) in 20% of patients. Thus, 67% had an alteration in BMD at the time of diagnosis. 100% had a Vit D deficit, with a mean value of 14.3 ng/mL (range 4.15–26.8). 75% of them had values below 20 ng/mL (40% less than 10 ng/mL). 40% had secondary hyperparathyroidism (SHP), 83% of which had an alteration in BMD (67% osteopenia and 16% OP). The BD of the patients with SHP and alteration of the BMD showed a histological pattern type Marsh III. No patient presented an alteration in the values of calcemia, phosphataemia or calcuria.

The relationship between the degree of alteration in BMD and the Marsh classification (table) was studied. 72% of patients with a Marsh III had an alteration in BMD (3 OP and 5 osteopenia vs 3 normal).

Conclusions: Most patients with celiac disease have an alteration in BMD. In our study, all patients with celiac disease had a Vit D deficiency with no alteration of calcemia or calcuria. Only in patients with SHP, there is a correlation between alterations in BMD and a higher degree of Marsh. Most patients with a histological Marsh III have abnormalities in BMD.

AB0845 FALSIS: RISK AND PREVENTION IN PRIVATE RHEUMATOLOGY PRACTICE

L. Poulain1, V. Zrostz2, X. Grapton3, P. Lemesle4 on behalf of Groupe CREER.
1Private Rheumatology Practice, la Garenne-Colombes; 2Private Rheumatology Practice, Antony; 3Private Rheumatology Practice, Colombes; 4Private Rheumatology Practice, Bois-Coulombes, France.

Background: Menopausal and osteoporotic women have a higher risk of fractures when falling. Fall prevention is important when taking care of those women.

Objectives: After identifying fall risk factors, defining the % of fractured fallers and the part of osteoporotic women in this population, we want to evaluate the relevance of balance tests and to favor prevention measures for those patients.

Methods: 110 patients, 60 years and older (including 24 controls), having fallen within a year, have seen 28 private practice rheumatologists in the larger Paris area and were subject of our multicentre retrospective study.

Results: Fallers mean age was 75 years. 37% of the fallers within a year fractured after falling. Among them, 95% were post-menopausal fractures versus 64% when including the control group. After dexamethasone was given to all groups except the blank group to induce osteoporosis, the rats in different groups were treated with saline, MDP, or different doses of

AB0846 TECHNETIUM-99 CONJUGATED WITH METHYLENE DIPHOSPHONATE AMELIORATES GLUCOCORTICOID INDUCED OSTEOPOROSIS IN RATS

L. Shi1, Y. Ning2, J. Li1, F. Hu2, X. Zhang3, 1Peking University International Hospital, 2Peking University People's Hospital, Beijing, China

Background: 99Tc-MDP has been used in Chinese RA patients for over 15 years and many more studies have focused on this agent in RA. However, the previous studies limited in its effect on the effects of anti-inflammation. As a special form of bisphosphonate, the anti-osteoporotic effect of 99Tc-MDP is unclear.

Objectives: To systematically investigate the effect of technetium-99 conjugated with methylene diphosphonate (99Tc-MDP), an anti-inflammatory drug effective in treating rheumatoid arthritis (RA), on cortical and cancellous bones in glucocorticoid-induced osteoporotic (GIO) rats, as well as comparing the effect of

Methods: Forty-eight Sprague-Dawley rats were randomly divided into six groups: blank, negative control, high dose, medium dose, low dose, and positive control groups. After dexamethasone was given to all groups except the blank group to induce osteoporosis, the rats in different groups were treated with saline, MDP, or different doses of

AB0847 OSTEOPOROSIS AND ATHEROSCLEROSIS - ALTERNATIVE OR COEXISTENCE

L. Lagvilava. Rheumatology, Clinic "Consilium Medulla", Tbilisi, Georgia

Background: The majority of scientific research data promote the idea that OP and Atherosclerosis are inter-connected via OPG system. Scientists have speculation that OPG is the molecular bond between artery hardening and bone resorption. Thus the mechanism explained above makes obvious the co-existence of two: Artery hardening and Osteoporosis.

Objectives: There are number of ongoing Clinical trials on Denosumab therapy in preventing diagnosis of Osteoporosis and Atherosclerosis. The increase of Bone mineral density is associated with less intensive hardening of arteries. This fact inspired us to study bone mass in patients with cardiovascular events and atherosclerosis.

Methods: 1675 men, age range 38–78 years, mean age 59±4.3 Disease duration 6.4±1.75 with the diagnosis of Atherosclerosis (revealed on coronaryography, assessed lipid profile). At the moment of research Stable Angina Pectoris (Stable Angina) found in 20% (335); unstable angina non-ST elevation in 48% (804); - Myocardial Infarction 32% (536) Bone Mass was assessed by DXA Absorbtimetry technique (Hologic 1000) and T and Z Scores (WHO 1994). As a control group 680 healthy Georgian men 40–70 age range were assessed.

AB0848 OSTEOPOROSIS AND Atherosclerosis - ALTERNATIVE OR COEXISTENCE

L. Lagvilava. Rheumatology, Clinic "Consilium Medulla", Tbilisi, Georgia

Background: The majority of scientific research data promote the idea that OP and Atherosclerosis are inter-connected via OPG system. Scientists have speculation that OPG is the molecular bond between artery hardening and bone resorption. Thus the mechanism explained above makes obvious the co-existence of two: Artery hardening and Osteoporosis.

Objectives: There are number of ongoing Clinical trials on Denosumab therapy in preventing diagnosis of Osteoporosis and Atherosclerosis. The increase of Bone mineral density is associated with less intensive hardening of arteries. This fact inspired us to study bone mass in patients with cardiovascular events and atherosclerosis.

Methods: 1675 men, age range 38–78 years, mean age 59±4.3 Disease duration 6.4±1.75 with the diagnosis of Atherosclerosis (revealed on coronaryography, assessed lipid profile). At the moment of research Stable Angina Pectoris (Stable Angina) found in 20% (335); unstable angina non-ST elevation in 48% (804); - Myocardial Infarction 32% (536) Bone Mass was assessed by DXA Absorbtimetry technique (Hologic 1000) and T and Z Scores (WHO 1994). As a control group 680 healthy Georgian men 40–70 age range were assessed.

Disclosure of Interest: None declared

deteriorated than cortical 3. Correlation between T Score values and clinical forms of Atherosclerosis were not observed 4. The best understanding of interrelations of bone mineral density (BMD) is the main diagnostic tool in osteoporosis, and it is the most effective and accurate measurement for identifying and monitoring the disease. However, several studies have been conducted with the object of detecting whether these skeletal changes in the mandible are specific to the osteoporotic stage.

Objectives: The purpose of this study was to determine whether the mandibular indices on panoramic radiographs are useful for identifying women with osteoporosis or osteopenia (low BMD).

Methods: Tunisian women aged from 30 to 60 years, who consulted the Rheumatology department of Fattouma Bourguiba university hospital in 2017. The mean BMD using the dual-energy X-ray absorptiometry (DEXA), were recruited to participate in this case-control study. Among the 60 women selected, 30 were diagnosed with osteoporosis or osteopenia (T-score < -1; cases) and 30 with normal T-score (T-score > -1; controls). The mandibular cortical index (MCI) and the panoramic mandibular index (PMI) were measured from digital panoramic radiographs in the right and left mandibles and the mean was calculated for each subject. The M, PMI and M/M ratio values were evaluated using the Z test, and the MCI was evaluated using the Chi2 test.

Results: The mean age of patients with osteoporosis/osteopenia was 58.61±8.11 and 56.07±9.72 in the control group. The mean bone mineral density (BMD) in vertebral site was 0.856±0.090g/cm² and 1.216±0.185g/cm² in control group. In femoral site, it was 0.877±0.221g/cm² and 1.061±0.142g/cm² respectively. The mean T-score in vertebral site was -2.38±0.185D in osteoporosis/osteopenia group and 0.64±1.58DS in control group. In femoral site, it was -1.57±0.97DS and 0.21±1.16 respectively. The analysis of the panoramic radiography showed that in the osteoporosis/osteopenia group: the mean value of M was 3.56±0.89, the mean PMI was 0.255±0.06 and the mean M/M ratio was 0.71±0.14; concerning the MCI: 46.7% were classified C2 stage and only 16.6% were classified C1 stage. This study showed that the M and the PMI were significantly smaller in the group with osteoporosis/osteopenia. However, the M/M ratio was not significantly different. Therefore, the MCI was significantly more affected in the osteoporosis/osteopenia group.

Conclusions: In our study, we proved that the M, PMI and M/M values were affected in women with osteoporosis/osteopenia, compared with normal patients. Therefore, these indices could be used as an ancillary method in the diagnosis of osteoporosis in women.

AB0849
ASSOCIATION BETWEEN PERIODONTITIS AND OSTEOPOROSIS

M. Brahem 1, M. Gugirm 1, M. Khemiss 2, I. Chababni 2, E. Chebil 3, M. Yones 4, T. Ben Aliya 2, M. Ben Khelifa 2, I. Bejia 1, M. Touzi 1, S. Zrour 1, N. Bergaoui 1, 1Rheumatology; 2Stomatology; 3Fattouma Bourguiba Hospital Monastir, Monastir; 4Maxilla-Facial; 1Rheumatology, Tamer Star Mahdia, mahdia, Tunisia

Background: Both periodontitis and osteoporosis have similar sign of bone resorption and have multifactorial etiological factors, although the mediator factors or mechanism may be different. How to prevent and treat these two bone-loss diseases is always an important issue in public health. However, the relationship of them is still uncertain.

Objectives: The aim of our study is to evaluate the relationship between periodontitis and osteoporosis.

Methods: Tunisian women aged from 30 to 60 years, who consulted the Rheumatology department of Fattouma Bourguiba university hospital between February to December 2017. The measure the bone mineral density (BMD) using the dual-energy X-ray absorptiometry (DEXA), were recruited to participate in this case-control study. Among the 60 women selected, 30 were diagnosed with osteoporosis or osteopenia (T-score < -1; cases) and 30 with normal T-score (T-score > -1; controls). The oral examination was done by a dentist in the stomatology department in the same hospital.

Results: The mean age of patients with osteoporosis/osteopenia was 58.61±8.11
[51–56 and 57-72 in the control group.]The mean bone mineral density (BMD)in vertebral region was 0.856±0.095g/cm² and 1.216±0.185g/cm² in control group. In femoral site, it was 0.877±0.221g/cm² and 1.061±0.142g/cm² respectively. The mean T-score in vertebral site was -2.387±0.814 DS in osteoporosis/ osteopenia group and 0.643±1.587 DS in control group. In femoral site, it was -1.577±1.670 and 0.513±1.162 respectively.

The study showed an excessive tooth mobility in 60% and 36.7% of controls without a significant difference, a gingival recession in 50% and 30% of controls, the presence of periodontal pockets in 23.3% and 16.7% of controls without a significant difference, a plaque index ≥2 in 53.3% of osteoporosis/osteopenia patients and 63.3% of controls and a non rectilinear trajectory of mouth opening in 13.3% and 3.3% of controls.

Conclusions: Our study showed that patients with osteoporosis or osteopenia have a poor oral hygiene, but without significant difference with control group. However, patients who were diagnosed as osteoporotic must pay more attention to their periodontal health. Good oral hygiene maintenance might be a crucial factor for preventing the deterioration of osteoporosis progressing.

Conclusions: The majority of our patients had improvements or stability in bone mineral density T-scores with only 20% experiencing side effects. Our results show that the vast majority of our patients are treated with zoledronate in concordance with guidelines. Nonetheless we can make improvements in recording FRAX scores and monitoring vitamin D levels. This has been highlighted to the multidisciplinary osteoporosis team and changes have been instigated. We plan to reaudit in due course.

AB0852 INCREASED INFECTION RATE WITH CONCOMITANT RANK LIGAND INHIBITOR DENOSUMAB AND BIOLOGIC THERAPIES FOR RHEUMATIC DISEASES: REALITY OR ILLUSION?

EXPERIENCE WITH 40 PATIENTS OVER 66 MONTHS AT THE UNIVERSITY OF SOUTHERN CALIFORNIA

P.S. Chhibbar, G. Ehresmann. Rheumatology, University of Southern California, Los Angeles, United States

Background: Patients with autoimmune diseases are at increased risk of early onset osteoporosis due to multiple reasons including prolonged exposure to corticosteroids and the disease process itself in RA patients. Same patients are more likely to be on TNF inhibitors or other biologics, which causes them to be at an increased risk of infections. Denosumab, an anti-RANK ligand inhibitor, itself a biologic, used to treat osteoporosis, is associated with increased infection risk as Receptor activator of nuclear factor kappa B ligand (RANKL) is also expressed on activated T and B lymphocytes (1). It is unknown if there is an added risk of infections when TNF inhibitors/biologic agents and denosumab are used concomitantly.

Objective: To determine if denosumab and biologics are associated with increased infection risk.

Methods: Data was collected and analyzed on 40 patients in the rheumatology clinic who had been on denosumab and TNF inhibitor/ other biologic for 66 months at the Keck Medical Center of USC.

AB0851 ZOLEDRONATE AUDIT – ARE WE MEETING EUROPEAN GUIDELINES?

N. Begum1, A. Khan1, A. Nandagudi2. 1Rheumatology/General Medicine; 2Rheumatology, Basildon & Thurrock NHS Foundation Trust, Basildon, United Kingdom

Background: Zoledronate is recommended by European guidelines for the treatment of osteoporosis particularly where first-line oral drugs are ineffective or contraindicated. EULAR’s guidelines are complemented by UK organisations including the National Institute of Health and Care Excellence (NICE), National Osteoporosis Guidelines Group (NOGG), British Society of Rheumatology (BSR) and the National Osteoporosis Society (NOS).

Objectives: The aim of our audit was to ascertain whether our use of zoledronate was compliant with current guidelines and review the real life experience.

Methods: We performed a retrospective audit of fifty patients who were commenced on zoledronate for the treatment of osteoporosis during 2012–2016 in our Trust. Data gathered included the reasons for commencement, whether patients had appropriate monitoring and the effect it had on DXA and FRAX scores.

Results: The age ranged from 44–88 years; 67% were between 60–80 years with 80% females. Vertebral fracture fragility were the most common type of fracture (42%), Zoledronate was commenced primarily because of either intolerance or inefficacy to oral anti-osteoporotic treatment (Table 1). It was commenced as first line in 20% because of contraindications to oral drugs. Almost 70% of our patients received zoledronate for two or three years. There was an improvement by 43% and 38% in the DXA T-score for the spine and hip respectively. Stable T-scores were recorded for the spine and hip in 49% and 54% respectively, whereas 8% deteriorated. Three patients sustained a fragility fracture and a further 11 experienced side effects (Table 2); five patients consequently stopped treatment. Only 3% had recorded FRAX scores pre- or post-zoledronate treatment. All of our patients had their calcium and renal function measured before each zoledronate infusion whilst over 80% had their vitamin D checked. All of our patients had dental checks prior to treatment. Following post-treatment DXA scans 46% continued zoledronate and 16% were on a drug-free holiday. A third were switched to denosumab due to ineffectiveness, side effects or contraindications.
Denosumab has become a useful parental therapy for the treatment of postmenopausal women with osteoporosis. The annual BMD of the lumbar spine showed a 9.11% increase, while also positive changes were noted in the proximal femur as a 1.89% increase. The BMD changes were 11% (L: Lumbar spine) and 1.1% (F: Femur) for the T-scores >-4.0, 6.3% (L) and 0.9% (F) for the T-scores -3.0~ -4.0, and 3.8% (L) and 0.5% (F) for the T-scores >=-3.0 respectively. This study suggests that Ibandronate (Bonviva®) treatment in postmenopausal women with osteopenia or osteoporosis is effective in terms of improving BMD.

**DENOSUMAB: CLINICAL PERSPECTIVE AND DRUG SURVIVAL IN A SECONDARY CARE SET UP IN UK**

**Rheumatology, Queen's Hospital, Burton on Trent, United Kingdom**

**Background:** Denosumab has become a useful parental therapy for the treatment of osteoporosis. FREEDOM extension study has shown safety and effectiveness of denosumab beyond 8 years. Real life data on the efficacy and safety of denosumab is lacking. There are no studies looking at the drug survival in postmenopausal women with osteoporosis population either. Observational data from clinical practice can provide unique clinical perspective for novel therapies like denosumab.

**Objectives:**
1. To look at the baseline characters of patients receiving denosumab in a secondary care unit in UK.
2. To study the drug survival rate, analyse the reasons for discontinuation of therapy.
3. To assess fractures during the course of denosumab therapy.

**Methods:** We looked at the case records retrospectively of all the patients receiving denosumab therapy from 01/01/2011 to 31/12/2016. A database to record baseline characters, indications and previous fracture was prepared. Renal function, calcium, alkaline phosphatase (ALP), vitamin D levels at baseline and renal function, calcium and ALP levels for each injection visit were noted. Vitamin D status was assessed at least once a year. Reasons to stop therapy were recorded.

**Results:** 237 patients were offered the treatment. One patient declined the treatment at the beginning. 5 (2.1%) patients had fracture on treatment. 2 had a hip fracture and one of them had a previous fracture (humerus). Other fracture sites were ankle, humerus and metatarsal. None of them had any further fractures during the follow up period. 61 patients discontinued therapy during the course of treatment over 3 years. 8 (4.2%) had infections, 7 (3.6%) due to declining eGFR and 9 (4.7%) were lost to follow up. 1 patient had jaw necrosis after the first injection. 1 developed hepatitis after the first injection which resolved on withdrawal of therapy. 6 (3.1%) patients withdrew consent for therapy. 19 (8%) patients died causes unrelated to denosumab therapy. 23 (9.7%) patients moved away. Treatment was stopped due to other side effects in 3 patients (2 had rash and 1 headache). There were no reports on hypersensitivity, hypercalcemia.

**Conclusions:**
1. Majority patients were elderly and female. Majority were high risk and had received osteoporosis treatments previously.
2. Denosumab therapy was well tolerated and nearly 2/3rd were still receiving therapy at 3 years. Treatment was withdrawn due to an adverse event in only 14 (6%) patients.
3. Fracture rate was very low and there were no repeat or multiple fractures.

**THE BMD CHANGE AFTER IBANDRONATE (BONVIVA®) TREATMENT IN OSTEOPENIC POSTMENOPAUSAL WOMEN**

S.E. Park, K. Choi.

Orthopaedic Surgery, Dongguk University International Hospital, Seoul, Korea, Republic Of

**Background:** Ibandronate (Bonviva®) is effective in the treatment of postmenopausal women with osteoporosis. But, there were few data about Ibandronate (Bonviva®) treatment in Korea. We evaluated the effect of Ibandronate (Bonviva®) therapy on bone mass and compared the effectiveness on bone mineral density (BMD) in 1-year treatment group.

**Objectives:** The aim of the study is to assess the effect of 1-year treatment with Ibandronate (Bonviva®) on bone mineral density (BMD) in postmenopausal women with osteopenia or osteoporosis.

**Methods:** The BMD was assessed in 118 postmenopausal women with osteopenia or osteoporosis from March 2007 to January 2011. 42 patients who treated with 2.5 mg per day of Ibandronate (Bonviva®) were enrolled to study. BMD of lumbar spine (L2-L4) and femur was assessed by dual energy absorptiometry at baseline, 12 months after treatment.

**Results:**
- The annual BMD of the lumbar spine showed a 9.11% increase, while also positive changes were noted in the proximal femur as a 1.89% increase. The BMD changes were 11% (L: Lumbar spine) and 1.1% (F: Femur) for the T-scores > -4.0, 6.3% (L) and 0.9% (F) for the T-scores -3.0~ -4.0, and 3.8% (L) and 0.5% (F) for the T-scores > -3.0 respectively.
- The 10-year risk of a major osteoporotic fracture was 20% in those with BMD measurements (P=0.001, P=0.002) respectively among male patients with BMD measurements (n=74).

**THE DISPARITIES BETWEEN FRACUTURE RISK ASSESSMENT (FRAX) WITH BMD AND WITHOUT BMD IN KOREAN PATIENTS WITH ANKYLOSING SPONDYLITIS- MULTICENTER TRIAL**

1 Division of Rheumatology/Dept. of Internal Medicine, College of Medicine, Inha University, INCHEON; 2 Division of Rheumatology/Dept. of Internal Medicine, College of Medicine, Chung-Ang University, Seoul; 3 Division of Rheumatology/Dept. of Internal Medicine, College of Medicine, Ajou University, Suwon; 4 Division of Rheumatology/Dept. of Internal Medicine, College of Medicine, Ulsan University, Gangneung Asan Hospital, Gangneung; 5 Division of Rheumatology/Dept. of Internal Medicine, College of Medicine, Keimyung University, Daegu, Korea, Republic Of

**Objectives:** The aims of this study are to determine the proportion of patients with ankylosing spondylitis (AS) at high risk for major osteoporotic and hip fractures of Fracture risk assessment (FRAX) in Korean and to determine if a care gap exists for high risk.

**Methods:** This study is a multicenter study including 163 AS patients in 5. All of the AS patients fulfilled the modified New York criteria. The classification of osteoporosis according to each AS Criteria was based on T-score < -2.5. The FRAX criteria for high risk of osteoporotic fracture, which is 10-year probability of ≥20% for major osteoporotic fracture or ≥3% for hip fracture, were calculated by the FRAX tool including the bone mineral density (BMD) values. We assessed various demographic factors, clinical and laboratory findings of AS, and medication use for AS and osteoporosis, and then evaluated the risk factors for osteoporotic fracture.

**Results:** The mean age of AS patients was 44.3 years, and 42 patients were female (25.2%) with 23 postmenopausal women 56.1%. Osteoporotic fracture was detected in 16 (9.8%) male and 14 (6.5%) female AS patients. Among the patients >65 years of age, 2 (12.5%) and 8 (50%) were at high risk for a major osteoporotic fracture (10-year probability >20%) and hip fracture (>3%), respectively. Among patients with BMD measurements (n=106), the 10-year risk of a major osteoporotic fracture was 36.5% in those without BMD measurements. (P=0.001, P=0.002) respectively among male patients with BMD measurements (n=74). There is no statistic difference of the 10-year risk of a major osteoporotic fracture

AB0856 T-SCORE OF THE SPINE AS PREDICTOR OF THE FEMORAL NECK FRACTURE

S.D. Jandric
Department for FRM, Faculty of Medicine, University of Barjala, Banja Luka, Republic of Srpska, Bosnia and Herzegovina

Background: Osteoporosis is defined as a progressive, systemic skeletal disorder characterized by low bone mass and micro-architectural deterioration of bone tissue with a consequent increase in bone fragility and susceptibility to fracture. There are numerous hip fracture risks. Bone mineral density (BMD) and T-score measured by dual-energy X-ray absorptiometry (DXA) are the main determinants of the clinical evaluation of hip fracture risk. World Health Organization classification defined osteoporosis as T-score below -2.5 SD.

Objectives: The aim of this study was to estimate differences in DXA measurements (BMD and T-score of the spine) and potential predictors of the femoral neck fracture in the patients with osteoporosis.

Methods: This study included 181 patients with osteoporosis (165 female and 16 male), average age of the 65, 6±5.8 years (range of 44.1 to 87.3 years). Eighty one patients had fracture of the femoral neck. All patients in this group were managed operatively by hip arthroplasty, after clinical and radiological diagnostic procedures. DXA measurement was performed on Advanced Prodigy Lunar densitometer. Reference for these patients was postoperatively. BMD of the femoral neck was measured on the no operated side. Age, sex, height, weight, BMI, BMD and T-score of the spine at the level of L1-L4, BMD of the right and left femoral neck were estimated. The control group included 100 patients with osteoporosis (93 female and 7 male), average age of the 65.1±8.5 years. Student’s t-test and Logistic regression were used for statistical analysis. Dependent variable was presence of the fracture of the femoral neck and independent variables were age, sex, height, weight, BMI, BMD and T-score of the spine and BMD of the femoral neck.

Results: Results of our study showed statistically significant difference between T-score of the spine (t=-2.973, p<0.001) as well as between BMD of the spine (t=-12.376, p<0.001) of patients with and without fracture of the femoral neck. T-score of the spine was significant predictor of fracture of the femoral neck (p<0.01) when controlled by age, sex, height, weight, BMI, BMD and T-score of the spine of the right and left femoral neck were estimated. The control group included 100 patients with osteoporosis (93 female and 7 male), average age of the 65.1±8.5 years. Student’s t-test and Logistic regression were used for statistical analysis. Dependent variable was presence of the fracture of the femoral neck and independent variables were age, sex, height, weight, BMI, BMD and T-score of the spine and BMD of the femoral neck.

Conclusions: T-score and BMD of the spine were statistically significantly lower in patients with fracture of the femoral neck than in patients with osteoporosis without fracture. T-score of the lumbar spine was significant predictor of fracture of the femoral neck in patients with osteoporosis. Probability of femur neck fractures increased with the decrease of T-score of lumbar spine in patients with osteoporosis. These results can help in predicting femur neck fractures.

AB0857 PROBLEMS OF DIAGNOSTICS AND PROPHYLAXIS OF GLUCOCORTICOID-INDUCED OSTEOPOROSIS IN REAL CLINICAL PRACTICE

S. Yakupova, R. Demidov. Kazan State Medical University, Kazan, Russian Federation

Background: Oral glucocorticoids (GC) are used in different medicine fields and appear as risk factors of glucocorticoid-induced osteoporosis (GIO).

Objectives: The aim is to estimate the frequency of use of prophylaxis of OP, use drugs that are approved for GC and also an awareness of GIO of patients with prolonged intake of GC.

Methods: 50 patients (10 men and 40 women), taking GC, took part in research. 30 patients (60%) were from rheumatology department, 5 patients (10%) from pulmonology department, 5 patients (10%) from gastroenterology department and 10 patients (20%) from nephrology department of Republic Clinical Hospital. Mean age of patients - 48.84±14.03 years (from 26 to 73). The following signs were estimated: clinical data, osteoporosis risk factors, instrumental tests (X-ray, densitometry). FRAX assessment of fracture risk was performed, the Questions A and B about osteoporosis risk factors were estimated.

Results: The duration of intake GC – 5,9±3.4; 5.8 years. Minimal dose of GC per day (if receiving prednisone) – 7.5 mg; maximal dose – 60 mg. 10-year risk of major osteoporotic fractures by FRAX, adjusted according to GC dose - 18.1±11.01, 32 patients (64%) were given recommendations for changing lifestyle and diet for GIO prophylaxis, 40 patients (80%) - recommendations for intake of calcium and vitamin D medications, but only 31 patients (62%) followed recommendations and started the intake of calcium medications. From the said number of patients only 14 patients (45.2%) used appropriate daily dose of calcium and vitamin D.

Discussions: Drugs that are approved for GIO were have to be prescribed for 18 patients, but only 6 patients (33.3%) underwent treatment, principally bisphosphonates. Only half of them underwent densitometry after starting the therapy. 72.2% patients with GIO used calcium and 30.7% were taking appropriate daily dose of calcium and vitamin D. 70% rheumatologic patients knew about GIO and in 90% cases calcium and vitamin D drugs were recommended. Only 50% of patients from non-rheumatologic departments knew about GIO and in 65% cases calcium and vitamin D drugs were recommended.

Conclusions: Clinical recommendations in real clinical practice are rarely applied. Glucocorticoids constitute a significant risk factor of GIO. 50% patients recommend pharmacological prophylaxis. Only half of patients received osteoporosis therapy, only half of them underwent densitometry. Patients are insufficiently informed about necessity of changing lifestyle and diet for GIO prophylaxis. Education for patients taking GC and training for rheumatologic and non-rheumatologic specialties are necessary.

AB0858 ASSOCIATION OF BONE MINERAL DENSITY WITH DEVELOPMENT OF HEART FAILURE IN DIABETIC PATIENTS

V. Vasilkova 1, T. Mokhort2, E. Naumenko 3, M. Zmailik 4.
1Endocrinology, Gomel State Medical University, Gomel; 2Endocrinology, Belarusian State Medical University, Minsk; 3Functional Diagnostics; 4Endocrinology, The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus

Background: Diabetes mellitus has shown to be a significant risk factor for the development and prognosis of heart failure (HF) and associated with an increased risk of fractures [1]. Osteoporosis and heart failure are generally considered two distinct diseases, but recent evidence suggests a link between both diseases.

Objectives: The aim of the study was to investigate the association of bone mineral density with the risk of developing heart failure in diabetic patients.

Methods: 85 patients both sexes with type 2 diabetes aged 58.69±9.07 years were studied. Besides standard laboratory parameters, the echocardiographic and BMD measurements were performed. Estimated glomerular filtration rate was measured.

Results: Among diabetic subjects, 8 patients (9.4%) had osteoporosis, 21 (24.8%) had osteopenia and 56 (65.8%) had a normal BMD. Increased serum NT-proBNP (p<0.001) and decreased left ventricular ejection fraction (EF) (p<0.03) were significantly correlated with low T-score L1-L4 cutoff points between groups (normal, osteopenia, and osteoporosis). Multivariable stepwise linear regression analysis of the significant variables revealed that NT-proBNP, EF were independent predictors of lumbar BMD among female patients with diabetes mellitus. After adjusting for age, gender, and related comorbidities, the osteoporosis group was associated with a significantly higher risk of coronary artery disease in women with diabetes. However, no association between BMD and HF was found in men.

Conclusions: Osteoporosis and bone mineral density may independently increase the risk of heart failure in women with diabetes mellitus. Our data suggested that early detection of abnormal BMD should warrant for early search of undetected HF in diabetic women. A further study is needed to elucidate the effects of BMD on cardiac function in diabetic patients.

AB0859 CAN ZOLENDRONIC ACID USE LEAD TO IMPAIR RENAL FUNCTION IN OSTEOPOROSIS PATIENTS?

Y.-C. Chen, C.-H. Ko. Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China

Background: Bisphosphonates are recommended in patients with osteoporosis patients, clinical concerns had been considered in kidney safety.

Objectives: This study investigated the safety of bisphosphonate effects on renal function in patients with magnetic resonance imaging (MRI)-proven acute osteoporotic vertebral fractures after vertebroplasty.

Methods: This retrospective study was conducted in osteoporotic patients with acute vertebral fractures treated with vertebroplasty between January 2001 and December 2005. Their gender, age, body mass index (BMI, kg/m²), co-morbidity were recorded, as well as their use of zolendronic acid. Those with increase in creatinine was defined as progression of renal function. Logistic regression was used to adjust the variables.

Results: There were 989 patients (783 females; mean age, 74.08±9.26 years).
Results: Activity and BTMs besides baseline data of every 6 months were utilized for analysis with respect to data of RA disease activity [DAS28-CRP, SDAI, CRP, MMP-3] and bone turnover markers (BTMs) and various data (baseline patients' characteristics, parameters of RA disease). The correlation coefficient was calculated between %increase of BMD at 24 months were measured at baseline and every 6 months until 24 months. Spearman's rank correlation coefficient which were correlated with %increase of LSBMD at 23 months were %increase of LSBMD at 6 months (0.61), baseline P1NP (0.33) and time averaged %decrease of TRACP-5b (0.30). Parameters (correlation coefficient) which were correlated with %increase of THBMD at 24 months were %increase of LSBMD at 6 months (0.42), %increase of THBMD at 6 months (0.69), baseline P1NP (0.36), time averaged %decrease of P1NP (0.37), baseline TRACP-5b (0.29) and time averaged %decrease of TRACP-5b (0.29). Although denosumab (DMB) at 24 months was not correlated with disease activity of RA, taCRP was significantly correlated with taP1NP (0.57) and taTRACP-5b (0.45).

Conclusions: DMB was effective in RA-OP. Early response of BMD, baseline values of BTMs and response of BTMs were suggested to be the predictors of the efficacy of DMB in RA-OP. Inflammation of RA was correlated with not BMD but BTMs.

Crystal diseases, metabolic bone diseases and bone diseases other than osteoporosis

## AB0861 EXPRESSION CONTROL BY METHYLATION OF THE TLR1, TLR2, TLR4, IL1B, ALPK1 SLC2A9 AND SLC22A12 GENES IN MONOCYTES OF PATIENTS WITH GOUT

N. Paniagua Díaz1, E.G. Tranquilino Batres1, A.P. LópezFlores2, A. Lozano Cardenas2, E. Vallarino Reyes2, A.L. AlvarezGrijalva2, L. Sanchez Chapul2, C. HernándezDíaz3, L. Villalobos3, A. Lopez Macay1,2, Enfermedades Neuromusculares, Instituto Nacional de Rehabilitación,2 Ciencias de la vida, Instituto de Estudios Superiores Monterrey;3 LUMA, Instituto Nacional de Rehabilitacion, Mexico City, Mexico

Background: The gout is an inflammatory multifactorial disorder where the diet, age, sex, absorption regulation of uric acid in kidney and genetic, contribute to the onset of the disease. The balance of uric acid concentration not only depends on metabolism of purines but also on the clearance of uric acid, in which many proteins participate in the reabsorption and transport of urate. Is unknown if the peripheral blood leukocyte cells can change their expression and regulation mechanism of the urate transporters by the presence of uric acid in these patients. The asymptomatic patients with a higher mean of uric acid expression and methylation analysis are designed specific primers which can analyze the gene expression and methyltion pattern of the TLR2, TLR4, SLC2A9, SLC22A12, SLC22A3 and ABCG2 in neutrophils and peripheral blood monocytes from patients with gout and controls

Methods: The isolation of peripheral blood monocytes and monocytes cells was performed by negative immunomagnetic selection (MACSpress kit, EUA). By flow cytometry were analyzed the previously separate cell populations, mononuclear (MN), polymorphonuclear (PMN) cells and neutrophils (N) (CD15, CD16, CD14). The DNA and RNA extraction was realized with a without columns kit and with trizol technique. Taq DNA polymerase, DNA polymerase (Taq DNA) and dNTPs were added to the reaction. The DNA standard samples were extracted with a without columns kit and with trizol technique. The DNA standard samples were extracted with a without columns kit and with trizol technique. The DNA standard samples were extracted with a without columns kit and with trizol technique. The DNA standard samples were extracted with a without columns kit and with trizol technique.

Results: The difference between asymptomatic gout patients (n=12) and controls (n=12), in the biochemical parameters (Table 1), in the higher levels of uric acid and triglycerides that the patient presents. Actually, we’ve already evaluated the genetic expression of TLR1, TLR2, TLR4 and IL1b in mononuclear cells of 5 asymptomatic gout patients and 5 controls (Pilot 1). Interestingly, IL1b is UP-regulated in sample group by a mean factor of 16.350 and TLR2 is UP-regulated in sample group in comparison to control group by a mean factor of 3.686.

THE SENSITIVITY OF THE DOUBLE CONTOUR SIGN IN HAND JOINTS WOULD BE BETTER BY THE DORSAL SURFACE EXAMINATION

A.M. Mahdi 1,2, H. Rkain 1, M. Erraoui 1, R. Watfeh 3, S. Aktaou 3, L. Tahiri 1,

OBJECTIVES:
To compare the prevalence of ultrasonographic gout specific sign double contour between the dorsal and palmar surfaces of the hand joints.

METHODS: This is a cross-sectional study which includes 15 patients with chronic gout, defined according to the American College of Rheumatology criteria (ACR 1977). Ultrasound (US) examination was performed using a high-frequency linear probe (Toshiba Xario®, frequency (8–14 MHz)) in B and Doppler modes. 560 articular sites were studied at their dorsal and palmar surfaces. We compared the prevalence of the hyperechoic band over the superficial margin of the articular cartilage described as a double contour (DC) between the dorsal and palmar surfaces at each site studied.

RESULTS: The mean age at onset was 54.7±12.6 years, and the median diagnosis duration was 0 (0.3) years.

The results of the US examination are summarized in Table 1

Table 1. comparison of double contour prevalence between the dorsal and palmar surfaces of wrist, MCP, PIP and DIP joints in the studied population

CONCLUSIONS: These preliminary results suggest that the popliteus groove could be regarded as a sentinel area for detecting MSU crystals. These findings lead to further investigations aimed at identifying the factors and associated with MSU crystals deposition at popliteus groove level.

DOI: 10.1136/annrheumdis-2017-eular.4462
than 6 month) was examined by clinical, laboratory, X-ray and ultrasonography. After investigation the following diagnoses were made: Gout in 32 patients, Osteoarthritis in 28 patients, Rheumatoid arthritis in 28 patients, Psoriatic arthritis in 16 patients. Ultrasound investigation of affected joints was performed in all subjects by linear probe 18 MHz. Urate crystal deposits were seen on the surface of the hyaline cartilage as a hyperechoic thin line or dots on the cartilage, wich sometimes imitate double contour of bones [2, 3]. Sensitivity and specificity of ultrasound sign were compared with subcutaneous tophi, bone cysts (X-Ray sign) and hyperuricemia.

Results: The urate crystal deposits in gyaline cartilage of at least one of affected joints were revealed in 28 of 32 (87.5%) patients with Gout, in 3 of 28 (10.7%) patients with Osteoarthritis and 1 of 16 (6.3%) patients with Psoriatic arthritis. Comparative data of sensitivity and specificity of crystal deposits, bone cysts, subcutaneous tophi and hyperuricemia are represented in table below. Table 1. Sensitivity and specificity of different diagnostic markers in yearly stage of gout

SERUM URATE AND ITS ASSOCIATION WITH RACE IN YOUNG ADULTS: BASELINE ANALYSIS FROM A RANDOMIZED CLINICAL TRIAL

M.B. Saddekni1, A.L. Gafio2, P.J. Foster3, S.R. Biggers2, E.J. Rahn2, P. Li3, K.G. Saag1. 1UB School of Medicine, Division of Clinical Immunology and Rheumatology; 2Department of Medicine, Division of Rheumatology and Immunology; 3UB School of Public Health, Department of Biostatistics, University of Alabama at Birmingham, Birmingham, United States

Background: Increased levels of serum urate (sUA) have been reported in association with hypertension, chronic kidney disease and obesity. All these conditions are over-represented in US African Americans, who also have greater environmental risk factors for hyperuricemia development including elevated fructose intake. Our group has previously reported that young African Americans have lower sUA concentrations than Caucasians after adjustment for clinical and demographic factors.

Objectives: To determine whether there is a differential association between sUA and race in young adults.

Methods: We examined baseline data on consecutively enrolled individuals (age 18 – 40 years) in an interventional study aimed at lower blood pressure (BP) through the administration of urate-lowering therapy. African Americans were over-represented in the sample by study design. Inclusion criteria included a sUA of ≥5.0 mg/dL for men or ≥4.0 mg/dL for women. After means comparisons between races, we performed multivariable adjustments for age, gender, BP, and body mass index (BMI) a multiple linear regression model. Data reported are mean ±standard deviation.

Results: 86 participants recruited from Birmingham, AL were included in the analysis. Participants had a mean age of 28.5±6.9 years, 36% were female, 41% were African Americans (AAs), and the mean BMI was 29.2±6.8 kg/m². The mean sUA was 5.9±1.2 mg/dL (n=77, range: 3.9 to 8.5 mg/dL). We found a significantly lower sUA for African Americans compared to persons of other races (5.4±1.2 mg/dL vs 6.2±1.1 mg/dL, p=0.005). After multivariable analysis the difference in sUA between AAs and other races was attenuated to non-significance (p=0.03) due to the effects of BMI and gender. As expected, the association between sUA and gender was significant (Table).

Conclusions: In this cross-sectional analysis of young adults, AAs had lower sUA concentrations than other races. However, this difference is explained by the effect of gender differences in sUA and BMI. A potential limitation is that participants were enrolled after they met a sUA threshold so not all the ranges of sUA in a normal population are represented in this analysis. Larger studies will be needed to fully address this question.

EVALUATION OF THE ACHIEVEMENT OF A THERAPEUTIC TARGET OF ≤6 MG/DL IN ALGERIAN PATIENTS TREATED FOR GOUT

B. Bengana1, S. Slimani2, K. Testas3, F. Rahal4, M. Makhloufi5, A. Ladjouze4, S. Lefki-Taliani1, 1Rheumatology, Department of Rheumatology -University Medical Centre Beni Messous, ALGIERS; 2Rheumatology, University of Batna, Batna; 3Rheumatology, El Kherroub Hospital, Constantine; 4Rheumatology, Ben Aknoun Hospital, ALGIERS; 5Medicine, University of Batna, Batna, Algeria

Background: Gout is one of the most prevalent rheumatic conditions in the developing world, due of the aging of the population and the modifications in the life style. The 2014 EULAR recommendations for the management of gout have defined the therapeutic target of 60 mg/L for gouty patients (recommendation 8). The aim of the study was to assess the adherence of Algerian patients with gout to these recommendations.

Methods: We have retrospectively analyzed patients files aged 18 and more, followed in a rheumatology setting for gout, in 4 centers in Algeria. Demographic, clinical and lab data were collected. We have excluded files with missing data. Were noted the used therapeutics and serum uric acid in every patient through time. Tolerance was noted.

Results: We have analyzed 145 complete files: 98 men (68%), with a mean age of 65.4±11.4 years. All patients except two had rheumatic manifestations, which joints and what findings should be assessed for diagnosing gout? Ann Rheum Dis. 2014;73(10):1522–1528.

Tolerance was noted.

Conclusions: In rheumatology settings in Algeria, more than 93% of gouty patients received allopurinol, with an excellent tolerance. However, it seems that dosage is insufficient, with only 58% of patients achieving the EULAR recommendation 8. More efforts have to be provided to optimize this therapy.

AB0867
PEGLOTICASE RE-TREATMENT AFTER A GAP IN THERAPY: DATA FROM TWO PHASE III TRIALS AND AN OPEN-LABEL EXTENSION STUDY
H.S. Baraf1, A. Morton2, B. LaMøreux3, J. Kent3, 1Medicine, George Washington University, Washington DC; 2Internal Medicine, Michigan State University School of Osteopathic Medicine, East Lansing; 3Medical Affairs, Horizon Pharma, Lake Forest, United States

Background: Pegloticase is a PEGylated recombinant uricase approved in the US for treating adult patients with chronic refractory gout. As a biologic medication, pegloticase is administered intravenously every 2 weeks. It is currently not known whether a gap in the standard biweekly regimen can be tolerated or will be associated with a loss of efficacy. During the pivotal trial testing of pegloticase, some patients experienced a delay before participation in the randomized control trial (RCT) after the open-label extension (OLE) that followed. Analysis of the clinical impact of this gap was carried out to understand whether therapeutic benefit would be affected.

Objectives: The objective of this analysis was to determine, among pegloticase responders, the effect of a 28 or more day gap between doses of pegloticase on the subsequent urate lowering response and frequency of infusion reactions.

Methods: These analyses utilized results from two RCTs of pegloticase and a 2-year OLE. In the RCTs, 36 of 85 patients, who were dose with pegloticase every two weeks, were classified as responders (persistent urate lowering during intensive monitoring at 3 and 6 months of the RCT), and went on to enroll in the OLE and receive additional doses of pegloticase. Of these 36 patients, 14 had a gap between pegloticase doses of more than 28 days.

Results: Among the 14 patients with a gap of more than 28 days between doses of pegloticase therapy the length of the gap ranged from 34 to 167 days (mean = 72.5 days, median = 59.5 days). Of these 14 patients, 8 received pegloticase on an every-4-week dosing schedule in the OLE and remained on every 2-week dosing. Ten of the 14 patients maintained their serum urate level <6mg/dl in the OLE. Five of 6 that remained on every 2 week dosing and 5 of 8 that went to every 4 week dosing continued to have se rum urate <6mg/dl. (see table 1). By logistic regression analysis, the length of the gap had no significant effect on the subsequent urate lowering effect of pegloticase. Of the fourteen patients with a gap in pegloticase therapy, 2 (14%) had infusion reactions during a total of 632 infusions in the OLE yielding a re-treatment IR rate of 0.32%.

Conclusions: The majority of patients in this limited dataset who were previously responders to pegloticase dosed every 2 weeks continued to maintain a serum urate lowering response to pegloticase after a gap in therapy. Infusion reactions during re-treatment occurred in 2 patients with a re-treatment infusion reaction rate of 0.32%.

IS IT APPROPRIATE TO DISCONTINUE COLCHICINE THERAPY IN GOUT PATIENTS IN REMISSION?
Y. Özdem’Inan 1, N. Alpay Kanıtez 2, S. Çelik 2, S. Yılmaz Öner 2, C. Bes 2, 1Bakırköy Dr Sadi Konuk Training and Research Hospital, Istanbul, Turkey; 2Rheumatology, Bakırköy Dr Sadi Konuk Training and Research Hospital, Istanbul, Turkey

Background: Colchicine can reduce the risk of recurrent attacks and it is an appropriate first-line gout attack prophylaxis therapy. There is limited data in the literature about duration of colchicine treatment in patients with gout disease.

Objectives: In this study, we aimed to investigate the frequency of gout attacks between patients with colchicine treatment and patients who are colchicine terminated.

Methods: 54 gout patients under colchicine treatment were enrolled to the study. The subjects were divided into 2 groups. Group 1 (n=19) was consisted of patients whom colchicine therapy was terminated because of remission for three months; group 2 (n=35) was consisted of patients on colchicine treatment. Groups were compared according to the existing of new gout attacks after the 3rd month. Baseline and the third months of the uric acid levels were also analyzed in each group.

Results: The body mass indexes, the disease intervals, the number of the attacks, and the duration of the attacks were not significantly different (p > 0.05 for all) (Table 1). Compared to the group 2, the newly gout attacks were not found to be different in group 1 for 3 months (p > 0.05) (Table 1). The uric acid levels were significantly decreased both in two groups (p < 0.05) (Table 2).

Conclusions: The colchicine is the mainstay treatment for gout disease. It not only prevents the attacks of the gouts also prevents the development of uric acid nephropathy and tocolgize the secondary gout attacks. This study showed that, in gout patients in remission, termination of the colchicine treatment does not affect the development of the new attacks as shown similar attacks were also observed in non-terminated patients.

AB0869
STRESS FRACTURES, A RETROSPECTIVE STUDY OF 325 FRACTURES IN 227 PATIENTS IN RHEUMATOLOGY PRACTICE BETWEEN 2000 AND 2015
C. Nourisson, J.-J. Dubost, B. Pereira, A. Tournade, S. Maloche-Guimand, M. Soubrier. CHU Clermont Ferrand, Clermont-Ferrand, France

Background: Stress fractures are common in both young and active patients (fatigue fracture) as well as in elderly osteoporotic patients (insufficiency fractures).

Objectives: The aim of this study was to describe characteristics of stress fractures treated in rheumatology at the Clermont-Ferrand University Hospital, to compare them according to their anatomic location (pelvis, lower limb or feet/ankle) and their diaphyseal or metaphyseal/epiphyseal location.

Results: Between 01/01/2000 and 12/31/2015, 325 fractures were identified in 227 patients divided in 176 women (including 116 postmenopausal women) and 51 men. Population average age was 65.2 years (15–99 years), 142 (43.7%) fractures occurred at pelvis, 93 (28.6%) at lower limbs and 87 (26.8%) at feet and ankles. The fracture was spontaneous in 63.6% of cases. History of pain was recorded in 92.3% with more frequently (90.3%) mechanical pain. Diagnostic delay was on average 70 days. In 51 patients (22.5%) an orthopedic factor could have promoted stress fracture.

Conclusions: 94 patients (23.8%) had a history of chronic inflammatory rheumatism, 28 (12.3%) of cancer, and 20 (8.8%) had chronic renal failure. Among the possible iatrogenic factors, 51 patients (23.4%) received oral corticosteroid therapy, 20 (9.2%) methotrexate, 59 (27%) proton pump inhibitor and 17 (7.8%) serotonin reuptake inhibitor. 49 patients (22.5%) already had vitamin-calcium supplementation, 37 (17%) received biphosphonate therapy. 56.6% were osteoporotic and 29.5% were osteopenic.

METABOLIC AND CARDIOVASCULAR GOUT ARE THE MOST FREQUENT CLINICAL VARIANTS OF THE DEBUTING GOUT

E. Mikhnevich 1, T. Pavlovich 1, E. Mytnik 2
1 Department of Internal Medicine, University of Medicine; 2 Diagnostic Center, Rheumatology Clinic, Minsk, Belarus

Background: Gout is phenotypically and genotypically heterogeneous. In most cases, renal mechanism plays an important role in the development of gout. At the same time, gout, as a rule, occurs on the basis of pre-existing comorbid pathology.

Objectives: To determine clinic-pathogenic variants of gout depending on a leading comorbid pathology at the gout debut.

Methods: We included 604 patients with confirmed gout from our Center database. During 2010–2016, comorbidities were registered before the gout onset, at its appearance, during and at the last examination. Metabolic syndrome (MS) was defined as follows: DM, obesity, dyslipidemia. CVD included CHD, atrial fibrillation, CHF and stroke. Patients after organ transplantation and with terminal renal failure observed in specialized centers were not recruited.

Results: In 67.1% (n=405) of patients, the gout developed on the basis of pre-existing MS, thus, this variant may be called a metabolic gout (MG) and considered as a component of MS. The patients with MS were younger, the mean age of symptoms onset was 42 (35–48) years. At the first gout attack, all patients had BMI 25 kg/m², 8.2% (n=33) had pre-existing HTN, and in 14.3% (n=58) of cases the diagnosis of HTN was firstly made. No one patient had diabetes mellitus (DM). Regular frequent or regular alcohol intake alcohol intake together with other MS factors were favoring gout attack in all patients. At the last examination, only 38.1% (n=230) of patients had MS without any CVD, the mean age was 50 (45–55) years; 98.7% (n=227) had BMI 25 kg/m²; 73.9% (n=170) presented with HTN; 59.1% (n=136) showed dyslipidemia; 6.5% (n=15) had DM. In 8.3% (n=19) of patients, changing the lifestyle and normalizing the weight resulted not only in decreased hyperuricemia but lowers attack rate or even their total disappearance during a 5 year follow-up. The second variant of gout onset developing in patients with pre-existing CVD, can be called a CV gout or cardioenovascular (CRV) gout. This type of gout was revealed in 28.5% (n=172) of patients, the age at the debut of gout was 60 (55–64) years (p<0.001). 97.7% (n=163) had HTN (χ²=30.1, p<0.001) and 27.3% (n=47) – DM (χ²=32.65, p<0.001), both features were more common in CV gout. 85.5% (n=147) had BMI 25 kg/m² (F=0.066, p<0.001). Regular alcohol intake was considerably lower – 33.7% (n=58) (χ²=16.7, p<0.001), but medication use was higher – diuretics in 14.5% (n=25) (χ²=21.77, p<0.001) and low-dose aspirin in 37.2% (n=64) of patients (F=0.24, p<0.001). At the last examination, the mean age of patients was 63 (59–69 years) (p<0.001), chronic GFR 60 ml/min was observed in 47.7% (n=82) of patients (F=0.34, p<0.001).

Conclusions: In our opinion, there are two main clinic-pathogenetic variants of debuting gout – metabolic and cardiovascular, the both with different conditions of occurrence, progression and prognosis. In clinical practice, it is reasonable to differentiate these variants, that is determined by the need to simplify complex multimodal diagnostic and therapeutic approach to the patients with gout.

NSAIDS AND LIVER FUNCTION IN PATIENTS WITH GOUTY ARTHRITIS

E. Mikhnevich 1, T. Rayenevich 1, K. Leonich 1, E. Mytnik 2
1 University of Medicine; 2 Rheumatology Clinic, Diagnostic Center, Minsk, Belarus

Background: Nonsteroidal anti-inflammatory drugs (NSAIDs) have been associated with hepatotoxicity. Drug-induced liver injury (DILI) in patients under NSAIDs therapy is more frequently presented by hepatocellular damage with elevated serum alanine aminotransferase (ALT) levels (1).

Methods: 376 patients with GA registered in our database were included in our retrospective study. Males made 92.8% (n=349). Mean age was 57 (50–62) years; mean duration of gout – 7 (3–10) years. NSAIDs were prescribed to the patients in 24 (18–32) U/l after treatment (p<0.001). The second variant of gout onset developing in patients with pre-existing CVD, can be called a CV gout or cardioenovascular (CRV) gout. This type of gout was revealed in 28.5% (n=172) of patients, the age at the debut of gout was 60 (55–64) years (p<0.001). 97.7% (n=163) had HTN (χ²=30.1, p<0.001) and 27.3% (n=47) – DM (χ²=32.65, p<0.001), both features were more common in CV gout. 85.5% (n=147) had BMI 25 kg/m² (F=0.066, p<0.001). Regular alcohol intake was considerably lower – 33.7% (n=58) (χ²=16.7, p<0.001), but medication use was higher – diuretics in 14.5% (n=25) (χ²=21.77, p<0.001) and low-dose aspirin in 37.2% (n=64) of patients (F=0.24, p<0.001). At the last examination, the mean age of patients was 63 (59–69 years) (p<0.001), chronic GFR 60 ml/min was observed in 47.7% (n=82) of patients (F=0.34, p<0.001).

Conclusions: In our opinion, there are two main clinic-pathogenetic variants of debuting gout – metabolic and cardiovascular, the both with different conditions of occurrence, progression and prognosis. In clinical practice, it is reasonable to differentiate these variants, that is determined by the need to simplify complex multimodal diagnostic and therapeutic approach to the patients with gout.

AB0872

DIAGNOSTIC EFFICIENCY OF DETERMINING THE PURINE METABOLISM ENZYMES ACTIVITY IN THE DIFFERENTIATION OF GOUT

Background: Serum uric acid (UA) level is the most important risk factor for gout. At the same time many people with the gout do not suffer from the hyperuricemia, and UA level can return to normal during gout exacerbation.

Objectives: to improve the diagnostics of gout.

Methods: 53 gout patients were the target group. The mixed control group was consisted of 150 rheumatoid arthritis patients, 95 osteoarthritis patients, 55 ankylosing spondylitis patients. The diseases were diagnosed in accordance with the international standards. Adenine deaminase, Adenosine deaminase (ADA), AMP-deaminase (AMPADA), Guanine deaminase, Guanosine deaminase, Guanosine phosphorylase, 5-nucleotidase, Xanthin dehydrogenase (XDH), Xanthin Oxidase, Purine nucleoside phosphorylase activities were determined in blood serum with subsequent evaluation of sensitivity (Se), specificity (Sp), likelihood ratio of positive (LRP) and, likelihood ratio of negative (LRN) result, predictive value of positive and negative results.

Results: The AMPDA and ADA activities were defined as a screening marker to diagnose of the gout from a joint syndrome another genesis. Threshold AMPDA activity 1.67 IU was characterized with the predictive value of negative results (without taking into account the prevalence) near 100%, Se 98%, Sp 62.45%. Cutoff value (CV) of ADA activity (9.57 IU) was characterized with LRN 0.104, Se 92.45%, Sp 72.65%, the sum (Se+Sp) 165.10%, which was maximum not only for this test but also for all the studied enzymes. The predictive value of negative results (without taking into account the prevalence) was 98.20%. The clinically significant CV of positive result for the ADA activity definition was identified also: LRP was 6.93 (Se 22.64%, Sp 86.73%) for the range of 12.58 IU and above. This fact allows the use of this test not only for the screening, but also, in some cases, for the verification of gout with significant pretest probability of this disease. Two CV were selected for the XDG activity: 7.49 μM/1·min (Se 47.17%, Sp 97%), 13.9 μM/1·min (Se 99.25%, Sp 99.58%). The result of XDG activity determining in the range of 7.49 - 8.39 μM/1·min is an important argument in favor of the gout presence, but this may be useful for differential diagnosis only at high pretest probability of the gout.

Conclusions: Determination of the ADA activity was gave way to AMPDA activity determination at the gout screening and to XDG activity determination at gout verification. However, the ADA multi-functionality, evidenced clinically significant presence of the second CV (positive results) and a small proportion of the cases, which covered a "grey area" between CV (27.48%), provided the ability to use this marker as a backup in the absence of diagnostically relevant AMPADA and XDG activities.

AB0873
CHARACTERISTICS OF ADHERENCE, PERSISTENCE AND THERAPEUTIC ALLIANCE IN PATIENTS WITH GOUT
E. Alvarez-Hernandez1, L.D. Upegui-Arango2, J. Vazquez-Mellado1, E. Aranda-Arreola1 , R. Burgos-Vargas1, I. Pelaez-Ballestas1, 1Rheumatology, Hospital General de Mexico, Mexico DF, Mexico; 2Rheumatology, 2Universidad Industrial de Santander, Bucaramanga, Colombia
Background: Adherence is the extent to which the patient takes their medications and follow the directions prescribed by their doctor. It has two components: compliance (the degree or extent of conformity to the recommendations about daily-day treatment by the provider with respect to the timing, dosage, and frequency) and persistence (the duration of time from initiation to discontinuation of therapy). The therapeutic alliance is the patient physician relationship that allows the patient to participate actively in their treatment. The reported adherence varies from 43 to 70% in patients with chronic diseases. In gout, the adherence varies from 10 to 46%.
Objectives: To evaluate the characteristics of adhesion in patients with gout.
Methods: Patients with gout from the GRESGO cohort were included. Sociodemographic, clinical, and treatment data were collected and the HAC-DI, EuroQol-5d and a specific questionnaire of adherence and therapeutic alliance were applied.
Results: The study included 238 patients (97.1% male), with a mean age of 47.7±12.7 years, educational level 9.2±4.2 years. The adherence index (prescribed doses/doses taken) was 86%. Only 28.6% never stopped treatment. 41% took the doses at the correct time. Most frequent causes of suspensions were lack of supply (37%) and forgetfulness (30%). Only 5% buy all of their medications. 10% follow the lifestyle changes. 46.6% do not take the medication when they disagree with their doctor.
Conclusions: Despite having a good adherence index there are discrepancies with the qualitative answers, since more than 70% did not have good persistence and more than 90% did not comply with the schedule.

CHARACTERISTICS OF GOUT IN CAMEROON, CENTRAL AFRICA: A HOSPITAL-BASED STUDY
M.S. Doualla, F. Kamdem, F. Kemta Lekpa. Service de Médicine Interne, Douala General Hospital, Douala, Cameroon
Background: Few data are available on the characteristics of gout in sub-Saharan Africa (1). Objectives: We performed this study with the aim to present the clinical, laboratory and imaging characteristics of gout at the time of diagnosis in Cameroon. The results obtained will be compared with data from the Western literature.
Methods: We performed a cross-sectional study among the 10,186 out patients seen at the Rheumatology unit of Douala General Hospital, Cameroon, between 2004 and 2014. We included patients with gout diagnosis (ACR criteria 1977). The main socio-demographic and clinical data on gout at the time of diagnosis were collected.
Results: A p=0.05 level was significant.
Results: We included 511 patients (5.02%) including 415 men and 96 women. The mean age was 55.9±10.8 years. Joint pain (n=508, 99.4%), joint effusion (n=198, 38.7%) and fever (n=20, 3.9%) were the most frequent complaints. Joint stiffness and/or tenderness Tophi location

Comorbidities were present in 344 patients (67.3%), hypertension (n=208, 40.7%), obesity (n=151, 29.5%), osteoarthritis (n=111, 21.7%), osteogastroduodenal complaints (n=74, 14.5%), diabetes (n=52, 10.2%), and chronic kidney diseases (n=42, 8.2%). Associated factors (p<0.05) in the occurrence of gout were obesity, alcohol intake, diuretics intake, and menopause (in women). Conclusions: Gout has the same clinical, laboratory and imaging characteristics in Cameroon than in Western countries. The main difference comes from the place of the knee as the main joint involved by gouty arthritis at the time of diagnosis in our study.

AB0875
DO WE CONTROL GOUT IN PRIMARY CARE FOLLOWING EULAR RECOMMENDATIONS?
F Leon Vazquez1, C. Sanz Rodrigo2, C. Muñoz Martinez de Salinas2, M. Ferruego Magnán2, M. Metola Gómez2, A. Del Cacho Garrido1, C. González Fernandez2, 1CS San Juan de la Cruz, Servicio Madrileño de Salud, Pozuelo de Alarcón (Madrid); 2CS Puerta Bonita, Servicio Madrileño de Salud, Madrid, Spain
Background: Inadequate control of hyperuricemia in gout patients can lead to more arthritis, activity limitations and higher gout-related treatment costs. General Practitioners can use well tolerated urate-lowering drugs, but some patients are inadequately controlled. European League against Rheumatism (EULAR) has published new guidelines1 in 2016 with similar serum Uric Acid (sUA) goals.
Objectives: To evaluate sUA control in patients diagnosed with gout who were attended in primary care and to compare them to EULAR 2016 guidelines1.
Methods: Retrospective analysis, carried out in 2 primary care health centres (8 family doctors) in Spain. We selected patients that have consulted in the last year diagnosed with gout at any time. Demographic variables, gout-related drugs and last sUA level were collected. Adequate control was defined as sUA level <6 mg/dL.
Results: We analyzed 231 patients diagnosed with gout, mean 70.1±10.1 years old (CI95% 63.3–76.7), 199 (81.8%) were men. The mean sUA was 6.55 mg/dL (CI63.36–7.69 mg/dL). 39% were adequately controlled according to EULAR (sUA <6 mg/dL) and clearly inadequate (>7mg/dL) in 35.5%. 10% had Really bad control (sUA >9 mg/dL). There was no difference between control in male 6.58 mg/dL (IC95%, 6.33–6.83 mg/dL) and female 6.40 mg/dL (CI95%, 5.73–7.07). Control improves in elder people: <60 years 7.01 mg/dL (CI63.65–7.42) vs. >70 years 6.30 mg/dL (CI95%, 6.00–6.60). The only 14 patients receiving febuxostat achieved similar control using allopurinol (6.5 versus 6.7 mg/dL).
Conclusions: The degree of control of sUA in primary care patients in our area is mostly optimal and acceptable, but it can be optimized in more than half of the cases. In a few patients the control is lousy. The worst-controlled patients were the youngest.

AB0876
OSTEOMALACIA: MODALITIES OF PRESENTATION AND ETIOLOGY OF 20 CASES
H. Mounaaj, Z. Saoussen, A. Arfa, M. Jiguirim, I. Beija, M. Touzi, N. Bergaoui. Rheumatology Unit of the Monastir University Hospital, Monastir, Tunisia
Background: Osteomalacia is a defect of mineralization of the protein framework of the skeleton.
Objectives: We try through our series to determine the presentation modalities and the various causes of this fragile benign osteopathy.
Methods: It is a descriptive retrospective study of cases collected in our rheumatology department between 2001 and 2016, concerning patients with osteomalacia.
Results: Twenty patients were collected: 13 women and 7 men with an average age of 53±19 years [22 years, 80 years]. The mean duration of the disease is 45 months [5–172]. The findings were: bone pain in 55% of cases, pelvic pain in 45% of cases, a waddling gait in 5 cases (25%), fractures with low energy in 20% of cases. Functional impairment of the lower limbs in 35% of cases and a biological discovery in 2 cases (10%). Hypocalcemia, phosphorus deficiency and hypocalcioria were found in 14 cases, ie 70%. Alkaline phosphatases were elevated in 12 cases, with a variable rate of 2 to 7 times normal. The PTH, performed in 17 cases, was elevated in 53% of the cases. In our series, all
patients had hypovitaminosis D. In addition, an associated iron deficiency anemia was detected in 50% of the cases, biological stigma of digestive malabsorption in 40% of the cases and renal insufficiency in 15% of the cases. Standard radiographs showed diffuse demineralization in 90% of cases, Looser-Milkman streaks in 40% of cases and fractures in 30% of cases. Bone scintigraphy among 8 patients revealed diffuse hyperfixation in 4 cases (50%), localized hyperfixation in 3 cases (37%) and non conclusive images in only one case (12.5%). Bone densitometry performed in 5 patients showed secondary osteoporosis in 80% of cases. The diagnosis of osteomalacia was retained in 2 cases, celiac disease in 5 cases, renal insufficiency in 1 case, phosphate diabetes in 3 cases including Fracture due to hyperparathyroid and hyperphosphatemia in one case and tubular involvement as part of ankylosing spondylitis in one case. Etiology was a neoplastic cause in 4 cases including multiple myeloma. All the patients had a vitamin-calcium treatment (calcium intake between 500mg and 2g per day with an average of 2.5 gpd, phosphate in 2 cases and other vitamin C in 1 case and tubular involvement as part of the tumor was the reason behind a clinical-biological improvement in the case of thyroid tumors. The outcome was favorable in the short term for all cases.

Conclusions: Osteomalacia is a generalized benign osteopathy, essentially linked to a deficiency in vitamin D often unrecognized. The diagnosis is simple and the treatment is easy, but the ignorance of the etiological forms can be responsible for an unfavorable evolution.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.6986
16), mean body mass index was 33 kg/m² (SD, 10), 73% were male; 67% were
white Americans, 25% were African Americans and 7% other/mixed race/ethnicity.
Participants took a median of 35 minutes to complete study assessment.
Almost half of the participants were taking medications for the treatment of gout:
allopurinol, 42%; leflunomide, 1%; probenecid, 0%; colchicine, 29%. Forty-five
percent participants were taking none of these medications. 41% smoked ever,
27% were using a special diet and participants had alcohol use an average of
2 days in the last week. Average number of gout flares were four in the last
year. Dietary assessments showed that average daily intakes were as follows:
calories, 2005; carbohydrate, 221 gm; fiber, 19 gm; caffeine, 197 ml.
The HEI2010 score of 64 was comparable to what was observed with NHANES
for people in the average age range of this study.

Conclusions: Patients recruited in an Internet gout study, successfully responded to
assessments, and had patient characteristics similar to gout populations described previously.
The dietary assessments in this provide may provide a unique insight to design interventions to improve diet to improve gout outcomes.

AB0880 PHARMACODYNAMIC EFFECTS AND SAFETY OF VERINURAD (RDEA3170) IN COMBINATION WITH ALLOPURINOL VERSUS ALLOPURINOL ALONE IN ADULTS WITH GOUT: A PHASE 2A, OPEN-LABEL STUDY

R. Fleischmann1, P. Winkle2, J.N. Miner3, Y. Yan3, L. Hicks3, S. Valdez3, J. Hall3, M. Hernandez-Illas4,1, University of Texas, Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, TX; 2Anaheim Clinical Trials, Anaheim, CA; 3Aredea Biosciences, Inc., San Diego, CA; 4OPS MRA (Miami Clinical Research), Miami, FL, United States

Background: Verinurad (RDEA3170) is a high-affinity, selective URAT1 inhibitor in
development for the treatment of gout and asymptomatic hyperuricemia.

Objectives: This Phase 2a, randomized, open-label, multicenter study investigat-
gated the multiple-dose pharmacodynamics (PD), pharmacokinetics (PK), and
safety of oral verinurad in combination with allopurinol versus allopurinol alone in
adults with gout (NCT02498652).

Methods: Patients aged ≥18 and <75 years with gout and serum uric acid (sUA): >8 mg/dL were randomized to 1 of 2 cohorts to receive allopurinol (300 mg) in combination with verinurad (dose range 2.5 mg to 20 mg) and allopurinol 300 mg or 600 mg alone (each treatment period was 7 days). Medications were administered once daily ~30 min after breakfast (for allopurinol 300 mg b.i.d. group, the second allopurinol dose was in the evening). Colchicine 0.6 mg for gout flare prophylaxis was initiated at approximately Day -14 (start of urate-lowering therapy [ULT]) washout) or Day -7 if not on ULT. Serial blood and urine samples were measured on Days -1, 1, 7, 14, 21, 28, and 35 for PD and PK endpoints. Safety assessments included adverse events (AEs) and laboratory, electrocardiogram, and vital sign parameters.

Results: Forty-one patients were randomized (n=20–21 per cohort). Serum PD data pooled across cohorts demonstrated maximal % decrease in sUA from baseline (Emax) at 6–10 h after verinurad and allopurinol combination treatment. Addition of verinurad (2.5 mg to 20 mg) to allopurinol decreased sUA in dose-dependent manner (Figure). Greater sUA reductions were observed for dose combinations of verinurad: ≥5 mg with allopurinol 300 mg versus allopurinol 600 mg alone, while allopurinol 600 mg once daily was equivalent to allopurinol 300 b.i.d.

Conclusions: Verinurad coadministration with allopurinol dose-dependently decreased sUA. All dose combinations of verinurad and allopurinol in this study were generally well tolerated with no serious AEs or renal-related events during combination treatment.

AB0881 ASSESSMENT OF SUDOMOTOR FUNCTION IN PATIENT WITH GOUT

J.W. Lee1, H.O. Kim2, S. Lee3, G. Kim4, 1Busan St. Mary's Hospital, Busan; 2KyungSang University, ChangWon; 3Busan National University; 4Gosin university, Busan, Korea, Republic Of

Background: Sodinomotor function is an anti-invasive device measures sweat gland dysfunction using electrochemical skin conductance (ESC) of hands and feet and is useful for assessing peripheral small fiber nerve function. Little is known about the dysfunction of peripheral small fiber nerve in patients with gout.

Objectives: To evaluate the prevalence and characteristics of small fiber neuropathy (SFN) in patients with gout compared with a healthy control group and to identify factors associated with SFN in gout.

Methods: 80 male patients with well symptom controlled gout (age: 58±12) and 80 healthy controls were enrolled. Each patient was required to fast over 8 hours before blood samples. Serum fasting glucose, fasting insulin, uric acid, serum 25-(OH) D, lipid profiles, Creatinine (Cr) and r-GTP were measured. Body mass index (BMI) and Homeostatic model assessment insulin resistance (HOMA IR) were calculated. Patients already diagnosed with hypertension and diabetes were excluded.

Results: The mean feet and hands ESC were significantly lower in the gout group than the control group. Mean Hands ESC was irrelevant to age, BMI, fasting glucose and insulin, HOMA-IR, vtt D, uric acid, Cr, and lipids. However, mean feet ESC showed significant correlation with fasting glucose (r=-0.7, p<0.01) and HOMA-IR (r=-0.5, p=0.03).

Conclusions: Sudomotor function was significantly lower in patients with gout than the control group. Mean feet ESC was correlated with fasting glucose and insulin resistance in patients with gout. These results suggest that dysfunction of SFN in gout patients is associated with insulin resistance and impaired fasting glucose.

Disclosure of Interest: None declared.

AB0882 EFFICACY OF INTRALESIONAL SODIUM THIOSULFATE IN DISABLING TUMORAL CALCINOSIS: ABOUT TWO CASES

J. Gossens1, M. Courbebaise2, V. Ratsimbazafy3, D. Bazin4, M. Daudin5, V. Frochot5, P. Richette1, F. Liote1, H.-K. Ea1, V. Guigonis6, 1Rheumatology department, LARIBOISIERE Hospital; 2Physiology Department, Georges Pompidou European hospital, Paris; 3Pharmacy department, Mother and Child hospital, Limoges; 4Functional explorations department, TENON Hospital; 5Laboratoire Chimie de la Matiere Condensee de Paris, IMPMC, Paris; 6Pediatric Department, Mother and Child hospital, Limoges, France

Background: Tumoral Calcinos is (TC) is a difficult-to-treat complication that can occur during the course of several diseases such as dermatomyositis or genetic hyperphosphatemia. It is a painful and disabling condition that can give rise to local complications including joint mobility reduction, cutaneous ulceration and superinfection. Until now, many treatments have been used with inconsistent efficacy.

Objectives: Intravenous sodium thiosulfate gives promising results in calciphylaxis and ectopic calcifications, and intra-lesional injections could be effective for tumoral calcinosis.
Results: The mean age at onset was 54.7±12.6 years, and the median diagnosis duration was 0 (0.3) years.

Conclusions: Intra-lesional injection of STS seems to be a promising treatment for TC. More studies are needed to confirm these results, and to understand the mechanisms implicated in the calcinosis resorption.

AB0884 PREVALENCE OF ULTRASONOGRAPHIC GOUT SPECIFIC SIGNS OF HAND AND FINGERS JOINTS

M.A. Mahdi1, H. Rkain1, M. Erraoui1, R. Watfeh2, S. Aktaou1, L. Tahiri1, R. Bahiri1, F. Allali1, N. Hajjaj-Hassouni1, Rheumatology; 2Faculty of Medicine and Pharmacy, University Mohamed V, Rabat, Morocco

Methods: This is a cross-sectional study which includes 15 patients with chronic gout, defined according to the American College of Rheumatology criteria (ACR 1977). Ultrasound (US) examination was performed using a high-frequency linear probe (Toshiba Xario®, frequency (8–14 MHz)) in B mode. 540 articular sites were studied at their dorsal surface. The ultrasound has objectified the presence of two signs: hyperechoic band over the superficial margin of the articular cartilage described as a double contour (DC) and the tophaceous deposits at the joint cavity.

Results: The mean age at onset was 54.7±12.6 years, and the median diagnosis duration was 0 (0.3) years.

The results of the US examination are summarized in Table 1.

Table 1. Prevalence comparison of DC and tophaceous deposits between dorsal and planar surfaces at MTP joints

Conclusions: Our study suggests that globally, DC predilect significantly in dorsal than in planar surfaces of MTP joints. These results should be verified on a larger population.

AB0883 THE SENSITIVITY OF GOUT SPECIFIC ULTRASOUND SIGNS AT THE METATARSOPHALANGEAL JOINTS WOULD BE BETTER BY THE DORSAL SURFACE EXAMINATION

M.A. Mahdi1, H. Rkain1, M. Erraoui1, R. Watfeh2, S. Aktaou1, L. Tahiri1, R. Bahiri1, F. Allali1, N. Hajjaj-Hassouni1, Rheumatology; 2Faculty of Medicine and Pharmacy, University Mohamed V, Rabat, Morocco

Objectives: To compare the prevalence of ultrasonographic gout specific signs at the dorsal and plantar surfaces of the metatarsophalangeal joints (MTP).

Methods: This is a cross-sectional study which includes 15 patients with chronic gout, defined according to the American College of Rheumatology criteria (ACR 1977). Ultrasound (US) examination was performed using a high-frequency linear probe (Toshiba Xario®, frequency (8–14 MHz)) in B mode. 150 articular sites were studied at their dorsal and plantar surfaces. The ultrasound has objectified the presence of two signs: hyperechoic band over the superficial margin of the articular cartilage described as a double contour (DC) and the tophaceous deposits at the joint cavity. We compared the prevalence of the two signs between the dorsal and palmar surfaces at each site studied.

Results: The mean age at onset was 54.7±12.6 years, and the median diagnosis duration was 0 (0.3) years.

Conclusions: This study showed a predilection for the gout specific ultrasound signs (DC and tophaceous deposits) of the wrist and MCP joints. The contribution of musculoskeletal ultrasound seems to be very interesting to objectively the presence of gout specific signs in the hand and fingers joints.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.3877

Conclusions: This study showed a predilection for the gout specific ultrasound signs (DC and tophaceous deposits) in the tarsometatarsal and metatarsophalangeal joints, especially in the first MTP. The contribution of musculoskeletal ultrasound seems to be very interesting to objectify the presence of gout specific signs of the foot joints.

AB0886 PHARMACOKINETICS, PHARMACODYNAMICS, AND TOLERABILITY OF VERINURAD (RDEA3170), A SELECTIVE URIC ACID REABSORPTION INHIBITOR, IN HEALTHY ADULT MALE SUBJECTS

M. Gillen1, Z. Shen2, J.N. Miner3, 1AstraZeneca, Gathersburg, MD; 2Ardea Biosciences, Inc., San Diego, CA, United States

Background: Verinurad (RDEA3170) is a selective uric acid reabsorption inhibitor in clinical development for the treatment of gout and asymptomatic hyperuricemia.

Objectives: The aim of this study was to evaluate the pharmacokinetics, pharmacodynamics, and tolerability of verinurad following single and multiple doses in healthy adult males.

Methods: This was a Phase 1, randomized, double-blind, placebo-controlled, single- and multiple-ascending dose study. Panels of 8 male subjects (6 active, 2 placebo) received single oral doses of verinurad or placebo in either a fasted state or under the conditions of at least one concentration-time (tmax) was approximately 1.25–2.0 hours post-dose under fasted conditions. A

Results: A total of 81 adult males aged 18–54 years enrolled and completed the study. Following single oral doses of verinurad, absorption was rapid and exposure (maximum plasma concentration [Cmax] and area under the plasma concentration-time curve [AUC]) increased in a dose-proportional manner up to the maximum dose tested; Cmax was achieved at 0.5–0.75 hours post-dose in the fasted state, and was slightly delayed to 1.25 hours post-dose in the fed state. Food appeared to decrease AUC by about 23% and Cmax by about 50%. Following multiple daily doses, there was modest accumulation of verinurad. Urinary excretion is a minor elimination pathway for unchanged verinurad. Reductions in body weight. Mean reductions in serum uric acid following once-daily multiple doses, there was modest accumulation of verinurad. Cmax and AUC were 38% and 23% higher, respectively, in Japanese versus non-Asian subjects, largely due to the difference in body weight. Mean reductions in serum uric acid following once-daily multiple dosing of verinurad 10 mg were 62% and 58% at maximum reduction and 46% and 44% at 24 hours post-dose in Japanese and non-Asian subjects, respectively.

Verinurad was well tolerated at all doses. One Japanese subject discontinued verinurad due to an AE of urticaria that resolved after 11 days. No serious AEs, Grade 3 or 4 AEs, or clinically significant laboratory or ECG abnormalities were noted.

Conclusions: Verinurad significantly lowered serum uric acid and was well tolerated in both healthy Japanese and non-Asian males, despite small differences in plasma pharmacokinetics. These data support further evaluation of once-daily verinurad as a treatment for hyperuricemia with or without gout in the Japanese population.

AB0888 TENOFOVIR INDUCED OSTEOMALACIA: A PROFILE BASED ON THREE PATIENTS WITH LOW PHOSPHORUS AND NORMAL LEVELS OF VITAMIN D AND PARATHYROID HORMONE

M. Levy, Desert Oasis Healthcare, Palm Springs, California, United States

Background: Tenofovir can induce proximal renal tubular changes that result in vitamin D deficiency2, Less commonly, osteomalacia related to hypophosphatemia3 can occur and has been documented with bone biopsy4. The clinical details of 28 reported cases of tenofovir induced osteomalacia, some of whom had vitamin D deficiency and secondary hyperparathyroidism, was recently summarized3. To describe the clinical presentation and course of three HIV patients with tenofovir induced hypophosphatemic osteomalacia and compare to cases previously reported.

Methods: The clinical, laboratory, and radiologic features of three HIV patients referred for evaluation of pain and osteopathy were reviewed.

Results: All three patients were male, had diffuse pain, suffered multiple clinical fractures, and were on combination long and short acting opioids at the time of presentation. Two were in wheelchairs and two had neuropathy. All patients had hypogonadism and proteinuria and case 1 had glycosuria. All patients had normal serum albumin, vitamin D, vitamin A, and parathormone levels. Urinary protein electrophoresis, magnesium, CBC, calcium, CPK, sedimentation rate. TSH. Case 1 had fractures of the hip, sacrum, and humerus; case 2 hip and ribs; and case 3 ribs, pelvis and knee. The technetium bone scan showed a similar pattern of increased uptake in multiple ribs, calcaneus, metatarsal bones, knees, and

Factors contributing to length of inpatient hospital stay for patients with acute gout arthropathy at the Northern Hospital: An observational study

M. Mian, M. N. Hossain, M. Omair, D. Liew, C. E. Owen, A. M. Foote, R. R. C. Buchanan

Background: Gout is a common inflammatory arthropathy with a reported prevalence ranging from 1.7% to 4% within Australia – one of the highest in the world, second only to New Zealand. Epidemiological studies have established that its prevalence has increased steadily over recent years, with the impact of the disease on the rise.

Gout has been reported to be associated with a wide range of patient presentations, accounting for 2-3% of all hospital admissions each year. The acute medical presentation to hospital with a large corresponding economic burden.4

Conclusions: To review our experience regarding SLE patients who developed gout, and to perform a literature review of reported cases to date.

Methods: Retrospective review of patients with SLE and crystal-proven gout in our Rheumatology Unit, a tertiary care center. We recorded clinical and laboratory variables related to both diseases. Then, we performed a bibliographic review in Pubmed (1965 – 2016) to identify reported cases of coexistence of both diagnoses.

Results: Out 189 SLE patients seen in our Unit, we have identified two cases with crystal-proven gout: 1) A 68 years-old woman with SLE and nephritis diagnosed 30 years ago, who developed polyarthritis affecting her hands; 2) A 47 years-old man with lupus for 22 years with nephritis and renal failure, who developed acute arthritis involving right knee and ankle. In both cases, urate crystals were demonstrated at synovial fluid. The table shows the results of the literature review together with our two cases. To date, 36 cases with coexistent SLE and gout have been reported. Median age at time of gout diagnosis was 43.5 years (IQR: 75 32.5–52.0), being 26 females (72%). SLEA levels were found notably high (median 13.5mg/dL), and tophi, a marker of gouty severity, were demonstrated in almost half of cases (44.4%). The majority of patients (91%) were on glucocorticoids at time of gout diagnosis. According to common factors leading to hyperuricemia, lupus-related renal damage (8%) and use of diuretics (83%) predominated in the series.

Systemic Lupus Erythematosus and Gout: Really an Unusual Association?

N. Quíll, M. Andrés

Background: Patients with systemic lupus erythematosus (SLE) often suffer from cardiovascular comorbidity such as hypertension, dyslipidemia or coronary heart disease. However, the association with gout – an independent cardiovascular risk factor – is considered unusual - it is not reported in the EULAR textbook (1), and might not be taken into account when acute arthritis occurs in SLE patients, also due to the predominance of women in this disease.

Objectives: To review our experience regarding SLE patients who developed gout, and to perform a literature review of reported cases to date.

Methods: Retrospective review of patients with SLE and crystal-proven gout in our Rheumatology Unit, a tertiary care center. We recorded clinical and laboratory variables related to both diseases. Then, we performed a bibliographic review in Pubmed (1965 – 2016) to identify reported cases of coexistence of both diagnoses.

Conclusions: Nephropathy, obesity, and dyslipidemia are known to correlate to hyperuricemia and gout. Reciprocally hyperuricemia and gout may lead to development of comorbidities, i.e. hypertension, CVD, and nephropathy. Almost half the patients in this study were obese emphasizing the correlation between hyperuricemia and gout and obesity. Weight reduction is beneficial for control of hyperuricemia and gout, and is an important lifestyle factor that may be addressed in the treatment of hyperuricemia.

Disease-related knowledge of gout

Awareness of the cause of gout attack, flare prevention induced by ULT, tendency to have chronic arthritis, and relationship with adverse to UA lowering treatment.

Conclusion: There are significant sustained clinical benefits with long-term pegloticase treatment in patients with chronic refractory gout achieving a UA lowering effect during the initial 3 months of therapy. Significant decreases in TJC, SJC, and pain were noted along with significant improvements in PGA suppression of gout flares, and resolution of tophi. In most patients, maximal benefit was noted after 6–12 months of pegloticase therapy, with many patients meeting newly proposed criteria for gout remission.

RELATIONSHIP WITH ADHERENCE TO URATE-LOWERING THERAPY IN EAST CHINA

R. Yin1, T. Fu1, Q. Zhang1, L. Zhang1, L. Li2, Z. Gu1, Department of Rheumatology, Affiliated Hospital of Nantong University; 2School of Nursing, Nantong University, Nantong, China

Background: Gout is a chronic rheumatic disease caused by deposition of monosodium urate crystals in and around the joint, with a reported prevalence of 1.1% in mainland China and 6.24% in Taiwan, making it the most common form of inflammatory arthritis. With the disease progression, gout can cause permanent joint destruction, bone erosion, and organ damage. Urate-lowering therapy (ULT) is necessary to lower and maintain serum urate (sUA) levels at a therapeutic target of <360 μmol/L, as it is associated with fewer gout flares, reduction of tophus size, and deprecation of urate crystal stores in synovial tissues, making gout the only chronic arthritis that can be “cured.” Disease related knowledge of gout patients should be assessed before attempting to improve health education. To date, except one study from south China, all other published papers about gout knowledge and medication adherence are from other countries. To our knowledge, there is no survey from east China.

Objectives: The current study aimed to investigate knowledge related to gout and its risk factors, and the relationship with adherence to urate-lowering therapy in patients with gout in east China.

Methods: A cross-sectional study of 229 gout patients recruited from the Affiliated Hospital of Nantong University between April 2015 and November 2016 was conducted with two questionnaire, Gout Knowledge Questionnaire (GKQ) and Compliance Questionnaire on Rheumatoid (CQR). Chi-square analysis, t-test, rank sum test, as well as logistic regression analysis were used to analyze data. Results: 215 patients (94.28%) in east China had knowledge of gout, and 9.1% (13/143) adhered to ULT. Age, employment, income, alcohol use, family history, acute flares in preceding 1 year, and colchicine use were associated with awareness of gout-related knowledge, and age, income, alcohol use, and colchicine use were the predictors. Among patients with ULT, patients adherent to ULT tended to have chronic arthritis, knowledge of gout attacks, and adherence to ULT. Awareness of the cause of gout attack, flare prevention induced by ULT and comorbidity were correlated with medication adherence, and the cause of gout attack as well as flare prevention induced by ULT were predictors of adherence to ULT in gout patients in east China.
Conclusions: In this study, 78.5% of patients in east China didn’t have gout-related knowledge. Patients’ knowledge on gout is a significant independent determinant of adherence to ULT.

AB0894 TREATMENT ADHERENCE TO URATE-LOWERING THERAPY IN CHINESE GOUT PATIENTS

R. Yin 1, H. Cao 1, F. Fu 1, Q. Zhang 1, L. Zhang 1, L. Li 2, Z. Gu 1 1Department of Rheumatology, Affiliated Hospital of Nantong University; 2School of Nursing, Nantong University, Nantong, China

Background: Gout, which is characterised by deposition of monosodium urate monohydrate (MSU) in synovial fluid and other tissues, is the most common form of inflammatory arthritis in man and older women. In addition to recurrent acute arthritis, subcutaneous tophi and chronic painful arthritis, gout also affects morbidity and premature mortality. Previous studies have reported that effective ULT can decrease sUA levels enough to prevent further crystal formation, dissolve existing urate crystals and eliminate the causative agent, thus reducing the frequency of acute gout attacks and preventing urate nephropathy, uric acid nephrolithiasis, and the deposition of tophi: a common cause of progressive joint damage, deformity and functional impairment, making gout the only chronic arthritis that can be “cured”. However, gout patients’ adherence rate to ULT is low, ranging from 10 to 46%. Emerging data suggest that poor adherence to long-term ULT use may be an important contributor to the suboptimal outcomes seen in gout and nonadherence may be worse in gout than in any other chronic disease. This suggests that there is a strong need to make a further study on drug adherence and its risk factors.

Objectives: Non-adherence in gout patients using urate-lowering therapy (ULT) may lead to joint destruction and permanent disability. Purpose of this cross-section survey was to explore Chinese gout patients’ adherence rates and investigate potential risk factors for medication non-adherence.

Methods: A total of 129 gout patients were recruited from the Affiliated Hospital of Nantong University from August 2015 to September 2016. Patients were asked to complete a standardized self-report questionnaires (Compliance Questionnaire on Rheumatology, Treatment Satisfaction Questionnaire for Medication version II, Health Assessment Questionnaire, Confidence in gout treatment questionnaire, Gout Knowledge Questionnaire, Patient Health Questionnaire-9, Generalized Anxiety Disorder-7, and 36-Item Short Form Health Survey). Data was analyzed by independent sample t-test, rank sum test, chi-square analysis as well as logistic regression modeling.

Results: Based on CQ9, 9.6% of gout patients were adherent to ULT. Adherence was associated with HAQ, GKQ, treatment satisfaction for medication, confidence in gout treatment and MCS. Other demographic, clinical and psychological characteristics were not related to adherence. Logistic regression models identified HAQ, GKQ and MCS as predictors of medication non-adherence.

Conclusions: In the current study, 90.4% of gout patients didn’t adhere to their ULT prescription. HAQ, GKQ, treatment satisfaction for medication, confidence in gout treatment and MCS were relevant to medication adherence, and HAQ, GKQ and MCS were independent predictors of medication non-adherence in patients with gout. These findings could help medical personnel develop useful interventions to improve gout patients’ medication adherence and quality of life.

AB0895 OSTEOPOROISIS RISK FACTORS IN PATIENTS WITH CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION DISEASE (CPPD)

S. Vladimirov, M. Eliseev, O. Zheylabina, A. Smirnov, S. Glukhova. V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Osteoporosis (OP) risk factors (RF) in CPPD patients are not sufficiently studied, although some of these RFs may be more prevalent in CPPD pts than in general population [1].

Objectives: To identify the input of individual RFs into OP development in pts with CPPD.

Methods: 64 patients with CPPD (35 males and 29 females), but without OP were included into open prospective study. CPPD was confirmed based on McCarty criteria (detection of calcium pyrophosphate crystals in the synovial fluid using polarized microscopy and detection of chondrocalcinosis based on joint radiography or US examination). 40 pts of those had acute and/or chronic arthritis, and 24 pts had osteoarthrits with CPP crystal depositions. Mean age was 57.6±10.2 years, mean follow up – 4.85±0.96 years. Bone mass density (BMD) was measured by dual energy X-ray absorptiometry (DXA) at the forearm, lumbar spine and total hip was performed in all pts at baseline. OP was diagnosed by BMD (T-criterion < -2.5). The following OP risk factors were evaluated in this study: sex; age ≤ 55 years for females and > 65 years for males, smoking, alcohol, fractures in past medical history, fractures in parents, BMI ≥20 kg/m², BMI ≥25 kg/m², serum levels of calcium, magnesium, vitamin D, hyperparathyroidism (HPT), chronic kidney disease (GFR < 60 mL/min), intake of diuretics and glucocorticosteroids (GCs), Erythrocyte sedimentation rate (ESR) > 20 mm/h, C-reactive protein (CRP) > 5.0 mg/L. Odds ratio (OR) (95% confidence interval, CI) was estimated for each risk factor and logistic regression analysis was performed. Statistical analysis was made using SPSS v. 11 package, p values of < 0.05 were considered statistically significant.

Results: OP was identified in 22 (34%) out of 64 pts with CPPD (13 males and 9 females) by the end of the study. The following factors were associated with OP: age ≥ 55 years in females (odds ratio (OR) 5.0, 95% CI: 1.021–24.49; p=0.047), age > 65 years in males (OR 3.9, 95% CI 1.3–11.5; p=0.014), HPT (OR 15.38, 95% CI 1.7–137.9; p=0.015), elevated ESR (OR 3.38, 95% CI 1.14–10.5; p = 0.028) and CRP (OR 6.42, 95% CI 2.05–20.05; p = 0.001) (Fig. 1).

Only hyperparathyroidism was identified by logistic regression analysis (sensitivity- 71%, specificity- 82%) as OP-associated risk factor (OR 14.24, 95% CI 1.05–194.05; p=0.046) (Table 1).

Table 1. Data from multiple logistic regression analysis

Study | OR | Lower | Upper | p
---|---|---|---|---
sex | 2.115 | 0.259 | 5.709 | 0.805
BMI >25 kg/m² | 1.483 | 0.325 | 6.774 | 0.611
Age >65 | 1.293 | 0.274 | 6.093 | 0.745
Diuretics intake | 2.777 | 0.189 | 40.817 | 0.457
HPT | 14.245 | 1.046 | 194.055 | 0.046
CKD | 1.025 | 0.082 | 12.876 | 0.985
lower vit.D3 | 0.553 | 0.116 | 2.173 | 0.357
Elevated ESR | 3.830 | 0.764 | 19.214 | 0.101
Elevated CRP | 3.855 | 0.608 | 24.44 | 0.152

Conclusions: Hyperparathyroidism is the key risk factor for OP in CPPD pts. Among other risk factors chronic inflammation (ESR and CRP levels) is of highest importance.

AB0896 THE EFFECT OF SERUM URIC ACID LEVELS ON TOPHUS STATUS AND FLARES IN PATIENTS WITH GOUT: A SYSTEMATIC REVIEW

S. Mitchell 1, L. Manounah 1, H. Liedgens 2, E. Johannes 3. 1 Decision Resources Group, Bioes, United Kingdom; 2Head Health Economics and Outcomes Research, Market Access, SBU Europe; 3Head Market Access Europe, Grünenthal GmbH, Aachen, Germany

Background: Gout is a chronic, progressive, inflammatory disease characterised by elevated serum uric acid (sUA) levels. sUA levels above its saturation point result in the deposition of monosodium urate crystals, which lead to gout flares and tophi (1). Multiple studies support the use of sUA levels as a marker for clinical improvements; hence the therapeutic goal is to lower sUA levels (<6.0 mg/dL) to improve the symptormorosity of gout and reduce the risk of associated comorbidities (2,3).

Objectives: To conduct a systematic review to identify studies reporting the effect of sUA levels on the incidence of gout flares and tophus status in adult patients with gout/hyperuricaemia, with a focus on publications reporting a correlation between the parameters.

Conclusions: Hypouricemia is the key risk factor for OP in CPPD pts.
Methods: Publications were identified by interrogating electronic databases: Medline & MEDLINE In-Process, EMBASE and the Cochrane Library (accessed 6 Sept 2016). Eligibility criteria included adult patients with a diagnosis of acute/chronic gout or hyperuricemia, with no restriction on publication date, study design or geography.

Results: In total, 69 studies met the pre-defined inclusion criteria and were reviewed; of these, 17 reported the relationship between sUA levels and flares (n=12) and/or tophus status (n=11). Two studies were multinational (North America), and 15 were single country [US (n=10); Spain (n=2); New Zealand (n=1); Germany (n=1); Japan (n=1)]. The majority of studies had a follow-up period of <1 year and 31% reporting 10 years' follow-up. All 12 studies evaluating flares reported that achieving sUA levels <6 mg/dL was associated with a decreased risk of gout flares, compared with sUA levels >6 mg/dL (p < 0.05 in 8 studies). All 11 studies evaluating tophus status reported that achieving sUA levels <6 mg/dL was associated with improvements in tophus status, compared with sUA levels >6 mg/dL (p < 0.05 in 4 studies). The remaining 42 studies reported the impact of urate lowering therapy on sUA levels and gout flares or tophus status, but not the correlation between the parameters. The qualitative results in these studies indicated that increases in sUA levels were associated with an increased risk of gout flares and worsening of tophus status.

Conclusions: Maintenance of sUA levels <6 mg/dL is associated with improvements in tophus resolution and flare reduction in adult patients with gout/hyperuricaemia. Whilst longer-term follow up studies (>5 years) are warranted, this review further supports that decreases in sUA levels are a marker for clinical improvements.

AB0897 FUNCTIONAL DISABILITY AND HEALTH-RELATED QUALITY OF LIFE IN CHINESE PATIENTS WITH GOUT: A CROSS-SECTIONAL STUDY

T. Fu1, R. Yin1, L. Zhang1, Q. Zhang1, Y. Xia1, J. Ji1, Z. Da1, X. Zhu1, L. Li2, Z. Gu1. 1Department of Rheumatology, Affiliated Hospital of Nantong University; 2School of Nursing of Nantong University, Nantong, China

Background: As the most common arthritis in adults, gout is a painful, inflammatory disease that may cause functional disability and decreased health-related quality of life (HRQoL). However, there are currently no known reported studies related to functional disability and HRQoL of gout patients from China.

Objectives: This cross-sectional study aims to investigate the effect of demographic variables, disease parameters, and psychological status on functional disability and HRQoL of Chinese gout patients.

Methods: A self-report survey was administered to 226 gout patients and 232 healthy individuals using the Short Form 36 health survey (SF-36) for HRQoL and the Health Assessment Questionnaire-Disability Index (HAQ-DI) for functional disability. Gout patients were asked to complete the 10 cm Visual Analog Scale (VAS) for total pain, the Patient Health Questionnaire (PHQ-9) for depression, and the Generalized Anxiety Disorder (GAD-7) questionnaire for anxiety. Blood samples were taken to examine the level of uric acid (UA). Independent samples t-tests, Chi square analyses, and logistic regression were used to analyze the data.

Results: Our results found that individuals with gout have poorer HRQoL and the mean functional disability score was 0.34 (SD 0.54), representing mild disability. SF-36 and almost all components of the SF-36 score were associated with place of residence, hypertension, DM, cardiovascular disease, disease duration, number of flares/last year, total pain, number of tophi, presence of tender joints, colchicine use, corticosteroids use, depression, and anxiety (p < 0.05). This variable was also significantly related to the HAQ-DI score (p < 0.05). Additionally, there were significant relationships among age, income/year, allopurinol use and HAQ-DI (p < 0.05). Stepwise multiple linear regression identified number of flares/last year, place of residence, depression and anxiety as the most significant predictors of functional disability. Disease status (total pain, number of flares/last year, presence of tender joints, cardiovascular disease, colchicine and corticosteroids use) and psychological disorders (depression and anxiety) were significantly accounted for poor HRQoL.

Conclusions: Chinese gout patients experienced mild disability and poor HRQoL. Disease status and psychological status were important risk factors linked to functional disability and HRQoL in Chinese gout population. These data suggest medical personnel should pay more attention to functional disability and HRQoL of gout patients and make suitable interventions to relieve their psychological disorders and finally to reduce their functional ability and improve their HRQoL.

AB0898 SLEEP QUALITY IS ASSOCIATED WITH ALCOHOL USE AND FUNCTIONAL CAPACITY IN CHINESE PATIENTS WITH GOUT: A CROSS-SECTIONAL STUDY

T. Fu1, R. Yin1, L. Zhang1, Q. Zhang1, Y. Xia1, J. Ji1, Z. Da1, X. Zhu1, L. Li2, Z. Gu1. 1Department of Rheumatology, Affiliated Hospital of Nantong University; 2School of Nursing of Nantong University, Nantong, China

Background: Poor sleep quality is common in patients with chronic diseases and may lead to the decreased quality of life. The increasing prevalence of poor sleep in individuals with chronic medical conditions is associated with adverse demographic, clinical, and psychological characteristics. However, there are currently no known reported studies related to the sleep quality of gout patients.

Objectives: This study aims to evaluate the prevalence of poor sleep quality and investigate the contributors of poor sleep in Chinese gout patients.

Methods: A self-report survey was administered to 226 gout patients and 232 healthy individuals using the Pittsburgh Sleep Quality Index (PSQI) for sleep quality, the Patient Health Questionnaire (PHQ-9) for depression, and the Generalized Anxiety Disorder (GAD-7) questionnaire for anxiety. Gout patients completed the 10 cm Visual Analog Scale (VAS) for total pain, and the Health Assessment Questionnaire-Disability Index (HAQ-DI) for functional capacity. Blood samples were taken to examine the level of uric acid (UA). Independent samples t-tests, Chi square analyses, and logistic regression were used to analyze the data.

Results: Our results found that the prevalence of poor sleep (PSQI<5) was 55.3% and the mean global score of PSQI was 6.69 (SD 3.48) in patients, which were significantly higher than the controls (17.7% and 3.83 (SD 1.88), respectively). There were significant correlations among alcohol use, HAQ-DI, PHQ-9, GAD-7 and sleep quality in gout patients. Patients with yellow rice wine and wine use preferred to have better sleep quality. While, disease stage was associated with hypertension, total pain, number of tophi, presence of tender joints and swollen joints. Meanwhile, logistic regression models identified alcohol use and depression as predictors of poor sleep quality.

Conclusions: More than half of Chinese gout population suffered from poor sleep, which significantly higher than healthy individuals. These findings suggested medical personnel should pay more attention to the sleep quality of gout patients, especially those with depression. Additionally, it is beneficial for the patients with normal UA level to take moderate yellow rice wine and wine to improve their sleep quality.

AB0899 DEPRESSION AND ANXIETY CORRELATE WITH DISEASE-RELATED CHARACTERISTICS AND QUALITY OF LIFE IN CHINESE PATIENTS WITH GOUT: A CROSS-SECTIONAL STUDY

T. Fu1, H. Cao1, R. Yin1, L. Zhang1, Q. Zhang1, L. Li2, X. Feng2, Z. Gu1. 1Department of Rheumatology, Affiliated Hospital of Nantong University; 2School of Nursing of Nantong University, Nantong, China

Background: Depression and anxiety are common worldwide and may lead to disease aggravation and decreased health-related quality of life (HRQoL). The increasing prevalence of depression and anxiety in gout patients is associated with demographic and gout characteristics. However, there are currently no known reported studies related to the association between HRQoL and depression and anxiety in gout patients.

Objectives: This cross-sectional study aims to evaluate the prevalence of depression and anxiety and investigate the potential risk factors for depression and anxiety in Chinese gout patients.

Methods: A self-report survey was administered to 193 gout patients and 208 healthy individuals from September 2015 to September 2016. Patients were asked to complete a set of standardized self-report questionnaires [Visual Analog Scale (VAS), Health Assessment Questionnaire-Disability Index (HAQ-DI), Patient Health Questionnaire (PHQ-9), Generalized Anxiety Disorder (GAD-7) questionnaire, Short Form 36 health survey (SF-36)]. Independent samples t-tests, χ2 analyses, and logistic regression were used to analyze the data.

Results: We found 15% of gout patients had depression, and 5.2% had anxiety, which were significantly higher than the healthy controls (1.4 and 1.0%, respectively). There were significant correlations among education, pain, disease duration, stage of gout, disability, number of tophi, presence of tender joints, HAQ-DI, and psychological status. Meanwhile, logistic regression analysis identified number of tophi, HAQ-DI, and MH scale as predictors of depression in gout patients. Education, GH, and VT domains were significantly accounted for anxiety.

**SERUM URIC ACID LEVEL VARIATIONS DURING GOUT ATTACKS ARE LINKED NEITHER TO INFLAMMATION NOR TO URIC ACID FRACTIONAL EXCRETION: A PROSPECTIVE STUDY OF 35 PATIENTS**

V. Masson Behar1, C. Desthiels1, C. Aparicio2, P. Manivet3, T. Bardin1, P. Richette1, F. Liote1, A. Ostertag 1, H.-K. Ea 1.

**Background:** Acute gout is usually associated with a decrease in serum uric acid (SUA) level but the mechanism responsible for this phenomenon remains unclear.

**Objectives:** We aimed to investigate relationships between changes in SUA level, urinary excretion of uric acid and biochemical markers during gout attack.

**Methods:** SUA, eGFR (estimated glomerular filtration rate), serum CRP level and urinary excretion of UA, expressed as fractional excretion of UA (FeUA), from 35 ULT (urate-lowering therapy)-free and diuretic-free gout patients were prospectively measured during acute gout attack (Tc) and intercritical (Tic) phase.

**Results:** In 11 patients, data were available after achievement of SUA target (Tt) (< 360 μmol/l) under ULT. Demographics data and waist circumference (WC) were collected. Data are expressed as mean ± SD.

**Results:** There were 32 men, mean age 57.9 years, mean body mass index 28.6 kg/m², and mean waist circumference 104 cm. Overall 17.1% had type 2 diabetes, 37.1% dyslipidemia, 54.3% hypertension, 34.4% obesity, 74.3% abdominal obesity and 51.4% chronic kidney disease (CKD, 31.4% CKD 2 and 20% CKD 3–5). Gout duration was 3.9±6.7 years, 28.6% of patients had tophus abdominal obesity and 51.4% chronic kidney disease (CKD, 31.4% CKD 2 and 10.1% CKD 3–5).

**Objectives:** The prevalence of depressive and anxious symptoms among gout patients was higher than healthy individuals. Education, disability, tophi and HRQoL were important risk factors linked to this disorder in Chinese gout population. These findings suggested medical personnel should pay more attention to the psychological health of gout patients and make objective interventions to relieve their depression and anxiety, especially those with low education level, more than two tophi, severe disability, and poor HRQoL.

**AB0901**

**CLINICAL SIGNIFICANCE OF URATE DEPOSITION IN TENDON: A DUAL-ENERGY CT STUDY**

Y. Eun1, I. Y. Kim1, H. Jeong1, E.-J. Park2, H. Kim3, J. Lee1, E.-M. Koh1, H.-S. Cha1, 1Department of Medicine, Samsung Medical Center, Seoul; 2Department of Medicine, Jeju National University Hospital, Jeju, Korea, Republic Of

**Background:** Dual-energy computed tomography (DECT) is an advanced imaging modality that shows the deposition of monosodium urate (MSU) crystal in tissue as a color signal. The MSU crystal deposit around the symptomatic joint is considered as positive finding, but the clinical significance of urate deposition around the tendon is still unclear.

**Objectives:** The aim of this study was to compare the clinical characteristics and DECT findings in people with MSU crystal deposition in the joints and people with urate deposition in the tendons.

**Methods:** DECT was performed in 71 patients who complained of recurrent painful swelling of the joints, and 35 of them showed MSU crystal deposition in the joints on DECT. Clinical manifestation and serum uric acid level data were collected.

**Results:** Most of the included patients were middle-aged (mean age 50 years, SD 15) and 67 patients (94%) were male. All patients who had MSU crystal deposition in joints on DECT had a history of typical gout attacks, and 29 patients (81%) had a history of gout attacks among patients with urate deposition only in tendons (p<0.01). The mean uric acid level of patients included in the study was as high as 7.5±2.2 mg/dL. In the highest uric acid level, the absolute value was higher in patients with urate deposition in joints, but there was no statistical significance. The correlation between the gout attack site and the urate deposit sites was 91% in patients with joint involvement, but only 6% in patients without joint involvement (p<0.001). There were 4 patients (11%) who showed gouty erosion without MSU crystal deposition in joints on DECT.

**Conclusions:** The MSU crystal deposition in the tendon was not correlated well with clinical features, suggesting that it is more likely to be associated with artifact or asymptomatic hyperuricemia. However, in some patients, MSU crystal deposition may be observed only in the tendon, even with gouty erosion. Therefore, careful interpretation of the DECT results is necessary.

**Infection-related rheumatic diseases**

**AB0902**

**TUBERCULOSIS SCREENING IN PATIENTS RECEIVING BIOLOGIC THERAPY**

**Background:** The advent of biological treatments has greatly improved the management of chronic inflammatory diseases (CID). However, these biologics increase the risk of infection including the possible development of tuberculosis (TB). Screening of latent tuberculosis infection (LTBI) is therefore necessary prior to their initiation, especially in Tunisia, which is considered as a high-incidence area of TB.

**Objectives:** The aims of this study were to identify the prevalence of LTBI among patients candidate to initiate biologics, to analyze the tolerance of preventive therapy and to detect active TB or conversions of immunodiagnostic tests under biologics.

**Methods:** A retrospective study was conducted, over a period of 14 years (2002–2016). Patients with CID, candidate to initiate biological treatment, were included. The screening of LTBI was performed according to the national Tunisian guidelines. Clinical data, screening and follow-up information on biological therapy were assessed.

**Results:** A total of 76 patients were enrolled in the study, 32 men and 44 women with a mean age of 66 years [17–80]. Rheumatoid arthritis (RA) was the most common CID (44%). The diagnosis of LTBI was established in 16 cases (21%). Among them, 3 had a Tuberculin Skin Test (TST) more than 10mm associated with a positive Interferon Gamma Release Assay (IGRA), 11 had only a positive TST, and 2 had only a positive IGRA. One of them had a history of pulmonary TB but adequately treated. All patients with positive screening were considered for preventive treatment. Thirteen (81%) received an association of isoniazid-rifampicin for 3–6 months, and 3 (19%) received isoniazid for 6 months.

**Toxicity** was reported in 4 cases (25%): hepatotoxicity (n=1), dermatologic toxicity (n=1), fever (n=1) and stomachache (n=1). During the follow-up period, no case of reactivation has been reported among patients with LTBI. Out of the 60 patients with negative baseline screening, only 4 have been re-screened (6%) and none had conversions in immunodiagnostic tests. However, among patients who screened negative, one case of active pulmonary TB has been reported in a woman who had an ankylosing spondylitis (AS) and who was receiving infliximab (n=1). She had CAD/PH and TB exposure.

**Conclusions:** Our study showed that the Tunisian recommendations allowed detecting a LTBI in 21% of biologic therapy candidates. The initial screening and the prophylactic treatment improve the safety of these treatments. However, we noted a low rate of re-screening, as the Tunisian guidelines do not recommend
Laboratory FINDINGS in patients with Chikungunya fever in subacute/chronic phases

A. Ranizolin1,2, R.M. Correia2, H.D. de Lima3, M.R.D.A. Freitas2, A.F.R. de Oliveira4, A.L.B.P. Duarte1, C.D.L. Marques1, P.R.S. de Melo1, L.F. da Rocha Jr1,2,3, Hospital Das Clinicas of Pernambuco; Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil

Background: Chikungunya fever (CF) is an arbovirus with a high attack rate, affecting large proportion of the population in its outbreaks (85%-90% of infected are symptomatic). In general, it is recommended to carry out laboratory tests when patients reach subacute phase or show signs of severity at the beginning of the disease. There are few studies showing which laboratory results are relevant and their clinical applicability.

Objectives: To recognize the most frequent findings of laboratory tests in a cohort of patients with CF and chronic joint symptoms and to correlate laboratory results with clinical data.

Methods: Patients with diagnosis of CF (clinical and epidemiological criteria) were followed in a cohort study. Clinical data and laboratory tests were collected in a regular schedule in the first months of the disease.

Results: A total of 54 patients were enrolled during 10 months, persistent changes in some patients were recorded (table).

Table 1. Persistent laboratory findings in patients with Chikungunya Fever in subacute/chronic phases

CRP = C reactive protein, GGT = gamma glutamyl transferase, LDH = lactate dehydrogenase, ALT = alanine aminotransferase, CPK = creatine phosphokinase.

In the subacute phase, the ESR (erythrocyte sedimentation rate) correlated with number of swollen joints (r=0.45, p=0.03), VAS (visual analogue scale) of pain (r=0.72, p=0.0002), WAS patients’ general health (r=0.50, p=0.02), VAS by physician (r=0.45, p=0.03) and with HAQ (r=0.51, p=0.01). In subacute phase the VAS of morning stiffness correlated with CRP (r=0.46, p=0.02). In chronic phase, CRP correlated with VAS of pain (r=0.47, p=0.02) and there was a reversal in the correlations between ESR and WAS of general health of the patient (r=0.54, p=0.03), VAS of physician (r=0.52, p=0.02), swollen joints (r=0.46, p=0.03) and HAQ (r=0.56, p=0.01). ESR and SF-12 (mental component) were correlated (r=0.61, p=0.01).

Conclusions: Levels of ESR correlated with measures of pain and worsening of functional capacity in subacute phase. In chronic phase, there was reversal of this correlation, indicating that ESR does not reflect clinical worsening of patients at this stage. Further clinical studies are needed to better analyze other alterations.

AB0906 PYOGENIC SEPTIC ARTHRITIS: IS THERE A DIFFERENCE WHEN GERM IS NOT IDENTIFIED?

H. Sahli1, M. Sahli2, R. Tekaya2, O. Saidane2, R. Khalfallah1, I. Mahmoud2, L. Abdelmoula1, 1Rheumatology Department, Mohamed Taher Maamouri University Hospital, nabeul; 2Rheumatology Department, Charles Nicolle Hospital, tunis, Tunisia

Background: Pyogenic septic arthritis (PSA), defined by the presence of living microorganisms and a synovial fluid of purulent character, is a therapeutic emergency. Germ isolation is a primordial step in the diagnostic and therapeutic approach.

Objectives: The aim of this study was to study the differences between PSA with positive and negative bacteriology.

Methods: This is a retrospective study which included medical records of patients treated for PSA in a rheumatology department over seventeen years. The epidemiological and paraclinical data were recorded. We used the SPSS 11.5 for the statistical analysis to compare patients with (group 1) and without an isolated causative agent (group 2).

Results: We evaluated 49 patients with a diagnosis of PSA. They were 26 (53.1%) men and 23 (46.9%) women. The average age was 55±18.7 years (ranging from 15 to 95 years). Comorbidities were observed in 31 (63.3%) patients. The onset of symptoms was acute in 37 (75.5%) patients and progressive in 12 (24.5%) patients. The most common symptoms were joint pain and stiffness (100%) and functional impotence (87.8%). All patients were treated with double or triple antibiotics. Among the studied patients, 27 (55.1%) had negative culture results. Statistic analysis used to compare cases with an isolated pathogen to those cases without an isolated pathogen, noted female predominance in group 2 but there was no statistically significant difference (p=0.252). Patients in group 1 and group 2 had a comparable mean age (p=0.08). Patients in both groups had comparable risk factors for PSA (p=0.549). Acute onset was more common in group 2 (51.4% versus 48.6%) but without a significant difference (p=0.507). Biological inflammatory syndrome was more frequent in group 2 but with no statistically significant difference (p=0.235). The study of the appearance of the synovial fluid did not indicate a statistically significant difference between the two groups (p=0.125). The abnormalities of standard x-rays were similar in both groups (45.2% in group 1 versus 54.8% in group 2, (p=1)). The statistical study of all other variables didn’t show differences between the two groups.

Conclusions: PSA was not associated with major differences if the germ was or was not isolated.

Disclosure of Interest: None declared

AB0907 CONTRIBUTION OF IMAGING IN THE DIAGNOSIS OF INFECTIOUS SPONDYLODISCITIS

H. Sahli1, A. Bachali1, R. Tekaya2, I. Mahmoud2, O. Saidane1, L. Abdelmoula1, 1Rheumatology Department, Mohamed Taher Maamouri University Hospital, nabeul; 2Rheumatology Department, Charles Nicolle hospital, tunis, Tunisia

Background: Infectious spondylodiscitis represents a diagnostic and therapeutic emergency. Imaging is fundamental in the management of the disease.

Objectives: The aim of this study is to analyze the contribution of imaging in the diagnosis of infectious spondylodiscitis.

Methods: This is a retrospective study which included medical records of patients treated for psoas abscess during the twelve past years [2006–2016]. Epidemiologic, clinical, and imaging data (Standard X ray, Computed tomography (CT), magnetic resonance imaging (MRI)) were recorded and analysed.

Results: Ninety patients were included in this study. The average age was 55 years [16–86] with an even distribution between males and females. Mean symptom duration was 4 months. The most frequently isolated pathogen was Mycobacterium tuberculosis (83.3%), followed by pyogenic germs (21.2%) and Brucella (15.5%). Standard X ray were pathological in 89% of cases: showed narrowing of intervertebral space (72.2%), endplate destruction (42.2%), erosions of vertebra (13.3%), opacity (12.2%), vertebral fracture (10%), paravertebral spinal (5.2%) and posterior arch lesion (2.2%). Standard radiographs were normal in 12 cases and in 1 case, spinal CT showed vertebral destruction with “mirror image”. Spinal MRI, performed in the remaining 11 cases, confirmed the diagnosis in all cases and showed paravertebral collections (n=3), epiduritis (n=3), psoas abscess (n=2), microabscess (n=1) and spinal compression (n=1). In case of posterior arch lesion and vertebral fracture, MRI confirmed the diagnosis by showing paravertebral collections.

Conclusions: Management of infectious spondylodiscitis has benefited from advancements in imaging allowing an early diagnosis and treatment.

AB0908 BIOLOGICAL AND RADIOGRAPHIC FINDINGS IMPACT ON GERM IDENTIFICATION DURING SEPTIC ARTHRITIS

H. Sahli1, M. Sahli2, R. Tekaya2, R. Khalfallah1, O. Saidane2, I. Mahmoud2, L. Abdelmoula1, 1Rheumatology Department, Mohamed Taher Maamouri University Hospital, nabeul; 2Rheumatology Department, Charles Nicolle Hospital, tunis, Tunisia

Background: Septic arthritis may cause damage and inflammation in short period of time. The germ determination must be the first objective to allow targeted treatment. Bacteriologic tests remain negative in 7–35% of cases of septic arthritis.

Objectives: The aim of this study was to determine the impact of biological and radiographic findings on germ identification during septic arthritis.

Methods: This was a retrospective study which included medical records of patients treated for septic arthritis during the last seventeen years. Epidemiologic, biologic, bacteriologic and therapeutic data were recorded and analysed. We made a comparison between patients who had a germ identified (Group 1) with whom who hadn’t (Group 2).

Results: Fifty nine patients with septic arthritis were included in this study. The average age of the patients was 54.6±19 years and a sex ratio (F/M) of 0.9. Causative agents were isolated in 27 patients (45.7%). Biological data showed leukocytosis in 25 (42.4%) patients. Mean leucocyte count was 10673±5003. Leukopenia was noted in 1 case. One patient had neutropenia. Lymphopenia was observed in 4 patients (6.7%). Two patients had hyperlymphocytosis. Anemia, mainly of the inflammatory type, was noted in 47 cases (79.6%). The mean Creative protein (CRP) was 150.±16106, and the mean erythrocyte sedimentation rate (ESR) was 104.9. Twenty three patients (38.9%) had other perturbations of the biological balance: cholesterol (n=1), cytolysis (n=4) and renal perturbation (n=1). Radiological signs suggestive of septic arthritis were observed in 40 cases (67.8%): articular pinching (28.8%), geodes and erosions (14%), total destruction of the joint (0.76%) or thickening 1 the soft parts at the beginning (11.8%). Ultrasound exam, performed in 22 cases, showed articular effusion (n=15), synovial thickening (n=8), a soft tissue collection (n=3), and periartricular erosion (n=2). CT, performed in 6 patients, was normal in all cases but 1. No abnormalities were noted: collection of soft parts (n=2), joint effusion (n=2), bone demineralization (n=1), bone erosion (n=1) and osteochondritis (n=1). MRI, performed in 2 patients, was pathologic in both cases and showed synovitis and cortical erosion with medullary edema. The comparison of the 2 groups according to germ identification showed that biological inflammatory syndrome was more frequent in group 2 (100% versus 96.8%) but without a statistically significant difference (p=0.346). Mean value of CRP and ESR were comparable in the two groups (p=0.65 and 0.19). The mean value of hemoglobin was comparable in the two groups (10.87 versus 9.64 g/dl) (p=0.566). It was similar about the blood count. Abnormalities of standard x-rays were similar in both groups (70.4% in group 1 versus 65.5% in group 2) (p=0.784). The most frequent radiological abnormality in the two groups was articular pinching (40.7% in group 1 and 46.8% in group 2).

Conclusions: In our study, the biological and radiological data had not shown any impact on the identification of the germ.

AB0909 SEPTIC PSEUDARTHROSIS OF THE HUMERUS TREATMENT USING ORTHFIX EXTERNAL FIXATION

S. Daas1, H. Sahli1, M.A. Stal1, M. Souissi1, A. Khorbi1, 1Orthopedic Department; 2Rheumatology Department, Mohamed Taher Maamouri University Hospital, nabeul, Tunisia

Background: The septic pseudarthrosis of the humerus is a very difficult process that poses a twofold challenge: the infection eradication while trying to get consolidation.

Objectives: The aim of this study was to analyze the results of the treatment of septic pseudarthrosis of the humerus with Orthofix monolateral axial external fixator.

Methods: This is a retrospective study which included 17 medical records of patients treated for septic pseudarthrosis of the humerus during and stabilization by Orthofix over a period of 7 years.

Results: They were 13 women and 4 men with a mean age 44 years. The fracture site was most often at the distal half of the humerus. The initial treatment of the fracture was pinning or intramedullar nailing. Surgical management of pseudarthrosis was performed 3.5 months after the first surgical procedure. All cases had a bone debridement and stabilization with a monoplane Orthofix axial external fixator. Fifteen cases were performed bone graft. The mean period of stabilization was 7months. Patients were evaluated clinically and radiologically each month. At the mean of three years of follow-up, we obtain osseous consolidation for all patients in the average of seven months. All patients underwent rehabilitation of the shoulder and elbow after treatment. The functional result were excellent results for 42.9% of cases, good results for 35.3% and poor results in 21.7%. The Quick DASH score average was 28.5. The average of the elbow motion was 109 ° of flexion with an average of 30 ° of deficit in extension. The useful range of motion of the elbow was preserved in 14 patients. There was a shaft angulation under 20 ° in 3 cases and over 20 ° in 3 other cases. We noted
in four cases a bone shortening consolidations of 2 cm. We had a case of radial nerve neuroparesis which regressed spontaneously.

**Conclusions:** Orthosix is the method of choice for the treatment of the septic pseudarthrosis of the humerus.

> Associate eradication of the germ antibiotic and steroid intake sponges it allows to maintain the member. Furthermore, the monolateral axial fixator is tolerated well and allows movement of the shoulder and elbow throughout the period of treatment.

**AB0910 INFECTION SPONDYLODISCITIS IN THE SANITARY AREA OF TORREALEGA BETWEEN 2000 AND 62 CASES**

I. Morante Bolado 1, M. Santos-Gómez 2, I. Villa Blanco 1, E. Aurrecoechea Aguñaga 1, T. Ruiz Jimeno 1, J. Calvo Alén 1, 2Rheumatology, Sierrallana Hospital, Torrealega; 2Rheumatology, University Hospital of Araba, Vitoria, Spain

**Objectives:** To analyze the clinical characteristics, most frequent diagnostic methods and different treatments used in spondylodiscitis (SD) in our sanitary area.

**Methods:** Descriptive and retrospective study of patients with the diagnosis of infectious SD (clinical or microbiological) from 2000 to 2016. In each case we studied the presence of underlying diseases, an episode of infection in the previous 6 months, way of presentation, location, diagnostic methods, treatment and evolution, comparing among different etiologies.

**Results:** 62 patients were diagnosed of spondylodiscitis. 41 men (24–90 years: mean 71.7), 56 were pyogenic, 3 tuberculosis (TBC) SD, and 1 candida. The patients of TBC were younger (mean age, 45.5 ± 0.05). An underlying disease was observed in 51 patients, specially Diabetes Mellitus (DM) (31%) of SD. 4 patients were Rheumatoid Arthritis patients. A previous episode of bacteremia or a primary source of infection was identified in a 35% of the cases, obtaining a microbiological isolation in 135 (79.5%) SD (43 bacterial, 3 TBC and 1 Candida). The most frequent presentation symptoms were: lumbar pain (95.1%), fever (50%) and neurological deficit (18%). Leucocytosis was present in only a third (33.8%). In the 94% of SD caused by G+, hemocultures positive were obtained, in comparison to a 55% of SD caused by G (p = 0.016).

The most frequent presentation symptoms were: lumbar pain (95.1%), fever (50%) and neurological deficit (18%). Leucocytosis was present in only a third (33.8%). In the 94% of SD caused by G+, hemocultures positive were obtained, in comparison to a 55% of SD caused by G (p = 0.016).

**Conclusions:**

- The majority of the patients had pain in the presentation, but only half of them had associated fever.
- The most frequent location of SD was lumbar.
- We established a 8% of mortality rate in our sanitary area.

**AB0912 ASSESSMENT OF CLINICAL AND RADIOLOGICAL PROGNOSTIC VARIABLES IN PATIENTS WITH SPONDYLODISCITIS**

J.J. Frigio Gil 1, R. Gonzalez Mazzario 1, M. Tasias Pitarch 1, E. Calabuig Muñoz 1, I. Ivorra Cortés 1, C.M. Feced Olmos 1, F.M. Ortiz-Sanjuán 1, E. Labrador Sánchez 1, K. Arévalo Ruales 1, E. Grau García 1, I. Chalmeta Verdejo 1, L. Gonzalez Puig 1, J. Martinez Cordelliat 1, R. Negueiroles Albuixech 1, C. Alcaliz Escandell 1, J.E. Oller Rodriguez 1, E. Vicens Bernabeu 2, C. Nájera Herranz 1, I. Cánovas Olmos 1, A. Hervás Marín 2, M. Salavert Lleti 2, J.A. Román Ivorra 1, 1Rheumatology Department; 2Infectious Disease Unit, HUP la Fe; 3Biostatistic Unit, IIS la Fe, Valencia, Spain

**Background:** Spondylodiscitis is an infectious disease of the intervertebral space, often caused by hematological spreading from a distance septic focus, especially Endocarditis. Because of its low incidence combined with an ambiguous symptoms, delay diagnosis and treatment of this condition, raising probability of an undiagnosed outcome.

**Objectives:** To identify poor prognosis variables in patients with Spondylodiscitis

**Methods:** Observational retrospective study with non-naive population. Patients from 2010 to 2016 was performed. Demographic information, clinical history, laboratory test and radiological data were compiled from the clinical history management software. Statistical analysis was performed with the software R (version 3.4.2).

**Results:** We included 55 patients, with a mean age of 63.47 (16.11) years old. Males predominated (69%). The average time with axial pain was 64.44 (80.63) days. Mean length of hospital stay was 64.44 (80.63) days and readmission rate was 32.7%. 20% of patients required further surgical procedures. Most of patients showed high CRP levels in the first 48 hours and an average value of 112.97 (83.64) mg/L. Underlying endocarditis proportion was 16.4% and in this patients hospital stay was significative higher; nevertheless, it was not correlated with worse prognosis. 50% of patients showed vertebral destruction on MRI; 14.8% cord compression and 20.4% of patients developed neurological complications (7 of them paraparesia). Furthermore, vertebral destruction was statistically correlated with epidural abscess (P = 0.026). Isolation and microbiological identification in blood cultures was possible in 83.6% of patients. Most frequent bacteria was Gram positive (50.09%), then Gram negative (18.2%), mycobacteria (10.3%) and fungi (3.6%).

**Conclusions:** Delay in diagnosis is an important issue in Spondylodiscitis patients. Higher complications rates are mainly in relation to greater vertebral destruction. Underlying infectious endocarditis was described in a small proportion of patients in contrast to other studies. Presence of epidural abscess was also correlated with vertebral destruction, for this reason, patients with this finding should be more carefully follow-up.

AGREEMENT STUDY AND EXPERT CONSENSUS FOR THE CLINICAL PICTURE OF CHIKV INFECTION

J.C. Rueda1, J.-I. Angarita2, M. Pinzon1, A.M. Santos1, J.M. Rueda2, D.L. Salibí1, E. Forero3, I. Pelaez-Ballestas5, R.X. Pavía2, J. Londoño1, J.C. Rueda

1Reumatología; 2Universidad de la Sabana, Chia; 3Unidad de Reumatología, Centro Médico Imbanaco, Cali; 4Reumatología Ubit, Centro Médico Carlos Ardila Lulle, Bucaramanga; 5Medicina Interna, Reumatología, Universidad del Norte, Barranquilla, Colombia; 6Reumatología, Hospital General de México, Mexico, Mexico; 7Unidad de Investigación Científica, Hospital Militar Central; 8Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá, Colombia

Background: World Health Organization suggested case definitions to suspect and diagnose chikungunya virus infection which are: possible case, probable case and confirmed case. Although useful, when applied in practice, its lack definition for specific joint involvement and absence of other systemic symptoms apart from fever, leads to a broad clinical spectrum which increases the need for laboratory tests.

Objectives: To establish agreement on clinical criteria of CHIKV infection based on clinical expertise of specialists from affected areas of Colombia and to develop a set of clinical criteria.

Methods: A group of specialists in rheumatology, epidemiology and bacteriology from different parts of Colombia with experience in diagnosis and treatment of CHIKV patients from the epidemic of 2014–2015 met to reach agreements on clinical characteristics of CHIKV infection. A series of questions were formulated and agreement in percentage was calculated on the following answers: totally agree, not in agree or disagree, disagree and totally disagree. Agreement was set when the sum to the answers totally agree and agree or disagree and totally disagree of was ≥50%. When agreement was not reached, the moderator performed a discussion with the opinions of the confronting members of the group and after that reformulated the question. This procedure was made until agreement was reached. With the results a set of clinical criteria was proposed.

Results: The agreement percentage to the formulated questions are depicted in table 1. Disagreement was achieved with mucosal involvement (100%), G/I involvement (88%), and arthralgia and arthritis in shoulders (63% and 100%) and elbows (100%).

Conclusions: Agreement was achieved in abrupt onset of symptoms, and the presence of fever, rash, myalgia, fatigue, and symmetrical arthritis or arthralgia of wrists, hands, knees, ankles and feet. A set of clinical criteria was proposed (figure 1).

CUTANEOUS LEISHMANIASIS IN PATIENTS TREATED WITH BIOLOGICAL THERAPY

J. Lluch1, M. López de Recalde1, X. Michelet2, J. Marcoal2, X. Juanola3

1Department of Rheumatology; 2Department of Dermatology, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Barcelona, Spain

Background: Leishmaniasis is a chronic protozoon disease endemic in several areas of the world. In the Mediterranean basin cutaneous leishmaniasis is caused by Leishmania infantum and usually produces localized skin lesions. Biological therapy (BT) may increase the risk of reactivation or development of infections such as tuberculosis, mycoses and protozoan diseases. However, there is scarce literature on Leishmania infections in patients treated with anti-TNF drugs. We have diagnosed five cases of cutaneous leishmaniasis in patients treated with anti-TNF drugs in the last four years.

Objectives: To show the clinical characteristics and the evolution of cutaneous leishmaniasis in patients treated with BT at a tertiary level hospital.

Methods: We reviewed the clinical characteristics, previous treatments, the complementary tests used for the diagnosis, the main disease, the therapy used for the treatment of the infection, the clinical evolution and the reintroduction of the treatment.

Results: In the last four years we have diagnosed five cases of cutaneous leishmaniasis in patients treated with BT. Four of them were men and one a woman, the age range was 35 to 61 years old. In four of them the symptoms were only cutaneous, but one of them also had systemic impairment, basically hepatosplenomegaly. For the diagnosis skin biopsy, positive PCR for Leishmania DNA from skin samples, serology and response to treatment were all needed. Three cases were patients treated with adalimumab and two treated with infliximab. Three patients had Crohn's disease, one psoriatic arthritis and the other ankylosing spondylitis. The diagnostic delay was between 5 and 24 months. All patients were treated with EV liposomal amphotericin B, and two of them also received intralereal injections of meglumine antimoniate. In all cases resolution was achieved, and there have been no relapses to date after reintroduction of BT.

Conclusions: We have to consider cutaneous leishmaniasis in patients with BT who present compatible skin lesions, especially in endemic areas. It is important to be aware of this type of condition in order to make a fast and accurate diagnosis.

FREQUENT CONVERSION AND REVERSE CONVERSION OF TUBERCULIN SKIN TEST BUT NOT OF AN INTERFERON GAMMA RELEASE ASSAY (T-SPOT.TB) DURING LONG TERM BIOLOGIC TREATMENT OF RHEUMATIC PATIENTS

K. Thomas, A. Makris, C. Tsalapaki, A. Lazarian, K. Klavdianou, K. Antonatou, C. Koutsianas, C. Hatzara, E. Hadziyannis, D. Vassilopoulos. Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens, Hippokration General Hospital, Athens, Greece

Background: There are limited data regarding the value of tuberculin (TB) rescreening in rheumatic patients on biologic (bDMARD) therapies who had a negative baseline TB screening.

Objectives: To examine the rates of conversion and reverse conversion at repeated TB screening testing with 2 available assays (tuberculin skin testing-TST and an interferon gamma release assay-IGRA: T-SPOT.TB) in rheumatic patients with negative baseline screening during long term bDMARD treatment.

Methods: Rheumatic patients with negative baseline screening (TST and T-SPOT.TB) were re-screened one year after TNF inhibitor (TNFi) therapy (1st rescreening) and ~6 years later on bDMARDs (2nd rescreening). The rate of conversion and reverse conversions of the 2 assays were recorded. Only patients who did not receive isoniazid (INH) therapy between the 1st and 2nd rescreening were analyzed.

Results: Among 70 patients with negative TB baseline screening, 21 patients with 2 re-screenings were identified; one patient with TST conversion at the 1st rescreening who converted back to negative at the 2nd rescreening after INH treatment, was excluded from the study. 20 patients were finally included in the study (RA-7, PsA-6, AS-5, other diseases=2). 50% were women with a mean age of 57±12.4 years and mean disease duration at the last screening of 13.1±6.2 years. The mean interval between the 1st and 2nd rescreening was 68.6±13 months. At the last evaluation, 90% (18/20) were still on bDMARDs (TNFi=55%, non-TNFi=45%), 45% (9/20) on non-biologic DMARDs and only one patient (5%) on corticosteroids. None of the patients displayed conversion or reverse conversion with TST rescreening compared to 6 (30%) with TST at the 2 rescreenings (p=0.02). At the 1st rescreening, 4/20 (25%) had converted their TST to positive; at the 2nd rescreening, 2 reverted back to negative (1 patient with PsA on etanercept and 1 with RA on steroids, methotrexate and golimumab) while the other 2 remained TST positive (1 with PsA on etanercept and 1 with Still's disease exposed to etanercept, tocilizumab and canakinumab). Among the 16 patients who remained TST negative and T-SPOT.TB negative at the 1st rescreening, 2 (12.5%) became TST positive at the 2nd rescreening (12 mm and 7 mm, respectively). Both patients were on long term infliximab treatment without history of TB exposure. After thorough evaluation, no evidence of active TB infection was found in any of the 6 patients who converted TST either in the 1st or 2nd rescreening.

Conclusions: Among rheumatic patients with negative baseline TB screening, conversion or reverse conversions were much more frequent with TST compared to an IGR (T-SPOT.TB) at repeat testings during long term bDMARD therapy. These preliminary findings need to be taken into account while designing the appropriate repeat TB screening strategy for this group of patients.

WHIPPLE DISEASE: A RARE DISEASE DIFFICULT TO DIAGNOSE

L. Ferrieres, L. Alric, M. Laruche, D. Bonnet, S. Thebault. CHU Toulouse France, Toulouse, France

Background: Whipple disease is a very rare disease needing a long term treatment. The most frequent symptoms are recurrent arthralgia or arthritis, chronic diarrhoea, abdominal pain and weight loss.

Objectives: In this work, we have highlighted the main clinical features and diagnostic procedures that lead to the diagnosis and comment on the clinical response, treatment, and the factors of relapse.

Methods: Subjects were recruited from the Internal Medicine and Rheumatologic Departments of an University Hospital from November 1997 to January 2016. Overall, 12 subjects were finally diagnosed.

Results: Mean age was 54.3 years (age range: 30–81), with more male patients (58.3%). Almost all patients had articular symptoms and impaired general condition (91.7%); and a majority had digestive symptoms (75%). Regardless of the symptoms, the most efficient diagnostic tools were the PCR screening on the gastrointestinal biopsies and saliva (83.3% and 72.7% positive results, respectively). More than half of the patients relapsed (55.6%). The relapsing patients were older (63.2 (44–81)) and mostly male with a majority (60%) of digestive symptoms and a delayed diagnosis.

Conclusions: In current practice, it is very difficult to diagnose Whipple disease. In order to decrease the delay between the first symptoms and the diagnosis, effective tools such as saliva and stools PCR should be used since higher delays of diagnosis lead to a higher number of relapses.

AB0918 REACTIVE ARTHRITIS POST VIRAL – AN UNUSUAL PRESENTATION IN AN EPIDEMIC IN NORTH INDIA
N. Mendiarrata, R. Gupta, D. Rawal on behalf of Dr Dhiren Raval. MEdanta, MEcity, New Delhi, India

Background: This study was performed at a Private hospital in New Delhi, India during the epidemic phase of Viral fever. The peak months of viral fever from mosquitoes (Aedes Aegypti) like Dengue and Malaria (Anopheles) has been from July to October, till the holy festival of Diwali arrives. Chikungunya came like a wave this time along with dengue and Malaria. The worst epidemic since the last 6 years. A disease common in South India, took North India by a storm. 15–20 deaths were also reported due to Chikungunya virus. Apart from Chikungunya (serology negative) there were a lot of other viruses causing arthritis. Our study deals with post viral arthritis, a new variant which has never been described before.

Objectives: 1. To study the pattern of arthritis after viral fever. Is it reactive or a new variant
2. To observe for the evolution of Acute viral arthritis into chronic arthritis
3. The management of Post viral arthritis

Methods: It is a retrospective study conducted at the end of the epidemic. The patients are being followed up for next 3 months to observe for resolution of symptoms, persistent arthritis or evolution into chronic form. 100 patients are being included which were examined and independently assessed by 3 different consultants.

Inclusion criteria: 1. All patients who presented with complaints of persistent joint pains and swelling preceded by fever (Average duration 4–8 weeks). 2. Documented synovitis (Oligoarticular and polyarticular)

Exclusion criteria: 1. Known case of Rheumatoid Arthritis, Connective tissue disease, Vasculitis and Spondyloarthopathy. 2. Arthralgia with no documented synovitis. 3. Patients on DMARDS previously.

Results: Detailed results are still under compilation as patients are under follow up (6 months) for further course.

No of patients: 100
Average Age: 47
Average Disease Duration: 6 weeks (after fever)
Average No of Joints involved: 3–4
Symmetry: All Asymmetrical (Large+ Small)
80% patients had asymmetrical joint involvement. Most common joints were: MCP followed by PIP and then the large joints: shoulders and ankles. It was associated with significant early morning stiffness (30 minutes) like other inflammatory arthritis. 60% had response to short course of NSAIDS and low dose steroids (Injection Depomedrol 80 mg intramuscular once a week) and recovered in 2 weeks, 30% had a prolonged course of 4–6 weeks, but did not need any further medications. 5% developed into Chronic arthritis (Further follow up pending)

Conclusions: Reactive arthritis is a known entity and it has typical involvement of the lower limbs, usually preceded by urinary tract infection or GI infection. Even with Viral arthritis, the presentation of joint pains and swelling is usually during the acute fever episode. The pattern described here was different. All the patients had fever at presentation which lasted for 3–5 days and 4–6 weeks later they developed synovitis. There was characteristic involvement of Small joints of the hands (PIP and MCPS) (different from reactive).We are still in process of collecting follow up data which will give us a clue on prognosis of this arthritis and future prospects. So, what do we label it as ... Reactive arthritis-a new variant or a post viral arthritis.

AB0920 TUBERCULOSIS OSTEOARTHRITIS OF THE PUBIC SYMPHYSIS: REPORT OF TWO CASES
R. Sonia, S. Boussaid, I. Abdelkafi, S. Hela, C. Ilhem, E. Mohamed. Rheumatology, la Rabta, Tunis, Tunisia

Background: Infection of the symphysis pubis is a rare complication for less than 1% of cases of osteoarthritis. The predisposing causes reported are pelvic surgery, trauma and intravenous drug abuse. We report cases of osteoarthritis of the pubic symphysis due to mycobacterium tuberculosis which is extremely rare.

Results: The two patients were 47 and 75 year-old women. They were admitted because of three month’s history of progressive perineal pain and a hypogastric mass without fever in the first case, and bilateral inguinal pain with limited flexion and rotation of the right hip in the second one. Blood tests showed an elevated erythrocyte sedimentation rate (ESR) of 27 mm and 75 mm. The leucocytes rates were at 5580/mm³ and 6000/mm³. Plain X-ray revealed irregularity and widening of the symphysis pubis. Tuberculin skin test was positive in one case and negative in the other. Chest radiograph was normal. The bacteriological cultures for tubercule bacillus in sputum and urines negative. The typhic and brucellian serological diagnosis as well as blood cultures were negative. CT scan showed irregular destruction and erosion of the pubic bone with a soft tissue mass. A biopsy of the symphysis was performed. Histologic examination of the bone material revealed a granulomatous inflammation with caseous necrosis confirming the diagnosis of tuberculosis. Anti-tuberculous treatment was prescribed and led to recovery.

Conclusions: Tuberculosis is a major health problem in Mediterranean countries, including Tunisia. These two cases present a timely reminder that tuberculosis should always be considered as part of the differential diagnosis of treatment of tuberculosis osteoartthritis of the pubic symphysis. Radiological investigations with plain X-rays, CT, MRI and bone scan are helpful. Treatment of tuberculosis osteoarthritis of the pubic symphysis is based mainly on anti-tuberculous drugs.

AB0921 INFECTIOUS SPONDYLODICTYSIS: EPIDEMIOLOGICAL, CLINICAL, PARACLINICAL AND THERAPEUTIC ASPECTS
A. Feki, R. Akrout, I. Sellami, M. Ezzeddine, H. Fourati, S. Bakhouri. Hedi Chaker Hospital, -Stax, Tunisia

Background: Spondylodictysis is an infection of a disc and the two adjacent vertebrae due to the introduction of a pyogenic, usually by the haematogenous route. It’s quite a rare disease accounting for 2–7% of all cases of septic osteoarthritides [1, 2].

Objectives: To study the clinical, microbiological, radiological, therapeutic and evolving of infectious spondylodictysis

Methods: A retrospective descriptive study conducted over years in the department of rheumatology, including all patients with infectious spondylodictysis. Clinical given were collected from paper patients records.

Results: We included 67 patients. There were 38 men and 29 women. The mean age was 55 years. The male to female ratio was 38:29. Risk factors of spondylodictysis were observed in 19 patients. The approximate time from onset of symptoms to diagnosis was from 3 to 365 days (median, 132 days). Back pain was the most common symptom. Spinal syndrome was found in all patients. The most frequent location of spondylodictysis was lumbar spine. Signs of spinal cord compression including paraplegia or paraparesis of the lower limbs were observed in 31 patients. Pachymeningitis was associated in 1
case. The paravertebral abscesses were associated to the disc involvement in 23 cases. Epiduritis was associated in 21 cases. Plain radiography, performed in the majority of cases (83 cases, 94%), demonstrated pathologic pictures in 56 (83.5%) patients. MRI, performed in 60 (89.5%) patients, disease was in all patients. Pathogens were isolated in 43 (64.1%) cases. Tuberculosis was the most common cause. The leading causative agents in non tuberculous spondylodiscitis were: Staphylococcus aureus (8 isolates, 11.9%), brucella (7 isolates, 10.4%), Escherichia coli (2 isolates, 2.9%) and streptococcus B (1 isolates, 1.4%). Two microorganisms combined (mycobacterium tuberculosis and a pyogenic) was found in one case. Medical treatment was adapted to the prescribed seed. Surgical treatment was performed in 6 patients. After therapy, 59 (98%) patients had regression of symptoms, two patients had a permanent neurological impairment (paraplegia), one patient had recurrence of infection and one patient was dead.

Conclusions: Infectious spondylodiscitis has been diagnosed with increasing frequency. It should be taken into consideration in differential diagnosis in patients with significant back pain and laboratory evidence of an acute inflammatory process, especially metastatic spinal disease or inflammatory spondylodiscitis.

AB0922 CLINICAL MANIFESTATIONS AND OUTCOMES OF ACUTE SEPTIC ARTHRITIS IN SONGKLANAGARIND HOSPITAL: A 10-YEAR RETROSPECTIVE STUDY

T. Yaowmaneerat, D. Kiewueangsurat, Internal Medicine, Prince of Songkhla University, Hatyai, Songkhla, Thailand

Background: Septic arthritis is a rheumatologic emergency. Its delayed diagnosis and treatment cause joint morbidity and mortality. Cases involving antimicrobial-resistant bacteria have been reported.2,3

Objectives: To determine the clinical manifestations and outcomes of septic arthritis, find the factors associated with mortality, and discover the incidence of drug-resistant organisms in our institution

Methods: A retrospective study was performed. Septic arthritis was defined as the presence of acute inflammatory arthritis indicated by a positive synovial fluid or synovial tissue culture for bacteria. A total of 116 septic arthritis patients, who visited Songklanagarind Hospital from January 2005 to December 2014, were reviewed.

Results: The patient median age was 58 (IQR: 46, 72). Sixty-one patients (52%) were female. The median onset of symptoms and symptoms until diagnosis were 5 (IQR: 2, 7) and 6 (IQR: 3, 10) days, respectively. Eighty-eight cases (76.7%) had underlying diseases that might predispose to joint infection. Sixty-nine cases (59.5%) had pre-existing joint disease. Joint pain was the most common presenting symptom, and 58% of the cases had fever. The most common presentation was monoarthritis (87%), which was predominantly associated (78%) with knee joint involvement. The median synovial fluid leukocyte counts were 64,460 cells/L (IQR: 30,300; 129,000). Blood cultures were positive in 53 patients (49.1%). Synovial fluid cultures commonly had Streptococcus spp. growth (41%). Seven cases (7%) involved drug-resistant organisms. All of them were either diagnosed with septic arthritis during hospitalization or had a history of previous surgery. Twenty-five percent of the cases obtained the empirical antibiotic, ceftriaxone, and 86 patients (80%) underwent arthroscopy drainage. The mortality rate was 12%, and its associated factors were cancer, liver disease and advanced age.

Conclusions: Streptococcus spp. is an emerging cause of septic arthritis in Southern Thai patients. Physicians should be aware of this in patients presenting with fever and acute monoarthritis, particularly those with comorbidities and underlying joint diseases. The proper empirical antibiotic of choice is ceftriaxone.

AB0924 THE ROLE OF SELF LIMITING BEHAVIOUR, DEPRESSION AND SLEEP IN THE SEVERITY OF FATIGUE IN PATIENTS WITH FIBROMYALGIA

M. Fernandes 1, M.P. Guzzo 2, C. Iannuccelli 2, L. Mailla 1, F. Lucidi 3, M. Di Franco 1, C. Violani 3, 1Department of Psychology; 2Department of Internal Medicine and Medical Specialties; 3Department of Developmental and Social Psychology, “Sapienza” University, Rome, Italy

Background: Fatigue and sleep disturbances are prominent symptoms in Fibromyalgia (FM) and significantly affect the level of the patients’ impairment. Some studies reported a synergic interaction of depression and poor sleep quality associated with fatigue (e.g. [1]): while Marques et al. [2] showed a significant association of the fatigue severity with a limiting behaviour self-regulatory style of the patients, i.e. reducing daily activities and excessive resting.

Objectives: The purpose of this cross-sectional study was to analyse the predictors of severity of fatigue in Italian patients with FM.

Methods: Outpatients with a FM diagnosis who fulfilled both ACR/EULAR 1990 and 2010 criteria [3,4], after a medical visit at the Fibromyalgia center at Sapienza University Hospital “Umberto I”, were invited to participate in a study on their cognitions and behaviours where during one week a wrist actigraph (AMTI MotionLogger Watch). Actigraphic sleep parameters were averaged over six days. After 7 days the participants returned the actigraph and answered a structured interview conducted by a trained psychologist which included validated scales measuring depression (Brief Symptom Inventory [5]), perceived fatigue (Checklist of Individual Strength [6]), sleep habits (Sleep Disorder Questionnaire [7]) and behaviour regulation patterns (All-or-nothing and Limiting behaviour scales from Behavioural Responses to Illness Questionnaire [8]. In the previous month and during the study, pharmacological and non-pharmacological treatments were unchanged.

Results: Actigraphic monitoring and structured interview were completed by 39 female FM patients, with a mean age of 44.9 years (SD=8.55) and an illness mean duration of 6.5 years (SD=5.72). The majority of the patients reported insomnia complaints (80.5%) and 29 (74.4%) met the DSM criteria for chronic insomnia. Fatigue severity resulted as the best subjective measure of fatigue, and was positively and significantly correlated with self-management through limiting behaviour, and with Total Time in Bed (TTB) measured through actigraphy. The correlation between TTB and Total Time Slept (TTS) and depression were not significant. Hierarchical regression considering TTB, Depression and Limiting behaviour, showed that all these variables give a significant independent contribution to the prediction

Fibromyalgia

AB0925 MEETING THE FIBROMYALGIA CRITERIA HAS A NEGATIVE IMPACT ON TNF INHIBITORS EFFICACY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

A. Dantu 1, 2, J. Michaud 2, M. Gauthier Prieur 1, F. Da Silva 1, S. Poupin 2, T. Lequerre 2, O. Vittecoq 2, M. Verdet 1, 1Rheumatology, Eubeuf Louviers Val de Reuil Hospital, Saint Aubin les Eubeuf; 2Rheumatology, Rouen University Hospital, Rouen, France

Background: Fibromyalgia and spondyloarthritis can coexist and the overlap between the two diseases could have consequences on TNF inhibitors efficacy.

Objectives: To evaluate TNF inhibitors efficacy in patients with axial spondyloarthritis fulfilling or not fibromyalgia criteria.

Methods: Prospective observational bicentric study on 25 patients who met ASAS 2009 axial spondyloarthritis criteria. Fibromyalgia was defined by ACR 2010 fibromyalgia criteria or by a ≥5/6 score of the Fibromyalgia Rapid Screening Tool. Following items were recorded before and after a 6 months treatment with TNF inhibitors: Visual Analog Scale for pain and for patient global disease activity, values of ESR and CRP, number of tender joints. NASSE score, number of Yenus tender points. All patients filled a self-questionnaire with BASDAI, BASFI, FIRST and ACR 2010 fibromyalgia scale items using SSS and WPI. Criterion of judgment: an ASAS partial remission state was compared in patients with or without fibromyalgia.

Results: Of the 25 patients enrolled, 15 (60%) fulfilled ACR 2010 fibromyalgia criteria and 9 (36%) had a ≥5/6 FIRST score. The proportion of patients fulfilling an ASAS partial remission state was significantly lower in patients with fibromyalgia according to the ACR 2010 criteria (20% vs 70%, p=0.034) or to the FIRST score (0% vs 62.5%, p=0.002). These patients had more severe disease activity and physical function than the patients without fibromyalgia. In this study, some factors were related with absence of ASAS partial remission: female gender, prior TNF inhibitor failure, ACR 2010 fibromyalgia criteria positivity, to have more than 11 Yenus points and to have a ≥5/6 FIRST score.

Conclusions: Meeting the fibromyalgia criteria might have an impact on ASAS partial remission state and on efficacy of TNF inhibitors in patients with axial spondyloarthritis. The FIRST score was more specific to predict an absence of ASAS partial remission than the ACR 2010 fibromyalgia criteria. TNF inhibitors should be used with circumspection in case of FIRST score ≥5/6 in patients with axial spondyloarthritis.

GENDER DIFFERENCE IN FIBROMYALGIA: COMPARISON BETWEEN MALE AND FEMALE PATIENTS FROM AN ITALIAN MONOCLINICAL COHORT

M.P. Guzzo 1, C. Iannuccelli 1, M.C. Gerard 1, B. Lucchino 1, G. Valesini 1, M. Di Franco 1, 1Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome; 2Unità di Reumatologia, ASST - Fatebenefratelli Sacco – Polo Universitario, Milan, Italy

Background: Fibromyalgia (FM) is one of the main causes of chronic widespread pain (CWP). It is characterized by CWP, which is the cardinal symptom, and the presence of more than 11 tender points (hyperalgesia). [1] Other symptoms such as fatigue, sleep disturbances, difficulties with memory and concentration, irritable bowel syndrome, headache, depression are frequent. Worldwide mean prevalence of FM is 2.7% with female/male ratio of 4:1. In Italy the prevalence is 3.7% with the same female/male ratio. [2]

Objectives: The aim of the study is to analyze clinical features of a cohort of male patients with CWP and to evaluate gender differences in patients diagnosed as FM.

Methods: The study population consisted of 101 consecutive male subjects referred to the Clinic for the Diagnosis and Therapy of Fibromyalgia, in the period between January 2007 and October 2016, matched with a control group of 101 females with CWP referred to the clinic in the same period. Complete clinical evaluation was performed in all patients.

Results: Ninety-seven male subjects (96%) were referred to the clinic for a history of musculoskeletal pain, among these 53% reported fatigue and 60% complained about sleep disorders. A stressful trigger (work or family problems, bereavement, infections) at the onset of pain was reported by 42% of patients. Fifty-two percent of patients reported mood changes. Physical examination showed hyperalgesia in 15% of the subjects and a mean tender points’ (TP) count was 4.6 (range 0–18). The diagnosis of FM was performed according to ACR 1990 criteria, since the enrollment included patients referred to the clinic before the publication of the latest ACR criteria [3, 4]. Only 18 male subjects (18%) fulfilled the classifying criteria. In the female group CWP was reported by 97%, fatigue by 65%, and sleep disorders by 72% of patients. Stressful events were reported by the 50% of female population. Mood changes were described by 54% of female subjects and were predominantly depressive. Physical examination revealed hyperalgesia in 48 subjects (47%) and the mean TP count was 11 (range 0–18). The diagnosis of FM was confirmed in 60% of subjects. Comparing the two cohorts of patients with FM, mean age at the time of the visit and mean age of onset of symptoms resulted significantly higher in females than in males (p=0.02 and p=0.04 respectively). There was no statistically significant difference in the number of TP, in fatigue, sleep and mood disorders and in the percentage of stressors considered as a trigger for the disease. Hyperalgesia was the only feature more common in females than in males (p=0.03).

Conclusions: The significant higher frequency of hyperalgesia in women suggests a different presentation of CPW, that is the cornerstone of FM, in the two sexes. Moreover, the prevalence of FM was higher in females than in males when 1990 ACR criteria were used. It can be assumed that further gender differences could be showed applying 2010 ACR criteria.

AB0926 AUTONOMIC DYSFUNCTION IN FIBROMYALGIA MAY BE MEDIATED BY HYPERMOBILITY SYNDROME

D. Aslanian 1, Z. Cipinova 2, N.A. Harrison 1, H.D. Critchley 1, K.A. Davies 1, J.A. Eccles 1, 1BSMS; 2BSUH, Brighton, United Kingdom

Background: Neuropsychiatric symptoms are common in Fibromyalgia (FMS). FMS is associated with dysautonomia, particularly orthostatic intolerance, in which there is a phenomenological overlap with anxiety. FMS and dysautonomia are both associated with joint hypermobility (JHS).

Objectives: To investigate whether signs and symptoms of dysautonomia in FMS are mediated by JHS.

Methods: Eighteen patients with FMS (all female; mean age 41.06 years) and 19 controls (14 female; mean age 46.62 years) were recruited. JHS was assessed by Brighton Criteria. Multi-systemic symptoms suggestive of dysautonomia were quantified using Autonomic Symptoms and Quality of Life Scale (ASQoLS). Neuropsychiatric symptoms were formally quantified including anxiety level (BAI), depressive symptom level (BDI), panic disorder symptom severity (PDSS) and dissociative experiences (DES). All participants underwent autonomic function testing (9 minute tilt table with heart rate (HR) recording).

Results: Statistical comparison between groups was performed using independent samples t test and chi squared as required, correlations were explored using pearson or spearman rho as appropriate. Formal mediation analysis was performed using the method of Baron and Kenny (1), which stipulates that a mediator variable must reduce the statistical relationship between the independent and dependent variable.

Conclusions: FMS patients had significant objective features of dysautonomia including higher baseline HR (p=0.01) and maximal HR during tilt (p=0.02) compared to controls and reported significantly higher autonomic symptom burden (p=0.001). Symptoms correlated with changes in physiology during autonomic challenges in patients (r=0.53, p=0.039), but not controls. Across the study anxiety score correlated with absolute change in pre-tilt and average HR during tilt (r=0.483, p=0.050) and symptoms of dysautonomia (r=0.813, p=0.001). Dysautonomia symptoms correlated with DES (r=0.793, p=0.001), PDSS (r=0.742, p=0.001), interoceptive sensibility (r=-0.627, p=0.007) and BDI (r=0.502, p=0.040). There was a significant association between JHS and FMS (p=0.001), but not generalized joint laxity. Across all participants, dysautonomia symptoms correlated with JHS (r=0.353, p=0.032) and JHS participants reported higher heart rates during autonomic challenge (p=0.002) and greater symptom burden (p=0.001). The significant relationship between autonomic symptoms and maximum HR during tilt was fully mediated by presence of JHS or FM (Figure 1). JHS partially mediated the relationship between FMS and increased anxiety scores and fully mediated the relationship between FMS and maximum HR during tilt (Figure 2).

DOI: 10.1136/annrheumdis-2017-eular.5048
Background: Fibromyalgia (FMS) is a chronic health problem characterized by a wide range of physical and psychological symptoms. There are few high-quality instruments to evaluate the participation and social functioning of fibromyalgia patients. Farin et al. designed the Fibromyalgia Participation Questionnaire (FPQ) as an instrument for measuring the participation and social functioning of FMS patients. The original version of FPQ has been demonstrated to have acceptable internal consistency, reliability, and criterion validity.

Objectives: To test reliability and validity of Turkish version of Fibromyalgia Participation Questionnaire (FPQ-T).

Methods: One hundred and eighty-four female fibromyalgia syndrome patients were included in the study. All patients filled FPQ-Turkish (FPQ-T) questionnaire which was obtained by translation from German according to the guideline for the cross-cultural adaptation process. The patients filled the revised Fibromyalgia Impact Questionnaire (FIQ) and reevaluated FPQ-T two hours later. Internal consistency reliability of FPQ-T was assessed by calculating “if item deleted” using Cronbach alpha and “item-total correlation” coefficient for each item of the questionnaire. Consistency of scale scores and correlation of test-retest values were assessed. Test-retest values were compared using Wilcoxon test. Criterion validity was measured using FIQ scales by Spearman’s rho correlation coefficient.

Results: For internal reliability, Cronbach alpha coefficient was calculated as 0.957 for non-working and 0.958 for working patients. Cronbach alpha values of 0.939, 0.871, and 0.914 were obtained for daily, social, and work life, respectively. Correlation coefficients were 0.888 for daily life, 0.859 for social life, and overall 0.901 in non-working group versus 0.896 in working group. Comparison of scores obtained from test-retest measurements showed no significant difference except for Item-3. Correlation of symptom severity score (SSS) and FPQ-T were r=0.390 (p<0.001) for the non-working and working sub-groups, respectively. Construct validity evaluation showed significant correlation between SSS and FPQ-T.

Conclusions: The results of our study showed that FPQ-T is reliable and valid for assessing participation and social functioning in fibromyalgia patients in our society.

RELIABILITY AND VALIDITY OF TURKISH VERSION OF FIBROMYALGIA PARTICIPATION QUESTIONNAIRE

A. Mutti, P. Sarzi-Puttini.

Aim of our work was to study the relationship between fatigue, being reported by over 75% of patients. However, the relationship between fatigue and disease duration (p<0.001), SSS score (r=-0.651, p<0.001), PSD score (r=-0.522, p<0.001), and with the total number of somatic symptoms (r=-0.594, p<0.000) (Fig. 1, right panel). Furthermore, for each of the 40 somatic symptoms suggested by 2010 criteria, the presence of the symptoms was associated with higher levels of fatigue (Fig 1, left panel).

Conclusions: The results of our study confirm that fatigue is a prominent feature of fibromyalgia. Higher levels of fatigue reflect higher levels of widespread pain, and a higher burden of somatic symptoms.

CROSS-SECTIONAL ANALYSIS OF THE AUTONOMIC NERVOUS SYSTEM (HEART RATE VARIABILITY): CORRELATIONS WITH PSYCHOLOGICAL DIMENSIONS IN WOMEN WITH FIBROMIALGIA, RHumatoid ARTHRITIS AND HEALTHY WOMEN

T.L. Santiago, D. Peixoto, C. Costa, J.A. Pereira da Silva. Rheumatology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

Background: Autonomic nervous system (ANS) dysfunction has been proposed to play a role in the pathophysiology and maintenance of rheumatic diseases, including fibromyalgia (FM) and rheumatoid arthritis (RA). Heart rate variability (HRV) analyses provide a quantitative marker of ANS activity. Some studies suggest an association between reduced HRV parameters and psychological dimensions, namely a negative emotional state. This led us to hypothesize an association between rheumatic diseases and higher sympathetic activity mediated by a negative emotional state.

Objectives: To establish correlates between HRV parameters with rheumatic disease groups and psychological dimensions.

Methods: Sixty women (FM, n=20; RA, n=20; healthy controls (Ct), n=20) completed a self-reported questionnaire addressing demographic characteristics, the Eysenck Personality Questionnaire, the Hospital Anxiety and Depression Scale, and the Beck Depression Inventory-II (BDI-II). HRV analysis was performed by photoplethysmography between 8:00 and 10:00am, after an overnight fast, in a sitting position, for 5 minutes. We obtained the time and frequency-domain indices of HRV, including SDNN (standard deviation of the NN intervals), RMSSD (root-mean square differences of successive R-R intervals), high frequency power (HF), low frequency power (LF) and very low frequency power (VLF). Statistical analyses were performed considering: A) Rheumatic disease groups (FM/RA/Ct), and B) Psychological scores (irrespective of disease group): higher versus lower tertile in the personality questionnaires and score above (depression) versus below 20, in BDI-II. Between-groups comparisons were performed with Kruskal-Wallis test and analysis of covariance (age was adjusted during analyses), as appropriate.

Results: Neuroticism, anxiety and depression scores were significantly higher in FM and RA patients compared with controls (p<0.05). However, no statistically significant difference was observed in HRV parameters between disease groups and psychological dimensions, except for depression. The values of HF power (parasympathetic activity) were lower in the high depression group compared to the low depression group (p<0.05). The ratio of LF/HF was higher among the depression group than the control group (p<0.05).

Conclusions: This study did not find significant differences in the HRV between the three rheumatic disease groups. The results confirm that depression is accompanied by dysfunction of the autonomic nervous system, specifically lower parasympathetic activity. These results suggest that psychological dimensions, namely depression, must be taken into account when evaluating the ANS and its impact in disease pathogenesis.

PREVALENCE OF TYPE D PERSONALITY IN TURKISH PATIENTS WITH FIBROMYALGIA SYNDROME

Y. Garip 1, T. Gulier 1, O.B. Tuncer2, S. Onen 1 1Physical Medicine and Rehabilitation, Ankara Numune Training and Research Hospital, Ankara; 2Physical Medicine and Rehabilitation, Medipol University Medical School, Istanbul; 3Psychiatry, Sekvet Yılmaz Eğitim ve Araştırma Hastanesi, Bursa, Turkey

Background: Type D personality is a distressed personality type involving two personality traits, namely negative affectivity and social inhibition, which are described as tendency to experience negative emotions and to inhibit self-expression in social relationships, respectively (1).

Methods: The present study investigated the prevalence of type D personality in Turkish patients with fibromyalgia (FM) and evaluated the association between type D personality and clinical parameters of FM. Although there is adequate number of studies focusing on the relation between FM and psychological conditions such as depression and anxiety; this topic has been rarely addressed in the literature.

Methods: A total of 100 patients with FM fulfilling 1990 American College of Rheumatology (ACR) diagnostic criteria and 50 healthy controls were included. Type D personality was assessed by Type D Scale-14 (DS-14). FM disease severity was determined by Fibromyalgia Impact Questionnaire (FIQ), functional status by Stanford Health Assessment Questionnaire (HAQ), and health-related quality of life (HRQoL) by Nottingham Health Profile (NHP). Severity of pain and fatigue were measured by Visual Analog Scale (VAS).

**AB0933** PREDICTIVE MODEL FOR SHOULDER PAIN USING CLINICAL AND EPIDEMIOLOGICAL VARIABLES

C. Feced Climos 1, E. Labrador Sánchez 1, J. Ivorra Cortes 1, E. Grau García 1, E. Vicens Bermeu 1, J.J. Frigo Gil 1, R. González Mazario 1, C. Alcañiz Escalona 1, I. Cáceres Vázquez 1, I. González Puig 1, I. Martínez Cordellat 1, C. Nájera Herranz 1, R. Negueroles Albuixech 1, J.E. Oller Escandell 1, I. Cánovas Olmos 1, I. Chalmeta Verdejo 1, L. González Puig 1

**Background:** Shoulder pain is a very common complaint with poor prognosis and high recurrence. To evaluate the shoulder pain, anamnesis and physical examination are used, but a diagnosis of certainty is difficult. Clinical history and specific exploration maneuvers tend to be poorly correlated with the underlying problem. There are few studies that assess the predictability of shoulder pathology using patient characteristics and exploration.

**Objective:** To assess if the combination of exploratory maneuvers and clinical data predicts the type of affection of the painful shoulder in a sensitive and specific way.

**Methods:** We conducted a prospective study with patients who attended to the Rheumatology Department of HUP la Fe by painful shoulder between February 2016 and January 2017, excluding those with known inflammatory diseases.

A rheumatologist performed the anamnesis and the selected exploratory maneuvers: Jobe and Gerber test and palpation of the acromioclavicular joint. A second rheumatologist, blind to physical examination and medical history, performed the shoulder ultrason sound scan. Biostatistical analysis was performed using software R version 3.3.2.

**Results:** 119 patients (66.4% women) with a mean age of 60±12.56 years and shoulder pain were collected. Time of pain evolution was 20.43±24.09 months and the right shoulder was the most affected one (71.4%). The association between the maneuvers of Jobe and the involvement of the supraspinatus (SE), as well as the Gerber maneuver with the affection of the subscapular were statistically significant. However the sensitivity and specificity of both maneuvers are very low, so that alone is not suitable to identify the affected tendon or the type of affection. Thus, a predictor model (nomogram) of the most common shoulder pathologies (subacromiodeltoid bursitis, tendinosis or SE tears) was developed using epidemiological and clinical examination variables.

**Conclusions:** Based on our results, the predictor model performed using epidemiological and clinical examination variables would be able to predict the most frequent pathologies of the shoulder. Imaging tests have a certain delay time, and by applying this predictor model, a diagnosis of presumption could be established in primary care, giving the opportunity to institute an early treatment.

In addition, patients could be referred more efficiently to the appropriate specialty (rheumatology, traumatology or rehabilitation), avoiding delays.

**AB0934** TREATMENT OF LATERAL EPICONDYLITIS WITH ESWT: A SHAM-CONTROLLED DOUBLE BLINDED RANDOMISED STUDY

E.A. Gokmen 1, O. Karatas 2, E. Gligi 3, 1Physical Medicine and Rehabilitation, Antalya Training and Research Hospital; 2Physical Medicine and Rehabilitation, Korkuteli Public Hospital; 3Physical Medicine and Rehabilitation, Akdeniz University Hospital, Antalya, Turkey

**Background:** Lateral epicondylitis is a term describing the clinical condition that causes pain and sensitivity in musculotendinous adhesion sites of the wrist extensor muscles originating from the lateral epicondyle of the humerus, resulting in repetitive stresses due to overuse (1.2).

**Objectives:** The aim of this study was to investigate the efficiency of extracorporeal shockwave therapy (ESWT) in the treatment of lateral epicondylitis as randomized, non-blinded, controlled and randomized trial.

**Methods:** 47 patients (35 women, 12 men) with lateral epicondylitis were included in the study. The mean age of patients was 45.94±10.46 years. Patients were randomized into two groups: active ESWT (n=22) and sham ESWT (n=25). Patients were randomly allocated to receive 1 session per week for 3 weeks of either sham or active ESWT.

Patients were evaluated before the treatment, and at the end of the first week, first month and third month after the last treatment session with Patient-rated Tennis Elbow Evaluation Questionnaire (PRTEE), Visual Analogue Scale (VAS) for pain assessment and physical examination of lateral epicondyle of the elbow with special clinical tests.

**Results:** Compared with pretreatment values in ESWT group, significant improvement was observed in all parameters after treatment. At the first week after the therapy significant improvement was observed in sham group but at the first and third month after the therapy no significant difference was found. Comparison of ESWT and sham over 3 months after the treatment, significant improvements were observed in ESWT group in all parameters.

**Conclusions:** There was a significant decrease in pain and a significant improvement in function following ESWT. Although there was a reduction in pain and improvement in function with sham treatment as well, this difference was not as significant as in active group.

**AB0935** THE ROLE OF EPIDURAL INJECTIONS IN PATIENTS WITH CHRONIC SCIATICA: A REVIEW BASED ON THE EVIDENCE OVER THE PAST 5 YEARS

G. Ferreira Dos Santos 1, M. Amaral Silva, E. Marques, M. De Fátima Carvalho. Physical and Rehabilitation Medicine Department, Hospital de Curry Cabral - Centro Hospitalar de Lisboa Central (CHLC), Lisbon, Portugal

**Background:** Among various modalities applied in the management of painful conditions of the spine, epidural injections (EI) are one of the most commonly utilized interventions. EI can be administered in the lumbar spine by either caudal (CE) or interlaminar (IEL), or transforaminal (TEI) approaches and various steroids have been used in these injections(1,2). The purpose of EI is to provide analgesia for a varying duration, whilst making it easier for the patient to undergo a rehabilitation program during this time(1).

**Objectives:** The aim of this review is to evaluate the efficacy of the different types of EI in patients suffering from chronic sciatica, based on the evidence published over the past 5 years.

**Methods:** Relevant studies were retrieved by searching PubMed, Medicine, The Cochrane Library and UpToDate. Publications from 2012 to 2016 which specified the use of EI to treat chronic sciatica were considered, and all the studies selected were written in the English language only.

A total of 11 articles were gathered, of which 5 were excluded after analysis of their title and abstract. Of the 6 papers included in this study, 5 are systematic reviews and 1 is a meta-analysis of 10 randomized controlled trials. The outcomes measured were improvement in pain and functional status. TheNumeric Rating Scale (NRS) and Visual Analogue Scale (VAS) were the most commonly used baseline scales for pain evaluation. The Oswestry Disability Index (ODI) was the most used scale for the functional disability scoring system in the literature.
Results: 4 of the 6 papers included in this review reported improvements in pain ranging from 30 to 83% and in functional status ranging from 26 to 86% from the pre-injection state, with follow-up periods lasting up to 2 years after the EI. 2 of these 4 studies showed Level II evidence for EI for long-term efficacy in managing chronic sciatica, with no significant difference among CEI, IEI or TEI. The remaining 2 papers (out of the total 6) associated EI with immediate improvements in both pain and function, but found the benefits to be unsustained. 1 paper reported 1 serious adverse event in one of the trials analyzed and found the data on harms to be sparse on most trials. Another paper concluded that injecting local anesthetic alone might be preferable to injecting local anesthetic with steroid as omitting the steroid could lessen the risk of rare, but possibly fatal, complications.

Conclusions: Despite variability in the studies included and methods used for data synthesis, most of the articles included in this review showed positive results for both pain relief and improvement in function for EI. Although no studies found significant difference among CEI, IEI or TEI in terms of efficacy, each approach has its advantages and these should be taken into account when choosing the best approach for each patient. As supporting evidence, this review shows that EI with or without steroids are a fast, safe and clinically effective treatment method for patients with chronic sciatica.

AB0936 FLEXIBILITY AND STRENGTH OF THE TRUNK IN CHRONIC LOW BACK PAIN TWO YEARS AFTER A FUNCTIONAL RESTORATION PROGRAM

R. Maaco1, S. Zrida1, I. Kaïbi1, N. Mouhi1, R. Rahal1, M. Sghir2, W. Kossomtini1. 1Physical and Rehabilitation Medicine, military hospital Tunis, Tunisia; 2Physical and Rehabilitation Medicine, regional hospital Tahar Star of Mahdia, Mahdia, Tunisia

Background: Low-back pain affects significantly the flexibility and the muscular strength of the trunk. It was demonstrated in literature the positive effect of restoration programs in these parameters at short-term evaluation.

Objectives: Evaluate the flexibility and the muscular strength and endurance of the trunk two years after a functional restoration program

Methods: Prospective study on patients with low back pain evaluated before, at the end of the restoration program and two years later. We have evaluated the following parameters: trunk flexibility by use of the Schöber index and the finger–ground distance test (FGD), hamstring flexibility by measurement of the thigh-leg (TL) angle, back flexor and back extensor endurance, assessed with the Shirado test and the Sorenson test, respectively.

Results: Thirty patients were evaluated. Initially, the results reported decreased flexibility: 53% with FGD >15° cm; 37% with the thigh-leg (TL) angle >15° and decreased muscle endurance: Shirado 30.26±29.662s; Sorenson 26.3860±18.5208s. The short-term efficacy of the program showed significantly improvement in all parameters (p<0.01). However, this improvement decreased 2 years later but remained significant. This loss can be attributed to the fact that 70% of patients abandoned self-rehabilitation exercises.

Conclusions: The restoration program seems to have good effect in short and long term evaluations in the flexibility and muscular strength of the trunk.

AB0937 DUPUYTREN'S CONTRACTURE: 15 YEARS OF EXPERIENCE WITH 36 CASES

H. Mourad1, M. Jguirim2, A. Arfa1, A. Farhat1, M. Brahmi1, A. Mnemi1, Z. Saoussen1, I. Bejia1, M. Touzi1, N. Bergaoui1. 1Rheumatology Unit of the Monastir University Hospital, Monastir, Tunisia

Background: Dupuytren's contracture is characterized by thickening and retraction of the palmar aponeurosis due to fibroblastic proliferation leading to progressive and irreducible fingers' flexion. Dupuytren's contracture appears to be a disease with poor clinical symptomatology and the therapeutic progress, in particular the needle aponeurotomy, continues to increase.

Objectives: We propose to describe the epidemiological, clinical and therapeutic characteristics- particularly the needle fasciotomy- of Dupuytren's contracture diagnosed and treated in our Rheumatology department.

Methods: This is a retrospective descriptive study that collected patients with Dupuytren's disease over a 15-year period from 2001 to 2016.

Results: Thirty-six patients were collected. The mean age was 63±10 years (46 years, 83 years, 83 years) and the sex ratio was 5. 34% of the patients were manual workers, of whom 42% were masons, 25% were farmers and 17% were carpenters. 8% of longshoremen and 8% of dressmakers. The personal history was diabetes in 63% of cases, of which 26% were unbalanced, hypertension in 31% of cases and hypercholesterolemia in 14% of cases. 6% of patients were epileptic. 23% of patients were ethyl and 13% were smokers. 6% had an associated Ledderhose disease. 9% of our patients had a family history of Dupuytren's disease. The mean time to diagnosis was 60 months (03 months to 180 months). The clinical examination noted an exclusive involvement of the left hand in 22% of cases, right hand in 12% of cases and bilateral involvement in 66% of cases. The fingers affected were: 59% the ring finger, 49% the little finger, 23% the middle finger, 12% the index and 5.5% the inch, in order of frequency of mention. The stages of Dupuytren's disease at their discovery were as follows: stage 4 (25%), stage 3 (34%), stage 2 (24%) and stage 1 (17%). Skin examination showed that 58% of the skin was inflicted and 42% of the skin was soft. From a therapeutic point of view, 86% of the patients benefited from a needle aponevrotomy with a good progression in 97% and a recurrence in 8% of the cases. In all stages combined, the average postoperative therapeutic gain was 0.83 stage at the Left hand and 1.43 stage at the right.

Conclusions: The Dupuytren's contracture is the object of a scientific subject whose wealth grows exponentially. These range from the paternity of his first description, to the place of the last therapeutic modalities.

AB0939 CHANGE IN THE SURGICAL TREATMENT FOR CERVICAL SPINE DISORDERS RELATED TO RHEUMATOID ARTHRITIS DURING RECENT 15 DECADES

K. Sakuraba, K. Kai, H. Miyahara. National Hospital Organization Kyushu Medical Center, Fukuoka, Japan

Background: Since the appearance of biological DMARDs in Japan, disease control of rheumatoid arthritis has been ameliorated. Inflamed synovitis and destructive arthritis declined dramatically, which resulted in a decrease in the number of synovectomy and joint prosthesis gradually. On the other hand,
AB0940 EFFICACY AND SAFETY OF PLATELET RICH PLASMA PERI-NEURAL INJECTION IN TREATMENT OF DIABETIC NEUROPATHY: DOUBLE BLIND RANDOMIZED CONTROLLED TRIAL

M. Hasseni1, Y. Saad1, A. Alawamy2, W.A. Khalifa3, D. Abdelkareem4.
1Rheumatology Department, 2Anesthesia department. Assuit University; 3Internal Medicine; 4Clinical Pathology, Assuit University, Assuit, Egypt

Background: Neuropathy is a common complication of diabetes mellitus (DM) not only leads to an impaired quality of life, but also to an increased morbidity and mortality. Autologous platelet-rich plasma is easy and cost-effective method. Platelet-derived angiogenesis factor capable of stimulating new capillary growth and revascularisation.

Objectives: evaluate the clinical efficacy and safety of perineural PRP injection in the treatment of diabetic neuropathy (DN) compared to tradition medical treatment.

Methods: Sixty patients were selected from Endocrinology unit Department of Internal Medicine, Assuit University Hospital, Egypt that type II diabetes mellitus neuropathy (DN) of at least 5 years duration of symptoms, regardless of age and gender double blindly divided into two groups, both groups had control blood glucose. Group I underwent PRP pre-neural injection under ultrasound guidance and group II underwent medical treatment. Baseline pain and nerve conduction study of upper and lower limb nerves and sural nerve conduction studies, F-wave nerve conduction study were determined at 3 months after the procedure. Primary outcome was the total effective rate. The total effective rate = (the number of patients with significant effect - the number of patients with effect)/total number of patients. A “significant effect” meant that limb pain, numbness, and fatigue were significantly reduced, nighttime sleep was improved, and NCV from electrophysiology increased >5 m/s or returned to normal. An “effect” meant that the symptoms mentioned above were relieved, and NCV compared with pre-treatment increased ~5 m/s. “Failure” meant that the symptoms did not improve, and there were no changes in NCV electromography.

Results: We recruited 60 diabetic patients (type II) with peripheral neuropathy with a mean age 35.27±12.86 years with disease duration of 7.42±3.51 years. Of these, 56% cases with upper limb neuropathy only while the rest 44% had sural nerve plus upper limb nerves neuropathy. Nerve conduction study showed axonal affection in only 26% and all had delayed distal latency and prolonged motor conduction velocities. generalized DN is found in 70% of total patients and 30% of had focal Entrapment of the nerve includes median neuropathy at the wrist 50%, ulnar neuropathy at the elbow 30% and peroneal neuropathy at the knee 20% and no patients had radiculoplexus neuropathy.

Conclusions: Autologous platelet-rich plasma is an easy and cost-effective method as a treatment of diabetic peripheral neuropathy.

AB0941 PATIENTS PROFILE AT ORTHOGERIATRIC UNIT: NEW MODEL OF CARE

S. Hammami, A. Meziani, A. Ioana, C. Dumont, V. Latteur. Geriatric, GHdC Belgium, Charleroi, Belgium

Background: Fractures in elderly patients its a prevalent problem. Older patients due their characteristics requires a specific care. The orthogeriatric Unit has been shown to be one of the most beneficial units. It is important to evaluate the model results.

Objectives: Evaluate the main variables of fractures patients treated at a orthogeriatric Unit and their complications

Methods: This is a partially concurrent prospective study, taking place in a large urban academic hospital GHdC in Belgium. The participants were 87 consecutive elderly people, admitted directly to a geriatric-based orthogeriatric ward.

Results: A total of 87 patients were included. The average age was 85.2±5.2 years, 20 male, 67 female. Most of them (n=44, 52%) were admitted for a hip fractures, 44% (n=38) were transferred from emergency department, ISAR score was 3.8±1.1, Preoperative stay was less than 24 h for 54% of our population, delirium incidence was 24%, Mini mental state examination was 20.6±6,4, the Cumulative Illness Rating Scale was 17±4.5, the mean number of medicine was 6.8±3.3, Activity of Daily Living 15 days after admission was 12.2±5.5. Delirium was the principal complication 55% (n=44). Mean hospital stay between admission and discharge/transfer to convalescence unit was 23.8±12.9. In-hospital mortality was 11% (n=10).

Conclusions: Fractures is a frequent and disabling pathology among geriatric fragile population, its treatment requires an interdisciplinary approach. This must be managed by the collaboration between geriatrician and orthopedist. We believe that the orthogeriatric Unit providing subspecialty and acute care will improve the general outcome of fragile geriatric patients.

**AB0943** SIGNIFICANCE OF MUSCLE VOLUME & FATTY DEGENERATION OF LUMBAR PARASPINAL MUSCLE IN SPINAL IMBALANCE

Y.-S. Park, J. Lee, J.-S. Park. Department of Orthopaedic Surgery, Hanyang University Gumi Hospital, Gumi city, Korea, Republic Of

**Background:** Spinal sagittal imbalance which is closely associated with low back pain is considered as a factor in a variety of spinal disorders.

**Objectives:** The present study was to determine the relationship between the sagittal imbalance and sarcopenia, especially cross sectional area (CSA) and fatty degeneration (FD) of muscle around the spine.

**Methods:** Overall, 165 patients were included in this study, classified by three groups according to the distance from sagittal vertical axis to posterior end of upper end plate of sacrum. 38 patients were classified as group 1 (distance ≥9cm), 50 and 53 patients as group 2 (distance 5–9cm) and group 3 (distance <5cm). For measurement of CSA and FI of paraspinal muscles, five transverse T1W images of S1-S5 were obtained from PACS and measured with Adobe Photoshop 7.0, by counting the number of pixels included in each selected muscle area. A variance analysis on average muscle surface area of those five images was done with SPSS 19.0 Windows version (SPSS Inc., Chicago, IL, USA).

**Results:** Of 37 responders, 15 (40.5%) did not show any flare (Table 2). Disease free survival on Et: Of 37 responders, 22 flared. No factors could predict flare in pts who recd tapering Et dose or after stopping Et. Some needed repeat cycles of Et/2nd BRM. Kaplan Meier curve of responders confirmed that no pt would be flare free at 63mths of follow up.

**Conclusions:** Et is safe to use & had no adverse events in 89%. Needed most for ERA. Effective in 84%. On using shortterm Et, 59% flared either on tapering/stopping. These pts responded to reinitiation of Et/BRM. Kaplan Meier curve of responders confirmed that no pt would be flare free at 63mths of follow up.

**Paediatric rheumatology**

**AB0944** USE,SAFETY AND EFFICACY OF ETANERCEPT IN JIA—A SINGLE CENTRE RETROSPECTIVE STUDY FROM NORTH INDIA

A. Shivpuri, S. Mittal, M. Agarwal, S. Sawhney. 1 Fellow in Training, Pediatric Rheumatology; 2 Consultant, Sir Ganga Ram Hospital, New Delhi, India

**Background:** The treatment paradigm for Juvenile Idiopathic Arthritis (JIA) has changed in last decade:Early diagnosis,objective assessment & appropriate use of biologic response modifiers (BRMs) are common place.ETanercept (Et) is available in India for 15yrs. BRM use in developing world is fraught with the cost & safety concerns regarding TB, at our centre, full dose Et is used for 3–6 mths, followed by dose tapering as tolerated.

**Objectives:** 1. To determine use, safety & efficacy of Et in JIA. 2. To determine the factors that determine responders vs non responders. 3. To determine the factors that determine disease free survival on stopping Et

**Methods:** This study was done by 15thJune15 to 15thDec16 (18mths) at Sir GangaRam Hospital. Inclusion criteria: All JIA pts who took Et for min 12 wks & attended the outpatients during the study period. Outcome: All pts who achieved the Wallace criteria of inactive ds, clinical remission on (CRoM) or off medication within 4 months were termed as responders.

**Results:** Use: 46pts recd Et (29M,17F). Median (Md) age at JIA onset: 9.08yrs (1.16–16.5).Md delay to diagnosis: 4mths (0.5–60). Md age at initiation of Et: 11.6yrs (4.25–20.3). Indications: Partial response to Intraarticular steroids/bridging steroids & DMD-ARD-32; Started upfront for high dis burden: 14: Diagnoses: ERA30 (65%), Poly JIA (17%), OJIA 3 (7%), SOJIA 3 (7%) & UJIA 2 (4%). Safety: Screening: Mantoux <6, Quantiferon <2; anti tuberculosis therapy for latent TB: 8. Side effects: 41 (88%) had no adverse event. 5 pts – 1 each had enteric fever, varicella, uveitis, hemolysis, malaria. Follow up: Md duration of follow up=47.5 mths (2–147). Medications at last follow up: Et ongoing in 20 (43.5%), 12 on 2nd BRM, 12 off BRM & 2 lost to follow up. Status at last follow up: Of 37 responders - 8 currently active.

**Disclosures of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.4228

**AB0945** COHORT STUDY OF 112 PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS DURING TRANSITION FROM PEDIATRIC TO ADULT CARE

A.-C. Debrab 1, A. Beaumel 2, A. Rougelot 2, J.-P . Larbre2, M. Couret1, F. Coury2. 1Rheumatology, CHUV, Lausanne, Switzerland; 2Rheumatology, HEL, Lyon, France

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic inflammatory arthritis in children. The International League of Associations for Rheumatology 2001 (ILAR) classification includes 7 subgroups: systemic JIA, polyarticular JIA, oligoarticular JIA, enthesitis related arthritis (ERA), psoriatic arthritis and undifferentiated arthritis. Most paediatric inflammatory arthropides persist into adulthood. Therefore, a transition from paediatric to adult rheumatology is a necessary step. Transition is defined as an active process by which a young patient with a chronic disease develops skills and resources to gradually take control of their condition. The transition phase should be anticipated and structured because of the risk of failure in monitoring. However difference in classification criteria in paediatric and adult rheumatology can cause significant difficulty for adult rheumatologists.

**Objectives:** The aim of this study was to determine the characteristics of juvenile-onset arthritis seen during the transition period and to compare paediatric classification criteria to those of adults.

**Methods:** A retrospective bi-centre study was performed. Patients with JIA according to ILAR classification were included and had a consultation at transition. JIA classification criteria were compared to ACR/REULAR 2010 criteria

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2017-eular.4892
CALCINOSIS IN CHILDREN WITH JUVENILE DERMATOMYOSITIS FROM A SINGLE-CENTRE IN NORTH INDIA

A. Sharma, A. Jindal, A. Gupta, D. Suri, S. Singh. Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Juvenile dermatomyositis (JDM) is a rare childhood autoimmune inflammatory muscle disorder that can result in severe disability or death. Calcinosis is a unique and a poorly understood long-term complication of JDM (1). Calcinosis can present in various forms like nodular calcinosis, tumoral deposits, calcinosis universalis. We present here the images of calcinosis in children with JDM.

Methods: All children diagnosed to have JDM and registered in Pediatric Rheumatology Clinic at Post Graduate Institute of Medical Education and Research, Chandigarh, India, were evaluated for presence of calcinosis. Consent was taken from patients or caregivers.

Results: A total of 36 patients were evaluated. Twelve (33.33%) patients had calcinosis (Fig 1). Interestingly, 4 children had calcinosis at the time of diagnosis. In any of the two first appointments, 20 patients (24.7%) were active in the 2 first appointments N (%) 20 (24.69) 15 (28.30) 4 (40) Time of disease onset - Median (IQR) 10.3 (4.5–14.2) 6.5 (2.1–12.9) 0.02 (11.5–15.6)

Conclusions: Our study confirmed the articular destructive potential of polyarticular systemic JIA and an ocular risk in polyarticular JIA. Comparison of JIA criteria to adult rheumatism criteria showed that polyarticular JIA with positive rheumatoid factor fulfilled ACR/EULAR criteria for RA. However, oligoarticular JIA and polyarticular JIA without rheumatoid factor did not fulfill any adult rheumatism criteria and seem to be paediatric entities. Finally, most patients with ERA and psoriatic arthritis fulfilled the ASAS criteria for spondyloarthritis.

AB0948 INSUFFICIENT CALCIUM INTAKE IN PEDIATRIC POPULATION WITH RISK FACTORS FOR OSTEOPOROSIS

B. Magallaretz López1, J. Betancourt2, G. Fraga3, N. Pardo2, M. Torrent2, A. Marin2, S. Herrera1, E. Carreras1, J. Casademont1, J. Malouf Sierra1, 1Rheumatology; 2Pediatrics; 3Hospital Santa Creu i Sant Pau, Barcelona, Spain; 4Internal Medicine, Hospital Santa Creu i Sant Pau, Barcelona, Spain

Background: Compliance with daily calcium requirements in paediatric and young age is necessary to acquire peak bone mass, especially in populations that meet one or more risk factors for fractures.

Objectives: To study the characteristics of the pediatric population with at least one risk factor for developing low bone mass/osteoporosis and to measure their calcium intake.

Methods: Demographic and clinical data were prospectively collected from patients aged 2 to 20 years that met at least 1 risk factors for bone fragility, including: inflammatory diseases, treatment with Immunosuppressants and/or compliance with daily calcium requirements in paediatric and young age is necessary to acquire peak bone mass, especially in populations that meet one or more risk factors for fractures.

corticosteroids, malabsorptive disorders, chronic systemic disorders such as nephropathies or hematologic diseases, etc. The patients or their legal tutors signed the Informed Consent in order to participate in the study. The average daily calcium intake was collected through the Spanish INDICAD 2001 study survey, together with a comprehensive anamnesis. If patients or their family reported taking food not included in the survey, its calcium content were consulted in the Spanish Food Composition Database published by the BEDCA Network of the Ministry of Health Science and Innovation.

Results: Data were collected from 50 patients, with a mean age of 9.2 years (2–20); 28 (56%) female, 86% Caucasian, 6% Arab, 2% Asian and 6% Latin. The most frequent factors of treatment were: Food intolerances/ malabsorption: 32%; nephropathies: 22%; JIA: 16%; vasculitis: 10%, other inflammatory diseases: 8%. 42% had received systemic corticosteroids at some point, and 16% were receiving corticosteroids at present. Average daily calcium intake was 718 mg/d. They were divided by age groups, attending to daily calcium needs per group. In Table 1 we can observe the Recommended Daily Amount (RDA) of calcium by the Spanish Association of Pediatrics and the consumption collected, by age group.

Only 3 children with low calcium intake were taking supplements. A decrease in calcium RDA adherence was observed with increasing age, statistically significant (p<0.005). There was also a lower calcium intake in the non-Caucasians compared to Caucasians statistically significant (p=0.044), which was not associated with age.

Conclusions: Calcium intake in the population under 21 years old with at least 1 risk factor for developing low bone mass/osteoporosis is lower than recommended. In addition, recommendations are based on the physiological needs of the healthy populations and it could be expected to be insufficient for those with chronic diseases. It should be noted that calcium intake in the groups with higher requirements (adolescents and young people) is lower, with a reduction in the proportion of patients who meet the compliance with the RDA as age increases. Studies with a larger population are needed to ratify these results together with serum calcidiol levels.

AB0949 THE ANNUAL COST OF PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

B. Serpen1, O. Altug-Gucenmez1, C. Acar1, M.K. Sozmen2, B. Makay1, S.E. Unsal1.

1Faculty of Medicine, Unit of Pediatric Rheumatology, Dokuz Eylul University, 2Faculty of Medicine, Department of Public Health, İzmir Katip Celebi University, Izmir, Turkey.

Background: The management of juvenile idiopathic arthritis (JIA) includes various methods including such as medication, hospitalization, rehabilitation.

Objectives: To determine how much juvenile idiopathic arthritis cost; the components of this cost; how new treatments, i.e. biologics, improve the disease course and hospital expenditures.

Methods: This study was conducted in Dokuz Eylul University, Pediatric Rheumatology Unit between March 2015-March 2016. One-hundred six JIA patients who had a follow-up period of at least 1 year according to International Edmonston 2001 criteria were included. This retrospective cost study evaluated the data of these patients and calculated the direct cost for the follow-up period. Clinical data was collected from patient files that were in department’s archive and cost data was gathered from Probel Hospital Information Management system. Patient data form covering sociodemographic and clinical information, patient drug form and annual medical cost form was filled out for each patient.

Results: 58.5% (n=62) of patients was female and 41.5% (n=44) was male. The mean age was 12.0±4.3 years. 34.0% (n=36) of patients was oligoarticular type, 7.3% (n=8) was polyarticular type, 22.6% (n=24) was enthesitis related arthritis (ERA), 8.5% (n=9) was psoriatic type and 6.6% (n=7) was systemic type. The cost of medication counted for 87.1% (453,244.94 TL) of total direct annual cost. The most total direct medical cost was highest for ERA (n=742.55±381 TL) while the annual cost was calculated as 10451 TL per person for biologic using patients, for the patients using non-biologic treatments it was determined as 1472 TL per person. 1 TL=0.32 € 1 TL=0.35 $

Conclusions: Medication is responsible for most of the total direct medical cost in patients with JIA. Our results showed concordance with previous studies on the subject. This situation could be attributed to biological agents that are being used in treatment in recent years. More prospective studies on the effectiveness of cost of treatment, with greater amount of patient and more homogenous subgroups are needed.

AB0950 PREDICTORS OF RESPONSE TO ETANERCEPT TREATMENT DEPENDING ON JUVENILE IDIOPATHIC ARTHRITIS CATEGORY

E. Kashchenko1, E. Alexeeva1, T. Bzarova1, S. Valieva1, R. Denisova1, O. Lomakina1, K. Isayeva1, M. Soloshenko1, A. Karaseva1, E. Kashchenko1.

1Federal State Autonomous Institution “National Scientific and Practical Center of Children’s Health” of the Ministry of Healthcare of the Russian Federation; 2I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.

Background: Anti-TNF biologics are highly effective and widely used in clinical practice for the treatment of JIA. However, some children lack of response with low reliable predictors of a good or poor response to treatment found [1–3]. As clinical picture patterns are significantly differ for 7 JIA subclasses, we propose to find predictors of response to therapy for each of JIA category.

Objectives: To identify clinical and laboratory parameters associated with response to etanercept treatment in 12 months in patients with different JIA categories.

Methods: Patients from four JIA categories (n=195) were divided to groups with excellent, intermediate and poor response after 12 month treatment with etanercept according to ACRPedi criteria, achieving inactive disease by Wallace criteria and JADAS-71 cut-off point. For each of JIA category univariate and multivariate logistic regression analysis was conducted to identify potential baseline factors associated with treatment response. Baseline factors included clinical, laboratory and anamnestic data.

Results: From total cohort 91/58/88.5 percent of patients achieved ACR30/50/70/90 in one year etanercept treatment: 45.5% patients were considered excellent responders, 30% - intermediate responders, and 24.5% - poor responders. Highest efficacy of therapy was shown in persistent oligoarticular patient, lowest – in enthesitis-related arthritis and polyarthritis patients. Potential baseline predictors of excellent and poor response which were significant are described in the table.

JIA category | Predictors of excellent response | Predictors of poor response |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Persistent oligoarticular</td>
<td>smaller amount of DMARD</td>
<td>–</td>
</tr>
<tr>
<td>Extended oligoarticular</td>
<td>–</td>
<td>–</td>
</tr>
<tr>
<td>Enthesitis-related arthritis</td>
<td>shorter disease duration (DD)</td>
<td>– longer DD</td>
</tr>
<tr>
<td>RF-negative polyarticular</td>
<td>– smaller number of joints with limited range of motion (LOR)</td>
<td>– lower CRP level at the baseline</td>
</tr>
<tr>
<td></td>
<td>lower age at disease onset (ADD)</td>
<td>older ADD</td>
</tr>
</tbody>
</table>

Analysis showed that poor response in all JIA categories was mainly associated with demographic data (longer DD and older ADD). However, factors associated with excellent response significantly differed depending on JIA category (anamnestic factors, number of involved joints, laboratory factors, and demographic factors).

Conclusions: Response to etanercept therapy is strongly associated with JIA category. Shorter disease duration and lower number of DMARDs used before start of etanercept, lower number of joints with LOM, and lower C-reactive protein at baseline are predictors of better response to etanercept.

AB0951 FACTORS ASSOCIATED WITH RESPONSE TO ADALIMUMAB TREATMENT IN JUVENILE IDIOPATHIC ARTHRITIS

E. Kashchenko1, E. Alexeeva1, T. Bzarova1, S. Valieva1, R. Denisova1, O. Lomakina1, K. Isayeva1, M. Soloshenko1, A. Karaseva1, E. Kashchenko1.

1Federal State Autonomous Institution “National Scientific and Practical Center of Children’s Health” of the Ministry of Healthcare of the Russian Federation; 2I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation.

Background: Tumor necrosis factor inhibitors are highly effective and safe in treatment of juvenile idiopathic arthritis (JIA). Nonetheless, to select the optimal therapy and to achieve maximum therapeutic effect it is necessary to consider the individual characteristics of the patient. Adalimumab (ADA) is widespread use for mild and severe polyarticular JIA especially in the presence of uveitis, but there is lack of data about clinical and laboratory predictors of response to ADA in different JIA categories.

Objectives: To identify clinical and laboratory parameters associated with
response to adalimumab treatment in 12 months in patients with different JIA category.

Methods: Analysis include patients with enthesis-related arthritis (ERA, n=56), RF-negative polyarthritis (pRF, n=50), extended oligoarthritis (extOligo, n=30), and polyarthritis (polyArth, n=62) with median age 10.5 (IQR 6–14) and median JADAS-71 19.5 (IQR 15–28). Patients were divided to response groups after 12 month treatment with ADA according to ACRpedi criteria, achieving inactive disease by Wallace criteria and JADAS-71 cut-off point as excellent, intermediate and poor responders. For each JIA category univariate and multivariate logistic regression analysis was conducted to identify potential baseline factors associated with treatment response. Baseline factors included clinical, laboratory and anamnestic data.

Results: ADA was shown to be effective in all groups with 90%/89%/82%/63% children with ACR30/50/70/90 during one year therapy. The most significant factors (p<0.05) associated with response to ADA treatment are presented in summarized table. Our findings demonstrated that different predictors corresponded with different JIA categories. Interestingly subjective scales of disease activity was shown to be strongly associated to therapy. At the same time VAS severity at baseline were inversely correlated with achievement of good response. Duration of morning stiffness correlated with excellent response in children with 2 different categories. However, for ERA patients shorter duration was associated with better response to treatment while vice versa for ExtOligo patients.

Conclusions: Predictors of response to ADA treatment differ in JIA categories. Low disease activity parameters (clinical and laboratory) at baseline not always predict good response to therapy.

AB0953

ARTHRITIS FOLLOWING PARASITIC INFECTION IN THE DIFFERENTIAL DIAGNOSIS OF JUVENILE IDIOPATHIC ARTHRITIS

M. Maschio1, S. Pieropan2, F. Caldonazzi1, G. Dallagiacoma3, V. Ravagnani3, D. Degan1, G. Piacenti3, D. Biasi3, M. Rossini1,1 UOC pediatrici; 2UOC pediatria; 3UOC pediatria; AOUI, Verona; 2Reumatologia, Azienda Ospedaliera Carlo Poma, Mantova, Italy

Background: According to literature arthritis is a rare complication following parasitic infection. In the Italian pediatric population parasitic infection is mainly caused by Enterobius vermicularis; it is often asymptomatic but common symptoms can be anal nocturnal itching, insomnia, irritability, abdominal pain together with arthralgia.

Objectives: To describe cases of mono or poliarthritus due to parasitic infection in young patients followed at the Verona’s Pediatric Rheumatology Clinic from 2010 to 2016.

Methods: Medical records of 8 patients followed at the Pediatric Rheumatology were analyzed. The mean age of 8 patients was 8 (F:M 3.5). The following data were evaluated: anamnesis data, clinical symptoms (anal itching, irritability, arthralgia, abdominal pain and arthritis), Blood test and scotch tape test. All patients underwent joint ultrasound (US). Physical symptoms of joint’s involvement were evaluated in all children by an experienced rheumatologist.

Results: 6 patients had symmetrical poliarthritus, 2 patients had monoarthritus (knee and hand). Symptom’s complaint were systemic (12,5%), abdominal (25%), and general pruritus (25%). Blood test confirmed high inflammation indices (25%) and hyperesinophilia (12,5%).Serological tests and stool investigations allowed to diagnose the following infections: Enterobius vermicularis (6 cases) giardia lambiia (1 case); dientamoeba fragilis (1 case).Joint US evidenced synuvium hyperplasia in 75% of the cases and tenosynovitis in 50% of the cases.After appropriate antiparasit treatment complete articular and systemic symptomatic remission was observed (100% cases); also joint US control normalized 2 cases, after about 6 months, were re-evaluated for arthritus relapse and in both cases a parasitic reinfection was confirmed.

Conclusions: Analysis of this series of patients underlimes the following data: arthritis can be a manifestation of parasitic infection; treatment must be aimed against the parasite involved in order to achieve complete clinical and laboratory data remission; reinfection must always be considered in cases of relapse; differential diagnosis of this form of arthritis with other chronic polyarthritis is fundamental due to the risk of disseminated infection in case of immunosuppressive treatment.

AB0952

EXPERIENCE OF TOCILIZUMAB USE IN TREATMENT OF JUVENILE IDIOPATHIC ARTHRITIS IN CHELYABINSK REGIONAL CHILDREN HOSPITAL

G.A. Glazyrina1, N.A. Kolyadina2, Y. South Ural Governmental Medical University; 2Chelyabinsk Regional Children Hospital, Chelyabinsk, Russian Federation

Background: Recently due to application of interleukin (IL)-6 inhibitors prognosis for systemic juvenile idiopathic arthritis (sJIA) has significantly improved. 526 children with JIA are under monitoring in Chelyabinsk region, 42 children have sJIA. Tocilizumab is the drug of choice for sJIA treatment. It is registered within the Russian Federation for use in children older than 2 years. In Chelyabinsk Regional Children Hospital tocilizumab has been used for 5 years.

Methods: 18 children (12 boys, 6 girls) aged from 2 to 17 (mean age 10.7 years) diagnosed with sJIA were under monitoring. Disease duration was from 6 months to 15 years (mean duration 6 years). JIA was diagnosed based on ILAR diagnostic criteria. SJIA was diagnosed in 16 children, severe polyarthritis was diagnosed in 2 children. Tocilizumab was introduced intravenously every 2 or 4 weeks in dose of 12 mg/kg for children <30 kg or 8 mg/kg for children ≥30 kg. Therapy duration was from 3 months to 5 years (average duration 23 months). Assessment of disease activity and therapy efficiency was conducted in accordance with ACR pedi criteria. Nonparametric statistical methods were used to compare results.

Results: Prior to tocilizumab use high disease activity was observed in all children. Average number of joints with active arthritis was 13.5 [6;15] (Me [25.75%]). Average number of joints with functional impairments – 12.5 [6;15]. Average ESR (according to Panchenko) – 50 [40;60]mm/h, CRP 98.6 [55;139]g/L. Assessment of functional activity according to CHAQ questionnaire – 2.08 [2.25]. Activity assessment according to VAS by doctor – 82 [75;90]. No eye lesions were found in children under monitoring. All 16 children with sJIA had fever, hepatosplenomegaly and lymphadenopathy, the rash had 11 children, polyserositis - 8. In 5 children there was a complication in the form of a syndrome of macrophage activation.

During the tocilizumab therapy a decrease in disease activity was observed

in all patients. Mean number of joints with active arthritis was 1 [0;2] (Me [25.75%]) (P=0.0002). Mean number of joints with functional impairments – 3 [0;3] (P=0.0003). Average ESR was 4 [3.5;5]mm/h (P=0.0002), CRP 0.75 [0;1]g/L (P=0.0003). Assessment of functional activity according to CHAQ questionnaire was 0.25 [0.0;0.5] (P=0.0004). Activity assessment according to VAS by doctor – 16 [10;20] (P=0.0002). Assessment of parents according to VAS 18 [10;20] (P=0.0002).

Clinical disease remission (according to ACR pedi criteria – ≥90%) was observed in 11 patients after 6–9 months of treatment. Remission duration up to now is from 3 months to 4 years. Efficiency according to ACR pedi criteria is 70% in 6 children, 50% in 1.

The drug was well-tolerated. Undesirable effect such as allergic skin reactions were observed only in one child. In one child the lack of efficiency produced by switching to canakinumab. Drug was cancelled in 3 patients due to long-term remission (≥3–4 years), before of them after a year needed the resumption of therapy in connection with the aggravation of the disease.

Conclusions: Tocilizumab therapy was highly effective and safe in patients with JIA. Clinical remission was achieved in 61,1% children. Decrease in disease activity was observed in 39.9% of children. No serious undesirable effects were reported.

AB0954 RELATIONSHIP BETWEEN SERUM COMPLEMENT LEVELS AND RENAL PATHOLOGICAL CLASSIFICATION IN CHILDREN WITH SILENT LUPUS NEPHRITIS

H. Wakiguchi1, T. Kubota2, S. Takei3; 1Department of Pediatrics, Yamaguchi University Graduate School of Medicine, Ube; 2Department of Pediatrics, Kagoshima University Graduate School of Medical and Dental Sciences; 3School of Health Science, Faculty of Medicine, Kagoshima University, Kagoshima, Japan

Background: Silent lupus nephritis is defined by some pathological evidence of lupus nephritis with normal urinary findings. It is therefore apparent only upon renal biopsy. Serum complement levels have been associated with overall lupus disease activity. Despite recent progress in understanding the pathogenesis of lupus nephritis, including complement, our understanding of silent lupus nephritis, especially in children, remains limited.

Objectives: To study whether serum complement levels are associated with renal pathological classification in children with silent lupus nephritis.

Methods: We determined serum C3 and C4 levels and International Society of Nephrology/Renal Pathology Society classification in 25 patients with paediatric silent lupus nephritis before initial therapy who were admitted to our hospital. Patients were classified as having silent lupus nephritis based on normal urinary findings at baseline renal biopsy in juvenile systemic lupus erythematosus.

Results: Serum C3 levels varied between International Society of Nephrology/Renal Pathology Society classes, with significantly lower levels for silent lupus nephritis patients in class III compared to class II, and for class II compared to class I. There was no significant difference in serum C4 levels between International Society of Nephrology/Renal Pathology Society classes in patients with silent lupus nephritis.

Conclusions: Our results suggest that serum C3 levels were associated with renal pathological classification in children with silent lupus nephritis. We propose that serum C3 levels would provide a useful tool for predicting latent severe nephritis in patients with juvenile systemic lupus erythematosus who have normal urinary findings before initial therapy.

AB0955 NEW ONSET OF UVEITIS, PSORIASIS OR IBD AS PARADOXICAL EFFECTS OF BIOLOGICS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS: SINGLE CENTER EXPERIENCE

I. Nikishina, O. Kostareva, M. Kaleda, S. Rodionovskaya, S. Arsenyeva, D. Alexeesev, E. Fedorov, A. Shapovalenko. V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia

Background: Biological agents (BA) are high efficacy options for current therapy for patients (pts) with juvenile idiopathic arthritis (JIA). They are successfully used not only for the arthritis but also for uveitis, psoriasis and inflammatory bowel disease (IBD). However, paradoxical induction of these conditions in pts treated with BA is a well-established phenomenon.

Objectives: To evaluate the frequency of new onset of uveitis, psoriasis or IBD occurring under BA therapy in JIA pts, to establish clinical features, which may be associated with such effects.

Methods: Retrospective cohort study involved all JIA pts (740) who were treated with BA in our clinic from 2004 to 2016. All cases of new onset (no)-uveitis/psoriasis/IBD collected; clinical features of disease onset and course, activity level, JIA category, exposure to Methotrexate (MTX) and BA, presence of ANA, HLA B27 were studied.

Results: We identified 20 (2.7%) pts (11 female/9 male) with new onset of uveitis, psoriasis or IBD occurring under BA therapy in JIA pts, 10 (50%) of pts received MTX. In all cases of new onset of uveitis the Z-score (by AAO) was &lt; 2 SD to Z-score &lt; 2,1 SD. Therapy may be discontinued under BA therapy in JIA pts, but - for IBD - BA therapy should be started at the beginning of disease.

AB0956 INFLUENCE OF BIOLOGICAL THERAPY ON BONE MINERAL DENSITY IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

I. Chzyheuskaya1, L. Byelyaeva2, N. Vasiljeva2, R. Filonovich1, L. Zajtseva1; 1Department of pediatric, 2Department of Pediatrics, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus

Background: Juvenile idiopathic arthritis (JIA) is one of the most common and most disabling rheumatic diseases in children. JIA is a systemic chronic inflammatory immunopathological disease, which leads to dysfunction of the joints, their deformation and limitations of life of the child, violates the child's growth and development. One of the complications of systemic JIA in children is osteoporosis. In the pathogenesis of osteoporosis important place is given to the use of glucocorticoids. In world Rheumatology successfully used drugs aimed at the major pro-inflammatory cytokines such as tumor necrosis factor (TNF), interleukin-1 (IL-1), interleukin-6 (IL-6), and others.

Objectives: The purpose of research - to determine the influence of biological therapy on bone mineral density in children with JIA.

Methods: 15 children with systemic JIA (mean age 11.9±3.4 years) were examined in the rheumatological department of 4th city clinical hospital of Minsk. Bone mineral density was assessed by 2-energy X-ray absorptiometry (DEXA) to two points of the skeleton. The level of mineralization of skeletal mineral content was assessed using the bone mineral density (BMD) and parameter Z-score. Z-score was used to determine the incidence of osteopenia and osteoporosis in children surveyed. In accordance with the WHO criteria for normal bone mineral density was diagnosed with the Z-score - &lt; 1 SD, osteopenia - &lt; Z-score - &lt; 1 SD, but - &lt; 2.5 SD, osteoporosis - with Z-score &lt; -2.5 SD.

Results: In a study of children osteopenia was diagnosed in 9 patients with systemic JIA (mean Z-score -2.3 SD) Osteoporosis was diagnosed in 6 patients with systemic JIA (mean Z-score -2.7 SD). All children received a mean dose of methotrexate 12.7 mg/m² of body surface area, an average dose of methylprednisolone 0.34 mg/kg body weight per day and treatment of IL-6 inhibitor - tocilizumab 8 mg/kg body weight every 2-4 weeks. Bone mineral density was measured prior to initiating therapy tocilizumab and after 2 years of therapy. During tocilizumab therapy achieved remission of the disease, all children was canceled methylprednisolone. After densitometry of 2 years after the beginning of therapy improvement noted tocilizumab Z-score in children with osteopenia with Z-score -2.3 SD to Z-score &lt; -1.4 SD, and children with osteoporosis with a Z-score -2.7 SD to Z-score &lt; -2.1 SD.

Conclusions: The results indicate a positive influence tocilizumab therapy to bone mineral density in children with JIA.

Acknowledgements: This study would not have been possible without the collaboration of numerous Belarusian pediatric rheumatologists, patients and their parents.

AB0957 IS THERE A DIFFERENCE IN THE CLINICAL PRESENTATION OF JUVENILE SYSTEMIC SCLERODERMA PATIENTS ACCORDING THE AGE OF ONSET: RESULTS FROM THE JUVENILE SCLERODERMA INCEPTION COHORT

I. Foekvandi1, J. Klotzsche2, O. Kasappopour1, A. Adrovic1, V. Stanevich1, M.T. Terreri1, E. Alexeave1, M. Katsicas1, V. Smith1, R. Cimaz1, M. Kostik1, T. Lehman1, J. Anton1, W.A. Sifuentes-Giraldo1, F. Szatmabok1, T. Avcin1, M. Janarthanan1, M.J. Santos1, M. Moll1, D. Nemcova1, C. Battagliotti1, K. Torok1, Y. Uziel1, A. Stevens1, C. Pilkington1, N. Helmus1, 1Hamburg Center for Pediatric Rheumatology, Hamburg; 2DFRZ, Berlin, Germany

Background: Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease. It was rarely looked at the differences between the clinical presentations of patients at different paediatric age groups. The juvenile scleroderma inception cohort (www.juvenile-scleroderma.com) is a prospective standardized register for patients with jSSc.

Objectives: Comparison of clinical characteristics of patients with different age range at the time of inclusion in the registry.

Methods: Patients with jSSc were included worldwide to the juvenile scleroderma inception cohort. We compared the demographics and clinical characteristics of
AB0958 PROPOSAL FOR A JUVENILE SYSTEMIC SCLEROSIS RESPONSE INDEX (JSScRI): RESULT OF THE CONSENSUS MEETING IN HAMBURG, GERMANY 11TH OF DECEMBER 2016

Background: Juvenile Systemic Sclerosis (JSSc) is an orphan disease. There is increasing interest in testing novel therapies in the management of fibrotic diseases. Therefore, it is very important to develop a Response Index for JSSc (JSScRI) to distinguish effective therapies from placebo. In 2014 at the 1st JSScRI Consensus Meeting in Hamburg, following two rounds of a Delphi process, a core data set items that could change as outcome measures) that will be adopted in the development of a JSScRI.

Methods: Before the 2nd JSScRI Consensus Meeting, the items from the 1st JSScRI Consensus Meeting (2014) were scored via Email, in a Delphi by the participants of the current meeting. Participants included 14 experts in adult JSSc and a patient partner. During the subsequent face to face NGT, participants of the current meeting. Participants included 14 experts in adult JSSc and a patient partner. During the subsequent face to face NGT, the participants after a nominal group discussion. The domains and items were scored regarding their importance for 1 year clinical trial from 1 (not relevant at all) to 9 (most relevant). A priori, it was agreed by the participants that the goal of the NGT was to exclude items that: 1. Are not feasible and 2. do not represent the impact of the disease on quality of life, vocational or recreational activity. Items with a median score less than 4 were excluded as they were felt to not represent an outcome measure or were non-feasible and items received a median score less than 4.

Results: Seventy-one items in 13 domains were scored. Six items were not scored as they were felt to not represent an outcome measure or were non-feasible and six items received a median score less than 4.

AB0999 EVALUATE THE CARDIOVASCULAR RISK THROUGH CAROTID INTIMA-MEDIA THICKNESS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS IN THE YOUNG ADULT AGE

J.J. Bettencourt1, L. Expósito, S. Bustabad, Rheumatology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain

Background: The relationship between inflammation and atherosclerosis has been demonstrated, so it is important to identify early markers of the disease. Ultrasound carotid intima-media thickness (CIMT) measurement is a non-invasive, consistent, validated technique used as a marker to identify subclinical arteriosclerotic disease.

We aimed to evaluate long-term risk of cardiovascular disease in young adult patients with juvenile idiopathic arthritis (JIA) is unclear and there are no risk management guidelines for these patients.

Objectives: To assess whether there is an increase in CIMT in the young adult with a history of JIA and to relate CIMT with classic cardiovascular risk factors in these patients.

Methods: Observational and cross-sectional study. Follow-up patients from transitional care between 18 and 36 years old, with JIA diagnosis by ILAR classification. Filtration data, anthropometric variables and activity disease scores were collected.

We performed, prior informed consent, CIMT measurement by radiofrequency with Esaote MyLab 70XVG. Three measurements were performed on each carotid artery, according to the protocol of the American Society of Echocardiography.

Results: Of the 20 patients, 17 (85%) women and 3 (15%) men. Subtype distribution was 8 (40%) oligoarticular, 1 of them ANA negative; 8 (40%) poliarticular being 4 seropositive and 4 seronegative; 1 (5%) systemic; 2 (10%) psoriatic arthropathy and 1 (5%) HLA B27 positive arthritis. 66.7% are with disease modifying drugs (26.7% synthetic and 40% biological), while 33.3% do not have specific treatment.

The main variables studied are described in the attached table (Table 1).

Conclusions: The carotid intima-media thickness of patients with JIA were lower than the controls previously described in the literature, so we will complement this study with our population controls.

In addition to classic cardiovascular risk factors such as systolic blood pressure and BMI, there is correlation with the evolution time in years of the disease and systolic blood pressure (r =0.621) was observed at the level of 0.01 and with C Reactive Protein (r =0.524) and BMI (r =0.471) at the 0.05 level.

GROWTH AND SEXUAL MATURATION IN GIRLS WITH JUVENILE IDIOPATHIC ARTHRITIS

L.M. Gonçalves 1, S.H. Machado 1, R.M. Xavier 1, P.J.C. Maróstica 1, P. Lora 1, L. Trindade 2, Student, PUCRS, 1, Rheumatology service, HCPA; 2, Rheumatology service, UFRGS; 4, Pediatrics service, UFRGS/Hcpa; 5, Unisinos, Porto Alegre, Brazil

Background: Juvenile idiopathic arthritis (JIA) is a heterogeneous group of diseases with onset before the age of 16 years and joint inflammation as a main feature. Longitudinal growth is one of the main physical changes in childhood and adolescence. The etiology of delayed growth in children with JIA is multifactorial and strongly associated with prolonged inflammatory activity.

Objectives: To evaluate growth, sexual maturation, and the difference between final and expected height in girls with JIA and no glucocorticoid treatment for at least six months, as compared to a group of healthy girls.

Methods: This cross-sectional study involved 44 girls with JIA, diagnosed according to International League of Associations for Rheumatology (ILAR) criteria, and 59 healthy controls, aged between eight and 18 (incomplete) years with no comorbid chronic diseases. Demographic data were collected from all participants, and disease and treatment variables were compiled for the patient group. Anthropometric measurements were converted into z-scores based on WHO standards. Sexual maturation was classified according to Tanner stages.

Results: BMI and height z-scores were lower in girls with JIA as compared to controls. These values differed significantly in Tanner stage II. Three (6.8%) girls with JIA had height-for-age z-scores < -2 (short stature). Girls with polyarticular JIA and higher cumulative glucocorticoid doses were significantly more likely to present with short stature. The percentage of prepubertal girls in the JIA group was significantly higher than that observed in the control group, p = 0.012. Age of menarche, adult height, and the difference between actual and expected height did not differ between groups.

Conclusions: These findings suggest that even six months after the suspension of glucocorticoid treatment, children with more severe forms of JIA and exposure to higher doses of glucocorticoids are still susceptible to growth impairment and delayed puberty.

AB0961 A COHORT OF PATIENTS WITH AUTOINFLAMMATORY DISEASES FOLLOWED-UP IN A UNIT OF PAEDIATRIC AND TRANSITIONAL RHEUMATOLOGY: A DESCRIPTIVE STUDY

A. Boteanu, M. Llop Vilatella 1,1, M.A. Terán Tinedo, M.A. Blázquez Cañamero, W.A. Sifuentes Giraldo, M. Vázquez Díaz, M.L. Gámir Gámir. Rheumatology, Hospital Universitario Ramón y Cajal, Madrid, Spain

Background: The autoinflammatory diseases (AD) are uncommon, most of them are presented as episodes of recurrent fever and may be accompanied by other inflammatory symptoms. This group of diseases includes polygenic entities (without a single known genes mutation) such as Behcet’s disease (BD), systemic-onset juvenile idiopathic arthritis (soJIA), Chronic recurrent multifocal osteomyelitis (CRMO) and PFAPA syndrome. On the other hand, we found the entities that present with specific monogenic monomutations, such as Familial Mediterranean Fever (FME), TNF receptor-associated periodic syndrome (TRAPS), hyper-IgD syndrome and periodic fever (HIDS), cryopyrinopathies (FCAS, MWS, CINCA). Blau’s syndrome and PAPA. A group of patients who can not be classified into a specific diagnosis are clustered as recurrent fever without known genetic anomaly (RFW).

Objectives: To describe and compare the clinical features of monogenic and polygenic AD and RFW seen in a paediatric and transitional rheumatology unit of a Spanish tertiary care hospital.

Methods: We performed a retrospective study including 39 patients with AD followed in our center.

Results: The distribution of diagnoses was: soJIA 19 patients (48.72%), BD 5 (12.82%), PFAPA 6 (15.38%), CRMO 3 (7.69%), RFW 4 (10.26%), HIDS 1 (2.56%) and CINCA 1 (2.56%). Patients came from different regions of Spain, being 22 of them boys (56.41%) and 17 girls (43.59%). The genetic study was performed in 10 patients, being positive in 7 (17.95%). Mean age at onset of symptoms was 5.5±6.5 years in monogenic diseases, 7.96±4.8 years in polygenic disorders and 9.5±5.91 years RFW. Delay in diagnosis in monogenic diseases was higher than in polygenic diseases (67.69±29 months vs. 24.03±30.33 months, respectively). The clinical manifestations more frequently found were fever, followed by joint involvement, being more common in monogenic diseases than in polygenic disorders (table). Haemoglobin levels were lower in monogenic than in polygenic diseases 9.9±2 g/dL vs. 11.9±0.63 g/dL, ESR and CRP was higher in monogenic diseases 106 mm/h±6.5±80.5 μg/dL vs. 84.14±56.1 mm/h±33.78 and 57.9±59.5 mg/L, unlike ferritin that was more elevated in polygenic disease 896 μg/dL±1788.34 than in monogenic diseases 183 μg/dL±195.7. During his follow up 84.62% of patients received corticosteroids, 51.8% metronexthate and 46.15% biological therapy.

Conclusions: soJIA was the most frequent AD in our center. All the patients had a similar gender distribution. Delay in diagnosis was greater in monogenic diseases compared with polygenic disorders. Fever and joint involvement were the more common clinical manifestations, especially in monogenic diseases. Ferritin levels were higher in polygenic diseases, whereas CRP and ESR which were higher in monogenic diseases. During the follow-up most patients required treatment with corticosteroids and approximately half of them required biological therapy.

AB0962 CLINICAL AND LABORATORY CHARACTERISTICS OF NON-BACTERIAL OSTEOMYELITIS: DATA ANALYSIS OF 91 PATIENTS

M.M. Kostik 1, O. Kopchak 1,2, A. Mushkin 3, 1Saint-Petersburg State Pediatric Medical University, Saint-Petersburg; 2Kirov’s regional children’s hospital, Kirov; 3Federal State Budget Institute “Science research Institute of Phtisisiopulmonology”, Saint-Petersburg, Russian Federation

Background: Non-bacterial Osteomyelitis (NBO) is a sterile inflammatory bone disorder of unknown etiology. It typically affects children and most commonly presents with bone pain and/or swelling.

Objectives: The aim of study is to evaluate clinical and laboratory features of non-bacterial osteomyelitis in children.

Methods: Our retrospective – prospective study was included 91 patients with NBO. A routine blood test (WBC, platelets, ESR, C-reactive protein (CRP) and hemoglobin levels), a radiological examination and a bone biopsy with evaluation bacteriological and morphological data were performed in all patients.

Results: The mean age of onset NBO was 7.3 years (2.5; 10.6). We did not reveal any gender peculiarities in our study. Family history of immune-mediated diseases is found in 5/75 (6.7%) in prospective group. Concomitant immune-mediated diseases were noted in 62/89 (68.1%). Diagnostic delay was 6.3 (2.0; 17.8)
Lipid abnormalities in children and adolescents with systemic lupus erythematosus

L.F. Bogmat, N.S. Shevchenko, I.N. Bessonova, V.V. Nikonova. Department of Cardiorheumatology, Institute of Children and Adolescents Health Care, Kharkiv, Ukraine

Background: Systemic lupus erythematosus is an autoimmune disease that leads to the progressive destruction of the vital organs and systems, promotes early disability, premature mortality. The main reasons for the latest adult population of patients have complications of atherosclerotic vascular lesions such as the myocardial infarction and the stroke. The greatest effectiveness of the population of patients have complications of atherosclerotic vascular lesions, and (1,64±0,54) mmol/L (1,45±0,19) mmol/L vs (0,72±0,08) mg/L (p<0,05). In parallel, the concentration of HDL cholesterol patients of the disease before treatment (r = -0,59). During the treatment, exacerbations were marked only in 1 case, adverse events in 3 cases (skin infections, leukopenia). TCZ therapy allowed to completely discontinue CS in 63,6% cases, minimize them to 4 mg/day in others. DMARDs are discontinued in 9% cases.

Conclusions: Administration of TCZ is rather effective towards the drug induced remission even in long-time JIA process, but the least joint damage, osteoporosis and stunted growth can be obtained with earlier tocilizumab prescription. Reclassification of patients according to specific clinical and immunological features leads to optimization of the selection of targeted therapy.

References:
[1] While identifying in onset of JIA polycellular destruction and systemic features (hyperthermia, anemia, leukocytosis, high laboratory activity and severity of osteoporosis) one should consider the feasibility of early administration of tocilizumab.

EVALUATION OF BONE MINERAL DENSITY IN CHILDREN WITH CHRONIC RECURRENT MULTIFOCAL OSTEOYELITIS AT DIAGNOSIS

O. Serf1, E. Çomak2, G. Kaya Aksoby, A. Gemici2, M. Koyun2, S. Akman2. Pediatrics, 1Department of Pediatric Nephrology and Rheumatology, Akdeniz University School of Medicine, Antalya, Turkey

Background: Chronic recurrent multifocal osteomyelitis (CRMO) is a rare autoinflammatory disorder that has sterile bone inflammation as a main phenotypic feature. Diagnosis of CRMO is based on typical clinical and radiologic findings and presence of some inflammatory markers. Plain radiographs, technetium bone scan and MRI may be used for diagnosis of children with suspected CRMO. Despite data for other imaging methods in children with CRMO, little information is available regarding the bone mineral density.

Objectives: The aim of the study was to evaluate bone mineral density (BMD) findings in children with CRMO at time of diagnosis.

Methods: The medical records of children with CRMO were reviewed retrospectively. Children who met Bristol diagnostic criteria were included in the study. Clinical and laboratory findings, bone scan and MRI features were analyzed. Bone mineral density was measured by DEXA technique at femoral neck and lumbar spine regions; a Z-score was considered as osteoporosis.

Results: Among children treated with TCZ 63,6% were sJIA cases, 63,6% were female. Age of onset 6,1±4,7y (6m–10,5y), all had acute onset, hyperthermia, severe pain syndrome, exudative arthritis in all pJIA cases and half of sJIA cases. ESR 39,7±11,2 mm/h, CRP 53,8±16,1 mg/L, all patients had anemia, leukocytosis and were seronegative for RF and anti-CCP. 3 of pJIA patients revealed ANA (1:1200–2400), 1, IL-6 19,78±5,7 pg/mL. Before biological therapy has begun, SJC courses were continuously relapsing in all cases with 4,7±2,1 exacerbations per y; during the 1st y of illness 8 cases run with coxitis, 7-cervical spine involvement, 9-wrists damage. All patients received CS therapy before initiating TCZ, 45,4% of them with pulse therapy, all marked by the inability to minimize the CS dose, all received 2–4 DMARDs in high doses. 2 patients received adalimumab before TCZ treatment. Elapsed time from the onset to biological agent prescription was 5,3±5,1 years. At the start of biological therapy JADAS was 19,6±5,7, stunted growth -1,88±0,3, α, according to densitometry, osteoporosis took place in every case (Z=−2,7±1,1). After 6 month JADAS was 1,8±1,1, ESR and CRP normalized, IL-6 rate remained high in 36% cases. After 1 year the severity of osteoporosis decreased (Z = −1,17±0,8), bone deficiency on duration of TCZ exposure (r = −0,72) and on the elapsed time from onset of JIA before the start of biological therapy (r = −0,84). The mean increase in height was 7,73 cm/patient-year (−1±0,8). Stunted growth depended on the duration of TCZ course (r=0,81) and the elapsed time from the onset of the disease to the start of biological therapy (r=0,72). After 1 y of TCZ all children had normal weight and BMI for age (19,89±1,9). After 1–5 y of treatment JADAS was evaluated 2,1±2,9 (0–7), the degree of joint damage didn’t depend on the duration of the biological therapy (r=0,24) and correlated with the time elapsed from the onset of the disease before treatment (r = 0,59). During the treatment, exacerbations were marked only in 1 case, adverse events in 3 cases (skin infections, leukopenia). TCZ therapy allowed to completely discontinue CS in 63,6% cases, minimize them to 4 mg/day in others. DMARDs are discontinued in 9% cases.

Conclusions: Administration of TCZ is rather effective towards the drug induced remission even in long-time JIA process, but the least joint damage, osteoporosis and stunted growth can be obtained with earlier tocilizumab prescription. Reclassification of patients according to specific clinical and immunological features leads to optimization of the selection of targeted therapy.

AB0965  THE CLINICAL OBSERVATION OF IMMUNOADSORPTION IN TREATMENT OF CHILDREN WITH REFRACTORY AUTOIMMUNE DISEASES

P. Zeng 1, H. Zeng 2, 1 Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou; 2 Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China

Objectives: Explore the clinical efficacy and safety of the immunoadsorption assisted treatment of children with refractory autoimmune diseases.

Methods: Use HA280 type resin perfusion machine for four times of whole blood immunoadsorption treatment for one case of a 4-year-old child combined with severe dermatomyositis and pulmonary infection, one case of 9-year-old child with severe allergic purpura combined with gastrointestinal bleeding, intestinal perforation and subcutaneous tissue.

Results: Four cases were treated with partial hepatectomy, one case of 11-year-old child with systemic juvenile idiopathic arthritis combined with head and facial cellulites and macrophage activation syndrome. Observe the improvement of its clinical manifestations, serum immunoglobulin, complement, liver and kidney function, myocardial enzymes, autoantibodies.

Conclusions: The whole blood immunoadsorption treatment is able to reduce blood plasma IGG, improvement complement C3 and C4 level, eliminates anti-CCP immune body in vivo, reduce the cardiac muscle zymogrom and the liver enzyme in a short time, increase sensitivity to the adrenal cortex hormone, alleviates immunological disease's symptom in active stage, have the advantage of operation simplicity, high efficiency.

AB0966  HYPOVITAMINOSIS D IN JUVENILE IDIOPATHIC ARTHRITIS: PREVALENCE AND RELATED FACTORS

R. Galindo Zavala 1, L. Martín Pedraz 2, E. Núñez Cuadros 3, G. Díaz-Cordovés Rego 4, A.L. Urda Cardona 2, 1 Paediatric Rheumatology; 2 Paediatrics; 3 Universitary Regional Malaga Hospital, Malaga, Spain; 4 Rheumatology, Universitary Regional Malaga Hospital, Malaga, Spain

Background: 25hydroxy-vitamin D not only plays a key role in calcium homeostasis, but also has antiinflammatory and immunomodulatory properties. Hypovitaminosis D prevalence in children suffering from Juvenile Idiopathic Arthritis (JIA) ranges from 6% to 30% according to different publications.

Objectives: Evaluate hypovitaminosis D prevalence in JIA pediatric patients in Spain and assess involved factors.

Methods: Observational cross-sectional study in JIA Spanish patients from 4 to 15 years, monitored by a Pediatric Rheumatology Unit. Monocarticular forms and patients with other chronic diseases or receiving different treatments from those indicated for JIA were excluded.

Results: 76 children participated. Their characteristics are included in table 1. The population’s prevalence estimation of hypovitaminosis D in children with JIA was 16 - 35% (CI 95%). We found no relationship between 25 hydroxy-vitamin D levels and sex, JIA subtype neither duration or dose of systemic glucocorticoids.

Conclusions: Hypovitaminosis D was defined as 25hydroxy-vitamin D plasma levels lower than 30 ng/ml

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.4120

AB0967  CLINICAL, LABORATORY PROFILES AND LONG-TERM OUTCOME OF JUVENILE CUTANEOUS PAN: A SINGLE CENTER EXPERIENCE

R.A. Castellanos-Moreira 1, J.M. Mosqueru 1, S.C. Rodríguez-García 1, J. Caizada 1, A. Vicente 2, E. Iglesias 1, R. Bou 1, J. Anton 1, 1 Dermatology, Hospital Sant Joan de Déu, Barcelona, Spain

Background: Cutaneous polyarteritis nodosa (cPAN) is an immune complex-mediated rare disease that affects small and medium sized vessels in the dermis and subcutaneous tissue.

The clinical course is characterized by periodic exacerbations and remissions that may persist for many years. Most patients respond to NSAIDs and glucocorticoids (GC), whereas some may require DMARDs and/or immunomodulatory therapy.

Objectives: To describe the different clinical patterns, laboratory findings and long term outcomes of juvenile cPAN in a tertiary care hospital.

Methods: Retrospective observational study, including all patients diagnosed with cPAN between 2002–2016. Diagnosis relied on clinical features confirmed by histological study. Recorded data included clinical features, laboratory results and long-term outcomes.

Results: 10 children were included (7 female), mean age at onset was 9.9 years (r:4.1–16.3). Delay from symptoms onset to biopsy confirmed diagnosis was 2±2.3 months; 4 patients underwent a second biopsy due to inconclusive results in the first performed.

Clinical features included cutaneous (100%) and osteomuscular involvement (50%), fever (40%), neuropathy (10%) and weight loss (10%). Reported cutaneous symptoms were 8 patients with nodules, 4 livedo, 4 purpura, 1 ulcer and 1 necrosis. Most lesions were localized in the lower limbs (8), even though it was also reported in upper limbs (3) and trunk (3). Most cases exhibited raised CRP, ESR and symptoms were 8 patients with nodules, 4 livedo, 4 purpura, 1 ulcer and 1 necrosis.

Conclusions: Clinical and laboratory findings in our series was similar to previous reports. However, our patients presented a greater number of relapses and DMARDs requirement.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.2119

AB0968  HYPOVITAMINOSIS D IN JUVENILE IDIOPATHIC ARTHRITIS: PREVALENCE AND RELATED FACTORS

R. Galindo Zavala 1, L. Martín Pedraz 2, E. Núñez Cuadros 3, G. Díaz-Cordovés Rego 4, A.L. Urda Cardona 2, 1 Paediatric Rheumatology; 2 Paediatrics; 3 Universitary Regional Malaga Hospital, Malaga, Spain; 4 Rheumatology, Universitary Regional Malaga Hospital, Malaga, Spain

Background: 25hydroxy-vitamin D not only plays a key role in calcium homeostasis, but also has antiinflammatory and immunomodulatory properties. Hypovitaminosis D prevalence in children suffering from Juvenile Idiopathic Arthritis (JIA) ranges from 6% to 30% according to different publications.

Objectives: Evaluate hypovitaminosis D prevalence in JIA pediatric patients in Spain and assess involved factors.

Methods: Observational cross-sectional study in JIA Spanish patients from 4 to 15 years, monitored by a Pediatric Rheumatology Unit. Monocarticular forms and patients with other chronic diseases or receiving different treatments from those indicated for JIA were excluded.

Anthropometric, clinical and treatment data were recorded. Bone metabolism parameters and validated diet (KIDMED) and exercise (PAQ-C/PAQ-A) questionnaires were obtained.

Hypovitaminosis D was defined as 25hydroxy-vitamin D plasma levels lower than 30 ng/ml

Results: 76 children participated. Their characteristics are included in table 1. The population’s prevalence estimation of hypovitaminosis D in children with JIA was 16 - 35% (CI 95%). We found no relationship between 25 hydroxy-vitamin D levels and sex, JIA subtype neither duration or dose of systemic glucocorticoids.

In bivariate analysis we found direct association between hypovitaminosis D and Body Mass Index percentile (BMI(%) (p=0.05), received dose of prednisone (p=0.03) and clinical activity duration (p=0.04) and an inverse relationship with physical activity level (p=0.04).

In multivariate analysis, relationship between hypovitaminosis D and BMI(%) (B 0.024; p 0.016) and with disease activity (B 0.015; p 0.01) were maintained. Moreover, we found an inverse association with biological disease-modifying antirheumatic drugs (B=-4.69; p 0.048), specifically with anti-tumoral necrosis factor (antiTNFα) (B=-4.7; p 0.042)

Conclusions: Hypovitaminosis D prevalence in our population is similar to previously described.

JIA patients with higher BMI(%) have more hypovitaminosis D, as it has been reported in other inflammatory diseases.

A direct relationship exists between inflammatory activity and vitamin D, but we need more studies to assess if one is cause or consequence of the other.

Patients treated with antiTNFα have better plasma levels of 25 hydroxy-vitamin D, this can be explained because these drugs may increase 25 hydroxy-vitamin D
levels or due to a better response to anti-TNF of those patient with higher plasma levels of 25 hydroxy-vitamin D.

AB0969 IMPACT OF JUVENILE IDIOPATHIC ARTHRITIS ON SCHOOLING
S. Rahmouni, A. Fazaa, K. Guenniche, S. Kassab, S. Chekili, K. Ben Abdelghani, A. Lastar. Rheumatology Department, Mongi SLIM hospital, marsea, Tunisia

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in children and is one of the major causes of morbidity and physical disability.Due to frequent absences,children with chronic health impairments are confronted with educational difficulties.

Objectives: The aims of this study were to assess the impact of JIA on children’s schooling and to determine the factors that influence their school level.

Methods: This is a cross-sectional study including patients with JIA (ILAR criteria). A detailed questionnaire was completed for each participant by interviewing them or their parents as well as by information obtained from their medical records.Collected data included age,sex,subtype of JIA,disease duration,level of disability according to the Childhood Heath Assessment Questionnaire (CHAQ),visual analog scale for patient’s overall assessment of disease activity,duration of morning stiffness, joint counts,erythrocyte sedimentation rate,C-Reactive Protein,Disease Activity Score (DAS28).Medications used for JIA treatment were also documented.

Data on the school performance of patients and their siblings were obtained using telephone interviews (educational level, absenteeism, school delay by repetition, drop-out).

The comparison of quantitative variables was performed with the Mann-Whitney test and the comparison of qualitative ones was performed with the chi square test. The significance level was set at 0.05.

Results: A total of 38 patients with JIA were included, 23 female and 15 male, with a mean age of 26 years [12–51] and a mean disease duration of 237 months [5–496].The average age of the onset of the disease was 7.4 years [1,15–16].

The most common subtype was rheumatoid factor-positive polyarthritis (n=16) followed by systemic (n=7), oligoarticular (n=4), rheumatoid factor-negative polyarthritis (n=5) and Enthesis-related arthritis (n=4). The mean DAS28 was 2.63 [0.76 - 5.55] and the median CHAQ was 0.528 [0–3].Twenty-seven of the children were receiving corticosteroid. Disease-modifying anti-rheumatic drugs were used by 34 of the 38 patients: methotrexate (n=22), sulfasalazine (n=8),lefunomide (n=7).Ibrotherapies had complications:Hip arthritis (n=15), growth stunting (n=12), uveitis (n=4). Joint replacement was required in 9 cases. Four patients were illiterate,12 had dropped out of school,21 reported repeated absences due to illness.A year of schooling was repeated by 61.7% of patients.Ten out of 32 patients over the age of 20 had an university level.Almost 80% of patients were exempted from physical education.

There were no significant associations between the school-related problems, the socio-demographic characteristics and the various parameters of clinical and biological activity studied.

School failure was similar among patients and their family members.

Conclusions: Our study suggested that JIA negatively affects schooling of children.More studies with a larger sample are needed to identify the variables associated with school failure in order to ensure the proper management of these patients and to increase their academic performance.

AB0970 CLINICAL AND IMMUNOLOGICAL CHARACTERISTICS IN CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS TREATED WITH RITUXIMAB
S. Garrote, A. Alia Jimenez, A. Botegan, M.A. Blazquez, M.L. Gamir. Rheumatology, Ramon y Cajal Hospital, Madrid, Spain

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that is more severe in pediatric population than in adults. Biological therapy with anti-CD20 (rituximab) is an option in patient that do not respond to conventional therapy.

Objectives: The aim of this study is to determine the clinical and immunological response in 9 patients with childhood-onset systemic lupus erythematosus (cSLE) that received treatment with rituximab in a third level hospital

Methods: This is a retrospective observational study. 9 patients treated with Rituximab between November 2007 and October 2016 were included and their medical records were reviewed. The response to treatment at 6 months and one year after the first infusion of Rituximab were assessed. Patients with overlap syndromes were excluded. All patients fulfilled four or more of the 1982 revised American College of Rheumatology criteria for the diagnosis of SLE (<16 years).

Results: Nine pediatric patients with SLE treated with rituximab were included, all of them were female. The age at diagnosis of SLE was a mean of 15.22 years.

Two patients and the median time duration of disease was 87.55months (5–255m). 7 patients were Caucasians. Rituximab was indicated in 6 patients with class IV of lupus nephritis (LN) 1/9 with class III LN, 1/9 with severe cutaneous lupus, and with severe hematological manifestations in 1 case (haemolytic anaemia). In addition, 6/9 patients had mucocutaneous and articular manifestations. The disease activity of all patients was assessed using SELENA-SLEDAI index pre rituximab infusion, the mean was 17.11 (8–33). All patients had low level of complement C3 and C4 and 8/9 increased anti-DNA. In 8/9 patients Rituximab was used as a rescue treatment and in a single case as a first-line treatment.

4/9 patients with renal involvement were previously treated with cyclophosphamide (CYC) IV and mycophenolate, 2/6 CF. In case of cutaneous involvement the previous treatment was methotrexate, azathioprine (AZA) and dapsone and in case of hemolytic anaemia was AZA.

The treatment protocol was 1 gram x 2 (1 cycle) in 7 patients, 75mg/m2 x 4 in 1/9 cases and 600mg monthly for 5 months in the case of haemolytic anemia. Five patients received more than 1 cycle. After the administration of Rituximab, the SELENA-SLEDAI activity index was 4.5 points. At 6 months a complete response was observed in the case of hematological and cutaneous manifestations, in 2 cases of lupus nephritis, in 1 case of severe cutaneous lupus and in 2 cases of cutaneous involvement. Mortality was 11.11% (1/9 patients, per infection and lupus activity, SLEDAI pre rituximab =33).

Conclusions: In our study, although it consisted of few patients, it was objected that Rituximab therapy in patients with cSLE is effective, reduces lupus activity index, especially in cases of renal, cutaneous and hematologic involvement, that 2/9 responded to conventional therapy. It may be consider in the future as an effective alternative treatment at first line treatment.

S. Tatsis1, I. Foeldvari2. 1Department of Rheumatology, Marienkrankenhau; 2Hamburg Center for Pediatric and Adolescent Rheumatology, Am Schön Klinik Elbek, Hamburg, Germany

Background: The issue of transition from pediatric to adult rheumatology service is an emerging important topic. In 2012 a transition clinic was established according to the “Berliner Transitionsprogram” [1] in cooperation of the Hamburger Zentrum für Kinder- und Jugendrheumatologie and the Rheumatology Unit of the Marien Hospital in Hamburg. The Berliner programme suggests three visits of the patient in transitionprocess, in the presence of the pediatric and an adult rheumatologist together, and the fourth visit conducted by the adult rheumatologist alone. We present the characteristics of the patients at the time of the 4th visit.

Objectives: To characterise the patient population at the time of enrollment into the adult service in the frame of our transition programme.

Methods: We collected patient data starting 8/2012 to 11/2016. We summarized the patient population, who successfully transitioned from pediatric to adult rheumatologic service, concerning diagnosis, sex, age at the time of diagnosis, disease duration at the time of transition, JADAS, HAQ, VAS globular assessment, VAS pain, medication and disease activity.

Results: 73 patients were transitioned. 65% of them female. Mean age at diagnosis of the patients was 12.5 years. Mean disease duration at time of transition was 10.8 years. The mean JADAS Score was 3.18 and the mean HAQ Score was 0.136. The patients global activity score was, on a VAS of 0 to 100, 14.03 and the global pain score, on a VAS of 0 to 100, 12.33. 39.7% of the patients received synthetic DMARDS and 34% biologic DMARDS: Only 1 patient received steroids. 24.6% of the patients were off medication. 63% of the patients were in remission, 31% of them on medication and 39% off medication.

Conclusions: In this monocenter cohort 63% of patients were in remission, and with the mean JADAS Score of 3.18 most of them have low disease activity under the current treatment. The mean HAQ Score with 0.136 reflects a score, which is expected in healthy controls. But 75.4% of the patients needed medication to
AB0972 CHILDHOOD ONSET STROKE AND VASCULITIS ASSOCIATED WITH DEFICIENCY OF ADENOSINE DEAMINASE 2 (DADA2)

V. Paisal1, E. Al-Abadi1, T. Southwood1, E. Wassmer2, Paediatric Rheumatology, Aswan University, Aswan, Egypt

Background: The deficiency of Adenosine Deaminase 2 (DADA2) is a rare autosomal recessive condition resulting from mutations in CECR1 (Cat Eye Syndrome Chromosome Region 1) gene, mapped to chromosome 22q11.1. It is a type of autoinflammatory disease, mainly characterised by early-onset polyarteritis, haemorrhagic, ischemic strokes and hypogammaglobulinemia (1). We report a case of a 7 year boy presenting with haemorrhagic stroke and vasculitis responding to immunosuppression with Anti-TNF drug.

Objectives: A 7 year boy presented to the emergency department with reduced consciousness, headaches and nose bleeds. Initial imaging showed an intraparenchymal haemorrhage requiring frontal craniotomy and evacuation of the haematoma. This acute presentation was preceded by a history of recurrent fevers, weight loss, testicular pain, erythema nodosum and tender lymph nodes.

Methods: The laboratory findings revealed anaemia, ESR of up to 61mm/h, Complement C3 and C4 levels, positive Anti nuclear antibody (ANA), mildly raised antibodies to double stranded DNA (dsDNA) and Proteinase 3 antibody. Skin biopsy confirmed panniculitis. CT imaging and angiography of the head at the time of acute presentation showed intraparenchymal haemorrhage and aneurysm of the left middle cerebral artery. Further CT angiography of the whole body revealed renal and liver microaneurysms. A provisional diagnosis of Polyarteritis nodosa was made and started on steroids and cyclophosphamide. He had further genetic testing, showing mutation in CECR1, leading to Adenosine deaminase 2 deficiency. Patient responded to cyclophosphamide induction regime, which was followed by Etanercept.

Results: We report a case of ADA2 deficiency presenting initially with features of an autoinflammatory disorder, complicated by acute stroke secondary to haemorrhage. Our patient exhibited most of the clinical symptoms previously reported in ADA2 deficiency, including its association with polyarteritis nodosa (2). Although, he did not exhibit hypogammaglobulinemia (3) which has been reported, interestingly, he was positive for markers of autoimmunity (ANA, ANCA) (4). It has been reported that treatment with anti-TNF and IL-6 (5) could lead to improvement, and our patients initial response to cyclophosphamide was excellent, followed by continued treatment with Etanercept.

Conclusions: Screening for adenosine deaminase 2 deficiency should be considered in all children presenting with neurological symptoms and features of vasculitis.

AB0973 ANTIPHOSPHOLIPID ANTIBODIES IN CHILDREN WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND JUVENILE IDIOPTATIC ARTHRITIS

W. Gouda1, A. Mohamed2, 1Rheumatology, Aswan University, Aswan; 2Pediatrics, Mansoura University, Mansoura, Egypt

Background: Antiphospholipid antibodies (aPL) are a family of autoantibodies that present in a small percentage of the population but occur more commonly in patients with Antiphospholipid syndrome (APS) and Systemic lupus erythematosis (SLE).

Objectives: We aimed to determine of the level of anti-β2-glycoprotein I (anti-β2GPI) (IgG and IgM) isotypes and anticardiolipin antibodies (aCL) as inflammatory markers in children with SLE and Juvenile Idiopathic Arthritis (JIA) and figure out their relation to the clinical manifestations and activity of the disease.

Methods: This prospective study included one hundred twenty children, sixty five having SLE and fifty five having JIA, their ages range between 4.5 – 16 years (37 males and 83 females). In addition, twenty apparently healthy children of comparable age, sex and nutritional status were used as a control group. All patients and normal controls were subjected to full clinical and laboratory investigations included aCL and anti-β2GPI level (IgG and IgM) measured by a standardized ELISA.

Results: IgG isotype of anti-β2GPI was found to be positive in 27.7% and 14.5% for SLE and JIA groups respectively. However IgM isotype of anti-β2GPI was found to be positive in 24.6% and 7.25% for SLE and JIA groups respectively. The mean levels of both IgG and IgM isotypes of anti-β2GPI were found to be significantly increased in comparison to controls (P<0.001) in both SLE and JIA groups. IgG isotype of aCL was found to be positive in 23.1% and 18.2% for SLE and JIA groups respectively. However IgM isotype of aCL was found to be positive in 19.5% and 18.2% for SLE and JIA groups respectively. A significant positive correlation was found between IgM and IgG isotypes of anti-β2GPI and with their corresponding class of aCL in both SLE and JIA groups. A significant positive correlation was found between the elevation of anti-β2GPI (IgG) and thrombocytopenia together with neuropsychiatric disease in SLE. While in JIA elevation of anti-β2GPI was found to be correlated only with elevation of aCL irrespective to clinical or laboratory data.

Conclusions: The study reported a higher prevalence of aPL in children with SLE and JIA. Elevated levels of anti-β2GPI (IgG) correlated with thrombocytopenia together with neuropsychiatric disease in SLE.

AB0974 ETANERCEPT TREATMENT FOR A PATIENT WITH REFRACTORY MACROPHAGE ACTIVATION SYNDROME IN JUVENILE SYSTEMIC LUPUS ERYTHEMATOUS

V. Ramirez, T. Diaz, R. Maldonado, E. Faugier, A.V. Villarreal, N. Acevedo on behalf of Pediatric Rheumatology. Hospital Infantil de México Federico Gómez, Mexico City, Mexico

Background: Macrophage activation syndrome (MAS) is a serious, potentially fatal complication of childhood systemic inflammatory disorders, and it is most frequent in Systemic Juvenile Idiopathic Arthritis, for instance, it is increasingly reported in other pediatric rheumatic diseases as lupus erythematous and Kawasaki disease.

Objective: To describe clinical case report of a 16 year old girl with Juvenile Systemic Lupus Erythematosus and Macrophage Activation Syndrome refractory.

Methods: A 16-year-old woman with recent diagnosis of Systemic Lupus Erythematosus in November 2015. At admission with continuous fever lasting 2 months, with initial laboratory studies with Triglycerides 395 mg/dl, Ferritin 3.300 ug/l, soluble receptor IL-2 2.838 U/ml, fibrinogen 166 mg/dl, Hemophagocytes in bone marrow, presence of persistent cytopenias. Initial management with methylprednisolone 30 mg/kg/day (3 days) without clinical response was initiated. Management is added to Cyclosporin A (10 mg/kg/day), reporting subtherapeutic serum levels despite high doses without clinical response and improvement of laboratory controls. During the hospital stay complete 13 months of treatment with Etoposide 180 mg/l/day, with ferritin levels in 4,180 ug/l, triglycerides 438, Fibrinogen 455 mg/dl, WBC 5,000 u1 (3,400 neutrophils, lymphocytes 1,050), platelet count 78 x 103 ml-1, hemoglobin 7.2 g/dl. After three months of treatment, she was given with Etanercept 0.4mg/kg/dose, 2 times a day. Currently in week 3 of treatment with WBC 6,500 ml-1, hemoglobin 9.7 g/dl, platelet count 140 x 103/ml-1 and ferritin 4,270 ng/ml. The patient remains disease with costicosteroid, cyclosporine, and etanercept, without adverse events.

Results: Patient treated with Etanercept during 5 weeks, presenting clinical response for MAS.

Conclusions: A general therapeutic protocol for MAS is not available: first line treatment is usually represented by parental administration of high dose corticosteroids. Mild forms are reported to respond to steroids alone in association with supportive medications. Steroid-resistant cases or the most severe forms of MAS, the addition of cyclosporine A, other therapeutic regimens have been studied such as high-dose intravenous immunoglobulin, antithymocyte globulins, etanercept, etoposide and plasmapheresis.

AB0975  
INCIDENCE OF INFECTIONS WITH BIOLOGICAL THERAPIES IN PARAGUAYAN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: BIOBADAGUAY (BIOLOGICAL THERAPIES ADVERSE EVENTS PARAGUAYAN-URUGUAYAN REGISTER)

Background: Biological Therapies (BT) are important in the therapeutic arsenal of rheumatic diseases; however there is an increased risk of infections with their use.

Objectives: To determine the frequency and type of infections in Paraguayan patients with Juvenile Idiopathic Arthritis (JIA), included in the BIOBADAGUAY Register.

Methods: A prospective observational study of patients with JIA treated with BT, included in the BIOBADAGUAY Register. Patients at the onset of BT were included. The change and/or discontinuation of BT and the occurrence of adverse events (AEs) were recorded. Infectious events as affected organ, type, severity, outcome and need of temporary or permanent suspension of the biological agent were analyzed.

Results: 59 patients with JIA and 69 BT were identified between May 2012 and December 2016. Female: 63% (37); Men: 37% (22). The mean age was 10 (3–18) years old. Mean disease progression of 2.8 (0.2–12) years from the diagnosis to BT beginning. JIA subtypes: poliarticular negative RF (27%), oligoarticular (27%), systemic (12%), polyarticular positive RF (7%), psoriatic (3%), other (indeterminate) (3%). Biologic treatments: Adalimumab (ADM) 41 (59%), Etanercept (ETN) 19 (28%), Infliximab (IFX) 14 (21%), Tocilizumab (TCZ) 9 (13%). There were 83 AEs of all treatments, 80 (96%) non-serious and 3 (4%) severe with 1 death. Infections and infestations 54 (65%) of AEs were recorded. Of all TB infections: the 94% (51) were not serious and recovered without sequela. Most infections recovered without sequelae, except one death due to pneumonia (Table 1).

Conclusions: 1) Infections and infestations (65%) were the AEs more frequently observed. 2) Of all infections, respiratory tract were the most frequently observed. 3) Most of the infections were not serious and recovered without sequela. 4) Although the frequency agent involved in infectious events wasADM (52% of all infections); even so it is the most frequently administered agent. 5) Increased number of patients, greater diversity of treatment as well as a longer data to corroborate the observation period is required.

AB0976  
REMISSION OF MULTICENTRIC RETICULOHISTIOCYTOSIS WITH COMBINATION TOCILIZUMAB AND ZOLEDRONATE

A. Gough1, B. Barber2, H. Evennett3, S. Herr4, M. Lloyd1. 1Rheumatology; 2Radiology; 3Dermatology, Frimley Park Hospital, Frimley; 4Dermatology, Spire Clare Park Hospital, Crollands, United Kingdom

Background: Multicentric reticulohistiocytosis (MRH) is a rare non-Langerhans cell histiocytosis. It can affect any organ but predominantly skin and joints. Joint involvement usually precedes skin involvement and can be very destructive. Early diagnosis and treatment is therefore important but can be difficult.We describe a woman with MRH and severe erosive joint disease who responded to combination tocilizumab and zoledronate.

Objectives: A 43 yr old woman presented in 2012 with a 3 mth history of rash on her face, chest and ears and fingers, and arthralgia affecting shoulders, wrists, fingers and knees. On examination she had diffuse hand swelling, right knee effusion and erythematous eruption affecting her face, chest and ears with papules on the sides of her fingers. Investigations: normal FBC; CRP; U-Es, LFTs. ESR 12 mm/hr. ANA +ve at 1:1280 (finely speckled). Ro +ve; ENA including Jo-1, ANCA and dsDNA antibodies -ve, C3/C4, lgs all normal/-ve. Hand XR: periarthritis DIP erosions. Skin biopsy: large multinucleate cells with abundant cytoplasm staining positive with CD68 (histiocyte marker); CD1a negative (Langerhans cell marker), consistent with MRH. PET-CT body: incidental finding of thymic remnant.

Methods: Initial Rx:prednisolone 20 mg od + HCQ 200mg bd with initial good response of joint and skin symptoms, but recurrence of symptoms on reducing steroid dose. Nov 2012: MTX up to 20mg /week added. Stopped after 4 mths because of a linear rise in P3NP levels to 11.2. Fibroscan showed slightly raised stiffness of 7.4kPa. AZA 75mg od introduced in Feb 2013, then etanercept 50mg weekly. This led to good control of symptoms for approximately 4 mths on single agent therapy. March 2014: relapse of joint and skin symptoms. June 2014: tocilizumab 8mg/kg iv 4 weekly started. After 5 infusions, her skin cleared for the first time. December 2014: relapse of joint and skin symptoms. Tocilizumab was adjusted to 650mg per mth from 620mg in view of slight weight gain. Annual iv zoledronate 5mg was started. She has had no further joint or skin exacerbations.

Conclusions: The pathogenesis of MRH is poorly understood. The overexpression of cytokines including TNFα, IL-1 and IL-6 in inflammatory lesions gives a number of logical drug options, including tocilizumab. The observation that mononuclear cells in both skin nodules and synovium in MRH exhibit some properties of osteoclasts might explain the mechanism behind reported success using bisphosphonates. To our knowledge, this is only the second case to report success with using tocilizumab in the treatment of MRH and the first to report on concomitant treatment with a bisphosphonate. No adverse effects have been observed throughout treatment, and remission appears to be sustained. Without withdrawing treatment we cannot know if the remission is natural or drug induced, though the relatively short timescale suggests a drug effect.

AB0977  
DETERMINATION OF A CUT-POINT BETWEEN LOW/HIGH ANTI RNP ANTIBODIES TITRES, IN PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE

D.A. Botello Corzo1, C. Bouroncle Ailana1, C. De la Puente Bujidos1, A. Boteanu*, G. Roy Arino2. 1Rheumatology; 2Immunology, Hospital Ramón y Cajal, Madrid, Spain

Background: Sharp described Mixed Connective Tissue Disease (MCTD) in 1972[2]. MCTD is characterised by the presence of Raynaud phenomenon, puffy hands, synovitis, acrosclerosis, myositis and positive ribonucleoprotein (RNP) antibodies. Classification criteria for MCTD except for Kasukawa’s criteria demand the presence of high titres of anti-RNP antibodies (measured by hemagglutination). As a result, the cut-point between low and high anti-RNP titres must be well defined. In best of our knowledge, this cut-point have not been established for modern laboratory techniques.

Objectives: Determine a cut-point between low/high anti-RNP titles measured by ELISA, for the diagnosis of Mixed Connective Tissue disease. Describe the clinical and immunological characteristics of patients with positive titres of anti-RNP antibodies.

Methods: It was a Retrospective cohort study of patients with positive anti-RNP antibodies (>10) measured by ELISA. We had identified all patients with positive anti-RNP antibodies titles in the last five years, using our laboratory base date. Clinical histories were reviewed, we recollected clinical and paraclinical data. We performed descriptive analysis and ROC curves for diagnostic tests with STATA software.

Results: We detected 75 patients with positive antiRNP antibodies, we obtained 65 clinical records. 89,23% (58) of patients were women and 10,77% (7) men.
ASSOCIATION OF INFLAMMATORY ARTHRITIS WITH VOGT-KOYANAGI-HARADA SYNDROME (VKHS)

D. Ramos-Bello 1, G. Aguilera Barragán-Pickens 1, A.J. Pedro-Martínez 1, G. Martínez-Flores 1, T.A. Luna-Zúñiga 1, A.N. Rangel-Botello 1, P.L.R. Hernández-Briano 1, M.G. Rangel-Charqueño 2, E. Santillán-Guerrero 1, D. Ramos-Bello 1, P.L.R. Hernández-Briano 1, M.G. Rangel-Charqueño 2, E. Santillán-Guerrero 1, C. Abud-Mendoza 1, U. de Reumatología y Osteopatía, Hospital Central “Dr. Ignacio Morones Prieto” y P. Universidad de Guadalajara, México

Background: VKHS is a rare cause of granulomatous uveitis leading to significant visual loss in patients who develop it, usually accompanied by extracocular manifestations that include meningitis, vitiligo, poliosis, and hearing loss. In our country it is responsible for 13% to 27% of all uveitis, affecting mainly young women.

Objectives: To describe the presence of inflammatory arthritis in patients with VKHS at a third level hospital.

Methods: A cross-sectional study of 4 patients with established VKHS that fulfilled the 2001 revised diagnostic criteria for Vogt-Koyanagi-Harada disease (1) was rolled out. Ultrasoundography was performed to all patients by a trained rheumatologist in carpal, metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints evaluating presence of power Doppler (PD) signal, bone erosions, and cartilage changes.

Results: We included 3 women and 1 man, mean age was 34.7±10.3 years, and they all had characteristics of complete VKHS. Mean disease duration (since first manifestation of ocular symptoms) was 5.2±3.5 months. One patient had synovitis (36.8%) and in the majority one did not find trigger factor. There was presence of arthritis in a significant percentage of patients. In the last years the use of the RMN has been added to the diagnosis and to the follow-up. Throgh there are no clinical tests that support it the use of the metotrexato has been generalized as adjuvant treatment to the steroids.

Conclusions: The prevalence of inflammatory arthritis in patients with VKHS has only been described in one case (2). Despite the exceptionality, we propose that polyarthritis and probably erosive arthritis can represent part of the spectrum of the disease, processes that share some features of the genetic susceptibility with rheumatoid arthritis as HLA-DR4, CTLA-4 and STAT4.

EOSINOPHILIC FASCITIS: CLINICAL EXPERIENCE IN A SERIES OF 21 PATIENTS

J.C. Quevedo 1, R. Lopez 1, M. Garcia-Bustundy 2, C. Rodriguez-Lozano 1, B. Rodriguez-Lozano 2, S. Bustabad 2, E. Trujillo 3, Servicio de Reumatología, Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas; 2Servicio de Dermatología; 3Servicio de Reumatología, Hospital Universitario de Canarias, La Laguna, Spain

Background: The Eosinophilic fascitis (EF) is an uncommon sclerodermiform syndrome with unknown etiology and poorly understood pathogenesis and natural evolution. The published cases are short, with a total of 280 cases described in the literature from 1974. There is neither clinical tests nor consensus on the EF treatment.

Objectives: To describe a series of 21 patients with EF.

Methods: Multicentric, retrospective Case Series Study

Results: We reviewed 21 patients diagnosed of EF (cutaneous induration-consistent biopsy) between January 1998 to January 2015. A total of 13 males and 8 females.

Conclusions: In our series, the EF prevals in males, in the decade of the 40 and in the majority one did not find trigger factor. There was presence of arthrits in a significant percentage of patients. In the last years the use of the RMN has been added to the diagnosis and to the follow-up. Throgh there are no clinical tests that support it the use of the metotrexato has been generalized as adjuvant treatment to the steroids.

AB0981 CLINICAL FEATURES OF 28 CASES OF LIMB RESTRICTED VASCULITIS AND FASCITIS
H. Mukoyama, K. Nishimura, R. Saito, Y. Nakamura, T. Nagamoto, T. Yokota. Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Kurashiki, Okayama, Japan

Background: We sometimes experience the cases with fever and muscle pain of lower limbs without any specific features. There are sporadic case reports of eosinophilic fasciitis and limb restricted vasculitis. However, few reports compare and discuss such cases.

Objectives: To describe the clinical features, MRI findings, histopathology, diagnosis and response to treatment of these cases.

Methods: We retrospectively analyzed the clinical features of 28 patients who were admitted to our hospital because of fever and muscle pain of lower limbs from 2004 to 2016.

Results: Among the 28 patients, 17 were vasculitis syndrome; eleven were limb restricted small vessel vasculitis (LrSvv), six were microscopic polyangiitis (MPA). Seven were fasciitis; three were eosinophilic fasciitis, three were diffuse fasciitis without eosinophila and one was tuberculosis fasciitis. One was relapsing polychondritis. The other 21 patients were without a specific diagnosis. In our study, average age was 57.5±19.9 years old and older than in previously reported cases of limb restricted vasculitis.[1,2] Sixteen were female; twelve were male. Abnormal MRI findings in non-inflammatory fasciitis and vasculitis syndrome were bilateral. Tuberculous fasciitis showed specifically abnormal intensity and fluid collection in unilateral thigh. Unilateral lesion and fluid collection may indicate infectious disease and bilateral lesion may indicate autoimmune or autoinflammatory diseases. MRI of vasculitis syndrome and fasciitis showed hyperintense T2-weighted signals in muscles of either legs, or thighs, or both. Twenty-three patients (n=23) showed atypical abnormal signal intensity in most cases with fasciitis and 6 (40%) with vasculitis syndrome. It was difficult to differentiate between vasculitis and fasciitis by MRI findings. Muscle biopsy was performed in 25 patients. In most cases, we performed en bloc biopsy, including muscle, fascia, skin and subcutaneous tissue. MRI was useful to determine the location of biopsy. All patients were treated with glucocorticoids. Immunosuppressive agents (azathioprine, n=10; methotrexate, n=5; cyclophosphamide, n=1; tacrolimus, n=1) were added in 15 patients and anti-tuberculosis drugs in one. None of the 11 patients with LrSvv showed positive blood tests of anti-nuclear, cytoplasmic antibody or developed any other organ involvement during follow-up period (median 96 months; range 3–125). They responded well to glucocorticoid therapy (oral prednisolone 0.5–6.0mg/kg/day or intravenous methylprednisolone at doses of 1g/day). Recurrence rate of LrSvv was 0%, although that of MPA patients was 50% (n=3). In four patients with LrSvv, treatment was ceased and they achieved drug-free remission. There were no apparent differences between the patients who achieved drug-free remission and who didn’t.

Conclusions: MRI and muscle biopsy were useful for diagnosis of disease with fever and muscle pain of lower limbs.

AB0983 MEFV MUTATIONS IN ARMENIAN PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES
K. Ginosyan, A. Beglaryan 1, 1, V. Vardenany. Internal Medicine, Yerevan State Medical University, Yerevan, Armenia

Background: The systemic diseases of connective tissue have autoimmune mechanism in development. While autoimmunity involves adaptive immune activation, autoinflammation involves innate immune activation. The prototype of autoinflammatory diseases is familial Mediterranean fever (FMF), which is the global medical problem for Armenian ethnics on the whole, affecting 1–2% of population.

Objectives: The aim of this study was investigation of MEFV mutations and their possible influence on the systemic diseases in Armenian patients.

Methods: We have examined 183 patients with FMF. All patients with FMF fulfilled Tel-Hashomer FMF diagnostic criteria. Molecular-genetic detection of 12 MEFV mutations common for Armenians carried out in Medical Genetic Centre of Armenia. In 49 patients one of autoimmune systemic diseases was diagnosed: in 24 patients-sarcoidosis, in 23 - systemic lupus erythematosus (SLE), in 1 - systemic sclerosis.

Results: In the SNSA group from 21 patients 16 were male, 8 were female, the mean age of patients was 35.4±12.2. The mean age at the beginning of the disease was 14.91±12.6. In all cases the symptoms of FMF were preceded by specific symptoms of arthritis. Unilateral saccroilitis was revealed in 6 patients, bilateral saccroilitis in 18 patients. The limitation of lumbar motion was assessed by Schober’s test. 7 patients with Schober’s test 1–2 cm had bilateral sacroiliitis grade III-IV and fulfilled the modified New York criteria for analysing spondylitis. HLA B-27 was examined in 7 patients. In 5 cases it was negative, and in 2 cases –positive. MEFV gene analyses were carried out in 21 cases: 7 patients had one heterozygote mutations: 6-M694,1-M680I; 5 patients -M694V/M694V, 9 patients had compound heterozygote mutations: 5- M694V/VT268A, 3 - M694V/E148Q, 1 - M690/V148Q. So, the prevalent mutation was M694V.

In SLE group from 23 patients female were 21 (91.3%), male – 2 (8.7%). Mean age of patients was 37.4±2.5 years. The beginning of FMF was earlier than SLE. The activity of SLE estimated by SLEDAI index was significant lower than in FMF. SLE and FMF co-occurring with M694V. M694V co-occuring lupus according to both clinical and laboratory findings including serological markers of SLE -ANA, anti-dsDNA. The prevalent mutation was M694V - 44.6%; VT268A was 21.7%, M680I-9.8%. Most common variations with M694V were M690I/V148Q. None of patients had mutation V726A.

Conclusions: MEFV is involved in the development of SLE. M694V is the main mutation in SLE patients in Armenia.

References:
Results: All patients were males with a mean age of 67 years (range 53–78). Two had pancreatic involvement; one had lymph node enlargement; one had pancreatic and lymph node involvement; one had pancreatic, aortic, submandibular gland and lymph node involvement. Patients with pancreatic involvement presented with increased serum amyloses or abdominal discomfort; none had obstructive jaundice; all had overt diabetes. The mean IgG4-RD RI, serum IgG4 concentration and plasmablasts counts at baseline were 8 (6–15), 483 mg/dL (136–983) and 3336/mL (330–9330 /mL), respectively. All patients had increased 18F-FDG uptake on PET/CT scan within the affected organs. After 6 months of methotrexate, Patients 1, 2, and 3 were on CR with improved or normalized PET/CT findings, serum IgG4 and plasmablasts levels. Patient 5 achieved PR, showing in loved 18F-FDG-PET/CT findings, normal plasmablasts level, but stable serum IgG4 concentration; after 10 months of methotrexate, persistence of disease activity prompted the introduction of glucocorticoids. Methotrexate was stopped in Patient 4 after 5 months of nausea and vomiting; at 6 months he showed persistently increased plasmablasts count and 18F-FDG uptake on PET/CT, thus requiring a rescue therapy with glucocorticoids. (Table 1)

Conclusions: In localized forms of IgG4-RD with mild manifestations, methotrexate represents a promising alternative strategy for inducing disease remission, especially in the presence of contraindications to glucocorticoids.

AB0986 FAMILIA MEDITERRANEAN FEVER GENE MUTATIONS: A POORLY STUDIED CAUSE OF INTERMITTENT HYDARTROSIS

M. Espinosa Malpartida1, C. Barbadiilo Mateos1, C. Ramos Giraldez1, B.J. Flores Robles1, E. Gonzalez Vioque2, C. Merino Argumanez1, M. Jimenez Palop1, J. Sanz Sanz1, H. Godoy Tundidor1, J. Campos Esteban1, J.L. Andreu Sanchez1, L.F. Villa Alcazar1, J. Mulero Mendoza1, 2Rheumatology

2Biochemistry, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain

Background: Familial Mediterranean Fever (FMF) is an inherited autoinflammatory disorder caused by mutations in the MEFV gene encoding pyrin, characterized by recurrent episodes of fever and serositis. Some patients with FMF present incomplete and atypical manifestations of FMF disease and pyrin manifests only as intermittent arthritis.

Objectives: Characterization of musculoskeletal clinical manifestations in patients with mutations of the MEFV gene in our hospital.

Methods: We retrospectively reviewed clinical records of patients with mutations detected in the Family Mediterranean Fever MEFV gene in our hospital from January 1, 2008 to October 1, 2016. We collected parameters such as age at diagnosis, age of onset Of the symptoms, sex, affected joints, other extra-articular manifestations and type of MEFV gene mutation.

Results: Eight patients (5 males, 3 females) aged from 3 to 51 years (mean 36) were identified. All patients had fever, polyarthritis or pericarditis and serositis (pericarditis 7/8, pleuritis 6/8, abdominal pain 5/8). Four patients had pericarditis, pleuritis and serositis. Five patients were treated with colchicine, two with glucocorticosteroids. Three patients had a complete response, one a partial response and four a poor response to treatment.

Conclusions: Few case reports have already shown the efficacy of tocilizumab (TCZ) in PMR patients. IL-6 is involved in the pathogenesis of PMR and quite a few case reports have already shown the efficacy of tocilizumab (TCZ) in PMR patients and some of them received TCZ mono-therapy without GC. TCZ mono-therapy may be a good alternative therapy instead of GC for elderly patients with various comorbidities.

AB0985 METHROTAXITE AS INDUCTION OF REMISSION THERAPY FOR LOCALIZED MANIFESTATIONS OF IGG4-RELATED DISEASE

L. Rovati1, E. Della-Torre1, M. Lanzillotta1, E. Bozzalla Cassione1, E. Bozzolo1, C. Canavari2, M. Falconi3,4, L. Dagna1,4. 1, E. Della-Torre1, M. Lanzillotta1, E. Bozzalla Cassione1, E. Bozzolo1, C. Canavari2, M. Falconi3,4, L. Dagna1,4.

Background: Medium to high dose glucocorticoids represents the treatment of choice for inducing remission in patients with IgG4-related disease1. However, clinicians might prefer alternative equally effective drugs in clinical settings where long-term corticosteroids treatment is contraindicated, such as diabetes or osteoporosis. We recently reported the efficacy of methotrexate in maintaining glucocorticoid-induced IgG4-RD remission2.

Objectives: To evaluate the efficacy of methotrexate as induction of remission therapy in selected cases of mild and localized IgG4-RD complicated by clinical scenarios that might advise against corticosteroids treatment.

Methods: Five patients with active untreated IgG4-RD were started on oral or subcutaneous methotrexate (up to 15–30 mg/week). Efficacy of methotrexate in inducing remission was assessed at 6 months by 18F-FDG PET/CT scan and by measuring the IgG4-RD Responder Index (RI)3 and circulating plasmablasts4. Partial response (PR) corresponded to an improvement of the IgG4-RD RI > 2 points. Complete response (CR) corresponded to an IgG4-RD RI score < 3.

Conclusions: In localized forms of IgG4-RD with mild manifestations, methotrexate represents a promising alternative strategy for inducing disease remission, exceptionally in the presence of contraindications to glucocorticoids.

Disclosure of Interest: None declared

Results: Seven patients with MEVF gene mutations were reviewed, all of them were women, ranging in age from 14 to 61 years old. Two of them had recurrent knee monoarthritis, one had a history of arthritis in the hands and erratic arthralgias, one had erratic arthralgias and two had no musculoskeletal manifestations. The 2 patients with intercurrent hydrarthrosis responded satisfactorily to colchicine, but not the other patients with other musculoskeletal manifestations.

Conclusions: Genetic testing of the common mutations of the MEVF gene should be considered in patients with recurrent episodes of monarthropathy without justifying cause (palindromic rheumatism, intermittent hydrarthrosis, etc.)

AB0088 BEHÇET’S DISEASE IN A DEFINED AREA OF NORTHERN WESTERN SPAIN

M. Estévez, A. Argibay, R. Lorenzo, M. Freire, J. Fernandez-Martín, B. Gimena, C. Vázquez-Trihano, A. Rivera. Systemic Autoimmune diseases and Rheumatology Unit, University Hospital Complex of Vigo, Vigo, Spain

Background: Behçet’s disease (BD) is a multisystemic inflammatory chronic disease. There is a wide variation in the clinical features of BD among geographical groups.

Objectives: To determine the demographic and clinical characteristics of BD in a defined area of northwestern Spain (Vigo).

Methods: Patients with BD (International Criteria BD) and seen in the University Hospital of Vigo in Spain, from 1994 to 2016, were retrospectively enrolled. Demographic, clinical, treatment and evolution data were recorded and analyzed using SPSS 22.0.

Results: Our patients were 26 male and 25 female. The mean age at the onset of the disease was 33±11.95 years (11–62). Oral and genital ulcers were seen in 100% and 84.3% respectively and skin lesions in 88.2%. Ocular involvement occurred in 35.3%, neurological disease in 39.2% and gastrointestinal involvement in 29.4% (the area worst affected was colon and small bowel). Vascular disease was present in 33.3%. See table 1. Pathergy test was performed in 18 patients (35.29%) and 10 (55.5%) were positives. HLA BS1 was studied in only 13 patients (25.5%) and 8 (61.5%) were positives. 62.7% of patients had no cardiovascular risk factors (CVRF), 27.4% were smokers, 7.8% were hypertensive and 3.9% were hyperlipidemic and diabetic respectively. CVRF were not related to thrombotic events (p<0.05). In regard to gender influence, only pseudofolliculitis was significantly more frequent in men (p<0.001). There was a trend for increased prevalence of ocular disease and elevated erythrocyte sedimentation rate/serum C-reactive protein in men, and anemia in women, which, however, did not reach statistical significance. Treatment consisted of corticosteroids (92.2%), colchicine (88.6%) and another immunosuppressive agent (35.3%). During the disease course 78.4% of the patients had an outbreak, 45.1% initiated or changed to immunosuppressive agent and 19.6% used biological drugs. Most of our patients (92.1%) were admitted to hospital and these constitute an evident bias. Two patients died during the follow-up period, but only one in relation of BD (upper gastrointestinal bleeding and seizures).

Conclusions: Our series has some particular aspects especially the high frequency of gastrointestinal lesions and neurologic involvement. CVRF do not seem to play a role in the development of thrombotic events. Our results confirm the high geographic variation of BD expression.

AB0089 RHEUMATOLOGIC COMPLICATIONS OF THALASSEMSIA: SHOULD RHEUMATOLOGISTS JOIN THE MANAGEMENT TEAM?

M.H.A. Noureldine1, A.T. Taher2, A.A. Haydar2, A. Berjawi2, M.A. Khamashia1, I. Uthman2, aDepartment of Neurosurgery, Lebanese American University; bDepartment of Internal Medicine, American University of Beirut; cDepartment of Internal Medicine, American University of Beirut; dGilbert and Rose-Marie Chagoury School of Medicine, Lebanese American University, Beirut, Lebanon; eLupus Research Unit, St Thomas Hospital, London, United Kingdom; fDepartment of Rheumatology, Dubai Hospital, Dubai, United Arab Emirates

Background: Beta-thalassemia major is accompanied by progressive multi organ systems involvement due to the disease pathophysiology as well as iron overload from blood transfusions on a regular basis. Rheumatologists are not frequently involved in the multidisciplinary management of the disease, in which rheumatologic complications are relatively common.

Abstract AB0089 – Table 1. Clinical manifestations of our BD patients

| Abstract AB0088 – Table 1. Clinical manifestation of our BD patients |
|-----------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
| Skin lesions | Ocular disease | Neurologic disease | Vascular disease | Gastrointestinal involvement |
| 41/55 (88.2%) | 19/51 (35.3%) | 20/51 (39.2%) | 17/51 (33.3%) | 15/51 (29.4%) |
| Pseudofolliculitis | 58.8% | Venous thrombosis 21.6% | Pain 11.7% |

PERI-ARTERITIS AS A NOVEL PARANEOPLASTIC PRESENTATION OF MYELODYSPLASTIC SYNDROME: A CASE SERIES AND REVIEW OF THE LITERATURE

N. Droz, C. Gota. Rheumatology, Cleveland Clinic Foundation, Cleveland, United States

Background: Myelodysplastic syndromes (MDS) are characterized by ineffective and dysplastic hematopoiesis resulting in peripheral blood cytopenias with varying risk for progression to acute myelogenous leukemia (AML). Autoimmune manifestations have been well described in association with MDS1. Peri-arteritis has rarely been reported.

Objectives: Here, we present a novel association of MDS with peri-arteritis.

Methods: Three patients within our institution and one in the literature were identified. Patients were diagnosed with MDS according to 2008 World Health Organization classification with concomitant occurrence of peri-arteritis on imaging2.

Results: See Table 1.

Conclusions: Autoimmune manifestations associated with MDS occur in 7–25% of patients. The most commonly reported conditions include vasculitis, inflammatory arthritis and connective tissue disease. There is a paucity of literature describing peri-arteritis associated with MDS. Review of the literature revealed only one other case of peri-arteritis associated with MDS outside of those identified at our facility3.

With this case series, we report peri-arteritis as a novel presentation of MDS. Peri-vascular inflammation may mimic idiopathic retroperitoneal fibrosis, however, may be attributed to genetic factors. Arthritis may develop secondary to iron deposition in the synovial tissue or due to iron chelators such as deferoxamine, which may provoke a self-limited arthritis due to synovial destruction sustained by free radicals production during iron interchange. Several studies reported increased incidence (16%–30%) of arthropathy in beta-thalassemia patients on deferoxamine therapy. Multiple etiologies contribute to osteoarthritis in thalassemia patients such as bone marrow expansion, iron deposition within the joint, and hypoparathyroidism. Only few cases of Salmonella enteriditis septic arthritis were described in thalassemia patients. The associations between osteopetrosis and hypogonadism, diabetes, and vitamin D and calcium deficiency were found significant. Skin lesions of PXE were reported in up to 16% in beta-thalassemia.

Patient 1

Age 67
Sex Female
MDS type CMML-1

Presenting Symptoms Hydropnephrosis, abdominal pain, weight loss
Bone Marrow Biopsy Hypercellular features of CMML-1

ANCA and ANA Negative
ESR (0–15mm/hr) 21
CRP (<0.9mg/dL) 5.4

Treatment Corticosteroids

Clinical Course Unilateral stenosing and nephrostomy tube placement improved symptoms. Inflammatory markers remained elevated despite treatment.

A DIFFICULT DISTINCTION – ERDHEIM-CHESTER DISEASE MIMICKING IGGA-RELATED DISEASE

P. Korsten1, C.O. Sahmann2, S. Hakroush3, 1Department of Nephrology and Rheumatology; 2Department of Nuclear Medicine; 3Institute of Pathology, University Medical Center Göttingen, Göttingen, Germany

Background: Rheumatologists are often confronted with systemic and rare diseases. Even among the rare diseases, clinical features may overlap, but treatment options for different diseases may differ.

Objectives: To illustrate the diagnostic challenges the clinician is confronted with when facing rare and systemic diseases in clinical practice with a case report where clinical features were overlapping.

Methods: A 64-year-old woman was presented to our institution after suffering from two ischemic strokes. Cerebral imaging was suggestive of large-vessel vasculitis. Additionally, imaging also revealed a left-sided retro-orbital mass. Her past medical history was notable for retropertioneal fibrosis with ureteral obstruction requiring percutaneous drainage six months before presentation and placement of a cardiac pacemaker several years ago. Treatment with high-dose prednisone had been initiated but showed no clinical or laboratory improvement.

Results: Clinical examination revealed mild persistent facial hemiparesis and difficulty with ambulation. Mild exophthalmos was present on her left side. On palpation, there were palpable axillary masses bilaterally. Otherwise, her physical examination was normal. Laboratory analysis revealed elevated soluble interleukin-2 receptor levels at 2800 IU/mL (N: 230–770 IU/mL) and mildly increased C-reactive protein at 10 mg/L (N: <5 mg/L). Autoantibodies, including rheumatoid factor, IgG4, ANCA, ANA, and ERA were all within normal range. Plasma cells were normal on flow cytometric analysis. A PET-CT was performed which revealed signs of alveolitis, retropertioneal fibrosis, axillary masses with strong tracer uptake (figure 1) as well as tracer uptake of the left femur and periaortic sheathing. We performed a biopsy of the left-sided axillary mass. Histopathologic analysis showed Touton giant cells and septal fibrosis. Staining was negative for CD1a and S100 but positive for CD68. Molecular pathologic analysis revealed the presence of the BRAFV600E mutation, findings that are consistent with the diagnosis of Erdheim-Chester disease. We initiated treatment with the BRAF-inhibitor vemurafenib and will follow the patient closely. Staining for IgG4 was negative.

Conclusions: Erdheim-Chester disease (ECD) and IgG4-related disease are very rare disorders and can present with similar clinical findings, such as retropertioneal fibrosis, alveolitis or lymph node enlargement. About 500 cases of ECD worldwide have been reported. ECD is a non-Langerhans cell histiocytosis with a reported five-year survival rate of about 68%. Roughly 50% of patients show a BRAF mutation. Various treatment options have been reported and are recommended by the recently published consensus guidelines (1). These include interferon-alpha, vemurafenib and also TNF-alpha inhibitors, such as infliximab, but also interleukin-antagonists, such as anakinra (IL-1) or tocilizumab (IL-6). Rheumatologists have to consider non-Langerhans cell histiocytoses in the differential of systemic diseases because the distinction can be difficult and imaging, as well as meticulous histopathologic analyses, are necessary to correctly diagnose these patients because treatment differs.

ELDERLY - ONSET SARCOIDOSIS: A SINGLE CENTER COMPARATIVE STUDY

S. Kobak1, F. Sevier2, H. Semiz2, M. Orman4, 1Rheumatology, Istinye University Faculty of Medicine, LIV Hospital, Istanbul; 2Chest Diseases, Medicalpark Hospital; 3Internal Medicine; 4Statistics, Ege University Faculty of Medicine, Izmir, Turkey

Background: Sarcoidosis is a chronic granulomatous inflammatory disease characterized with non-casefied granuloma formation. It is rarely affects patients older than 65 years old.

Objectives: The purpose of this study is to compare and evaluate the demographic, clinical and laboratory features of elderly-onset (EOS) and young-onset sarcoidosis (YOS) patients.

Methods: One hundred and thirty one patients diagnosed with sarcoidosis according to clinical, radiologic and histopathological evaluation were included in this study. The patients with initial symptoms started after age 65 were accepted as EOS. Demographic, clinic, radiologic, and laboratory data and the medication which the patients received were recorded and retrospectively evaluated.

Results: Twenty (15.3%) of 131 patients were diagnosed as EOS, and 111 (84.7%) patients were evaluated as YOS. Fifteen of 20 EOS patients were female and 5 and 5 of them were male. Average duration of the disease was determined as 38.4months for YOS and 22.5months for EOS (p=0.556). Delay of the diagnosis was 12months for YOS while it was 3months for EOS (p=0.001). Higher rates of fatigue, comorbid diseases and more Hydroxychloroquine (HQ) use were detected in EOS patients comparing to YOS (p=0.010, p=0.003 and p=0.049 respectively). There was obviously more disease modifying anti-rheumatic drugs (DMARDs) use by YOS group but statistical difference wasn’t significant. The 3-year survival rate after diagnosis of sarcoidosis was %95 in the EOS group, compared with %100 in the YOS group.

Conclusions: In this study we showed that EOS and YOS patients may be characterized with different clinical, and laboratory features. EOS patients are characterized with higher rates of fatigue and comorbid diseases, less inflammatory sign and delayed diagnosis, and less DMARDs usage.

ANTI TNF-ALPHA THERAPY WOULD BE LIFESAVING IN DEFICIENCY OF ADENOSINE DEAMINASE-2

S. Sahin1, A. Adrovic2, K. Barut2, S. Ugurullu2, E.T. Turanli3, H. Ozdogan2, D. Karsacopoulou1,1Department of Pediatric Rheumatology; 2Department of Rheumatology, Istanbul University, Cerrahpasa Medical Faculty; 3Department of Molecular Biology and Genetics, Istanbul Technical University, Faculty of Science and Letters, Istanbul, Turkey

Background: Deficiency of adenosine deaminase-2 (DADA2) is a rare form of autoinflammatory disorder with limited reported cases.

Objectives: In this study, we have characterized the clinico-immunological, radiological and genetic characteristics of eight childhood-onset DADA2 patients. We aimed to compare these features between surviving and deceased patients.

Methods: Demographic features, clinical characteristics, imaging findings, mutations and pharmacological treatments compared between surviving and deceased DADA2 patients.

Results: Eight patients from seven families were enrolled. While five of them were still surviving, three of them had died due to various reasons. Median age of the patients at disease onset and diagnosis were 7 years (range 0.5–13 years) and 14 years (range 5–27 years), respectively. The main clinical manifestations were cutaneous manifestations (7/8), recurrent low-grade fever (6/8), neurological involvement (6/8) and gastrointestinal involvement (5/8). All patients had increased acute phase reactants at presentation and also during flares. Until the diagnosis of DADA2, five patients had been followed-up with the diagnosis of PAN; two patients both with PAN and FMF, and one patient with CAPS and vasculitis.

Scientific Abstracts: Disclosure of Interest:
Demographic, clinical, neurological features and genetic mutations did not differ in surviving and deceased DADA2 patients. Deceased and surviving subjects differed in terms of medication usage after the diagnosis of DADA2. Anti-TNF alpha treatment has been initiated in 5 surviving patients soon after the diagnosis of DADA2. However, unfortunately three patients who have died, were able to use either a few dosage of anti-TNF alpha treatment or none; one patient due to reluctance of patient and two patients due to establishment of a definite diagnosis with genetic analysis after the patients had died.

Conclusions: Although this study includes limited number of patient, to our knowledge this study for the first time compares the phenotypic, genotypic and medication differences between surviving and deceased DADA2 patients. Anti-TNF alpha treatment seems to be very efficient and lifesaving in DADA2 patients.

CLINICAL, THERAPEUTIC, AND GENETIC ANALYSES IN A PATIENT WITH PAPA SYNDROME COMPLICATED WITH INFLAMMATORY BOWEL DISEASE

T. Koga 1, Y. Yidaka 1, K. Fujimoto 1, S. Kaida 1, K. Mitsuyma 2, K. Iwamoto 3, K. Fujita 1, R. Nishikomi 4, T. Hoshino 1, H. Iida 1, Division of Rheumatology, Department of Medicine, Kurume University School of Medicine, Kurume University School of Medicine, 1Division of Gastroenterology, Department of Medicine, Kurume University School of Medicine, 2Division of Gastroenterology, Department of Medicine, Kurume University School of Medicine, 3Polyarteritis Nodosa, Kurume University, Kurume, Fukuoka; 4Department of Pathology, Tenri Hospital, Tenri, Nara; 5Department of Pediatrics, Kyoto University Graduate School of Medicine, Kyoto, Japan

Background: PAPA syndrome is an autoinflammatory disease linked to mutations in the PSTPIP1 gene [1]. These mutations produce a hyper-phosphorylated PSTPIP1 protein and alter its participation in the activation of the "inflammases" [2]. PAPA syndrome is characterized by pyogenic arthritis with pyoderma gangrenosum and acne, and usually treated with corticosteroids. Reports from the literature suggest that patients with poorly controlled PAPA syndrome may benefit from IL-1 alpha treatment. We herein reported a Japanese PAPA syndrome patient who have been affected by a mutation of the PSTPIP1 gene.

Methods: We herein report a 25-year-old Japanese male who suffered from recurrent arthritis in his knee and ankle joints, pyoderma gangrenosum, and acne. He had experienced melena and multiple colonic ulcers had been detected by colonoscopy. His ulcerations resembled ulcers associated with Crohn’s disease. A biopsy of colon was performed for the evaluation of this colonic lesions. Histopathologically, the ulcer appeared as a deep ulcer leading to the submucosal tissue. The surface of the ulcer remained intact. Isolation of microorganisms from the ulcer was not carried out. The 45-year-old father of this patient had the same mutation, thus suggesting that this mutation of PSTPIP1 gene might not be related to his phenotype. We are currently carrying out genetic analysis to confirm this hypothesis.

Results: 1) A histological analysis revealed that a large number of neutrophils had accumulated in the skin lesions; however, very few neutrophils were detected in the pathological lesions of the knee joints and colon. 2) According to a gene analysis, we detected a novel heterozygous mutation (E101G) in the PSTPIP1 gene. This mutation was also found in the healthy father also had the same mutation, thus suggesting that this mutation of PSTPIP1 gene might not be related to his phenotype. A search of other affected genes besides the PSTPIP1 gene for PAPA syndrome in this case. 3) After treatment of biologics (infliximab), the clinical symptoms, such as arthritis and multiple colonic ulcers, were considerably improved and the serum level of IL-6 and TNF-α were decreased in this patient.

Conclusions: We herein reported a Japanese PAPA syndrome patient who was complicated with inflammatory bowel disease and had a good response to biologics. A genetic analysis suggested that this particular phenotype might not have been affected by mutation of the PSTPIP1 gene.

AB0996
FREQUENCY OF HLA-B*51 AND THE ASSOCIATION WITH CLINICAL MANIFESTATIONS IN ARABIAN PATIENTS WITH BEHÇET DISEASE

V.N. Mukuchyan, A. Haroyan. Erebuni Medical Center, Yerevan, Armenia

Background: Behçet disease (BD) is a systemic inflammatory disease mostly characterized by oral and genital ulcers and variable manifestations affecting other organs, mainly skin and eye. The HLA class I molecule HLA-B*51 allele is strongly associated with BD in many different ethnic groups and appears to be a significant risk factor for BD in the ancient Silk Route areas in contrast with Western and Northern Europe and U.S.

Objectives: Our purpose was to show the frequency of presence of HLA-B*51 allele in Arabian patients with BD and estimate any correlation with common symptoms of disease depended on presence of HLA-B*51.

Methods: Forty-seven patients of Arabian origin (28 males, 59.6% and 19 females 40.4%) fulfilling the International Criteria for BD (ICBD) with mean age 29.7±11.3 years; disease duration – 5±12.4 years were enrolled. We observed the clinical manifestations of BD of both HLA-B*51 carriers and non-carriers.

Results: HLA-B*51 was detected in 38 (80.8%) patients, of whom 25 male and 13 female (65.8% and 34.2%, respectively). Arthritis, erythema nodosum and genital ulcers were significantly more common in HLA-B*51-positive patients (83.3%, 83.3% and 80.6% respectively) than in HLA-B*51-negative ones (16.7%, p=0.032, 16.7% p=0.032 and 19.4% p=0.023 respectively).

Conclusions: In the HLA-B*51 first estimation of frequency gene in patients with BD in Armenia, our result indicated that the frequency of HLA-B*51 allele in BD is 80.8% which is higher than elsewhere (In Japan 58.9%, Iran 61.9%, Turkey 75%, Saudi Arabia 76.9% Greece 78.9%)5. Furthermore, this investigation revealed HLA-B*51 carriage much more often in male than in female BD patients. In addition HLA-B*51 carriers are in significant higher risk of development of arthritis, erythema nodosum and genital ulcers.

AB0997
ULTRASONOGRAPHIC EVALUATION OF ANTERIOR KNEE PAIN IN YOUNG ADULTS

A.A. Neem, M. Khairy, A. Asseb, K. Abbas. Rheumatology, Al-Azhar University, Cairo, Egypt

Objectives: The Primary outcome of the present work is to detect type and frequency of Ultrasonographic changes in patients with anterior knee pain. Secondary outcome is to determine the role of MSUS in early detection of causes of anterior knee pain (AKP).

Methods: Sixty patients with AKP and 20 sex and age matched healthy control were included in this study obtained from the outpatient of Physical Medicine and Rheumatology Department of El Hussein and Bab El-Sharia university hospitals. Inclusion criteria: age between 20–40. Exclusion criteria: trauma, Crystal induced arthritis, connective tissue diseases (RA, SLE, SpA), chronic liver or kidney disease and previous surgery. Full medical history and clinical examination (EMG, knee Conventional Radiography and Musculoskeletal Ultrasonography (MSUS) were done to all patients. Bilateral MSUS examination of the following common sites: Insertion of quadriceps tendon, Ligamentum patellae and Anterior aspect of the knee from medial to lateral. According to EULAR guide lines for musculoskeletal ultrasonography.

Results: The mean duration of knee pain in patients group was 11.4±9.134 months. ESR, CRP and WOMAC were higher in patients group (p<0.01). MSUS showed significantly more frequent Supra-patellar and Infra-patellar bursitis in patients than control group (p=0.000). Patients had higher frequency of cartilage thickness than control, 2.2±0.5 mm vs 2.7±0.261 mm respectively (P<0.000, 95% Cl: 0.31 to 0.58).

Conclusions: The degree of Knee pain, measured by WOMAC, is positively correlated with inflammatory biomarkers (ESR and CRP) in patients with Anterior knee pain. MSUS revealed a positive correlation between Femoral Articular Cartilage thickness and the periarticular tendon- thickness, namely Patellar origin, patellar insertion and Quadriceps insertion. Interestingly, our data present an evidence of the negative impact of the duration of knee pain over Femoral Articular Cartilage thickness as well as Patellar origin thickness. (FACh thickness get worse with longer duration of pain)
AB0998 DIAGNOSTIC VALUE OF 14-3-3 (ETA) IN RHEUMATOID ARTHRITIS

A. Novikov, E. Aleksandrova, M. Cherkasova, T. Popkova, E. Luchihina, D. Novikov, D. Karateev. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Protein 14-3-3 (eta) involved in the upregulation of inflammatory and joint damage factors [1]. 14-3-3 is the candidate biomarker of rheumatoid arthritis (RA) [2].

Objectives: To evaluate the clinical utility of 14-3-3 for diagnosis of RA.

Methods: We studied 44 patients (pts) with RA, 5 men and 39 women, median age (25-75 percentile) of age 45 (35-59) years; disease duration is 10 (5-20) months. DAS28 5.2 (4.4-6.2); 5 pts with systemic lupus erythematosus, 4 – ankylosing spondylitis, 5 – OVERLAP; 4 with psoriatic arthritis and 20 healthy individuals.

14-3-3, anti-cyclic citrullinated peptide autoantibody (anti-CCP) was measured in serum by commercial enzyme-linked immunosorbent assays, IgM rheumatoid factor (IgM RF). Measured by immunonephelometry.

Results: The diagnostic sensitivity of 14-3-3 for RA (cut off 0.19 ng/ml) is 70.5%, specificity – 83.7%; positive likelihood ratio – 4.33, negative likelihood ratio – 0.35; positive predictive value – 81.6%, negative predictive value – 73.5%; AUC = 0.78 (CI 0.68–0.88). Concomitant presence of 14-3-3 and IgM RF, anti-CCP was determined in 66%, 73% of the patients with RA respectively. 14–3–3 had correlation with IgM RF (r=0.7, p<0.05).

Conclusions: Serum 14-3-3 correlation with IgM RF (r=0.7, p<0.05) for RA (cut off 0.19 ng/ml) is 70.5%, specificity – 83.7%; positive likelihood ratio – 4.33, negative likelihood ratio – 0.35; positive predictive value – 81.6%, negative predictive value – 73.5%; AUC = 0.78 (CI 0.68–0.88). Concomitant presence of 14-3-3 and IgM RF, anti-CCP was determined in 66%, 73% of the patients with RA respectively. 14–3-3 had correlation with IgM RF (r=0.7, p<0.05).

AB0999 FINNISH COHORT OF PATIENTS WITH RAYNAUD’S PHENOMENON-NAILFOLD VIDEOKAPILLAROSCOPY FINDINGS AND AUTOANTIBODY VALUES

A. Háme1, K.-L. Vidqvist1, P. Parmanne1, A. Puhakka1, T. Hasan1, H. Mäkinen2, J. Panelius3, R. Peltomaa1, M. Perovaara2, R. Luosujärvi1.

1Rheumatology, Helsinki University Hospital, Helsinki; 2Rheumatology, Tampere University Hospital, Tampere; 3Actelion Pharmaceuticals, Espoo; 4Dermatology, Helsinki University Hospital, Helsinki, Finland

Background: Raynaud’s phenomenon (RP) is very common all around the world, especially in cold climates (from 3 to 22%) (1). Nailfold capillaroscopy and autoantibodies have a pivotal role in diagnosing of different diseases in the context of RP (2). This is a first study of patients with RP in Finnish tertiary care hospitals.

Objectives: Aim is to investigate nailfold videokapillaroscopy (NVC) findings and autoantibody-values in patients with Raynaud’s phenomenon first time in Finnish prospective multicenter study cohort.

Methods: We enrolled consecutive 160 patients with Raynaud’s phenomenon who underwent NVC 3/2012–4/2015. Nailfold capillaries of II-V fingers of both hands were examined by using an optical probe videokapillaroskope mounted with x200 magnification lens. Images where analyzed with Videoccapt software (DS Medigroup, Milan, Italy). NVC findings were classified with qualitative scoring, whereas the other 30% had symmetrical axonal neuropathies (entrapment neuropathies), whereas the other 30% had symmetrical axonal neuropathies (entrapment neuropathies). Ultrasound diagnosis of posterior tibial entrapment at the ankle was encountered in 20 (40%) patients. In addition, a positive power Doppler (PD) signal and medium titers of ANA and 76.0% (n=19) had high titers of ANA. 69, 2% (n=18) had anticitrulline antibodies (ACA) and 3, 8% (n=1) had antitopoisoenermase I antibodies (anti-Scl-70). Those patients who had positive ACA or anti-Scl-70 also had a NVC scleroderma-pattern.

Conclusions: The main reason for NVC in this cohort was differential diagnosis of Raynaud’s phenomenon, and in most patients in diagnostic group primary Raynaud’s phenomenon was diagnosed. NVC is useful method for differential diagnosis of Raynaud’s phenomenon.

References:
erosions of the ankle joint were prevalent among the active group in comparison with patients in remission (p<0.001), as shown in figure (1).

Conclusions: Peripheral nerve affection is common in the rheumatoid foot, irrespective of the disease activity level. The most common foot neuropathies are; posterior tibial entrapment at the ankle, peroneal entrapment at the fibular neck and pure median neuropathy. MSUS is valuable for diagnosis of posterior tibial entrapment at the ankle. In addition, a positive PD signal and erosions of the ankle joint are associated with disease activity.

CLINICAL VERSUS ULTRASOUND EVALUATION OF PERIPHERAL ENTHESITES IN A COHORT OF SPONDYLOARTHRITIS
A. Haddouche, S. Haid, S. Bencheikh, S. Slimani, A. Abdessemed, N. Brahimi, A. Ladjouze. Medicine, University of Algiers 1. Algiers, Algeria

Objectives: Clinical versus ultrasound evaluation of peripheral entheses in a cohort of spondyloarthropathy

Methods: A monocenter prospective study of all SpA >18 years meeting the ASAS criteria for SpA followed in a rheumatology center over a period from January 2015 to April 2016. Demographic, clinical, lab and ultrasound characteristics were noted. Fifteen enthesal sites were investigated bilaterally: insertions of sub-scapular, medial and lateral epicondylar tendons, triceps brachialis, Achilles tendon, plantar aponeurosis. These sites were assessed clinically and with US during the same visit and then results were compared between the clinical and the US examination.

Results: A total of 208 patients were included, mainly men (63.5%). The mean age was 40.2±11.7 years and the mean duration of the SpA was 11.8±8.7 years. Axial radiographic SpA was the most frequent phenotype (69.2%) and ankylosing spondylarthritis was the most frequent sub-group (57.7%). At examination, 88.9% had an active disease (ASDAS-ESR and/or ASDAS-crp >2.1) and 64.4% of SpAs were taking NSAID. Clinical examination and US revealed at least one abnormal enthesis in 55.3% and 86.1%, respectively.

Conclusions: In this cohort and as expected, ultrasound (with at least one elementary lesion) was superior to clinical examination for the detection of peripheral entheses (83.2 vs. 44.2%, P<0.001). Interesting sites to explore according to the prevalence and to the presence of a Doppler signal (<2mm cortical) would be insertions of the calcaneal, quadricipital, patellar, gluteal, plantar aponeurosis and triceps brachialis tendons.

MEDIUM AND ULNAR NERVE CROSS-SECTIONAL AREA IN CARPAL TUNNEL SYNDROME WITH EXTRATERRITORIAL SPREAD OF SENSORY SYMPTOMS
B. Mansiz Kaplan1, M. Akdeniz Leblebicier2, L. Yagi1. 1Department of Physical Medicine and Rehabilitation, University of Health Sciences, Ankara Training and Research Hospital, Ankara; 2Department of Physical Medicine and Rehabilitation, Gumushane State Hospital, Gumushane; 3Department of Physical Medicine and Rehabilitation, School of Medicine, Marmara University, Training and Research Hospital, Istanbul, Turkey

Objectives: To evaluate the relationship between extramedian spreading of sensory symptoms and median and ulnar nerve cross-sectional area in patient with carpal tunnel syndrome (CTS), to compare the ultrasonographic and electrophysiological findings in patients with CTS whose sensory symptoms are extramedian spreading or median distribution only.

Methods: Patients with CTS were divided into two groups as with and without extramedian symptoms and were assessed clinically, electrophysiologically and ultrasonographically by three blind investigators. In electrophysiological tests, median and ulnar nerve conduction studies were performed. Nerve cross-sectional areas were measured at hamatum hook, pisiform bone, radio-ulnar joint, one-third distal part of forearm, and medial epicondyle for median nerve; radio-ulnar joint, pisiform bone, one-third distal part of forearm, and medial epicondyle for ulnar nerve by ultrasonography.

Figure 1 summarizes the prevalence of elementary ultrasound lesions per site.

Elementary Lesions

Hypo-hypo-echoicn (Thickening
Enthesophytes Erosions Calcification

Conclusions: This study demonstrated that extramedian spreading of sensory symptoms is associated with increased nerve cross-sectional area.
Results: The study was completed with 61 patients (108 hands). Extramedian symptoms were present in 31 patients (54 hands). Finger grip strength was lower, pain values evaluated with visual analogue scale were higher in these patients (p<0.05). There was no statistically significant difference in electrophysiological and ultrasonographic parameters between two groups.

Conclusions: These results suggest that extramedian spread inCTS patients is more related to central and peripheral sensitization than peripheral causes.

AB1004 NOMENCLATURE ON MEDICAL, DIAGNOSTIC, AND THERAPEUTIC PROCEDURES IN RHEUMATOLOGY

B. Yoldi1, M.A. Martin2, C. Plana3, A. Gómez4, M. Valero5, J.L. Andreu6, J.V. Moreno7,1, Rheumatology, Hospital Universitari Dexeus, Barcelona; 2Sociedad Española de Reumatología, Madrid; 3Rheumatology, Hospital Clinic Provincial, Barcelona; 4Rheumatology, Hospital Parc Taulí, Sabadell; 5Rheumatology, HM Hospitals; 6Rheumatology, Hospital Universitario Puerta del Hierro, Madrid; 7Rheumatology, Hospital Vall d’Hebron, Barcelona, Spain

Background: One of the missions of the Spanish Society of Rheumatology (SER) is to provide professionals involved with the necessary tools to ensure a better care for patients suffering from a rheumatic disease. Up to now, there is no benchmark that quantifies the complexity of medical acts in this specialty. Therefore, there is a need to adopt a physician activity scale that would allow assessment of their professional activity and skills regarding patient care.

Objectives: To compile a nomenclature of medical, diagnostic, and therapeutic procedures in the field of rheumatology; and to establish a hierarchical classification system according to a complexity index which was calculated by two factors: time of completion and degree of complexity of each act.

Methods: A list of care, diagnostic, and therapeutic acts was compiled based on the nomenclature created by Drs Fernandez and Oliver. The hierarchical classification system was based on the construction of a complexity index which was calculated by two factors: time of completion and degree of complexity of each act.

Results: The total of included acts was 54. The results obtained with the Delphi method tended to show a consensus of opinion (media IQR2 – IQR1=0.8–1.9=-1.1). Furthermore, a validation of these results was carried out through a massive survey among the partners of SER. The survey results showed a high degree of agreement (at least 70.0 per cent of the partners agreed or strongly agreed with the complexity of each act).

The degree of complexity in successive visits was 100. In the query section for consultations, the highest scores were obtained by first visit to hospitalized patient (366) and home visit (369). Regarding diagnostic techniques, the highest scores were obtained with biopsies: bone (465), sural nerve (416), and synovial (380). Also worth mentioning the scores obtained by ultrasound scan (204), capillaroscopy (113) and densitometry (112). Regarding therapeutic techniques, intra-articular injection under sedation in children obtained a score of 388; while intra-articular injection with ultrasound control obtained a score of 163. The clinical report of disability was agreed to have a score of 323, and the expert report obtained a score of 370.

Conclusions: This work has made it possible to create a nomenclature of 54 acts in Rheumatology, where biopsies (bone, sural nerve, synovial), visits to hospitalized patients, home visits, infiltration under sedation in children, and expert reports are identified as the most complex acts. Musculoskeletal ultrasound is considered twice as complex as a successive visit, capillaroscopy, or bone densitometry. These results will make it possible to improve patient care and establish a solid and agreed foundation to negotiate the provision of public and private services.

AB1005 HYPERTHYROID AND HY珀THYROID STATUS WAS STRONGLY ASSOCIATED WITH MUSCULOSKELETAL ULTRASONOGRAPHIC ABNORMALITIES WITH ARTHRALGIA

B.Y. Kim1, S.S. Kim2, J.R. Choi2, H.-S. Kim3, 1Department of Internal Medicine, Soonchunhyang University college of Medicine, Seoul; 2Department of Internal Medicine, Gangneung Asan Medical Center, Gangneung; 3Department of Internal Medicine, Pohang Saint Mary’s Hospital, Pohang, Korea, Republic Of

Background: Thyroid dysfunction can cause musculoskeletal symptoms and sign. Ultrasonography is a useful tool for the evaluation of synovitis and is more accurate than clinical examination.

Objectives: The purpose of the study was to determine whether musculoskeletal ultrasonographic (MSUS) abnormalities were observed according to the state of thyroid disease.

Methods: Patients with thyroid disease were categorized as euthyroid, hypothyroid, or hyperthyroid status according to thyroid hormone levels and evaluated the association with MSUS abnormalities. In addition, the association of the presence of thyroid autoantibodies with MSUS abnormalities was also studied. In MSUS, an experienced rheumatologist examined the presence of synovial fluid, synovial hypertrophy, and grade of power doppler in the knee joint.

Results: Table 1. Patient characteristics

| Age – mean ± SD (years) | 58±13.0 |
| Sex – n (%) | Male 13 (11.9) Female 96 (88.1) |
| Thyroid diseases duration – median (range), (years) | 4 (0–13) |
| Distribution of thyroid diseases - n (%) | Euthyroid status 61 (56) Hypothyroid status 11 (10.1) Hyperthyroid status 37 (33.9) |
| Positive thyroid autoantibodies – n (%) | 68 (62.4) |
| Taking thyroid medication – n (%) | 100 (91.7) |
| Patient’s Knee VAS (100mm) – median (range) | 10 (0–80) |
| MSUS finding – n (%) | Normal 72 (66.1) Abnormal 37 (33.9) |

Conclusions: Both hypothyroid and hyperthyroid status was significantly associated with MSUS abnormalities with knee arthralgia. MSUS is a useful tool to detect clinically early joint abnormalities. We suggest that patients with diagnosed thyroid dysfunction and who remain uncontrolled, should assess the MSUS examination in patients with arthralgia. Moreover a thyroid function test for unexplained arthritis might be warranted.

AB1006 POWER-DOPPLER TECHNIQUE IN PAGET’S DISEASE OF BONE: A NEW MONITORING TOOL OF THERAPEUTIC RESPONSE. STUDY ON 43 PATIENTS

C. Artusi1, C. Mastaglio2, C. Arnoldi2, V. Gaiatl2, P.L. Meroni1, 1Chair and Division of Rheumatology, Gaetano Pini Institute, University of Milan, Milan; 2Unit of Rheumatology, Ospedale Moriggia-Pelascini, Gravevorda (CO), Italy

Background: To date the evaluation of the disease activity and the monitoring of the therapeutic response of patients affected by Paget’s disease of bone is based only on clinical and hematological data. However, in clinical practice the management of these patients is still challenging. Previous angiographic
and histological studies have revealed that the accelerated bone turnover is associated with an increased blood flow and hypervascularity, suggesting a role of high-resolution sonography with power-Doppler (PD) and color-Doppler (CD) in Paget's disease. Our preliminary data demonstrated that this technique shows not only the alterations of the pagetic bone profile, but also the hypervascularization of the osteoperiosteal-layer before the diagnosis and during follow-up.

**Objectives:** To validate the PD technique as a useful tool not only for the diagnosis of Paget's disease of bone but also for the evaluation of the disease activity and for the monitoring of the therapeutic response.

**Methods:** Forty-three consecutive patients affected by Paget's disease of bone and treated with neridronate were followed up over the last ten years. Patients were classified in eight clinical patterns defined by the presence of bone alkaline phosphatase elevation over the normal range (BAP+), bone pagetic pain as visual analogue scale $≥$70 (VAS+) and PD alterations of osteoperiosteal vascularization (PD+). Data were analyzed by Fisher exact test (two tails) to assess the associations between BAP+, VAS+ and PD+ at different times during follow up: before the start of the therapy, after the first, the second and the third neridronate cycle of therapy, and at the end of all cycles.

**Results:** At any time BAP+ and VAS+ were not associated. A trend of association between VAS+ and PD+ could be observed only after the first neridronate cycle. In contrast, the association between BAP+ and PD+ was statistically significant before the therapy, at the end of all cycles of therapy and after the second one, but not after the first one.

**Table 1. Associations between BAP elevation over the normal range, VAS and PD alterations of osteoperiosteal vascularization, $p<0.05$**

</tr>
</tbody>
</table>

Conclusions: The lack of association between VAS+ and PD+ or BAP+ or BAP+ may be due to the difficulty of the patients in identifying and quantifying the pagetic pain, and suggests the weakness of the clinical criteria in defining the disease activity. Otherwise, PD technique proves to be a fast, reliable and not expensive tool, which is also very useful for monitoring/achieving better control of Paget's disease of bone.

**DOI:** 10.1136/annrheumdis-2017-eular.5963

**Conclusions:** The SLE-key® RuleOut test detects a serologic signature which remains stable between sampling dates and over a long period of time after diagnosis in 84% of subjects. Subjects who were ruled out at T1 were generally ruled out at T2. Patients not ruled out at T1 remained not ruled out at T2. The clinical implications of a changing SLE-key® RuleOut score in the remaining 16% of patients may be meaningful, and are currently being carefully investigated.

**Objectives:** The aim of this study was to explore distributions of antibodies in SLE patients in different ethnic groups in xinjiang.
MRI CONTRIBUTES TO ACCURATE DIAGNOSIS OF NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN PATIENTS WITH SERUM NEGATIVE HLA-B27

Division of Rheumatology, Department of Internal Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei City, Taiwan, Province of China; 2Department of Pathology, University of Washington, Seattle, United States; 3Department of Radiology, Tri-Service General Hospital, National Defense Medical Center; 4Department of Health Promotion and Health Education, National Taiwan Normal University, Taipei City; 5Division of Rheumatology, Department of Internal Medicine, Taipei Tzu Chi Hospital, New Taipei City; 6Division of Radiology, Taoyuan General Hospital, Ministry of Health and Welfare, Taoyuan City, Taiwan, Province of China

Background: Based on ASAS axial spondyloarthritis (SpA) criteria, the presence of structural changes of sacroiliac (SI) joints such as sclerosis, bone erosion, joint space widening or ankyloses does not meet the definition of active sacroiliitis on magnetic resonance imaging (MRI), if there is no bone marrow edema (BME). However only less than half Asian patients with SpA were characterized by BME. Neither serum inflammatory markers such as c reactive protein (CRP) nor erythrocyte sedimentation rate (ESR) is able to be useful as diagnostic markers in the early phase of SpA. HLA-B27 is associated with early diagnosis of SpA and axial inflammation of SI joints on MRI. Nonetheless, HLA-B27 is not associated with structural lesions of SI joints. All factors contribute to difficult defining early Asian SpA patients in the absence of serum HLA-B27 and active imaging inflammation.

Objectives: The aim of this study is to evaluate the prevalence of structure changes of SI joints on MRI in Taiwanese SpA patients in the absence of serum HLA-B27.

Methods: Thirty-three patients with inflammatory back pain and morning stiffness (disease duration more than 3 months) and high disease activity (BASDAI>4) who had to be either serum HLA-B27 positive (10 patients) with >1 SpA-feature or HLA-B27 negative with ≥2 SpA-features (22 patients) were included in this prospective study. All patients did not meet the definition for a positive radiograph according to the modified New York criteria. MRI was performed with multiple sequence (Coronal and axial T1-weighted spin echo, coronal and axial short-tau inversion recovery). SI joints were evaluated for the prevalence of subchondral BME and structure changes (sclerosis, bone erosion, joint space widening and ankylosis). All patients were tested for X-rays of the pelvis and serum levels of ESR and CRP. Correlation analysis was performed among the different collected variables.

Results: Subchondral BME was only present in 8 of 23 patients with SpA in the absence of serum HLA-B27 (34.8%), while 7 of 10 (70%) HLA-B27 serum positive SpA patients revealed ≥1 BME on MRI. Although, including sclerosis, bone erosion and joint space widening were identified in 8 (80%), 10 (100%) and 5 (50%) SpA patients with positive serum HLA-B27, respectively. Nevertheless, these structural changes of SI joints on MRI were more common in HLA-B27 serum negative patients, as 15 (65.2%), 20 (87.0%) and 7 (30.4%) of 23 serum negative patients, respectively.

Conclusions: MRI contributes to detect structural changes of SI joints for patients with nonradiographic axial SpA in the absence of serum HLA-B27.

ULTRASOUND MORPHOSTRUCTURAL PATTERN OF THE TIBIOFIBULAR JOINT: PRELIMINARY RESULTS

C. Hernández-Díaz 1, L. Ventura-Rios 1, M. Maldonado 2, G. Sanchez-Bringas 3.
1Laboratorio de Ultrasonido Musculosquelético y Artricular, Instituto Nacional de Rehabilitación, Mexico City, Mexico; 2Reumatologo, Cuzco, Peru; 3Departamento de Embriología, Facultad de Medicina, UNAM, Mexico City, Mexico

Background: The anatomy of the proximal tibiofibular (TF) joint is directly related to its ability to withstand stress applied in either a longitudinal or axial fashion. It is traditionally evaluated by CT scan, however, in certain conditions, it could be evaluated by ultrasound (US) conveniently; so far US has not been using to evaluate the TF joint. US is an innocuous, accessible and cheap image technique, that has demonstrated its utility for evaluating joints in several pathologic conditions, and might have an important role in the early diagnosis of inflammatory, degenerative or even traumatic lesions at the level of the TF joint; there are no studies that have evaluated the morpho-structural pattern of the TF joint.

Objectives: To describe the morphostructural pattern of the tibiofibular joint in healthy subjects.

Methods: Subjects older than 18 yrs old, with no history of past/present lesion of the knee, without any joint or neurovascular disease were included. A short questionnaire related to physical activity applied, and clinical evaluation to discard instability performed. US of both knees in extension done, using an Esaote 6 MyLab 70 ultrasound equipment with a 7.5 - 12 MHz linear transducer. Descriptive statistics applied.

Results: Thirty-six patients (27 women, 75%) included, mean age 41±2.8±9 years, mean weight 71±12.46 kg, mean height 1.61±0.09 ms and BMI 71.07±12.40. 69% of the subjects practice mild exercise activities. By US mean distance between tibia and fibula were 3.2±1.7 cm; the mean thickness of the ligaments (superior and inferior tibiofibular ligaments 3.2±1.3, 3.6±1.6, 3.2±1.6 cm respectively and in the superior and inferior fibular ligaments 3.2±0.90 cm and 3.2±0.89 cm respectively. Ligaments were hyperchoic in 61.1%, a well-defined border was seen only in 48.6%. Inside of joints a hypoechogenic tissue was observed.

Conclusions: These preliminary results suggest that US can be a useful tool for evaluating the tibiofibular joint.

RELIABILITY OF SONOGRAPHIC PERITENON EXTENSOR TENDON INFLAMMATION PATTERN IN PSORIATIC ARTHRITIS

C. Macía 1, H.B. Hammer 2, S. Falcao 3, J. Medina 4, M. Guitierrez 4, E. De Miguel 5, 1Rheumatology, Hospital Universitario Severo Ochoa, Madrid, Spain; 2Rheumatology, Diakonjhemmet Hospital, Oslo, Norway; 3Rheumatology, Chronic Diseases Study Center (CEDOC), NOVA Medical School, UNL, Lisboa, Portugal; 4Rheumatology, Hospital Clinico Universitario, Valladolid, Spain; 5Rheumatology, Division of Musculoskeletal and Rheumatic Disorders. Instituto Nacional de Rehabilicion, Mexico City, Mexico; 6Rheumatology, Hospital Universitario la Paz, Madrid, Spain

Background: Preliminary results demonstrate that the peritenon inflammation of extensor digitum tendon (PTI) is a specific ultrasonic (US) pattern of Psoriatic Arthritis (PsA) and is associated with the presence of PsA. Nonetheless, PTI was suggested as a pattern playing a key role in the differential diagnosis between Rheumatoid Arthritis and PsA 1,2.

Objectives: In spite of PTI’s clinical impact, there are no data regarding the reliability of US PTI evaluation. The present study addressed this topic by testing the reliability of US on evaluation of PTI.

Methods: 27 consecutive non selected PsA patients with clinical involvement of at least one 2nd to 5th MTPJ were included. A rheumatologist trained in PTI assessments obtained the US images exploring the dorsal aspect of MTPJ from 2nd to 5th of both hands using a MyLab 70 XVG machine, Esaote, Genova, Italy, with a greyscale (GS) 13 MHz probe and a 7.1 MHz power Doppler (PD) frequency, PRF 750 Hz and a 60 Gain. 3–5 seconds videos of each MCPJ were obtained in transversal and longitudinal views for further reliability analysis. In the inter-reader performed by 5 readers from 5 different hospitals and four countries, it was scored as present or absent 1) PTI (defined as an hypoechoic swelling of the soft tissue surrounding the extensor tendon at MCPJ level with or without PD) and 2) intra-articular synovitis (IAS, OMERACT definition), both in PD and GS. The consensus of true US results for every joint and lesion was achieved when at least three readers had the same opinion.

Cohen’s Kappa test was used for statistical analysis.

Results: Clinical MCPJ involvement was present in 60 (27.7%) of the 216 joints whereas US detected IAS and/or PTI in 75 (34.7%), US showed GS PTI in 41 (19%) of the joints, while GS IAS was found in 63 (29.2%) with PD activity in 41 (19%) of the joints. The inter-reader reliability is shown in the Table. Intra-reader reliability results expressed as mean Kappa were 0.826 for PTI PD, 0.784 for PTI GS, 0.743 for IAS PD and 0.637 for IAS GS.

Conclusions: US examination of MCPJ shows that PTI is near as frequent as PsA with reliability of US evaluation. The present study addressed this topic by testing the reliability of US on evaluation of PTI.

Clinical Utility of Antihistone Antibodies: A Descriptive Study

D. Boveda-Ruiz1, B. Vilas-Pio2, M. Freire-Dapena2, R. Lorenzo-Castro2, A. Soto-Peleteiro2, S. Mirete-Bachiller2, A. Rivera-Gallego2, 1Internal Medicine, Hospital Clínico Universitario de Valladolid (SACYL), Valladolid; 2Internal Medicine; 3Immunology, Complexo Hospitalario Universitario de Vigo, Vigo, Spain

Background: Antihistone antibodies (AHA) have been linked to Drug-Induced Lupus Erythematosus (DILE) for decades. However, for some authors this relationship is not so clear and suggest that the presence of these autoantibodies is related to other autoimmune diseases more frequently.

Objectives: The main objective of this work was to study the association of AHA with different autoimmune entities (including DILE) and to look into which clinical manifestations and which autoantibodies are more frequently related to AHA.

Methods: We performed a descriptive study. A database was constituted using all patients with AHA+ in any blood analysis between years 2000 and 2016 in the University Hospital Complex of Vigo. The variables of the study were: presence of autoimmune disease, clinical manifestations and related autoantibodies.

None of the 73 patients AHA+ developed DILE while almost 50% of them suffer any other autoimmune disease. We found a high percentage of AHA+ patients with lupus erythematosus complications such as arthritis and hematological abnormalities. AntiDNAds antibody was the more frequent coexpressed autoantibody.

Conclusions:
- AHA detection is not useful as DILE screening.
- AHA+ suggest the presence of other autoimmune disease rather than DILE.
- AHA+ may be related to lupus erythematosus systemic complications.

References:
Conclusions: The novel FOI RA synovitis scoring system showed high reliability and moderate to good responsiveness in the wrist and hand. Future studies should focus on assessing the sensitivity and specificity of the FOI synovitis score with ultrasound and magnetic resonance imaging as gold standard.

AB1014 SAFETY OF OUTPATIENT PERCUTANEOUS NATIVE RENAL BIOPSY IN PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES: RESULTS FROM A MONOCENTRIC COHORT

D. Roccatello, S. Sciascia, D. Rossi, C. Naretto, M. Bazzan, L. Solfietti, M. Radin, S. Baldovino, E. Menegatti. Department of Rare and Immunologic Diseases, G. Bosco Hospital and University of Turin, Torino, Italy

Background: Renal involvement is common in patients with systemic autoimmune conditions, mainly systemic lupus erythematosus (SLE) and vasculitis, including cryoglobulinemia. Despite the advances in percutaneous kidney biopsy (PKB) techniques and overall improved safety of the procedure, clinically significant bleeding complications do occur.

Objectives: to investigate the safety of performing percutaneous native kidney biopsy (PKB) as an outpatient procedure (implying an observation period of 6 hrs) compared to the traditional inpatient policy in patients with systemic autoimmune conditions.

Methods: Group I, in whom PKB was performed was included in the outpatient department (2012–2016) and followed by 6 hours’ observation period and then by regular outpatient visits and group II, in whom PKB was performed and followed by at least 1-day hospital admission. Group II included retrospectively retrieved patients who underwent PKB in our Institution between January 2000 and November 2012 as in patient procedure. All biopsies were performed by a single nephrologist following a structured protocol.

Results: A total of 81 biopsies (group I and group II) were included in this study, 44 (54%) of patients were female and the mean age was 49.9±17.6 years. Twenty-six percent of biopsies were performed for the diagnostic workup of nphrotic range proteinuria, 21% for rapidly progressive renal insufficiency, and the remaining 53% for non-nphrotic proteinuria and/or hematuria. No patient suffered for a major complication and only 3 (3.7%) patients (one with cryoglobulinemic vasculitis and 2 with ANCA associated vasculitis) developed a minor complication, including gross hematuria in one case and sub-capular perinephric hematoma on sonography not requiring intervention in 2 patients.

Conclusions: The lack of major complications and the very limited rate of minor bleeding support that outpatient biopsy could be a valuable, safe, and perhaps cost-effective method of obtaining diagnostic renal tissue in the majority of patients with systemic autoimmune diseases.

AB1015 AUTOMATED SQUEEZE TEST (GAENSLEN'S COMPRESSION MANEUVER) IN RHEUMATOID ARTHRITIS PATIENTS. A PRELIMINARY STUDY

D. Vega-Morales, J.A. Esquivel-Valerio, A.C. Arana-Guajardo, M.A. Garza-Elizondo. Rheumatology Service, Hospital Universitario Dr. José Eleuterio González, Monterrey, Mexico

Background: The squeeze test (a.k.a Gaenslen’s Compression Maneuver) consists on the compression of the metacarpal-phalangeal (MCP) joints to elicit pain in a patient with active synovitis. The squeeze test has three main purposes: Screening of inflammatory arthritis, as a predictor of rheumatoid arthritis in arthralgia patients, and as a quick and practical evaluation of the presence/absence of synovitis in patients already diagnosed with RA. The force and the way to perform the squeeze test had been evaluated in rheumatologists on a biomechanical device, with conflicting results. We developed a biomechanical device to perform the squeeze test.

Objectives: Our aim is to determine the force whether the automated squeeze test discriminate patients with active RA from inactive ones. And the force that differentiates a healthy patient from a RA patient.

Methods: Observational study in RA (ACR/EULAR 2010) patients and healthy persons. We perform 3-squeeze test on the device in the MCP joints and record the force enough to elicit pain. And then compare them with the joint counts by the clinician.

Results: Two hundred MCP joints from 50 hands were tested. From 25 RA patients with a mean age of 54.6 years (SD 11.22), with a mean disease latency of 1.2 years (SD 2.7). The total swollen joint count was 16 (7 right joints + 9 left joints) and 70 total tender joint count (30 right joints and 40 left joints). The median of force that caused pain in the RA patient’s right hand was 3.07 kg (IQR 2.4) and the left hand was 2.78 kg (IQR 3.8). The cut-off for the force to detect a tender right hand joint was 1.020 grams with a sensitivity of 100% and specificity of 73.3%; for a swollen right hand joint was 1,400 grams with a sensitivity of 100% and specificity of 28.6%. For a tender left hand joint was 1620 grams with a sensitivity 70% and specificity of 6.7%; and for a swollen left joint was 1990 grams with a sensitivity of 100% and specificity of 27.3%. In the second phase, 560 MCP joints of 140 hands from 70 healthy volunteers were compressed. The median force to elicit pain in the right hand was 4.2 kg (IQR 9.5) vs. 3.07 kg (IQR 8.7) from RA patients (p=0.003), and for left hand 4.6 kg (IQR 9.7) vs. 2.78 kg (IQR 9.2) from RA patients (p=0.014).

Conclusions: It is necessary to continue the exploration of the maneuver in different clinical settings. Validate the strength in patients with different arthropathies, activity levels and different clinical stages (screening, activity, prediction) and also with imaging methods for evidence of inflammation (US, MRI).

AB1016 ANTI-DFS70, A TOOL IN USUAL CLINICAL PRACTICE: A CASE SERIES

D. Ybáñez-García, V. Valls-Pascal, C. Vergara-Dangond, M. Aguilar-Zamora 1, L. Montolío-Chiva 1, Á. Martínez-Ferrer 1, J.M. López-Ortega 2, J.J. Alegre-Sancho 1, 1Rhematology; 2Clinical Analysis Laboratorio Service, Hospital Universitario Dr. Peset, Valencia, Spain

Background: The presence of anti-nuclear antibodies (ANA) has been considered a characteristic of systemic autoimmune diseases (SAD). Patients are frequently referred for study because they have ANA and are followed because of the possibility to develop SAD. Approximately, 20% of healthy individuals with ANA detected by indirect immunofluorescence (IFI), especially at low titers, have a dense, line speckled pattern (DFS) that frequently corresponds to the presence of anti-DFS70 antibodies. The importance of this antibody is due to its low prevalence in subjects with ASD (1%) compared to its presence in 33.1% of healthy subjects with ANA.

Objectives: To describe the usefulness of Anti-DFS70 in a series of patients presenting ANA.

Methods: We collected prospectively throughout the year 2016 all the patients referred to a tertiary hospital for ANA study and in whom the presence of anti-DFS70 antibodies was confirmed. All patients underwent a thorough medical history, physical examination, and relevant follow-up tests were performed according to the clinical presentation. The IFI was performed in a Menarini Zenit-Up/GSight system, as well as ANA screening in Hep-2000 (Fluorescent IgG ANA-Ro Test System-immunocconcepts) and the detection of anti-DFS70 antibodies by immunoblot (ANA + DFS70 Dot Blot-Alphadia).

Results: We collected in a period of 12 months a total of 7 patients with anti-DFS70 antibodies. Most of them (6/7) were referred because of non-specific symptoms such as arthralgia, fatigue, thrush, edema, ... and the presence of ANA. The findings are detailed in Table 1.
Conclusions: Anti-DFS70 is a valuable biomarker, with a very low prevalence in SAD, which gives it a role as a negative predictive marker of developing SAD when it is absent. Its detection in serum with a dense fine speckled pattern ANA (IFI) should be part of the protocol of the immunology laboratory. It is a cost-effective determination, as demonstrated in a recent study, by avoiding the costs associated with the follow-up of these patients. In our case, its finding allowed us to reassure the patient and avoid the accomplishment of further complementary tests, as well as an unnecessary monitoring.

AB1017 THE DEFEAT OF THE HIP JOINT IN ANKYLOSING SPONDYLITIS BY MAGNETIC RESONANCE IMAGING

E. Agafonova 1, 2, T. Dubinia, A. Dyomina, O. Rumiantceva, D. Rumiantceva, M. Podbydnyova, A. Starkova, S. Krasnenko, M. Urumova, S. Erdes. Laboratory seronegative spondyloarthritis, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: According to the carried out epidemiological studies in Russia of patients with ankylosing spondylitis (AS) defeat of the hip joints was impairment in 46% of cases, but was the reason for the replacement in 7% of cases. Objectives: To compare the clinical manifestations of hip arthritis (coxitis) with the results of magnetic resonance imaging (MRI) of the joint hip (HJ) in patients with ankylosing spondylitis (AS). Methods: Examined 117 patients (mean age 31.7±12.7 y, age range 7–84 y), complaining of pain in the hip joints. The average age of onset of disease was 26.3±20.3 y, HLA-B27 identified in 93% of patients. The median duration of AS – 57 [2–384] months. RESULTS: BasDAI 5.7±5.1, Diagnosis of hip septic arthritis were made based on clinical signs – the presence of pain in hips and/or restriction of movements in HJ at the time of patient admission to the clinic. In addition to clinical and radiographic examination all patients were performed MRI of hip joints T1 and T2.

Results: The Median duration of clinical manifestations of coxitis by the time of the study was 60 months. [25%; 75%], evaluation of pain in HJ for numeric rating scale (NRS) – 4 [2; 8], According to MRI identified the following inflammatory changes (IC): synovitis-71 (83%) patients, bone marrow edema (BME) – 44 (31.6%) patients. In BME acetabulum 36%, BME heads 63%, a combination of synovitis and BME were 7 patients (9%). Depending on radiological stage (estimated by BASRI hip), patients were divided into two groups (table 1).

Conclusions: MRI allows to clarify the cause of the pain and limitations of movement in HJ with AS, determine the patient has inflammatory changes, including in the absence of radiographic changes in these joints. Patients with severe radiological change (BASRI II-V), have a greater duration of the disease, severe functional abnormalities in the BASFI index. With increasing radiological stage (BASRI hip I-V) increased the detection rate of osteos (MRI). Further research to clarify the relationship of clinical manifestations of coxitis (pain level) from MRI data.

AB1019 ASSOCIATION OF INFLAMMATORY DISEASES – A CURRENT TOPIC FOR THE PRACTITIONER

A. Cardoneanu 1, 2, A. Burlui 1, 2, C. Cijevschi Pilepicean 2, E. Rezuz 1, 2, Rheumatology, University of Medicine and Pharmacy “G.T.Popa”, 1Rheumatology Clinic, Rehabilitation Hospital; 2Gastroenterology University of Medicine and Pharmacy “G.T.Popa”, iasi, Romania

Background: Autoimmune, infectious, traumatic or neoplastic inflammation represents a warning for the practitioner. Numerous clinical specialities face daily with the presence of inflammation. The efforts of medical staff must aim to establish the pathogenesis, the expansion and to find the most effective ways of treatment. Objectives: Our study objective is to highlight the correlations between Spondyloarthropathies (SpA) and intestinal manifestations, the link between the antigen HLA B27 and joint and intestinal inflammatory changes and also the relationship between the presence of sacroiliitis and bowel disorders.

Methods: The study included 42 patients (28 men, 14 women). Of the 42 patients, 31 were diagnosed with ankylosing spondylitis (AS) (according to modified New York criteria), 8 with psoriatic arthritis (PsA) (using CASPAR diagnosis criteria) and 3 patients had had reactive arthritis (ReA) (according to ASAS criteria). All subjects enrolled in the study were screened for the presence of the antigen HLA-B27. The diagnosis of PsA was confirmed through helvis X-ray centered on the SI joints. All patients diagnosed with AS presented radiological sacroiliitis, only 5 cases in the group of PsA and 1 patient diagnosed with ReA. To investigate the presence of intestinal inflammation, a colonoscopy with biopsy was performed to all subjects included in the study. Among patients with AS, 5 of them had inflammatory changes suggestive of Crohn’s disease (CD) and 2 for ulcerative colitis (UC). Subclinical intestinal inflammation was evaluated in 15 cases: 12 of SA group and 3 of PsA group. We also highlighted 7 cases of irritable bowel syndrome: 1 patient with PsA and 6 patients with UC. Results: After the statistical analysis of the collected data, the following statistically significant correlations were found (p<0.05): radiological sacroiliitis correlated with AS and PsA; the antigen HLA-B27 is in close relation with all 3 forms of spondyloarthritides; subclinical intestinal inflammation was positively correlated with AS and PsA. No associations were found between the presence of intestinal inflammation and sacroiliitis.

Conclusions: This study points the link between intestinal and joint inflammation, primarily due to a common pathogenic mechanisms. A careful monitoring and a close collaboration between gastroenterologists and rheumatologists contributes to an optimal management of these patients.

MULTIFREQUENCY BIOIMPEDANCE COMBINED WITH VIDEOCAPILLAROSCOPIC FINDINGS IN PATIENTS WITH MUSCULOSKELETAL DISEASES

E.M. Bartels, J. Kvistgaard Olsen, H. Bliddal, L.E. Kristensen

Background: Musculoskeletal diseases may involve muscle function, which often deteriorates due to a combination of pain and lack of exercise. Possible correction of this by training, or at least achievement of optimal efficiency of involved muscles with therapy, taking age and affecting disease into account, is an area which needs easily applicable and non-invasive pain-free assessment methods capable of monitoring daily living tasks outside a strict laboratory setting. Multi-frequency bioimpedance (mfBIA), assessing muscle health prior to exercise, in combination with Acoustic Myography (AMG), which allows real-time tests while e.g. walking on a treadmill, may be such a method.

Objectives: To validate AMG combined with mfBIA for muscle-use assessment during a series of daily activity movements and exercise with the aim of introducing the method in the clinic.

Methods: 10 healthy subjects aged 25-68 years were assessed with mfBIA (beamformer, Brisbane, Australia) prior to and following exercise of m. gastrocnemius during walking, stair climbing and descending, and cycling with increasing load. AMG was recorded with a CURO unit (MyoDynamik ApS, Frederiksberg, Denmark), and data handling was carried out with software belonging to the devices. The mfBIA parameters considered were resistance (R), internal (Ri) and external (Re) conductance, central frequency (fc), and the AMG parameters were Efficiency (E) – synchronization of motoric units, Temporal summation (T) – how frequently do you use a particular muscle fibre, and Spatial summation (S) – how many fibres in use at a given time, all given as Median; Min.Max.

Results: The mfBIA data, showing the health state of the muscle, showed changes in R, Ri, Re and fc as expected for a healthy muscle as an effect of the exercise. The AMG data showed good reproducibility with repeated measurements. Walking on flat ground was less synchronized (E 2; 1.4) as were walking up (E 4; 1.6) and down stairs (E; 1.6), than cycling (E 5.5; 5.9). With increasing load during cycling, E decreased with the higher demand to E 5.5 (range 1-7). The T-score was similar around 7 for all types of walking, while overall decreasing with increasing load during cycling from 6.5 to 5.5. The S-score was low during the three types of walk, indicating use of many fibres (S around 3), which is in line with the low E-score. For cycling the S-score decreased slightly with increasing load, from 8 to 7.5.

Conclusions: The combined method of mfBIA and AMG shows good reproducibility. This method has the potential to assess training possibilities in patients with musculoskeletal diseases by testing directly on muscles during the movements of daily function. The method is applicable in real life settings outside the laboratory.

AB1020

MULTIFREQUENCY BIOIMPEDANCE COMBINED WITH ACOUSTIC MYOGRAPHY – A NON-INVASIVE PAIN-FREE ASSESSMENT OF MUSCLE USE

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that can present, as other collagen vascular disorders, changes in blood vessels. It can be evaluated by a non-invasive technique called periungual nailfold videocapillaroscopy (VCP). This technique is helpful in the diagnosis of systemic sclerosis (SSc), being part of the new classification criteria, and identifies individuals with Raynaud’s phenomenon who are at a higher risk for developing SSc.

Methods: This study aims to describe the videocapillaroscopic profile of a series of SLE patients and investigate if the VCP pattern is different among those with Jaccoud’s arthropathy (JA) compared to the patients without this complication.

Results: In a population of 113 female patients with SLE (67 without JA and 46 with JA), at least one alteration was observed in VCP in 89.40% of patients, and the “nonspecific changes” were the most prevalent. Minor changes were seen in 39 (58.2%) and 26 (56.5%) patients, and major changes were seen in 21 (31.3%) and 11 (23.9%) patients without and with JA, respectively. The SD patterns were observed in 02 (3.0%) and 03 (6.5%) patients without and with JA, respectively (p<0.05).

Conclusions: The majority of patients of SLE present changes in the VCP exam, but such a tool does not allow distinguishing those with or without JA.

ACOUSTIC MYOGRAPHY – A NON-INVASIVE PAIN-FREE ASSESSMENT OF MUSCLE USE

E. Filippucci 1, C. Bonali 1, P. Macchioni 1, I. Lagnocco 1, A. Delle Sedie 2, S. Tropea 2, O. Epis 1, M. Canzoni 1, C. Clinica Reumatologica, Università Politecnica delle Marche, Ancona; 2Rheumatology Unit, Ospedale San Paolo, Bari; 2Rheumatology Unit, Reggio Emilia Hospital, Reggio Emilia; 4Academic Rheumatology Unit, Università degli Studi di Torino, Torino; 2Rheumatology Unit, Università di Pisa, Pisa; 4ASP7, Busacca Hospital, Ragusa; 1Rheumatology Unit, Ospedale Niguarda Milano, Milano; 2Health Unit (ASL) Rome-1, Rome, Italy

Background: Ultrasound (US) has shown to be a sensitive imaging tool for the detection of subclinical signs of synovitis in patients (pts) with rheumatoid arthritis (RA); further studies are still required to delineate the impact of US findings in the management of RA pts in daily clinical practice.

Objectives: To investigate the relationship between US findings indicative of joint inflammation and US bone erosions at joint level in pts with RA.

Methods: In 2015 an educational event focused on the added value of US in RA pts was held in 22 rheumatology centers in Italy. In every center, the local rheumatologists provided RA pts to be examined by US. Pts signed an informed consent and a brief history of them was collected by the local rheumatologists (previous and current therapy, DAS28, HAQ score). Bilateral US examinations of wrists, metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints were performed by rheumatologists expert in US, to assess synovitis (joint effusion, synovial proliferation, and power Doppler (PD) signal), and bone erosions, using a Logiq E R7, General Electronics, with a 4.2–13 MHz linear probe. All US findings were scored using a 4 degree semiquantitative scoring system.

Results: In 465 RA pts, a total of 10.230 joints were scanned. Of these joints, 3.999 (39%) showed joint effusion and/or synovial proliferation and 1.784 (17%) were found positive for PD signal. The most frequently involved joints were the wrists followed by the second MCP joints and first MTP joints. In 749 joints US detected at least one bone erosion. The most frequently eroded joints were the wrists, the second and fifth MCP joints and the first and fifth MTP joints. A total of 226 RA pts showed at least one bone erosion and in 181 (80%) of these pts the eroded joints were found positive for PD signal.

Conclusions: A high prevalence of PD signal was found in the joints found eroded by US. This is the first study providing such an evidence using a portable US equipment.

AB1024 ULTRASOUND IN GIANT CELL ARTERITIS: CUT-OFF AND PITFALLS IN THE HALO SIGN

E. De Miguel1, L.M. Beltman2, I. Monjo1, F. Deodati2, W.A. Schmidt3, L.M. Beltran2, I. Monjo1, F. Deodati2, W.A. Schmidt3, L.M. Beltran2, I. Monjo1, F. Deodati2, W.A. Schmidt3

Objectives: The objective of this study was to assess reliability of QFT test for latent TB before biological treatment.

Methods: Hacettepe University Rheumatology Biologic Registry (HUR-BIO) is a single center biological registry since 2005. Between Nov 2011 and July 2015, 1347 patients were assessed by QFT for latent TB. All consecutive patients were evaluated by a standard questionnaire between July 2015 and October 2016. The questionnaire included demographics, characteristics, medical history, symptoms of active TB. 671 patients were assessed by the physicians. TB status of other 676 patients were checked from Turkish national tuberculosis registry records. It’s an obligatory disposition for physicians to inform health ministry about TB cases and all TB patients must be recorded in those registry. The mean TB incidence per year was calculated for every anti-TNF agents and non-TNF biological agents.

Results: Total 1347 (58.1% female) patients were recruited to study. Mean age was 42±12 years. Diagnosis were followed; RA 436 (32.4%), SpA 844 (62.9%), others 67 (5.1%). Total biological drug exposure was 2329 patient-years; adalimumab (660 years), etanercept (630 years), infliximab (426 years), golimumab (283 years), certolizumab (78 years), and total anti-TNF duration (2071 years). Non-TNFi exposure was 258 patient-years. Positive and indeterminate QFT results were found in 267 (19.0%) and 20 (1.5%) patients, respectively and therefor were prescribed INH prophylaxis. In addition, INH was prescribed to 37 (2.7%) patients according to chest X-ray and physician decision. Pulmonary TB was found in 3 of 1347 (0.22%) patients. TB was developed 38, 28 and 21 months after QFT. The mean TB incidence per year was 128.8/100,000 for all biological drugs. The mean TB incidence per year according to QFT positive and negative patients were 181.8/100,000 vs 112.4/100,000.

Conclusions: According to QFT screening for latent TB, INH was started almost 20% of patients. However, if we used TST for latent TB test in BCG vaccinated countries, INH would started almost 70–80% of patients. Therefore QFT was a good tool for latent TB screening in BCG vaccinated countries. Consequently, QFT test seems acceptable to determinate latent TB during biological drug usage. In addition, TB incidence has increased almost 7 times of our national TB incidence.

AB1025 THE SUPERB MICROVASCULAR IMAGE IS MORE SENSITIVE THAN CONVENTIONAL POWER DOPPLER IMAGING IN DETECTION OF ACTIVE SYNOVITIS IN RHEUMATOID ARTHRITIS PATIENTS

G.Y. Lee1, S. Kim1, S.T. Choi2, J-S. Song2, N. Radiology; 2Internal Medicine, CHUng-Ang University College of Medicine, Seoul, Korea, Republic Of

Background: Precise evaluation of synovial inflammation and bony deformity is very important for the management of rheumatoid arthritis (RA). One of the most popular used methods to detect synovial inflammation and bony erosion is ultrasonography. Previous literatures revealed that US using power Doppler imaging (PDI) could detect more sensitive synovial inflammation than conventional radiography. However, there are still some limitations in ultrasonography. The superb microvascular imaging (SMI) is a new software technology introduced by Toshiba, which can detect a vascularity more sensitively without artifacts.

Objectives: In this prospective study, we evaluated the clinical usefulness of the SMI compared to PDI for the detection of active synovits in patients with RA.

Methods: This prospective observational study includes 56 patients with RA (42 females; mean age), from June 2015 to October 2016. The mean age of RA patients was 53.2±17.6 years, and 42 patients were female (75.0%). All included patients underwent ultrasound about both wrists and hands (total 22 joints; wrist joints, metacarpophalangeal joints, and proximal interphalangeal joints). All the ultrasound examinations were performed at the volar side of the wrists and hands using both conventional PDI and SMI which use Aplo Tim 500 Ultrasound (Toshiba Medical Systems Corporation). Their results were scored for each joint from grade 0 to grade 3 according to the vascularity (grade 0, no vascularity; grade 1, single vessel; grade 2, vascular flow less than 50% in field of view; grade 3, equal to 50% or more). The sum of grades for 22 joints was compared between PDI (PDI-sum) and SMI (SMI-sum). The correlation between the sum of grades values and inflammatory laboratory parameters including the erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and disease activity score 28 (DAS28) were also evaluated.

Results: The mean values of ESR, CRP and DAS28 were 27.13±18.06 mm/hr, 6.78±9.14 mg/L, and 2.71±1.11 respectively. The positive rates of rheumatoid factor and anti-cyclic citrullinated antibody were 73.2% and 75.0%, respectively. The sum of grades for 22 joints was significantly higher in SMI-sum compared to PDI-sum (10.27±8.20 vs. 5.89±3.76, p<0.001). The SMI-sum was highly correlated with the PDI-sum score (γ=0.800, p <0.001). The SMI-sum showed positive correlation with DAS28, tender joint count, swollen joint count, visual analogue pain scale, and CRP level (γ=0.486, p<0.001; γ=0.385, p=0.003; γ=0.467, p<0.001; γ=0.351, p=0.008; and γ=0.329, p<0.001, respectively).

The number of clinical remission (DAS28 score below 2.6) was 28 (50.0%). The SMI-sum was significantly higher than PDI-sum in patients with clinical remission (7.96±3.59 vs. 4.6±3.03, p<0.001). All of the patients with clinical remission showed active synovitis at more than one joint in SMI.

Conclusions: SMI showed a more sensitive vascularity in RA patients than PDI. We could detect active synovitis through SMI in the RA patients with clinical remission. SMI could be a useful technology for the evaluation of synovitis in RA patients, especially for the detection of clinically subtle, but active synovitis in RA patients.

AN ANA SCREENING ASSAY (ELIA®, CTD SCREEN) CONTAINING MULTIPLE ANTIGENS INCREASES THE SENSITIVITY AND SPECIFICITY OF ANA TESTING BY INDIRECT IMMUNOFLUORESCENCE

G. Steiner 1, T. Perkann 2, T. Horn 3, H-P. Kiener 1, 1, Internal Medicine III-Rheumatology; 2Laboratory Medicine, Medical University Vienna; 3Phadia Austria GmbH, Thermo Fisher Scientific, Vienna, Austria

Background: Antinuclear antibodies (ANA) are the serological hallmark of connective tissue diseases (CTD) and indirect immunofluorescence (IIF) on Hep-2 cells is the gold standard for ANA screening. While this method is sensitive it lacks specificity. Moreover, lower-titer ANA subspecificities may escape detection by IIF.

Objectives: To investigate the usefulness of an ANA screening assay containing multiple diagnostic antigens for CTD diagnosis.

Methods: Sera from 265 consecutive patients presenting with symptoms characteristic of connective tissue diseases (but without a clear diagnosis yet) were analysed by IIF and the ELIA® CTD Screen (Thermo Fisher Scientific) containing the following antigens: dsDNA, U1-anRNP, Sm, Ro60, RRo52, La, Rib-P, topoisomerase I (ScI-70), centromere B, DNA polymerase III, fibrillarin, Jo-1, Mi-2, Pm-Scl. All positive sera were further analyzed by monospecific assays (Thermo Fisher Scientific).

Results: Among the 265 patients, 90 were positive by IIF and 78 by CTD Screen; 61 sera were positive in both systems, 17 only in the CTD Screen and 29 only in IIF. In double positive patients at least one relevantly reactive antibody was detected, with anti-Ro and anti-dsDNA antibodies being most frequently detected. Importantly, antibodies were also detected in 15 of the 17 patients who were exclusively positive in the CTD Screen: 7 patients had anti-dsDNA, 4 anti-Ro, 1 anti-La and 1 anti-U1RNP, and 1 patient had anti-Jo-1 antibodies. In contrast, among the 29 sera exclusively positive by IIF only two contained a diagnostically relevant antibody. Clinical evaluation revealed that 16 out of the 17 CTD Screen pos/IIF negative patients presented with at least one clinical sign commonly associated with systemic rheumatic disease (sccia syndrome, 12 patients; anti-Ro, 1 patient; anti-U1RNP, 13 patients; antibodies, 2 patients; levokucytopenia, 2 patients; Raynaud’s phenomenon, 5 patients; pericarditis, 1 patient; thromboembolic events, 2 patients). These patients may be at higher risk for developing a CTD, or, alternatively, may be at an early stage of a CTD in which a definite diagnosis is not yet to be made. The combination of distinct autoantibodies with clinical signs of systemic rheumatic disease, however, warrants a careful follow up in these patients.

Conclusions: ANA screening assays containing multiple antigens such as the ELIA® CTD Screen seem to be helpful diagnostic tools that should be used in addition to IIF for detection of disease-associated autoantibodies enabling the physician to substantially improve diagnostics of connective tissue diseases.

THE UTILITY OF LIP BIOPSY IN PATIENTS DIAGNOSED OF IPAF (INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES)

H.S. Park 1, P. Millan 2, D. Castillo 2, M. Millan 1, P. Noya 1, B. Magallares 1, A. Lai 2, C. Diaz 1, J.M. De Liebret 1, I. Castelvi 1, 1Rheumatology; 2Pneumology, Hospital Universitario de la Santa Creu i Sant Pau, Barcelona, Spain

Background: The European Respiratory Society/American Thoracic Society Task Force has defined a classification criteria for interstitial pneumonia with features of autoimmune disease that does not accord to a specific systemic disease. This criteria combines clinical, serological and radiological domains. The clinical criteria does not include dry syndrome even though the serological criteria does include anti-Ro and antiLa antibodies. It is known that some patients with dry syndrome with antibodies negativity undertake lip biopsy to confirm Sjögren Syndrome (SS). Therefore lip biopsy could be useful to IP AF if SS is suspected.

Objectives: The aim of this study was to identify the prevalence and distribution of sesamoid bones detected on CR and DTS in patients suffering from PsA. We also aimed to identify the sesamoid bones in the hand using digital tomosynthesis (DTS).

Methods: Using CR and DTS, hand images (81 left and 100 right) were taken at a tertiary hospital were retrospectively reviewed. The sesamoid bones were identified in the distal interphalangeal (DIP), interphalangeal (IP), and metacarpophalangeal (MCP) of the thumb (I), index (II), long (III), ring (IV), and small (V) fingers. Differences in number of sesamoid bones detected on CR and DTS were analyzed.

Results: Sesamoid bones were observed in MCP I (100%), MCP II (46%), MCP III (2%), MCP IV (2%), MCP V (53%), and IP (59%) on CR. Using DTS, sesamoid bones were found more often in DIP (100%), MCP II (54%), MCP III (2%), MCP IV (1%), MCP V (59%), and IP (75%). Differences in the mean number of sesamoid bones detected on CR and DTS were statistically significant. Sesamoid bones in DIP joints were frequently observed on DTS, but rarely found on CR.

Conclusions: Most sesamoid bones in the hand were detected in MCP I, II, V, and IP joints, and were more often detected on DTS than CR. DTS is a reliable tool to evaluate bony structures in the hand.

ULTRASOUND NAIL ASSESSMENT IN PSORIATIC ARTHRITIS AND PSORIASIS COMPARED WITH HEALTHY CONTROLS

J. I. J. S. 1, O. Baniandres Rodriguez 2, L. Valor 1, J. Martinez Barrio 1, T.G. Ovalles 1, J.C. Nieto Gonzalez 1, C. Gonzalez 1, J. Lopez Longo 1, J. G. Ovalles 1, J. C. Nieto Gonzalez 1, C. Gonzalez 1, J. Lopez Longo 1, J. Montagueo 1, E. Naredo 2, 1Rheumatologist; Dermatology, Hospital General Universitario Gregorio Marañon, Madrid, Spain, 2Research Unit, Hospital Universitario Fundacion Jimenez Diaz, Madrid, Spain

Background: Assessment of nail involvement is currently made by clinical assessment using nail psoriasis severity index (NAPSI). Whilst clinical assessment can detect superficial nail changes, the matrix and the extensor tendon region are not accessible for clinical assessment. In myositis (MS) ultrasound (US) is playing an important role in the evaluation of psoriatic arthritis (PsA) patients. Recently, MSUS has been more used in the evaluation of nail involvement in psoriasis (PsO) and PsA patients.

Objectives: The primary objective of this observational, cross-sectional study was to assess the MSUS morphological and vascular abnormalities in nail in PsA and PsO patients compared with healthy controls. The secondary objective was to compare MSUS and clinical assessment of the nail in PsA and PsO patients.

Methods: We included patients with PsA (diagnosed according to CASPAR criteria) and patients with PsO without joint involvement (diagnosed by an experienced dermatologist according to clinical findings) and healthy controls.
Clinical evaluation consisted in the evaluation of the NAPSI and PASI scores. The MSUS evaluation consisted in the evaluation of 10 hand nails. In B-mode (BM) we evaluated the followings: thickness of the nail bed from the distal phalanx bone surface to the ventral plate (PB) according to Worstman X et al.; thickness of the nail from dorsal to ventral plate (IP); dorsal and ventral plate morphology, echogenicity and integrity. Additionally, we performed a color Doppler (CD) evaluation for the presence of CD signal at the nail bed and matrix level. A score for BM and different scores for CD were calculated for each nail sums and of all nails for BM and CD scores were calculated for each patient.

Results: We evaluated 60 patients with PsA, 23 with PsO and 20 controls. 52.4% were female. The mean age (SD; range) was 50.2 (13.6; 23–83). The age was higher in patients (PsO and PsA) than in controls (p<0.001). Patients with PsA were more treated with DMARD (81.7%) while patients with PsO were more treated with topics (73.9%) than DMARDs (13%), (p<0.001). The majority of the patients (96%) had a PASI score less than 12. The NAPSI was higher in PsO patients than in PsA patients (p<0.001): for all controls the NAPSI was 0. US measurements of IP and PB were significantly higher in patients than in controls in the majority of the nail (p<0.045). Total US score for BM was significantly higher in patients than in controls (p<0.001). There were no significant differences for the majority of CD scores between patients and controls. Overall we found weak to moderate positive correlations between NAPSI and US scores for BM, both for matrix and bed. For most of the nails we found no correlation between NAPSI and CDUS scores; for the rest of the nails the US scores for BM, both for matrix and bed. For most of the nails we found no correlation between NAPSI and CDUS scores; for the rest of the nails the US scores for BM, both for matrix and bed. For most of the nails we found no correlation between NAPSI and CDUS scores; for the rest of the nails the US scores for BM, both for matrix and bed. For most of the nails we found no correlation between NAPSI and CDUS scores; for the rest of the nails the US scores for BM, both for matrix and bed.
AB1033 THE EXPRESSION OF IMMUNOGLOBULIN G AND IMMUNOGLOBULIN G4 IN LYMPHOMA

J. Li1, Z. Zhang2, 1. Rheumatology department, Shanxi Dayi Hospital, Shanxi; 2Rheumatology department, Peking University First Hospital, Beijing, China

Background: Although IgG4-related disease has been gradually recognized, its relationship with malignant diseases, especially lymphoma has been an area of concern.

Objectives: To explore the expression of IgG4 positive cells in lymphoma.

Methods: Surgical excision specimens with definite diagnosis of lymphoma from January 2010 to December, 2013 were collected. Hematoxylin-eosin staining and immunohistochemical staining of IgG and IgG4 were then evaluated on dense lymphoplasmacytic infiltration, storiform fibrosis and obliterative phlebitis. For the quantification of IgG and IgG4 positive cells, the areas with the highest density of positive cells were evaluated. Three high-powered fields (hpf) in each section were analyzed, and the average number of positive cells per hpf was calculated.

Results: 16 patients with lymphoma were selected in our study. There were 9 males and 7 females with an average age of 51 years old. The pathological type included 13 cases of non-Hodgkin lymphoma and 3 cases of Hodgkin lymphoma. Sub types of Non-Hodgkin lymphoma contained 8 cases of diffuse large B cell lymphoma, 2 cases of small B cell lymphoma, 1 case of mucosa associated lymphoid tissue marginal zone B cell lymphoma (MALToma), follicular lymphoma, peripheral T-cell lymphoma and hepatosplenic T-cell lymphoma. The 16 specimens all manifested as dense lymphocytic infiltration, accompanied by atypical lymphocytes. Proliferation of fibrous tissue was only seen in one specimen. 14 cases were IgG positive with the highest cell count from 20–350/hpf. IgG4 can be expressed in both cytoplasm and cytomembrane. 2 cases of IgG4 positive were Hodgkin lymphoma and the highest cell counts were 11 and 12/hpf respectively.

Conclusions: IgG4 positive cell, fibrosis and obliterative phlebitis seldom appear in lymphoma. Among specific tumor signature molecules, it may not be difficult to distinguish lymphoma from IgG4-related disease.

AB1034 SCORING SYSTEMS OF MUSCLE MRI IN IDIOPATHIC INFLAMMATORY MYOPATHIES

K. K uninbová1, H. Mann, J. Vencovský. Institute of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic

Background: MRI is a widely used radiological method for assessing muscle involvement in idiopathic inflammatory myopathies (IIM). There is still no universally accepted and validated scoring protocol for the quantification of pathological changes in muscles.

Objectives: To identify MRI scoring systems used in previous studies. To summarize the most frequently evaluated MRI features and to suggest parameters for a unified scoring system, that has to be validated in the future.

Methods: A detailed literature search was conducted in the standard medical databases. Information regarding individual MRI scoring systems were obtained from the methodological explanations and their parameters were compared.

Results: We identified different scoring systems with a large variability of assessed localizations and parameters (Table 1). Muscle oedema as a sign of active muscle inflammation was evaluated in all studies. There were some studies using modified Mercuri score for evaluation of the fatty infiltration as a marker of chronic muscle damage or the Goutallier grading (1,2), developed originally for the assessment of inherited neuromuscular disorders or structural changes in orthopedics. Perifascicular oedema or soft-tissue oedema were also assessed in some cases. There was no concordance between evaluated muscle groups.

Conclusions: MRI plays a significant role in the evaluation of pathological changes in IIM. This research demonstrated, that there is no widely used, standardized method for assessment of a MRI finding. According to our results, a future concept of MRI scoring system should include evaluation of muscle oedema, fatty infiltration and possibly also the presence of perifascicular (-fascial) and subcutaneous tissue inflammation. Muscle groups most convenient for evaluation have to be determined as well.

AB1035 EXAMINATION OF ULTRASOUND FINDINGS IN UNDIFFERENTIATED SPONDYLOARTHRITIS PATIENTS WITH DACTYLITIS

K. Fujikawa 1, Y. Endo 1, A. Mizokami 1, M. Mine 2, A. Kawakami 2

1Rheumatology, Japan Community Healthcare Organization, Isahaya General Hospital; 2Rheumatology, Suga Orthopedic Hospital, Isahaya; 3Immunology and Rheumatology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan

Objectives: To evaluate the ultrasound findings in undifferentiated spondyloarthriti- (uSpA) patients with or without dactylitis.

Methods: Between April 2014 and December 2016, sixty-six patients with uSpA diagnosed at our center were consecutively enrolled. The diagnosis of uSpA was made by the Japan College of Rheumatology (JCR)-certified rheumatologists and dactylitis was defined as sausage-digit appearance. Ultrasound, clinical and laboratory findings at diagnosis in patients with dactylitis (dactylitis group; n=30) were compared to those without dactylitis (non-dactylitis group; n=36). Grey scale (GS) and power Doppler (PD) signals of the wrist and finger joints, PD signal of extensor and flexor tendon sheaths, and PD signals of the collateral ligament of the fingers in both hands were assessed by ultrasound. Ultrasound assessment was made by JCR-certified sonographers.

Results: There were no significant differences in clinical and laboratory findings, including inflammatory back pain, arthritis of the lower limbs, tenderness of the entheses, radiographic/MRI changes of sacroiliac joint and HLA-B27 allele frequency, between two groups. In ultrasound findings, the dactylitis group had significantly more PD signals of the flexor tendon sheaths (83% vs. 22%, p<0.0001), the collateral ligament (83% vs. 25%, p<0.0001), and the MCP joint (30% vs. 3%, p<0.01) as compared with the non-dactylitis group. In logistic

AB1036 PREDICTIVE VALUE OF BASAL REACTANTS IN AN EARLY ARTHRITIS CLINIC. DOES ESR ELEVATION CRITERIA MAKE A DIFFERENCE?

L. Mayordomo 1, M.L. Velloso 1, P. González-Moreno 2, C. Gómez-Cano 1, A. Gutierrez-Leonard 3, J.L. Marenco 1, 1Rheumatology Department, Hospital Universitario Virate; 2Rheumatology Department, HVM; 3Physiotherapy, HVR, Sevilla, Spain

Background: The presence of high acute phase reactants may help the diagnosis and classification of patients with rheumatoid arthritis, specially in seronegative patients.

Objectives: Our objective was to establish if the presence of high basal reactants in early arthritis may help to establish the diagnosis of rheumatoid arthritis following criteria of ACR 1987 (which does not include positive reactants in diagnostic criteria) at 12 months of follow-up.

Methods: The presence of acute phase reactants at the baseline visit (elevated CRP and elevated ESR according to two different criteria) was studied in a population of 70 patients referred to the arthritis clinic with criteria for suspicion of early arthritis to meet at least one of the Following criteria: a) Swelling in 2 or more joints) b) Pain in MCFs, MTFs and/or wrists c) Morning stiffness greater than 30 minutes (* SERAP study criteria), with <12 months of evolution of symptoms. None of the patients had previous diagnosis of rheumatoid arthritis or other inflammatory joint disease nor had previous treatment with steroids or DMARDs. The presence of high VSG (mm/h) was considered according to two criteria: a) ESR 1: VSG ≥20 in men and VSG ≥15 in women; b) ESR 2 (criterion according to age and sex) (1): Age ≤50 years ESR 20 in men and ESR 30 in women; Age ≥50 years of age, ESR 15 in mm/h in men and ≥20 in women. Statistics: Chi-square or Fisher test (for any value ≤5). Odds ratio (OR) calculation.

Results: 70 patients, 45 women (64%), x age 51,5/6,16,0,8 y (18–85) were included, x disease duration 3,47 meses ± 2,59 (0,53–11,73), 48/70 (68,5%) of RA, 23/70 (32,9%) were classified in non-RA group because they meet criteria of other inflammatory conditions (eg. psoriatic arthritis RA-like). 45/70 patients had high baseline CRP (64,3%), ESR 1 38/70 (54,3%) and ESR 2 35/70 (50%). Basal CRP ≥5 showed statistically significant differences for RA diagnosis (ACR 1987 criteria) p ≤0.003, OR = 4,64 (1,62–13,24) but basal positive ESR 1 criteria did not (p =0.122). Basal positive ESR2 showed significant differences for diagnosis of RA, with p =0.036, OR =2,78 (0,99–7,47). In the subgroup of seronegative patients, basal CRP could predict ACR 1987 RA diagnosis at 12 months follow-up p =0,019, OR 4,2 (1,23–14,36), but ESR (both ESR1 and ESR2) not (p =1,000). If the 5 patients ACR 1987 meeting criteria RA-like but diagnosed on other inflammatory conditions were included, the results are similar but ESR2 reached p =0,019, OR 4,2 (1,23–14,36), but ESR (both ESR1 and ESR2) not (p =1,000).

Conclusions: The presence of elevated basal CRP-≥5 may be used as a factor that helps to predict the diagnosis of rheumatoid arthritis according to ACR 1987 criteria for RA. The baseline elevated ESR according to the sex and age criterion could be useful as a predictor factor for the diagnosis of rheumatoid arthritis, while the VSG criterion ≥20 in all patients does not demonstrate differences in the study between the two groups with final diagnosis AR and non-RA. In seronegative patients, only CRP demonstrated predictive value but ESR not.

AB1037 INTEROBSERVER RELIABILITY OF KNEE OSTEOARTHRITIS LESIONS USING MUSCULOSKELETAL ULTRASOUND: DIFFERENCES BETWEEN STATIC VERSUS REAL TIME READING

M.J. Auricka 1, A.M. Bertolì 2, G.E. Py 1, 1Reumatologia, DHEG; 2Reumatologia, Instituto Strusberg, CORDOBA, Argentina

Background: Musculoskeletal ultrasound (MSU) is an imaging technique proved to be valid in several musculoskeletal conditions. In osteoarthritis (OA) it allows the identification of inflammation and structural damage. However, MSU is an operator dependent method and its widespread use has been hampered by questions related to the reliability of both, image acquisition and image interpretation.

Objectives: The objective of this study was 1) to evaluate the interobserver reliability of knee OA according to the definitions used by the OMERACT reliability exercise of inflammatory and structural abnormalities in patients with knee osteoarthritis using ultrasound and 2) to compare the interobserver reliability on previous collected images (static reading, thereafter) versus after the acquisition and interpretation of images in real time (real time reading, thereafter).

Methods: A reliability exercise based on the reading of US images was conducted by two experienced rheumatologists in MSU. A set of 59 images of both, normal and OA knee lesions were collected for the static reading. A set of 20 knees were scanned by each rheumatologist for the real time reading. Dichotomous and semi-quantitative scoring (0–3) was performed for the presence of damage on the condrosynovial margin, osteochondral margin and matrix of the trochlear cartilage, osteophytes at the lateral and medial femoral condyle and proximal tibia, medial and lateral meniscal extrusion and Baker’s cyst. Interobserver reliability was calculated by the Cohen’s kappa coefficient.

Results: Interobserver reliability scores for the static reading were good for cartilage damage, meniscal extrusion and Baker’s cyst, while they were excellent for the presence of osteophytes. The scores for the real time reading were poor to moderate for cartilage damage, osteophytes and Baker’s cyst and good for meniscal extrusion. These results are shown in Table 1.

Conclusions: This exercise shows that the interobserver reliability of MSU for the detection of knee OA lesions is widely different depending on the type of reading (static versus real time). Although MSU seems to be reliable for the detection of knee OA lesions, caution needs to be taken in the interpretation of published data regarding the type of reading exercise performed.

AB1038 INFLUENCE OF AGE ON ENTHESIS IN TUNISIAN PEOPLE: AN ULTRASOUND STUDY

K. Ben Abdelghani 1, M. Chammakhi 1, A. Fazaa 1, S. Rejib 2, S. Kassab 1, S. Chekki 1, A. Laatir 1, 1Rheumatology, Hospital Mongi Slim; 2Epidemiology, Faculty of Medicine of Tunis, Tunis, Tunisia

Background: By aging, many changes occur in the different components of the locomotor system, leading to a pathological situation such as osteoarthritis or remaining totally asymptomatic.

Objectives: The aim of the current study was to compare, via ultrasound, the entheseal changes in two groups of people having different ages by calculating a modified Madrid sonography enthesis index.

Methods: The study was conducted in the rheumatology department of Mongi Slim Hospital in Tunisia, between July 2015 and December 2016, including 17 healthy subjects. We indentified two groups: (G1) 9 persons aged ≥50 years [51–68] and (G2) 8 persons aged ≤50 years-old [37–50].

All the included persons underwent an enthesis ultrasound exploration (Esaote MyLab 60 machine and a 13–18 MHz linear array transducer) by a rheumatologist.
EXPERIMENTED IN ULTRASOUND. FIVE ENTHESIS LOCATIONS BILATERAL DISTAL ACHILLES TENDON, DISTAL AND PROXIMAL PATELLAR LIGAMENTS, DISTAL QUADRICEPS, AND BRACHIAL TRICEPS TENDONS IN EACH PERSON WERE EXPLORED. THE FOLLOWING ELEMENAL DISECTIONS OF ENTHESIS WERE EVALUATED: THICKNESS, PRESENCE OF CALCIFICATIONS, EROSIONS, ERNATHROPHYES, LOSS OF FIBRILLAR PATTERN, AND POWER Doppler SIGNAL. THE CALCULATED INTRINSIC DISTAL ATHESIS INDEX WAS CORRELATED TO THE DISTAL PATELLAR LIGAMENT改变, SIGNIFICANCE LEVEL WAS SET AT 5%. RESULTS: IN OUR STUDY POPULATION, THE MEDIAN AGE WAS 51.8±2.3 YEARS AND THE MEDIAN BODY MASS INDEX WAS 30.2±1.4 KG/M². THIS LAST WAS SIMILAR BETWEEN THE TWO GROUPS. ALL INCLUDED SUBJECTS WERE FEMALE. THE TOTAL ATHESIS INDEX WAS HIGHER IN GROUP 1 (6.76±0.91) THAN GROUP 2 (3.50±0.73) WITH A STATISTICALLY SIGNIFICANT DIFFERENCE (P<0.01). CONSIDERING EACH EVALUATED ATHESIS, THE DISTAL PATELLAR LIGAMENT ARCHITECTURE WAS HIGHER THAN THE MEDIAN (1.67±0.55 VS. 0.25±0.16 WITH P<0.03). FOR THE OTHER ENTHESIS, THERE WAS A STATISTICALLY SIGNIFICANT DIFFERENCE BETWEEN THE 2 GROUPS. CONCLUSIONS: THE DISTAL PATELLAR LIGAMENT ENTHESIS CHANGES SHOWN IN OLDER PERSONS MAY BE THE TRANSMISSION OF A SILENT-STAGE OF KNEE OSTEOARTHRITIS.

AB1039 RELATIONSHIPS BETWEEN SONOGRAPHIC AND ELECTROPHYSIOLOGICAL MEASURES IN PATIENTS WITH IDIOPATHIC CARPAL TUNNEL SYNDROME WAITING FOR SURGERY

M. Valls Roc1, E. Junyent Vilanova2, A. Grau Martin3, O. Codina Guindo4, M. Sala Gomez1, I. Rheeumatology, 7. Traumatology, 8. Internal Medicine, HOSPITAL OF FIGUERAS, Girona, Spain

Background: Sonography is a diagnostic tool with great development in diagnosing entrapment neuropathy. It’s an easy, painless, fast, non-invasive technique and can explore how the nerve’s morphology and pathologies are associated. An electroencephalogram is used to assess the intensity of nerve involvement.

Objectives: To determine the relationship between the intensity of nerve involvement by electroencephalogram and the measurement of the cross-sectional area (CSA) of the median nerve by sonography in patients with idiopathic carpal tunnel syndrome (CTS) waiting for surgery.

Methods: 56 wrists of 39 consecutive patients waiting for surgery were tested; however, 5 were excluded because were found to have anatomic variants (4 bilateral nerves, 2 median arteries) and 1 fibrolipoma. Therefore, the final sample was 51 wrists of 37 consecutive patients (11 male and 26 females), with a mean age of 49.2 years (25–85), all with electrophysiologically confirmed idiopathic CTS. Patients were classified by their electrophysiologic grade. The median nerve cross-sectional area at proximal and distal carpal tunnel was measured using high frequency ultrasound.

Results: CSA, the severity of the electrophysiologic grade and the duration of symptoms were analysed. Also, a median nerve morphological characteristics examination (hypoecogenicity, loss of fascicular structure, Power Doppler signal and anatomical variants) was undertaken. A comparison between CSA and the severity of the electrophysiologic grade was made using an independent T test and the connection between CSA and the duration of symptoms was calculated using ANCOVA test.

Patients were classified by their electrophysiologic severity grade (8 mild, 13 moderate, 29 severe and 1 very severe). The mean ultrasonic area of distal median nerve was 8.7 mm² in mild/moderate and 9.2 mm² in severe/very severe cases (P=0.52). The average of proximal CSA was 11.6 mm² in mild/moderate and 14.1 mm² in severe/very severe cases with statistical significance differences (P=0.026). Relationship between CSA and symptom’s duration wasn’t identified. In 89.2% of the cases, hypoeccogenicity and the loss of fascicular structure were observed but no cases were found to show positive Power Doppler signal.

Conclusions: The most valid and relevant parameter regarding the electromyogram in the diagnosis of CTS is CSA at proximal carpal tunnel by sonography.

AB1041 ULTRASONOGRAPHY OF NORMAL MUSCULOSKELETAL STRUCTURES IN 100 SECTIONS: A BOOKLET AND A CD-ROM

M.A. Mandi, H. Rkain, M. Erraoui, S. Aktouf, L. Tahihi, R. Bahri, F. Allali, N. Hajji-Hassouni. Rheumatology, Faculty of Medicine and Pharmacy, University Mohamed V, Rabat, Morocco

Objectives: To present a booklet and a CD-ROM with a mini-atlas including 100 sections illustrating the normal ultrasonic musculoskeletal anatomy.

Methods: We performed an ultrasound examination of large and small joints of the medical staff not suffering from any musculoskeletal disorder. Ultrasound examination was performed using a high-frequency linear probe (Toshiba Xario®, frequency (8–14 MHz)) in B mode. Finally, for the sake of clarity of the presentation of this library, we presented each image accompanied with another showing the valid positioning of the probe and an annotated schema for each section made.

Results: We present in the form of a CD-ROM and booklet a photo library of a cross-section of the flexor digitorum superficialis and profundus tendons.

AB1040 CLINICAL UTILITY OF BONE SCINTIGRAPHY FOR INFLAMMATORY ARTHRITIS

M. Jiang, K. Le Marshall, K. Lim. Department of Rheumatology, Western Health, Footscray, Australia

Background: Bone scintigraphy is often used in the workup of patients with rheumatological disease, in particular for the investigation of inflammatory arthritis. It also has a role in the investigation of malignancy and fractures. As an imaging technique, it is very sensitive but not specific for inflammation. The most common technique used is triple phase scintigraphy, with the 2nd phase (blood pool phase) being the most useful for identifying inflammation.

Objectives: To evaluate the clinical utility of bone scintigraphy in the workup of patients with rheumatological disease, in particular for inflammatory arthritis.

Methods: This was a retrospective study of patients seen in the rheumatology outpatient between January 2011 and July 2014, who had bone scintigraphy as part of their workup. Their clinical record was reviewed to obtain pre- and post-test clinical diagnoses, bone scintigraphy reports and investigations (ESR/CRP, rheumatoid factor/CCP antibodies). For patients who had followup at one year we recorded their clinical diagnosis at this time.

Results: A total of 226 patients had bone scintigraphy, with a median age of 54 years. 63% were female. The main indication for bone scintigraphy was to assess for inflammation in 194 patients. For this group, the most common pre-test diagnosis of inflammatory arthritis (41%), followed by degenerative arthritis (36%), unclear diagnosis (20%) and mixed inflammatory and degenerative arthritis (3%). Overall, 49% (n=111) of patients had their diagnosis changed after bone scintigraphy.

The pre-test diagnosis was compared to bone scintigraphy findings with the highest confirmatory rate for degenerative arthritis (67%), followed by inflammatory arthritis (49%) and mixed arthritis (40%). Bone scintigraphy findings were also compared to post test diagnosis with the highest confirmatory rate for degenerative arthritis (91%), followed by inflammatory arthritis (70%) and mixed arthritis (14%). There was no significant association between patient factors (age, gender, ESR/CRP, RF/CCP) and having confirmatory or conflicting bone scintigraphy findings.

The post test diagnosis was compared to the diagnosis at one year, with the diagnosis being unchanged in 84% for inflammatory arthritis and 45% for degenerative arthritis.

Conclusions: This study showed that bone scintigraphy lead to a change in diagnosis in a large proportion of patients and was better at confirming degenerative arthritis or ruling out inflammatory arthritis.

DOI: 10.1136/annrheumdis-2017-eular.4514
The joints studied are:

- The wrist and hand
- The elbow
- The shoulder
- The ankle and foot
- The knee
- and the hip

100 sections were performed, we presented them together with images showing their normal corresponding musculoskeletal anatomy, the valid positioning of the probe, and also an annotated schema corresponding to each section. We give here below the example of a section illustrating a cross-section of flexor digitorum superficialis and profundus tendons

Conclusions: We hope that we give to rheumatologists a simple tool to recall and standardize the practice of musculoskeletal ultrasound. We intend to enrich it, in the future, with the pathological images and interventional ultrasound videos.

**AB1044 EVALUATION OF A FLUOROENZYME IMMUNOASSAY (ELIA-CTD) IN THE SCREENING OF PATIENTS SUSPECTED FOR AUTOIMMUNE CONNECTIVE TISSUE DISEASES**

M. Elkahfa1, R. Abdullahi1, H. Ramadan1, S. Barrientos1, S. Saleh1, O. Alsaaed2, A.-W. Al-Allaf2, 1Laboratory Medicine and Pathology; 2Medicine, Harnad Medical Corporation, Doha, Qatar

**Background:** Detection of auto-antibodies directed against nuclear antigens (antinuclear antibodies or ANA) have important diagnostic and prognostic implications in connective tissue diseases (CTD). The conventional indirect immunofluorescence assay on Hep-2 cell line (ANA-IIF) is the most commonly used method to detect ANA. The ANA-IIF can be labor intensive and suffers from lack of specificity.

**Objectives:** To evaluate the utility of a new fluoroenzyme immunoassay “ELIA-CTD” as an alternative for screening patients suspected for autoimmune connective tissue diseases.

**Methods:** Sixteen Hundred (1600) consecutive patients’ sera submitted for anti-nuclear antibodies testing were used using the ANA-IIF (Diaisorin S.P.A, Saluggia, Italy) and the new ELIA-CTD assay (Phadia GmbH, Frieiburg, Germany). ANA testing was ordered by both primary and secondary care physicians. The ELIA-CTD screening assay is a fluoroenzyme immunoassay which is performed on the Phadia-250 automated platform. The ELIA-CTD assay contains ANA-targeted recombinant antigens including dsDNA, Sm-D, Rib-P, PCNA, U1-RNP (70, A, C), SS-A/Ro, SS-B/La, Centromere B, ScI-70, Fibrillarin, RNA Polymerase III, Jo-1, Mi-2, and PM-scl. The test results are expressed as ratio, with >1.0 considered positive. For ANA-IIF, the cut off for positive results was 1.40 or greater. Additionally, further testing for dsDNA and other extractable nuclear antigens (ENA) was undertaken on a subset of sera that were ANA-IIF+ or whenever there was discrepancy between the two methods.

**Results:** The overall agreement between the two methods was 84.2%. Two hundred and eighty (308) out of 1600 (19.3%) samples tested positive by ANA-IIF as compared to 101/1600 (6.6%) for the ELIA-CTD assay. Additional testing showed that 105 samples were positive for ENA including dsDNA. Of those, 101 were ELIA-CTD positive and 81 were ANA-IIF positive. By incorporating the ENA results, the calculated sensitivity and specificity for the ELIA-CTD were 97.1% and 99.7% respectively with positive and negative predictive values for the ELIA-CTD assay of 96.1% and 99.8%, respectively. The corresponding sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for the ANA-IIF assay at different dilutions is shown below:

<table>
<thead>
<tr>
<th>Titer</th>
<th>Sensitivity (%)</th>
<th>Specificity (%)</th>

</tbody>
</table>

**Conclusions:** The new automated ELIA-CTD assay shows superior sensitivity and specificity compared to the conventional labor intensive ANA-IIF. The ELIA-CTD can be used as an upfront screening tool for connective tissue diseases. Depending on the clinical details, any ELIA-CTD positive results could be reflexively followed by additional testing including ANA-IIF testing to elucidate the titer and pattern.

**AB1045 MACROPHAGE TARGETED POSITRON EMISSION TOMOGRAPHY (PET) FOR THE IMAGING OF INFLAMMATORY ARTHRITIS: AN IN VIVO AND IN VITRO INVESTIGATION OF TRANSCLECTOR PROTEIN (TSPO) TRACER UPTAKE**

N. Narayan1, H. Mandhair1, C. Coello2, A. Saleem2, A. Sabokbar1, P. Taylor1, 1Clinical Biological Sciences, University of Oxford, Oxford, 1Imanova Centre for Imaging Sciences, London, United Kingdom

**Background:** TSPO targeted PET tracers are increasingly recognised as cellular imaging markers of macrophage infiltration, due to the high expression of TSPO on activated macrophages. Previous work demonstrated the ability of [11C]PK11195 TSPO PET to detect subclinical inflammation in RA, and predict flare in both those with established RA and AGPA positive arthritis. However, high background uptake of [11C]PK11195 in bone, and inability of [11C]PK11195 to detect lesions in AS has driven the investigation of newer TSPO tracers for the detection of inflammatory arthritis.

**Objectives:** Here, we present data confirming the ability of the TSPO tracer [11C]PBR28 to detect and quantify synovitis in both RA and PsA, and in vitro work that assesses more fully what TSPO tracer accumulation in inflamed synovium actually reflects at a cellular level, especially considering TSPO is ubiquitous expressed.

**Methods:** 10 patients (5 with RA, 5 with PsA) with evidence of inflammation in one or both knees (as confirmed by clinical examination and US) and 4 healthy volunteers underwent PET/CT both knees using the TSPO tracer [11C]PBR28. Arthritis patients underwent synovial biopsy of one knee within 7 days of scan. Healthy synovium was obtained from patients undergoing knee arthroscopy for ligamentous injury. Synovial tissue was stained for CD68, CD163 and TSPO. For in vitro work, human monocytes, lymphocytes and synovial FLS from RA patients were harvested, and macrophages differentiated from monocytes. DNA was extracted for PCR. Other cells underwent density centrifugation to extract the cytoplasmic cell fraction, and a radioligand binding assay with [3H]PBR28 was undertaken, to assess tracer binding to TSPO in each cell type

**Results:** Tracer uptake correlated significantly with severity of inflammation on clinical examination and ultrasound, as did synovial sublining staining for CD68, TSPO and CD163 (see table 1). There was negligible staining for all stains in healthy control synovium. qPCR demonstrated highest TSPO mRNA in stimulated FLS (fold change 62.75±10.03) and M2 macrophages (60.69±2.38), with lymphocytes having the least TSPO expression. PBR28 saturation binding confirmed these findings at protein level (see graph 1).

**Conclusions:** Our data demonstrates that the TSPO tracer PBR28 is capable of detecting and quantifying synovitis in RA and PsA. PBR28 tracer uptake correlates with macrophage marker staining, but not with fibroblast marker staining in our patient cohort. mRNA and protein data demonstrate, however, that there is a similar expression of TSPO in activated macrophages and activated FLS, hence TSPO tracer accumulation is as likely to represent FLS activation as it is macrophage activation.

**AB1046 COULD SERUM TWEAK LEVEL BE AN INDICATOR OF SUBCLINICAL ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS?**

M. Ucer1, N. Yilmaz2, B. Cengiz Elicioglu3, T. Sahin3, P. Gun Atak3, S. Yavuz2, 1Internal Medicine, 2Rheumatology, 3Cardiology, 4Biochemistry, Istanbul Bilim University, Istanbul, Turkey

**Background:** TWEAK is a type 2 transmembrane glycoprotein of TNF family that has multiple functions such as angiogenesis, regulation of tissue production-
CAN THE ACR/EULAR 2010 CLASSIFICATION CRITERIA BE USED AS DIAGNOSTIC TOOL FOR RHEUMATOID ARTHRITIS IN REAL LIFE?

N.F.L. Conijn1, D. Lopes Barreto 1, T.M. Kuiper 2, M. van der Steen 2, J. van der Rooij 2, A.E.A. Well 1, J.M.W. Hazes 3, M.R. Koek 1, Rheumatology; 2Business intelligence; 3Planning and Control, Maasstad hospital; 4Rheumatology, Erasmus Medical Center, Rotterdam, Netherlands

Background: To date, due to the large variability in its clinical manifestations, early identification of rheumatoid arthritis (RA) relies on practice-based evidence. Moreover, this variation hampers the comparability and accurate stratification of the base population within and between RA trials. In 2010 the ACR/EULAR working group developed RA classification criteria that were primarily intended for research purposes. Despite its use in scientific settings, one can speculate on the effectiveness of these criteria when used in the routine clinical practice of diagnosing RA.

Objectives: In this study we aimed to investigate the degree of concordance between the diagnosis of RA in routine clinical practice and the ACR/EULAR 2010 classification criteria.

Methods: All patients who received a diagnosis of RA between 2010–2016 within our hospital were identified according to the financial diagnosis treatment combination (DTC) code, which corresponds to the ICD-10. Clinical and demographic data were extracted from our digital patient records of which 10% of the data were cross-checked by random selection. In retrospect we collected variables at time of RA diagnosis such as: number and type of swollen/painful joints, inflammatory markers, rheumatoid factor (RF), anti-citrullinated protein antibody (ACPA), disease duration and patients primary/secondary/tertiary diagnosis according to the rheumatologist. Additionally, all patients were classified according to the ACR/EULAR 2010 criteria for RA. The degree of concordance was determined by descriptive statistics.

Results: The dataset included 977 patients with a DTC RA of which 673 (69%) had RA according to the rheumatologist. From the patients who were clinically diagnosed with RA, 463 (69%) fulfilled the ACR/EULAR 2010 criteria (see figure 1), this is 47% of the total DTC RA patients. The majority of the population was female (72%) and the mean age was 59. A number of 161 (24%) patients were diagnosed with RA according to the rheumatologists, but did not fulfil the ACR criteria. These patients had less inflammation, were more often RF and/or ACPA negative, and had less involved joints. About 5% of the data were missing.

Conclusions: It can be concluded that the DTC codes are not the most reliable source of information about the diagnosis. There is a discrepancy between the DTC code, the diagnosis according to the rheumatologist and the classification criteria. The degree of concordance between rheumatologist and the ACR criteria is comparable to the numbers described in literature. Since in our practice aspects of the ACR classification are used for diagnostic purposes, we will investigate factors that drive the specificity. Furthermore, reasons for the ICD-10/ DTC and final diagnostic mismatch is of great importance and will be studied as well. These factors will indicate the opportunities on the use of the ACR/EULAR criteria in clinical practice.

SYNTHETASE) DIAGNOSTIC VALUE OF ANTI-JO-1 (ANTI-HISTIDYL-TRNA SYNTHETASE) AUTOANTIBODIES IN PATIENTS WITH HAND OSTEOARTHRITIS

O. Balueva 1, A. Sarapulova 2, O. Teplyakova 2 1Ultrasound Diagnosis, Medical Association “New hospital”; 2Ural State Medical University, Yekaterinburg, Russian Federation

Background: The destruction of cartilage is one of the basic mechanisms of the progression of hand osteoarthritis (HOA). Radiographic study indicates the thickness of the cartilage indirectly based on the degree of joint space narrowing (JSN). At the same time, the ultrasound (US) method allows to measure cartilage thickness precisely. Objectives: To determine the degree of concordance in the interphysician groups of patients with HOA and to correlate this rate with the degree of JSN, identified by radiologic imaging, and the sonographic changes were assessed using Killman’s method. Next, US investigation was carried out. The thickness of the cartilage was measured in the central part of the 2–5 proximal phalanx heads of both hands in the dorsal longitudinal view in the static image in grayscale with the flexion position no more than 90 degrees. The cartilage is defined as a thin hypoechogenic smooth layer, parallel to the contours of the articular surface. The thickness of the cartilage was defined as the distance between the subchondral bone and the surface layer of cartilage, which was the border between the cartilage and the joint cavity. In the presence of synovial measurement of joint cartilage was carried out before the border and hypertrophic synovial if they differed in the degree of intensity of the US signal. The measurement of cartilage thickness was carried out by a conventional line, which was an exact perpendicular to the surface of the subchondral bone and parallel to the direction of US waves. Measurement was not carried out if visualization of the surface layer of cartilage was not possible. The control group consisted of 45 women 45–75 years old without HOA, but with ultrasound investigation. Data were analyzed using Statistica 10.0 and are presented as mean (standard deviation), ‘odds ratio’ coefficient (OR) and y Pearson’s correlation coefficient. Results: 360 joints of both hands were investigated with successful measurement of the cartilage thickness of 338 (94.7%) joints. The average value of the cartilage in all PIP was 0.31 (0.11) mm. The maximum thickness of the cartilage was obtained in the 2nd PIP joints - 0.34 (0.12) mm on the right hand and 0.36 (0.14) mm on the left hand. For the control group results were 0.38 (0.11) mm and 0.37 (0.13) mm respectively. We have found a reliable relationship between the degree of JSN and cartilage thickness with the OR 1.849 (95% confidence interval 1.198 – 2.855), y = 7.772, p =0.0053. Conclusions: US reduction of the cartilage thickness is a marker of cartilage loss which is correlated with the results of radiologic examination. This makes possible to use ultrasound as an alternative method of diagnosing HOA.

CLINICAL UTILITY OF AUTOANTIBODIES AGAINST EXTRACTABLE NUCLEAR ANTIGENS IN ROUTINE CARE: FREQUENCY OF REPEATED TEST REQUESTS AND DIAGNOSTIC VALUE OF ANTI-JO-1 (ANTI-HISTIDYL-TRNA SYNTHETASE)

P. Jobanputra 1, F. Malik 2, E. Derrett-Smith 1, T. Plant 3, A. Richter 4 1Department of Rheumatology, Queen Elizabeth Hospital Birmingham, Birmingham; 2Department of Rheumatology, Epsom & St. Helier University Hospitals NHS Trust, Carshalton; 3Department of Immunology, University of Birmingham; 4Department of Immunology, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom

Background: High-throughput high-sensitivity ELISAs for autoantibodies associated with CTD, such as extractable nuclear antigens (ENA), are used widely. Anti-Jo-1 (anti-histidyl-tRNA synthetase), one of this panel, is believed to confer a poor prognosis due to an association with interstitial lung disease (ILD) and myositis.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.6512

Scientific Abstracts
Objectives: To describe: the pattern of anti-ENA positive tests; frequency of repeated requests; stability and repeatability of anti-Jo-1 tests; clinical characteristics of anti-Jo-1 +ves compared with controls; and diagnostic value of anti-Jo-1 for ILD.

Methods: All anti-ENA test requests, from any hospital department, between July 2013 and Dec 2014 were identified. Serum samples are screened forENA (Quanta Lite® ENA profile, Inova Diagnostics) and positive samples have specific ENA antibodies levels quantified. Data from anti-Jo-1 positive patients and controls was extracted from electronic records allowing a minimum of 12 months after first test.

</table>

*Fisher's exact test, two tailed. **Statistical analyses were not done on these comparisons as by definition controls were negative for ENA antibodies.

Conclusions: 4009 samples from 3581 patients were tested. The first sample tested, chronologically, was designated test of interest. 616 (17.2%) patients were anti-ENA screen +ve, and 40 (1.1%) anti-Jo-1 +ve (≥ 20 AU/mL). Anti-ENA tests were done more once than 350/3581 (9.8%) patients (428/4009 (10.7%) samples) and for 7/40 (17.5%) of anti-Jo-1 +ve patients. The median interval between 1st and 2nd requests: 124 days (IQR 233 days). The Table shows data for anti-Jo-1 patients and randomly selected ENA-ve controls. The frequency of ILD, myositis and Raynaud’s was comparable. Sensitivity and specificity of Jo-1 for anti-Jo1 patients and randomly selected ENA -ve controls. The frequency of ILD, a key feature of “anti-synthetase syndrome”, were 50% (CI 19–81%) and negative predictive value 93.8% (CI 86–98%). Of patients with the highest anti-Jo1 titres (<40 AU/mL, 10/40 patients, 25%): 3 had ILD, 1 myositis and 2 had a malignancy (disseminated melanoma and CML); Bland-Altman plots show that anti-Jo-1 values remained stable when patients were re-tested at another time but re-testing available stored samples from +ve patients showed important variation (Figure).

Conclusions: Our results show the existing discrepancy between the clinical examination and ultrasonographic test in patients in low disease activity/remission by DAS28, even more with the use of doppler. In the comparison of both groups we observed an increase in the difference in those who did not receive biological therapy. In patients with optimized biological therapy, with higher swollen joint count in physical examination, kappa index was near of normality in grayscale. The detection of subclinical joint damage is often undertreated, showing ultrasound as a noninvasive technique of great help reducing joint damage.

DOI: 10.1136/annrheumdis-2017-eular.4406
Methods: Fifteen patients with HCVrA & 15 RA patients were subjected to: full history, clinical examination. Ultrasonography assessment using a Philips HDI 5000 system with 12–5 MHz Broadband Linear Transducer. Both knees were examined by one ultrasonographer who was blind to clinical data.

Results: In HCVrA, synovial hypertrophy was detected in 10% of knees (3/30) of which 2 (10%) exhibited Doppler signals, while in RA it was detected in 70% (21/30) of which 95% (20) knees exhibited Doppler signals. Significant difference was found between the two groups (p<0.01). Knee effusion was detected in 80% (24/30), & 86% (26/30), of patients with HCVrA & RA respectively, no significant difference was found. Cartilage degeneration was detected in 76% (23/30) & 83% (25/30), of patients with HCVrA & RA respectively. Bone erosions were detected in 20% (6/30) in the RA group. It was not detected in HCVrA patients. In HCVrA, there was no correlation between the presence of synovial hypertrophy with respect to cartilage degeneration and knee effusion.

Conclusions: We found no specific ultrasonographic feature specific for HCV related knee arthritis, the knee effusion is a predominant feature and the hypertrophied synovium is not frequently found. No destructive lesions were found to be related to the disease itself; however this should be confirmed by histopathological assessment.

AB1052 QUALITATIVE SYSTEMATIC REVIEW: LACK OF CONSENSUS ON THE CLASSIFICATION CRITERIA FOR DIFFUSE IDIOPATHIC SKELETAL HYPEROSTOSIS

J.S. Kuperus 1, E.E. de Gendt 1, F.C. Oner 1, P.A. de Jong 2, S.C. Buckens 2, A.E. van der Meere 3, G.J. Maat 4, E.A. Regan 5, D. Resnick 5, R. Mader 6, A.J. Verlaan 1, J. Verlaan 1. Orthopedics, University Medical Center Utrecht, Utrecht; 2Anatomy, Academic Medical Center, Amsterdam; 3Radiology, University Medical Center Leiden, Leiden, Netherlands; 4Medical, National Jewish Health, Denver, Colorado; 5Radiology, University of California San Diego, San Diego, California, United States; 6Rheumatology, Ha’Emek Medical Center, Afula, Israel.

Background: Diffuse idiopathic skeletal hyperostosis (DISH) is a condition characterized by flowing ossifications of the spine with or without ossifications of entheses elsewhere in the body.1,2 Studies on prevalence and pathogenesis of DISH use a variety of partially overlapping combinations of classification criteria, making meaningful comparisons across the literature difficult.3,4

Objectives: The aim of this study was to systematically summarize the criteria available to classify or diagnose DISH to aid in the development of a more uniform set of diagnostic and/or classification criteria.

Methods: A search was performed in Pubmed, Embase, Cochrane Library and Web of Science using the term DISH and its synonyms. Articles were included when two independent observers agreed that the articles proposed a new set of classification criteria for DISH. All retrieved articles were evaluated for methodological quality and the presented criteria were extracted. The criteria were placed into one of three groups being “descriptive studies”, “sets of criteria for dichotomous diagnosis” or “sets of criteria with consecutive phases”.

Results: A total of 24 articles met the inclusion criteria. Two articles were descriptive studies, 11 contained dichotomous classification criteria and 11 described a set of criteria with consecutive phases. In all articles spinal hyperostosis was required for the diagnosis of DISH. Peripheral, extraspinal manifestations were excluded as a co-requirement for the diagnosis DISH in five articles. Most discrepancies revolved around the threshold for the number of vertebral bodies affected and to defining different developmental phases of DISH. More than half of the retrieved articles described a dichotomous set of criteria and did not consider a consecutive or progressive character of DISH.

Conclusions: In our systematic review we summarize the available different classification criteria for DISH and highlight the lack of consensus on the diagnosis of (early) DISH. Consensus criteria, including consecutive phases of new bone formation that characterize DISH can be developed based upon established diagnostic and classification criteria.

AB1053 A NOVEL METHOD FOR IDENTIFYING RADIOGRAPHIC ALTERATIONS IN THE SUBTALAR JOINT USING AN ANISOTROPY-BASED TEXTURE ANALYSIS ALGORITHM: DATA FROM THE OSTEOARTHRITIS INITIATIVE

R. Ljühr1, T. Haftner2, Z. Bertalan1, D. Ljühr3, A. Fahletriner-Pammer4, H.-P. Dimai5, S. Nehrer2 on behalf of Osteoarthritis. 1ImageBissy Lab, Vienna; 2Department for Health Sciences and Biomedicine, Danube University Krems, Krems; 3Brainclin Technologies, Vienna; 4Division of Endocrinology and Diabetes, Medical University Graz, Graz, Austria

Background: Osteoarthritis (OA) is the most common form of arthritis and affects disproportionately the knee. Recent developments in imaging technologies showed that OA is not just a joint disease but also involves progressive changes in the subchondral/subarticular bone area of the tibia. On top of the accepted method of measuring the joint space width, assessments of the trabecular bone structure in selected regions of interest (ROI) in conventional X-rays may be offering an alternative method for quantifying the risk and progression of this disease.

Objectives: The accepted method for assessing OA - Joint space width (JSW) and Joint Space Area (JSA) measurements - have limited capabilities in regard to early identification and reproducible follow-ups of the disease. The objective of this abstract is to evaluate the subchondral bone structure as an area for early identification of OA risk, applying texture anisotropy algorithms and subsequently comparing the results to standard JSW and JSA measurements.

Methods: This study was performed using data from the Osteoarthritis Initiative. The analysis data set was restricted to female. OA knee exams recorded with the same modality. Furthermore we selected exams which had a KL grade of 0 at the baseline exam and a deteriorating KL grade ≥2 at the 96 month follow up. 22 cases fulfilled these criteria and we selected 22 matching controls with no signs of OA at the 96 month follow up. The selected region of interest (ROI) for the analysis was the subchondral bone area of the tibia. One additional ROI in each femur condyle – in total 6 ROIs. For each individual ROI, the degree of texture anisotropy was calculated and compared between case/control. In addition, JSW & JSA were calculated in both groups using a proprietary software-based method (ImageBissy Lab, Vienna, Austria).

Results: Whereas the JSW and the JSA measurements did not yield any significant differences with respect to their mean values (Cohen’s d = 0.199 and 0.038), the calculated texture parameters showed that differences in values between cases and controls could be found in text of the subchondral ROIs (ROI1 & 2) with Cohens’d values of 0.625 and 0.831. Respectively. With selected patient criteria, the differences in anisotropy results were significant using these texture parameters.

Conclusions: Our results indicate that using the selected radiographic texture parameters, an early identification of patients at risk for developing OA using conventional X-rays can be achieved. This may offer an additional method for quantifying the risk of baseline OA. This is supported by the Cohen’s d values that are by definition relatively large (0.625 and 0.831). Ongoing research focuses on larger sample set validation and the use of such algorithms for additional applications, such as the early identification of fracture risk.

AB1054 QUANTITATIVE ULTRASOUND FOR ASSESSMENT OF DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: RELIABILITY AND CONSTRUCT VALIDITY

R.P. Goswami 1, A. Ghosh, D. Lahiri, R. Ghosh. Department of Rheumatology, IPGMEER, KOLKATA, INDIA, Institute of Post Graduate Medical Education and Research, Kolkata, India

Background: Joint ultrasound is an integral part of assessment of patients with rheumatoid arthritis (RA). Semi-quantitative grading of ultrasound is subjective whereas quantitative ultrasound (QUIS) may be more objective.

Objectives: To evaluate the reliability and construct validity of QUIS of wrist joints in patients with RA.

Methods: We studied 95 patients with RA. Following parameters were studied: swollen and tender joint counts (SJC and TJC), patient and evaluator global assessment (PGA, EGA) and disease activity score (DAS28). Patients were classified as active disease and disease in remission as per expert clinician opinion. Colour Doppler ultrasound (CDUS) of wrists was done to obtain semiquantitative grading. Scans were processed in image analysis software (Photoshop CS4) to obtain the following: color fraction of intrasynovial (IS) vascular signals (CF(IS)) = pixel area of IS vascular signals/pixel area of entire IS area (area(IS)), CF(total) (pixel area of both IS and extravasynovial vascular signals/area (IS)) and number of IS (N(IS)) and extravasynovial (N(ES)) vascular signals. Images were stored and independently rated for both CDUS and QUIS by two different raters blinded to each other’s rating.

Results: Demographics of patients were: mean age 48±16.7 years, mean disease duration 24 months (range 4–600), mean DAS28 of 2.98±1.18 and 40% (38/95)
had active disease, CDUS findings were: synovial proliferation: grade 1: 27.4%, grade 2: 54.7%, grade 3: 11.6%; vasculitis: grade 1: 41.1%, grade 2: 32.6% and grade 3: 9.5%. Significant findings of QUS were: CF(IS): 8.6±10.63 (median 6.05, p<0.001) and CF(total): 0.996 (95% confidence interval (CI): 0.994–0.997) and ICC(1,2) for CF(total) was 0.995 (95% CI: 0.993–0.997). CF(IS) was correlated with SJ(C (r=0.22, p=0.029), TJC (r=0.39, p<0.001), PGA (r=0.5, p<0.001) and DAS28 (r=0.47, p<0.001); correlations for CF(total) were: SJ(C (r=0.25, p=0.013), TJC (r=0.41, p<0.001) and PGA (r=0.51, p<0.001) and DAS28 (r=0.5, p<0.001). Significant correlations were also observed for N(SI (r=0.282, p=0.006), TJC (r=0.411, p<0.001), PGA (r=0.48, p<0.001), EGA (r=0.514, p<0.001) and DAS28 (r=0.467, p<0.001). Spearman rank correlations of vascularinity with SJ(C (r=0.25, p=0.011), TJC (r=0.292, p=0.004), PGA (r=0.26, p=0.012), PGA (r=0.186, p<0.103) and DAS28 (r=0.275, p=0.007). Spearman rank correlations of CF(IS) (CF(total) and N(SI with CDUS vascularity were 0.828, 0.864 and 0.689 respectively (p<0.001). Cut-off values for CF(IS), CF(total) and N(SI for distinguishing active RA from RA in remission were 4.78 (AUC: 0.82, 95% CI: 0.73–0.9), 5.75 (AUC: 0.89, 95% CI: 0.69–0.88) and 2.5 (AUC: 0.77, 95% CI: 0.68–0.86) respectively. There were 40 patients with CDUS vascularity ≥2 among which 62.5% (25/40) had active disease. In this group only CF(total) ≥5.75 could distinguish between patients with active disease from disease in remission (p<0.001 (2015 vs. 10/125/2015 vs. 0.046). Conclusions: CF(IS) (CF(total) had excellent inter-rater reliability and construct validity. Simple quantitative cutoffs could distinguish between active RA from remission.

**AB1055 LEUKOCYTE ESTERASE REAGENT STRIPS FOR RAPID DIAGNOSIS OF INFLAMMATORY SYNOVIAL FLUID**

S. Rodriguez-Munuguz1, S. Malumbres 2, A. Olive3, O. Valero4, S. Holgado 3, L. Mateo 3, M. Martinez-Morillo 3, 1Rheumatology, Virgen de la Cinta Hospital, Tarragona, Spain; 2Clinical Biochemistry Service, Germans Trias I Pujol Hospital, Barcelona, Belgium; 3Rheumatology, Germans Trias I Pujol Hospital; 4Department of Statistics, Autònoma de Barcelona University, Barcelona, Spain

**Background:** The analysis of synovial fluid is an important tool for diagnosing joint disease. When synovial fluid is removed, the white cell count (WCC) decreases with time, and an inflammatory liquid could become a false non-inflammatory disease. When synovial fluid is removed, the white cell count (WCC) decreases with time, and an inflammatory liquid could become a false non-inflammatory disease.

**Methods:** Our results demonstrate that leukocyte esterase reagent strips are a rapid, cheap, and sensitive tool to identify inflammatory synovial fluid. Leukocyte esterase reagent strips had an excellent Se but a poor Sp, it could be used as a screening tool in primary care practice. A positive result may indicate an inflammatory process, then the patient should be referred to a rheumatologist.

**AB1056 RADIOPHARMIC ANALYSIS OF METATARSUS PRIMUS ELEVATUS IN PATIENTS WITH RHEUMATOID FOREFOOT DEFORMITIES**

S. Mizuki, D. Hiroaka, K. Kushimoto, H. Yamasaki, K. Yoshida, K. Oyjoji, K. Kamada, E. Yokota. The Center for Rheumatology, Matsuyama Red Cross Hospital, Matsuyama, Ehime, Japan

**Background:** Metatarsus primus elevatus involves dorsal elevation of the first metatarsal relative to the lesser metatarsals. The role of metatarsus primus elevatus in rheumatoid forefoot deformity is yet to be elucidated. We hypothesise that metatarsus primus elevatus can be attributed to a different pathomechanism than typical rheumatoid forefoot deformities such as hallux valgus, flat foot, and flat foot.

**Objectives:** To clarify the radiographic characteristics of metatarsus primus elevatus in patients with rheumatoid forefoot deformities.

**Methods:** We retrospectively reviewed standing anteroposterior and lateral radiographs of 51 feet (37 patients; mean age 65.7±1.7 years) before toplasty due to metatarsalgia at our hospital. The elevation of the first metatarsal relative to the second metatarsal (MPE), the hallux valgus angle (HVA), the intermetatarsal angle (IMA), talar pitch, and calcaneal pitch were measured. For statistical analyses, the Mann-Whitney U test was used.

**Results:** The group with higher MPE was significantly more under the age (p=0.011). There was no significant difference in HVA between the two groups (p=0.068), although IMA was significantly smaller in the group with higher MPE (p=0.033). In the group with higher MPE, calcaneal pitch was greater (p=0.011) and talar pitch was smaller (p=0.016).

**Conclusions:** In patients with metatarsus primus elevatus, other rheumatoid forefoot deformities such as plantar foot and flat foot were not observed. There was a wide range of hallux valgus severity. Metatarsus primus elevatus may be attributed to greater hindfoot calcaneal pitch.

**Disclosure of Interest:** None declared

**AB1057 MULTIDISCIPLINARY APPROACH FOR DIAGNOSING CONNECTIVE TISSUE DISEASE-RELATED LUNG DISEASE: IS IT USEFUL FOR RHEUMATOLOGISTS?**

S. Peña Montelongo1, A. Monroy Calero1, O. Acosta Fernández2, S. García Hernández1, L. Pérez Martín1, A. Bonilla Arjona4, H. Sánchez Pérez1, B. Bustamante Reyes1, B. Rodríguez-Lozano1, 1Rheumatology; 2Pathology; 3Chest Section, Radiology, Hospital Universitario de Canarias, Tenerife, Spain

**Background:** Many patients with idiopathic interstitial pneumonia (IP) have certain clinical, serological and/or pulmonary morphologic features suggesting an underlying autoimmune disease (AD), but without meeting established criteria for connective tissue disease (CTD), a situation labelled as ‘IP with autoimmune features’ (IPAF)1. To identify an underlying aetiology is important because it may impact on treatment and prognosis, and could be optimised by multidisciplinary approach.

**Objectives:** 1.To identify prevalence of IPAF in routine practice. 2. To determine the value of lung biopsy to diagnose underlying AD.3. To describe the course of IPAF.

**Methods:** Observational, longitudinal retrospective study in a tertiary hospital specific outpatient clinic for IP patients with cough and dyspnea as dominant symptoms requiring co-evaluation by rheumatologists in 2010–2016. Variables included: clinical, serologic and morphological findings by High-Resolution Computed Tomography of lungs assessed by 2011 current guidelines2 and open lung biopsy. Statistical analysis:SPSS 17.0.

**Results:** Of 410 patients evaluated for IP, 93 had rheumatologist assessment, 70 (75.3%), mean age at diagnosis 52.6 years (SD12.13), of whose 48 had no previous diagnosis. Mean follow-up 3.54 (SD2.77)years in undiagnosed patients. The most frequent radiological patterns were: inconsistent with usual interstitial pneumonia (UIP) (67.7%), UIP (22.6%), Possible UIP (4.3%), others (4.3%). Lung biopsy was performed in 15 patients (16%), 11 without previous diagnosis. Histopathology patterns: 8 non-specific interstitial pneumonia (NSIP) in whom final diagnosis of pulmonary fibrosis was confirmed by open lung biopsy. Statistical analysis:SPSS 17.0.

**Results:** Of 410 patients evaluated for IP, 93 had rheumatologist assessment, 70 (75.3%), mean age at diagnosis 52.6 years (SD12.13), of whose 48 had no previous diagnosis. Mean follow-up 3.54 (SD2.77)years in undiagnosed patients. The most frequent radiological patterns were: inconsistent with usual interstitial pneumonia (UIP) (67.7%), UIP (22.6%), Possible UIP (4.3%), others (4.3%). Lung biopsy was performed in 15 patients (16%), 11 without previous diagnosis. Histopathology patterns: 8 non-specific interstitial pneumonia (NSIP) in whom final diagnosis of pulmonary fibrosis was confirmed by open lung biopsy. Statistical analysis:SPSS 17.0.

**Conclusion:** The prevalence of IPAF was 21.1% (19.6%), with IPAF as clinical diagnosis in 24.7% of overall patients. 2. Surgical lung biopsy allowed to diagnose AD in 23% of unlabelled patients with clinical features diagnostic of IPAF. There was no significant difference in HVA between the two groups (p=0.068), although IMA was significantly smaller in the group with higher MPE (p=0.033). In the group with higher MPE, calcaneal pitch was greater (p=0.011) and talar pitch was smaller (p=0.016)

**Conclusions:** 1. Of patients with IP referred for rheumatologist assessment, 31% has no established CTD, with IPAF as clinical diagnosis in 24.7% of overall patients. 2. Surgical lung biopsy allowed to diagnose AD in 23% of unlabelled patients with clinical features diagnostic of IPAF.
patients. After a follow-up time of 3.5 years, 43% of patients that died had been diagnosed as a IAPF.

AB1058 SENSITIVE DETECTION OF DYNAMIC CHANGES OF BONE EROSIONS IN INFLAMMATORY ARTHRITIS BY MUSCULOSKELETAL ULTRASOUND: A COMPARATIVE ANALYSIS WITH HIGH-RESOLUTION PERIPHERAL QUANTITATIVE COMPUTED TOMOGRAPHY

S. Finzel 1,2, G. Schett 2, S. Kraus 3, R. Völlli 1, M. Backhaus 4, R. Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg; 2Department of Internal Medicine III, Rheumatology and Immunology, University Clinic of Erlangen, Erlangen, Germany; 3Department of Internal Medicine, Kontonsspalten Baden, Baden, Switzerland; 4Department of Internal Medicine, Rheumatology and Clinical Immunology, Park-Klinik Weissensee, Academic Hospital of Charité, Berlin, Germany

Background: Bone erosion is a hallmark of inflammatory joint diseases. Its meticulous detection is highly important for correct diagnosis and monitoring of therapy response. Earlier studies showed that musculoskeletal ultrasound (MSUS) has a higher sensitivity than conventional radiography with regards to detection of bone erosions (1) making MSUS more and more popular. The OMERACT ultrasound working group is currently standardizing and validating MSUS as an imaging outcome tool.

Objectives: To investigate the ability of MSUS to sensitively and specifically detect bone erosions in a longitudinal setting using HR-pQCT as a gold standard.

Methods: This is a sequel study to our 2011 cross-sectional comparative analysis on MSUS and HR-pQCT (2). 4/6 healthy individuals, 6/40 psoriatic arthritis patients at study entry, 4/6 patients with erosive RA and 1/6 patients with erosive spondyloarthritis were enrolled. They were assessed for prevalence and severity in MSUS and converted to HR-pQCT. Afterwards, half of the patients were followed up and received an MSUS and an HR-pQCT scan of the clinically dominant hand. Bone erosions at the radial, palmar, and dorsal sites of the second metacarpophalangeal (MCP) joint, as well as the palmar and dorsal sites of the third and fourth MCP joints were assessed for prevalence and severity in MSUS and by HR-pQCT. Afterwards, data were compared to the 2011-dataset. MSUS was graded as described earlier (2).

Results: Datasets without follow-up from the baseline cohort were eliminated. Sensitivity of MSUS in comparison to HR-pQCT regarding correct detection of erosions was 95% and specificity were 79%. For this analysis, grade 1 lesions were included. At follow-up sensitivity was 86% and specificity 79%. At follow-up, 36 MSUS-lesions were no longer detectable in MSUS; 21/36 were false-positive lesions at baseline. Only one false-positive lesion was detected at both time points. One new lesion was detected by MSUS and confirmed by HR-pQCT. Overall severity of bone erosions regressed in MSUS; these findings were confirmed by HR-pQCT (p<0.05).

Conclusions: This is the first study on change of bone erosions over time comparing MSUS and HR-pQCT. MSUS was confirmed being a sensitive imaging tool able to detect changes of erosions over time. Thus, it may be an adept tool to monitor treatment response in inflammatory joint diseases. Correct identification of bone erosions and differentiation from physiological vessel channels requires knowledge of predilection sites of erosions and physiological cortical breaks; this might aid to further increase the diagnostic value of MSUS.

AB1060 MEASURING AGREEMENT IN THE ULTRASONOGRAPHIC EVALUATION OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS. A LATIN-AMERICAN MULTICENTER EXPERIENCE ASSESSING THE INFLUENCE OF SONOGRAPHER EXPERIENCE AND EXPERTISE

T. Cazenave 1, 2, V.M. Martina 2, C. Waimann 2, C. Rosmefiet 1, Instituto de rehabilitación psicoafasica, Buenos Aires; 2 Hospital italiano de la Plata, la Plata; 3 Hospital Dr. Hector Cura, Olavarría, Argentina

Background: Ultrasonography (US) is an important tool in rheumatology practice but it depends on sonographer’s experience.

Objectives: To evaluate the reliability of US assessment among observers across Latin American using a web tool.

Methods: Cross-sectional study. Fifty-one Latin American ultrasonographers took part in a web-based US exercise evaluating images from 20 RA patients. The 4 joints US score was calculated for each patient including bilateral radiocarpal, midcarpal and second metacarpophalangeal joints. PD and GS were graded from 0 to 3, the highest disease activity. Five patients were evaluated twice in order to address intra – rater reliability. The inter and intra-rater reliability was assessed using a two-way random, absolute, individual and average-measures intra-class correlation coefficient (ICC). We stratified sonographers according to experience (defining High experience as: at least 5 years of experience and 80 US assessments/month).

Results: A total of 1020 US image assessments were performed. Mean 4-joints US score was 17.8. The ICC was in the excellent range for intra [individual ICC = 0.945 (CI95% 0.905-0.965); average ICC =0.972 (CI95% 0.950–0.982)] and
inter-reader reliability (individual ICC = 0.867 [95% CI 0.786–0.934]; average ICC = 0.997 [95% CI 0.995–0.999]).

When comparing high with low experience sonographers, there was no significant difference in intra-class correlation coefficient. However, there was a greater variation between the means among low experience readers (13 to 22) and higher experience sonographers (14–18) (Figure 1).

Conclusions: US is reliable to sonographer expertise and experience.

AB1061 THE HIGH DOSES GOLIMUMAB BRING BETTER SUPPRESSION OF ULTRASONOGRAPHIC SYNOVIAL INFLAMMATION IN PATIENTS WITH RHEUMATOID ARTHRITIS?

T. Okang1, K. Imu1, Y. Sugikoa2, K. Mamot1, T. Koike2,3, H. Nakamura1.

1Department of Orthopedic surgery; 2Center for Senile Degenerative Disorders (CSD), Osaka City University Graduate School of Medicine, Osaka; 3Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Wakayama, Japan

Background: Biologic diseases modifying antirheumatic drugs (bDMARDs) that target cytokines and cytokine receptors such as tumor necrosis factor (TNF)-alpha and interleukin (IL)6 have been established as a standard therapy of rheumatoid arthritis (RA) for patients with conventional systemic DMARDs, such as methotrexate (MTX), resistant disease. Golimumab, one of the bDMARDs, is an antibody targeting to TNF-alpha. In Japan, we can choose the dose of golimumab 50mg or 100mg according to the disease activity. Recent advance of ultrasound (US) equipment allows obtaining high-quality gray-scale (GS) imaging and sensitive or 100mg according to the disease activity. In Japan, we can choose the dose of golimumab 50mg or 100mg according to the disease activity. Recent advance of ultrasound (US) equipment allows obtaining high-quality gray-scale (GS) imaging and sensitive

Methods: Patients with RA treated by golimumab were consecutively included. Ultrasound examination was performed at 52 synovial sites, bilateral first to fifth MTP joints, by using a semi-quantitative scale from 0 to 3.

Objectives: The aim of this study was to compare the ultrasound findings between patients with rheumatoid arthritis (RA) treated by golimumab 100mg and 50mg.

Results: Fifty-five patients with RA (46 female, mean age: 64.2±12.1 years) were included and analyzed. In comparison between the dose of Golimumab at the time of ultrasound examination, disease activity (DAS28-CRP) was significantly higher in 100mg group (100mg, n=15: 3.6±1.0, 50mg, n=40: 2.3±0.9; p < 0.001), disease duration (years) 17.5±9.6 14.2±9.5 0.263, Total GSUS score 16.9±12.6 14.8±12.7 0.572

Conclusions: Even patients have high disease activity, golimumab 100mg suppress the synovitis and tenosynovitis very well. In the condition where disease activity was sufficiently controlled, there was very low level of ultrasound findings of ultrasound at the dose of golimumab.

AB1062 PATTERNS OF MUSCULOSKELETAL SYSTEM INVOLVEMENT IN PATIENTS WITH TYPE I AND TYPE II DIABETES MELLITUS

T.I. Adroso, M.I. Hanany, H.S. Hamoud, A.A. Negm. Rheumatology Department, Faculty of Medicine, Al-Azhar Univerist, Cairo, Egypt

Background: Diabetes mellitus (DM) is a chronic disease, no known cure except in very specific situations. Musculoskeletal Ultrasoundasonography (MSUS) has a great sensitivity that can help clinical examination for the detection of peripheral enthesis related to DM

Objectives: To study the different patterns of musculoskeletal (MSK) system affection in both types of diabetes mellitus (DM).

Methods: We performed a retrospective single-center study on sixty five patients during the period from May 2014 to February 2015, to evaluate MSK manifestations in diabetic patients at Sayyed Galal University Hospital, Cairo, Egypt. Patients were defined as diabetic on the basis of Diagnosis and Classification of Diabetes Mellitus diagnostic criteria (1997) (1). Clinical data, laboratory investigations, X-ray, musculoskeletal ultrasoundasonography (MSUS) (2) and Bone mineral density was measured using Dual energy X-ray absorptiometry (DEXA) scan (3) were all collected from all patients.

Results: We included 65 diabetic patients; of these 21 patients (32.31%) had type I diabetes while 44 patients (67.69%) had type II diabetes. Age in type I was 25±10.5 years while in type II was 50±18.44 years (P<0.001). DM type II showed higher BMI (P<0.001), fatigue (P<0.005), shoulder periarthritis (P<0.005), ankle periarthritis (P<0.005), large joint arthrosis (P<0.005), anserine bursitis (P<0.001) and planatar fascitis (P<0.003) than type I. Osteoporosis was found in both types but type II showed more prevalence 13/44 patients (29.5%) while type I showed only 3/21 (14.2%). No statistically significant difference between both groups as regard t-score in the three sites. MSUS showed increased prevalence of quadricaps tendon enthesopathy in type I (P<0.033), while Infrapatellar (P<0.023) and retrocalcaneal bursitis (P=0.001) were more prevalent in type II DM.

Conclusions: Early evaluation of any diabetic patient regarding BMD by DEXA scan and soft tissue by MSUS seems to be beneficial for early detection of any abnormality and therefore early management and prevention of complications.

AB1063 ULTRASOUND ASSESSMENT OF SYNOVITIS IN PATIENTS WITH LESSER TOE DEFORMITY DUE TO RHEUMATOID ARTHRITIS

T. Kashigawa1, Y. Kimura2, I. Wakabayashi3, M. Fuji2, M. Kobayashi4, M. Urayama5, T. Aiza wa6, Y. Sugimura7, H. Aonuma7, N. Miyakoshi8, Y. Shimada9, 10. Department of Orthopaedic Surgery, Akita City Hospital; 2Department of Orthopedic Surgery; 3Department of Rehabilitation Medicine, Akita City Hospital, Akita; 4Department of Orthopedic Surgery, Akita General Hospital, Yoko to; 5Department of Orthopedic Surgery, Ogaschi General Hospital, Huzawa; 6Department of Orthopedic Surgery, Kita Akita Municipal Hospital, Kita Akita; 7Department of Orthopedic Surgery, Nakadori general hospital, Akita; 8Kakunodate general hospital, Senboku; 9Akita University Graduate school of Medicine, Akita, Japan; 10Department of Orthopedic Surgery, Akita University Graduate school of Medicine, Akita, Japan

Background: In recent years, joint ultrasonography has been widely used for the diagnosis and treatment of rheumatoid arthritis (RA), allowing visualization of synovitis. Its clinical usefulness in early diagnosis and evaluation of disease activity has been reported. Continuous inflammation, osteochondral destruction, and soft tissue destruction due to synovitis in toe joints result in various clinical pictures of the foot. In the lateral toes in the forefoot, subluxation or luxation of the metatarsophalangeal (MTP) joints may occur, leading to painful calllosities and resultant disturbance in activities of daily living. Few reports have addressed toe deformity and joint ultrasonographic findings of synovitis in the forefoot.

Objectives: In this study, lateral MTP joints were assessed using joint ultrasonography in RA patients to examine the correlation with deformity.

Methods: Seventy feet of 61 RA patients were examined in the outpatient clinic of our hospital. Patients who underwent surgery were excluded. The mean age of the patients was 66 years (24 to 92 years), and the mean duration of disease was 12 years and 9 months (1 month to 40 years). Biologic products were used for 23 feet. Joint ultrasonography was performed by the same examiner, using the same room and apparatus. Synovitis was defined as Grade 1 or more as determined by Doppler manoeuvre on foot radiographs. In right position obtained before and after ultrasonography, patients with luxation, subluxation, and joint fissure narrowing were classified into the deformity group, those with bone erosion and geode formation into the bone erosion group, and lack of abnormal findings into the normal group.

Carpal tunnel syndrome (CTS) is the only known early clinical manifestation of wild-type transthyretin amyloidosis (ATTRwt), formerly known as senile systemic amyloidosis, which causes an amyloid cardiomyopathy. At the UK National Amyloidosis Centre 98% of those with proven ATTRwt have evidence of median nerve entrapment on neurophysiological studies and 48% have a history of carpal tunnel decompression as much as 12 years prior to heart failure symptoms. ATTRwt is diagnosed in approximately 150 individuals in the UK each year although post-mortem studies suggest presence of ATTRwt amyloid deposits 30% of males over 80 years (yrs)1. A novel bone tracer, Technetium-3,3-diphosphono-1,2-propanodicarboxylic acid (99mTc-DPD) largely abrogates the grade uptake.

Carpal tunnel biopsy can readily identify ATTR amyloid deposition and may identify those at risk of developing cardiac ATTR amyloidosis in the future, permitting earlier intervention with novel therapeutics aimed at preventing accumulation of amyloid. This ongoing study aims to identify the UK prevalence of ATTR amyloid in those with carpal tunnel syndrome and to create a cohort of those who may develop systemic ATTR amyloidosis to further elucidate the disease natural history.

AB1065 NEEDLE VERSUS FORCEPS TECHNIQUE IN ULTRASOUND-GUIDED SYNOVIAL BIOPSY OF THE KNEE JOINT

T. Högg 1, P. Urbaniak1, M. Müller-Gerbitz2, C. Marx3, G. Tamborrini3.
1Department of Rheumatology, University Hospital Basel; 2Institute of Anatomy, University Basel; 3Ultrasound Center Rheumatology, Basel, Switzerland

Background:
Ultrasound-guided synovial biopsy is increasingly applied in rheumatology. Usually forceps- or needle-based techniques are used. So far there has been no direct comparison of different devices regarding their suitability in high resolution musculoskeletal ultrasound (hrMSUS)-guided synovial biopsy.
Objectives: To compare different forceps and needle-based instruments in hrMSUS-guided synovial biopsy in a cadaver study.

Methods: A core needle biopsy (A, Quickcore, Cook Medical, Bloomington, IN, USA), a retrograde forceps (B, Retroforce, Karl-Storz GmbH Tuttingen, Germany), an antegrade arthroscopy forceps (C, Karl Storz GmbH, Tuttingen, Germany) and an antegrade shelled and integrated core needle system (D, Synovex, Hipp Medical AG, Kolbingen, Germany) were tested for ultrasound-guided synovial biopsy of the suprapatellar recess in cadaver knee joints. Four senior rheumatologists scored each intervention from 0–5 regarding the following characteristics: visualization, handiness, accuracy, synovial tissue yield, invasiveness and overall suitability. Each intervention was recorded as static images and video clips.

Results: In all devices, enough representative synovial tissue was obtained and the instruments were all well visualized by hrMSUS. Core needle biopsy and the integrated needle system were best visualized due to their horizontally shaped closing mechanism. The core needle obtained a high yield of superficial synovial tissue and was the least invasive procedure. Despite handiness and accuracy were higher in the forceps instruments, overall suitability for hrMSUS-guided synovial biopsy was rated highest for the core needle biopsy.

Conclusions: Technically, all of the tested devices can be used for hrMSUS-guided synovial biopsy. Core needle biopsy seems to be most suitable for this intervention due to a low invasiveness, good visualization and optimal yield of superficial synovial tissue.

**AB1066 DIAGNOSTIC UTILITY OF THE MEDIAN/ULNAR NERVE CROSS-SECTIONAL AREA RATIO IN CARPAL TUNNEL SYNDROME**

T. Atan 1, Z. Güneş 2, 3, 4
1Physical Medicine and Rehabilitation, Hittit University, Corum Training and Research Hospital, Corum; 2Physical Medicine and Rehabilitation, Gazi University Faculty of Medicine, Ankara, Turkey

Background: The most commonly used ultrasonographic measurements for the diagnosis of CTS are measurement of the median nerve cross-sectional area (m-CSA) at different levels of the carpal tunnel. The cross-sectional area of a nerve may differ according to biometric characteristics such as age, sex, weight and wrist thickness. 3,4

Objectives: The aim of this study was to assess the diagnostic utility of the ultrasonographic ratio of m-CSA to ulnar nerve cross-sectional area (u-CSA), the m-CSA/u-CSA ratio, in carpal tunnel syndrome (CTS).

Methods: Patients (n=50) with positive symptoms and electromyography results of CTS and control subjects (n=50) with negative electromyography results of CTS were evaluated. The most symptomatic hand of each participant were included in the assessment. Ultrasonographic m-CSA and u-CSA measurements were made at the level of the pisiform bone, and m-CSA/u-CSA ratio was calculated.

Results: Using the m-CSA cut-off value of 9.95 mm² showed a sensitivity of 92% and a specificity of 42%. Conversely, the cut-off value 13.90 mm² showed a sensitivity of 52% and a specificity of 90% in the diagnosis of CTS.

Conclusions: The ratio of m-CSA/u-CSA at the level of the pisiform bone did not provide an additional benefit for the diagnosis of CTS. Ultrasonographic m-CSA measured at the same level was found to be more sensitive and specific method.

**AB1067 SUITABILITY OF CADAVER MODELS IN ULTRASOUND DIAGNOSTICS AND INTERVENTIONS IN RHEUMATOLOGY: FOOT AND ANKLE**

V. Halášová 1, Á. Nemeskéri 1, D. Bong 2, P. Mandl 3, I. Möller 2, E. Naredo 4, P.V. Bämler 5 on behalf of EUALL Anatomy for the Image Study Group.

Background: Employment of cadaver specimens in ultrasonography provides a unique and safe model for education and enhances the anatomical knowledge of sonographers and may help determine the accuracy of ultrasound-guided interventions.

Objectives: In this systemic literature review we assessed the role and use of cadaver specimens in sonographic studies of the foot and ankle in the field of rheumatology.

Methods: For our literature review we utilized the MEDLINE database, which were supplemented by searches in Google Scholar and Science Direct when the articles were not available through PubMed. Original studies in English language were included in the full paper review with an exception of three German language studies with English abstracts were also included. In the full paper review studies were selected for each feature that used the cadaver specimens of the foot and ankle. Data were extracted on study characteristics and interventions.

Results: The search yielded 1241 articles, of which 130 were selected for detailed review. In the end, 23 full papers met inclusion criteria. The studies could be grouped as follows: description of detailed ultrasound anatomy (9), testing of accuracy of ultrasonic guided interventional procedures (8), examination of artificial tears and lesions (4), foreign bodies (1) and joint effusions (1). The results that were obtained in the studies of the fully reviewed papers utilized a total of 294 cadaveric specimens, with an average of 12.78 (range: 1–48) cadaveric specimens included in each study.

Conclusions: The use of cadaver specimens of the foot and ankle may facilitate the validation of new sonographic methods which assess these joint regions, however the major disadvantage of these studies was the low number of cadaveric specimens.

Disclosure of Interest: None declared.

**AB1068 ULTRASOUND DIAGNOSTICS AND INTERVENTIONS IN RHEUMATOLOGY: WHICH SEMI-QUANTITATIVE SCORING SYSTEM IS THE BEST?**

V.C. Jongveewang 1, V. Bojća 2, V. Vlado 3, D. Mazilu 4, I. Saulescu 2, L. Groseanu 2, D. Criş 5, A. Balănescu 2, C. Constantinescu 2, D. Predeteanu 2, R. Ionescu 2, 1Rheumatology, Carol Davila University of Medicine and Pharmacy; 2Rheumatology, Saint Mary Clinical Hospital, UMF Carol Davila; 3Rheumatology, Saint Mary Clinical Hospital, UMF Carol Davila, Bucharest, Romania

Background: Sjogren Syndrome (SS) affects mainly exocrine glands. The latest diagnostic criteria designed for clinical studies are also used as guidance in clinical practice [1].

Objectives: To apply and compare 9 US semi-quantitative scoring systems in B mode scanning of salivary glands in Sjogren Syndrome.

Methods: A research using keywords “salivary glands”, “ultrasonography”, “Sjogren Syndrome”, “semi-quantitative scoring” 2,3,4,5 in Medline/Pubmed was performed. There was a selection of most relevant articles. There were not considered relevant publications with impact factor <1. We performed the examination on SG in B mode US and applied these scores (De Vita, Niemela, Hoevar, Salaffi, Yukinori, Cornecl,Theander) to our patients (primary and secondary SS).

Results: Eighty four SG in patients diagnosed with primary and secondary (57.15%) SS were assessed. In the group of patients with SSA/SSB presence (57.15%), mean score was De Vita 1.78±1.21, Niemela 2.56±2.17, Hoevar and Wernicke 2.39±2.14, Salaffi 2.83±2.52, Yukinori 2.39±2.14, Milic 3.39±2.14, Cornecl 1.78±2.15, Theander 1.28±0.75, Schirmer test was critical and the need for using the artificial tears was correlated to SS alterations in scoring systems proposed by Niemela (r=0.465, p<0.05) and Salaffi (r=0.469, p<0.02). All scoring systems were strongly correlated between them (r=0.8, p<0.01).

Conclusions: Inhomogeneity of parenchyma was considered in all scoring systems. Others considered relevant glandular dimension and margins regularly [2.3,4]. There was no difference in relation to the scoring systems. Xerostomia validated through Schirmer test is correlated to SG parenchymal alterations. Our data is an update about semi-quantitative scoring systems in US of SG in SS.

SHOULDER ULTRASONOGRAPHY IN DIABETIC PATIENTS – IS THERE DAMAGE WITH NO CLINICAL SIGN?

V.C. Iorgoveanu, V. Bojincă, R. Maltchić, M. Gheorghe, C. Ionescu, R. Ionescu

Rheumatology, Carol Davila University of Medicine and Pharmacy; Rheumatology, Saint Mary Clinical Hospital, UMF Carol Davila, Bucharest, Romania

Background: Degenerative lesions in shoulder rises exponentially with age and diabetes was found to be associated with shoulder pain [1,2].

Objectives: To evaluate the prevalence and type of lesions shoulder in diabetic patients with no pain using ultrasound (US).

Methods: We included consecutive patients with diabetes with no pain or clinical tumeefaction in shoulder. US was performed in both shoulders using the standard scanning planes and dynamic maneuvers. Clinical data as fasting glyceremia, BMI, treatment were recorded.

Results: Forty two shoulders were examined in 21 consecutive patients (mean age 67.92 +/-7.35 years, weight 81.75 +/- 13.57 kg, BMI 25 +/-2 kg/m2, fasting glyceremia 151.85 +/-37.22mg/dl) with diabetes mean 5.33 years +/- 5.99. Majority of patients were under treatment with oral antidiabetics (58.3%). Degenerative lesions were found in subcapular (SSC) 33.3% and supraspinatus (SPS) 8.3% tendons as well as intratendinous micro ruptures with calcifications (33.3% bilateral calcifications in SSC, SPS). Impingement syndrome was objectified in 16.6% of examinations. Minimal inflammatory signs as: sub-acromion sub deltoid bursitis in 50% (minimum in 33.3%, 8.3% bilateral) and long head biceps tenosynovitis in 58.3% (8.3% minimal Doppler signal). 63.3% showed humeral irregularities and also erosions were found (8.3%).

Conclusions: Degenerative and minimal inflammatory lesions in shoulder of diabetic patients exist with no clinical sign (pain, tumeefaction). Ultrasonography might be an useful technique to confirm these alterations before the appearance of symptoms.

UNRELLAVING AUTOIMMUNE DISEASES THROUGH NAILFOLD CAPILLAROSCOPY

V.R. Bernardino, A.C. Rodrigues, A.C. Liadò, M.A. Fernandes, M. Vicente, A.C. Grilo, A. Panaré, M.F. Moraes-Fontes

Unidade de Doenças Auto-Imunes/Medicina 7.2, Hospital de Curry Cabral, Centro Hospitalar de Lisboa Central; NEDAI/SPMI – Núcleo de Estudos de Doenças Autoimunes, Sociedade Portuguesa de Medicina Interna, Lisboa; Serviço de Medicina Interna, Hospital Beatriz Angelo, Loures, Portugal

Background: Nailfold capillaroscopy is a non-invasive diagnostic technique designed to evaluate small vessels of the microcirculation. The most important indication for capillaroscopy is Raynaud’s phenomenon. The complexity and meticulous evaluation of the eight fingers is difficult to apply in daily practice given the limited availability of time to perform. For this reason it is necessary to develop simple and abbreviated techniques, to achieve an optimal and rapid evaluation of the patient.

Objectives: Determine the performance of the method of the 4 th finger for the diagnosis of SD pattern in patients with Raynaud’s Phenomenon taking the eight finger pattern as a gold standard.

Methods: Cross-sectional study with blinded and independent measurements. Nailfold Capillaroscopy was performed on the four fingers of each hand, except thumbs. Another observer evaluated the 4 th finger of the hands. The interobserver agreement was made before carrying out the study and was 100%. The 8-finger method (gold standard) was considered positive when at least one finger had SD pattern and the 4-finger method was considered positive when at least one of them presents the SD pattern. We included patients older than 18 years with a diagnosis of Raynaud Phenomenon. Patients with thickening of the skin in the nailfold, digital lesion that made it difficult to assess (trauma, amputation, burns, etc.) and patients who did not consent to the procedure were excluded.

Results: We included 78 patients, 78% was female. The mean age was 53 years (DS +/- 13.5). Sixty-three patients had a score of eight fingers positive (cases) and 15 had a score of eight fingers negative (controls). The sensitivity of the 4 th finger evaluation method was 89% (95% CI: 82–96%) and 93% specificity (95% CI: 89–97%). The positive predictive value of this method was 98% (95% CI: 95–100%) and the negative predictive value was 67% (95% CI: 56–77%). The positive likelihood ratio was 13 (95% CI: 2–89).

Conclusions: The simplified method of the 4 th finger showed good performance for the diagnosis of SD pattern compared to the standard method of evaluation of the 8 fingers.

SIMPPLIFIED ASSESSMENT IN NAILFOLD CAPILLAROSCOPY IN RHEUMATOLOGY

Background: Nailfold Capillaroscopy is a non-invasive diagnostic technique designed to evaluate small vessels of the microcirculation. The most important indication for capillaroscopy is Raynaud’s phenomenon. The complexity and meticulous evaluation of the eight fingers is difficult to apply in daily practice given the limited availability of time to perform. For this reason it is necessary to develop simple and abbreviated techniques, to achieve an optimal and rapid evaluation of the patient.

Objectives: Characterize the utility of NC assessment for diagnosis of AID and to evaluate main differences in NC pattern, according to the presence of RP.

Results: We included n=641 patients with no prior diagnosis of AID, most frequently Systemic Lupus Erythematosus (SLE) (21%, n=123), Sjögren’s Syndrome (SS) (10%, n=62), Mixed Connective Tissue Disease (MCTD) (9%, n=52) and Antiphospholipid Syndrome (APS) (8%, n=48). NC patterns allowed for the classification of RP+ subjects into primary (3%) and secondary (81%); in 4% of subjects NC findings were abnormal but inconclusive. From secondary RP, most patients (77%) and non-scleroderma pattern (62%) were further separated; the former was later classified according to scleroderma-like (15,02%), early (33%), active (38%) and late (15%) scleroderma patterns.29% of RP+ patients did not have AID diagnosed; NC disclosed the diagnosis of SSc (n=24), APS (n=5), SS (n=4), SLE (n=2), MCTD (n=1), overlapping syndrome (n=1) and dermatomyositis syndrome (n=1).

Conclusions: NC findings in RP+ were more pathological than in RP-subjects, probably due to pre-existing AID and more frequent positivity. Secondary non scleroderma pattern was more prevalent in RP+ patients. In RP- group, almost a quarter of NC assessments were normal, but capillary abnormalities were also revealed, suggesting this diagnostic approach can help to disclose microvascular disease, even if RP is absent. NC further disclosed important leads to diagnose SSc, APS and MCTD in our population.

THE DEVELOPMENT OF ULTRASOUND SEMIOTICS OF DEFEATS OF THE JOINTS IN RHEUMATOID ARTHRITIS

V. Sirotk 1, U. Sirotk 2, A. Litvyakov 1. 1Department of Internal Diseases No. 1; 2Department of Traumatology and Orthopedics, Vitebsk State Medical University, VITEBSK, Belarus

Background: Differential diagnosis of rheumatoid arthritis today is challenging in cases of atypical clinical and laboratory picture arthritis [1]. Often the use of standard x-ray is not informative for the first two years of the disease. Erosive joint damage detected by the standard x-ray only after 2 years from the onset of the disease and only 36% of cases (M. Bukhan et al., 2001), while the degree of articular destruction progresses with time and is correlated with a decrease in joint function.

Methods: We studied 113 patients with RA and 30 with no articular pathology – arthritis using ultrasonic method of investigation of the joints.

Results: The diagnosis of RA was established according to modified ACR criteria of 1987. The activity of the inflammatory process of the I degree was 19 (27,5%) patients, II – 36 (52,2%), III in 14 (20,3%).

Conclusions: The activity of the inflammatory process of the I degree is 19 (27,5%) patients, II – 36 (52,2%), III in 14 (20,3%).

AB1074
THE TYPES OFEROSE LESIONS OF JOINTS IN RHEUMATOID ARTHRITIS

V. Sirotk 1, U. Sirotk 2, A. Litvyakov 1. 1Dept. of Internal Diseases No. 1, Vitebsk State Medical University, VITEBSK; 2Dept. of Traumatology, Orthopedics and Military Field Surgery, Vitebsk State Medical University, Vitebsk, Belarus

Background: Early diagnosis of erosive lesions in rheumatoid arthritis (RA) remains today an important task, especially in the absence of specific laboratory markers. Promising research aimed at studying the informative instrumental diagnostic methods (ultrasound, Rg, MRI) to identify the characteristics of erosive joint damage in patients with RA and control.

Objectives: To study diagnostic possibilities of instrumental methods to identify the species of erosive joint damage in patients with RA.

Methods: We examined 104 patients with RA. Among patients of the 1st group were women 81 (77.9%), men - 23 (22.1%), average age was 58±12.1 years. Diagnosis of rheumatoid arthritis was exhibited with the EULAR diagnostic criteria [2] and the ACR [3]. All patients were Rg-graphy, ultrasound and MRI of the hands. Statistical processing of the information package.

Results: Erosive lesion of joints at RA is presented by the proliferation-caused pannus with vascularization and inflammatory-destructive erosion (true erosion inflammation) outside the pannus (image 1). In the study the true erosion of the articular surface of the bone ultrasound method identified at 87.9% of the joints in RA, significantly higher (p<0,0001) than 24.3% of the joints in the Rg-study. So erosion from the focal invasive growth of pannus, associated erosion, erosion, acute and chronic inflammation of the articular surface (erosion of the pannus) in combination with the development of the focal pannus with vascularization and inflammatory-destructive erosion (true erosion inflammation) outside the pannus (image 1). In the study the true erosion of the articular surface of the bone ultrasound method identified at 87.9% of the joints in RA, significantly higher (p<0,0001) than 24.3% of the joints in the Rg-study. So erosion from the focal invasive growth of pannus, associated erosion, erosion, acute and chronic inflammation of the articular surface (erosion of the pannus) in combination with the development of the focal pannus with vascularization and inflammatory-destructive erosion (true erosion inflammation) outside the pannus (image 1). In the study the true erosion of the articular surface of the bone ultrasound method identified at 87.9% of the joints in RA, significantly higher (p<0,0001) than 24.3% of the joints in the Rg-study. So erosion from the focal invasive growth of pannus, associated erosion, erosion, acute and chronic inflammation of the articular surface (erosion of the pannus) in combination with the development of the focal pannus with vascularization and inflammatory-destructive erosion (true erosion inflammation) outside the pannus (image 1). In the study the true erosion of the articular surface of the bone ultrasound method identified at 87.9% of the joints in RA, significantly higher (p<0,0001) than 24.3% of the joints in the Rg-study. So erosion from the focal invasive growth of pannus, associated erosion, erosion, acute and chronic inflammation of the articular surface (erosion of the pannus) in combination with the development of the focal pannus with vascularization and inflammatory-destructive erosion (true erosion inflammation) outside the pannus (image 1). In the study the true erosion of the articular surface of the bone ultrasound method identified at 87.9% of the joints in RA, significantly higher (p<0,0001) than 24.3% of the joints in the Rg-study. So erosion from the focal invasive growth of pannus, associated erosion, erosion, acute and chronic inflammation of the articular surface (erosion of the pannus) in combination with the development of the focal pannus with vascularization and inflammatory-destructive erosion (true erosion inflammation) outside the pannus (image 1).

Conclusions: When comparing the results of a comprehensive study of joints in patients with RA despite the fact that Rg and MRI allow us to visualize and measure bone structure and pathology, ultrasound is only allowed to identify two types of erosive lesions of the joints: true erosion inflammation and erosion of the pannus.

D-DIMER AS AN EARLY MARKER IN PATIENTS WITH LUPUS MESENTERIC VASCULITIS

X. Ma, X. Feng, H. Wang, B. Hua, L. Sun. Rheumatology, Drum Tower Hospital, Nanjing University School of Medicine, Nanjing, China

Background: Gastrointestinal manifestations are common in systemic lupus erythematosus (SLE) patients. Lupus mesenteric vasculitis (LMV) is a major cause of acute abdominal pain in SLE patients. No early serum marker contributes to the diagnosis of lupus mesenteric vasculitis.

Objectives: The aim of this study was to investigate clinical significance of serum D-dimer level as an early diagnosis marker of LMV patients.

Methods: The 57 systemic lupus erythematosus patients were retrospectively analyzed and classified into LMV group (n=19) and Non-LMV group (n=38) between May 2010 and January 2016. The serum D-dimer level was measured on the first day after SLE patients presented acute abdomen as well as imaging, other laboratory-testing parameters, and SLEDAI during the same period. The maximum and mean D-dimer values were analyzed and compared with other potential markers for diagnosis of LMV. The correlation of D-dimer level with other potential severity markers and inflammation parameters were also studied.

Results: Both maximum and mean D-dimer level on the first day of presentation of acute abdomen were significantly higher in LMV patients. The D-dimer level was correlated well with L-lactate and SLEDIAI. In addition, D-dimer level was detected poor correlation with white blood cell count and C-reactive protein level.

Conclusions: D-dimer level could be an effective and early serum diagnosis marker of LMV.

**AB1075** PHYSICIAN POSTGRADUATE EXPERIENCE HAS A PREDICTIVE ROLE FOR PHYSICIAN EFFICIENCY INDEX REGARDING PATIENTS WITH RHEUMATOID ARTHRITIS: A COHORT, EXPLORATORY STUDY

A. Emamifar 1, S.M. Mousavi 1, I.M. Jensen Hansen 1,2, 1Rheumatology, Svendborg Hospital, Odense University Hospital, Svendborg; 2DANBIO, Copenhagen, Denmark

Background: Much effort has been made to improve the efficiency of health care system by delivering cost-effective, high-quality care. Nurse staffing’s contribution to daily practice plays a significant role to reach this goal.[1]

Objectives: To elucidate the differences between ratios of nurse/physician consultation as well as physician efficiency index (PEI) of senior rheumatologists and junior physicians in rheumatology residency training regarding patients with Rheumatoid Arthritis (RA). In addition, to delineate the correlation of physician postgraduate experience and PEI.

Methods: The mean intervals between standard consultation by a physician or nurse for all senior rheumatologists and junior physicians as well as nurse/physician visits ratio and PEI (= nurse/physician visits ratio * mean interval), regarding RA patients seen during Nov 2013–2015, were calculated. Multiple linear regression analysis was performed to delineate the relationship between physician postgraduate experience and PEI. To monitor treatment outcome, Disease Activity Score in 28 joints-C-reactive Protein (DAS28-CRP) and Health Assessment Questionnaire (HAQ) were consecutively measured three times: first at physician consultation, second at following nurse consultation and third either at a nurse or physician consultation.

Results: 3699 visits, belonged to 672 RA patients (64.1% female, the mean of age 64.9±14.1 and DAS28 at baseline 4.5±1.2), were included. There was a significant difference between the nurse/physician visits ratios of senior rheumatologists and junior physicians (P=0.01). Additionally, the mean PEI of senior rheumatologists was significantly higher than of junior physicians (P=0.04) (Table 1). A positive correlation was found between physician postgraduate experience and PEI adjusted for DAS28 at baseline and number of patients for each physician (Regression coefficient (95% Confidence Interval): 5.427 (1.068–9.878), P=0.022). DAS28 and HAQ score were significantly decreased if physician visits were followed by nurse visits (P=0.004 for DAS28 and P=0.025 for HAQ) (Fig.1), indicating a good treatment outcome at nurse consultations.

Conclusions: Junior physicians should be supervised to delegate responsibilities to nurse staffing. So, entire department operates more efficient, leading to prevent extra expenses (due to the differences in yearly salary of physicians and nurses). Quality of care should be monitored continuously by markers of disease activity and CRP.

**AB1076** LOW BACK PAIN IN TURKISH BUS DRIVERS: PILOT STUDY

Z.B. Karakoc 1, Z. Sanı 1, F. Koroglu 2, M. Aamir Rashedi Bonab 3, S. Karakas 4, B. Kaspary 1, 1Physiotherapy and Rehabilitation, Marmara University Health Science Institute, Istanbul; 2Physiotherapy and Rehabilitation, Yalova University, Yalova; 3Physiotherapy and Rehabilitation, Gazitepe Medical Park Hospital; 4Physiotherapy and Rehabilitation, Goztepe Training and Research Hospital, Istanbul, Turkey

Background: Low back pain is a common problem which increases financial burden of government (1). The incidence of back pain that can be seen in every part of society is also high in drivers (2). We haven’t seen any investigation about low back pain of Turkish drivers in literature. We thought that it should be researched because of changeable ethnic differences.

Objectives: The aim of our study was to determine the rate of low back pain and its relationship between quality of life in drivers.

Methods: Intercity and municipality drivers of Istanbul and Yalova, participated in our study. They were selected according to being at least 18 years of age, working at least 8 hours per day, being a driver for at least three years. Those with congenital deformities, having an accident history and doing an additional job were excluded from this study. After getting drivers’ demographic data, “Oswestry Low Back Disability Questionnaire” for low back pain and “Nottingham Health Profile” for health quality of life were surveyed to face. Chi-square and Spearman’s correlation-parametric test in the SPSS statistics program were used for statistical analysis in this study.

Results: All of the 261 people who participated in this study were male. Their mean of age, weekly working hours and working year were 43±9.28, 50±13.09 and 18±1.04, respectively. %50 of participants had low back pain and those of 43% reported that job satisfaction was affected due to pain. It was determined that 10% of participants, whose job satisfaction was affected, didn’t apply the medical doctor. While there was a significant relationship between low back pain and quality of life (p=0.000); there was no relationship between these two parameters and age and working year (p>0.05). It was determined that applying to medical doctor (p=0.02) and drug use rate (p=0.015) increased if the painful period lasted longer.

Conclusions: Low back pain affects quality of life related to health status. In this study, it was seen that the incidence of low back pain was high in long-distance drivers and affected job satisfaction in a great way. We think that the rates of drug use and medication usage can be reduced by increasing leisure time activity before increasing the severity of back pain and lengthening painful period. In addition, half of this occupation group is influenced by low back pain and once again it has been shown that waist schools should be expanded in our country.

DOES PRECONSULT ELECTRONIC EXCHANGE AFFECT POSTCONSULT DIAGNOSIS?

G. Miller1, B. Chou1, N. Patel2, G. Karpouzas 1.

Background: Harbor UCLA is an urban safety-net hospital in Los Angeles for underserved patients. In 2014, LA County Department of Health Services adopted an electronic consultation (E-consult) referral and dialogue system to improve access to subspecialists in the ambulatory care setting. The E-Consult system provides a platform for primary care providers to ask questions or engage in dialogue with specialists, request consultation, and track submitted requests. Back and forth messaging prior to acceptance for face-to-face consultation is termed a “preconsult exchange”.

Prior studies of E-Consult systems have suggested benefits which include a reduction in wait times compared to paper referrals1 and a perceived improvement in patient care2. We sought to further clarify the effect of a preconsult exchange versus immediate booking on a patient’s diagnosis and wait time in an effort to provide some guidance on whether E-Consult should be used as a screening tool to reduce unnecessary visits or as a communication method to clarify details before a face-to-face visit.

Objectives: To determine whether preconsult exchange:
1. Influences the odds of arriving at a different diagnosis after face-to-face consultation compared to the requesting provider’s original diagnosis.
2. Influences the odds of arriving at a diagnosis of a different autoimmune condition versus a non-autoimmune condition (fibromyalgia, primary osteoarthritis, chronic pain, or other non-rheumatologic condition)
3. Results in a significant delay in face-to-face evaluation

Methods: We performed a retrospective chart review of all 238 new patient referrals between 11/2014 and 5/2016 to the Harbor UCLA Rheumatology clinic generated through the E-Consult system, reviewed by BC or GM, deemed appropriate, and seen for face-to-face evaluation. These patients were grouped by exposure (Preconsult exchange or not), Odds of change in diagnosis and confidence interval were calculated using 2x2 contingency tables and Chi-Square tests. A student’s T test was used to compare mean number of days between E-Consult initiation and face-to-face appointment.

Conclusions: There was a trend towards a change in diagnosis overall among patients for whom there was a preconsult exchange, but a statistically significant increase in odds for change to non-immunologic diagnoses. This suggests that preconsult exchange highlights those patients for whom there is a higher likelihood of a non-immunologic diagnosis.

However, preconsult exchange was associated with a significant time cost - an additional 26 day delay for a face-to-face visit (due to the time needed for both submitter and reviewer to complete their dialogue) in comparison to an immediately booked patient.

FOLLOW UP OF PATIENTS WITH RHEUMATIC DISEASES BY MEANS OF A SMARTPHONE APPLICATION: SATISFACTION INDEX BASED ON A SURVEY AMONG USERS AND CARE PROVIDERS

C.A. Guillen-Astete1, J.L. Alba-Barton2, 1 Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain; 2 Informatics, Surveys and Sta, Lima, Peru

Background: Therapeutic adherence is the main variable in order to assess success or failure of any treatment. It is matter of interest to any clinician to get information enough about treatment response along time to reach a better understanding of any factor that conditions adherence failure or treatment interruptions. However, this kind of information is quite difficult to obtain in real scenarios due to lack of time or memory issues.

Objectives: The aim of present study is to assess the opinion of users of a smartphone application developed to improve the follow up of patients with different rheumatic diseases.

Methods: We conducted a survey to the users of REUMapp, an electronic form based on Google Form® software. REUMapp is an electronic interactive form developed for four different clinical scenarios: REUMapp-Esp (spondyloarthritides), REUMapp-Cristal (gout and other microcrystalline arthropathies), REUMapp-AR (Rheumatoid arthritis) and REUMapp-MSK (soft tissues). All forms were developed over the basis of paper forms previously used for the same purposes and to be checked on follow up consultation. Forms were designed to gather information about daily treatment adherence (binomial), daily modifications (categorical), adverse effects (categorical) and therapeutic response in terms of visual analogical scale. REUMapp-Esp and REUMapp-AR include also specific joint recounts and indexes. All the forms could be completed in less than 3 minutes by the patient or his/her care provider. Every form contents became part of a database easily accessible during the follow up visit in a summarized way. Between 2014–2016, 419 apps were installed in patients or care provider’s smartphones from two non public rheumatology clinics of Madrid with fully consentent of them. A survey was send to every user at the third to twelfth month after installation who have had one follow up consultation at least and who previously used the paper forms. Survey was developed using a multiple answer scheme using visual 7-level horizontal Likert scales. Topics of the survey were as follows: simplicity, time consumption and usefulness. Surveyed patients also were asked for the usefulness of the paper-based form.

Results: 205 Patients or care providers answered the survey. From them, 36 patients had diagnosed by rheumatoid arthritis, 23 by spondyloarthritides, 68 by gout or other microcrystalline arthritis and the rest by any other soft tissue rheumatisms. Following table shows the results of the survey. In the non parametric analysis of usefulness, the app was considered more useful than the paper format with a wilcoxon coefficient of contrast for paired data of : -6.658 (p = 0.001).

Conclusions: The smartphone applications described in this study have a good acceptance among patients of care providers in terms of usefulness, time consumption and simplicity and they are considered more useful than the printed models.

IMPACT OF PRE-SCREENING ON RHEUMATOLOGY OUTPATIENT CLINIC PRACTICE

C. Orr, O. McElaney, M. McCullain, M. Hussein, S. Donnelly, G. McCarthy, C. McCarthy. Rheumatology, Mater Misericordiae University Hospital, Dublin, Ireland

Background: Chronic rheumatological diseases are predominantly managed in an outpatient setting, and these out patient clinics constitute a significant workload for rheumatology clinicians. When unnecessary outpatient visits occur, service provision to those most in need of rheumatology review, both new referrals and those with established diagnoses in need of urgent review, is compromised. There is an evidence base for such screening in secondary care centres from other internal medicine disciplines (1).

Objectives: To determine the impact of introducing pre-clinic screening, and exploring the potential for follow up using telephone, by a physician extender (PE), on attendances at a rheumatology outpatient department.

Methods: A retrospective analysis of all patients attending a rheumatology outpatient clinic was performed over a 4-week period, 15/08/2016- 09/09/2016. Patients were categorized into new or follow-up attendees and the follow-up patients were further subcategorized into 1 of 4 groups:
A) Attending to receive results of investigations requiring no further treatment;
B) Attending with a chronic rheumatological disease requiring no active change in management;
C) Attending to receive results of investigations requiring further treatment;
D) Attending with a chronic rheumatological disease requiring active change in management.

Patients in categories A and B, may be safely managed by a phone call from a physician, or PE. Those in C and D would need to be reviewed in clinic, following triage by phone using a PE.

Results: 232 subjects were included (5 category A, 118 category B, 4 category C, 105 category D). 123 (53.0%) could be managed by phone utilizing a PE, thus obviating the need for review in clinic. The remaining patients could be triaged by telephone by a PE, and the schedule for review adjusted to prioritise those most in need of review. It is likely that such a strategy for reviewing patients would be more resource efficient, have a greater impact on patient well-being, and be cost-saving.

Conclusions: Routine pre-screening for patients attending rheumatology clinics should be considered to improve effectiveness of the commodity rheumatology expertise.

RESULTS IN THE FOLLOW-UP OF THE NURSING INTEGRATING CASE FINDING AND INITIAL MANAGEMENT FOR IMPACT OF ANKYLOSING SPONDYLITIS VERSUS C. Alcañiz Escandell1, K. Arévalo Ruales 1, I. Chalmeta Verdejo1, C.M. Feced practice nurse (PN)-led LTC review consultations.

To test the feasibility and acceptability of integrating case-finding and outcomes of other long-term conditions (LTCs).

Background: Trials Unit, Keele University, Keele, United Kingdom

CONCLUSIONS: The NCIT has performed the follow-up of more than 500 patients for it provides patient monitoring before treatment administration and prior to rheumatologist consultation.

Disclosure of Interest: None declared

AB1082 RESULTS IN THE FOLLOW-UP OF THE NURSING CONSULTATION FOR THE MONITORING OF RHEUMATOLOGIC PATIENTS TREATED WITH INTRAVERSAL THERAPIES C. Nájera Herranz 1, I. Cánovas Olmos 1, J. Ivorra Cortés 1, E. Grau García 1, C. Alcántara Escarcha 1, K. Arevalo Ruales 1, I. Chalmeta Verdejo 1, C. M. Feced Olmos 1, J.J. Frago Gil 1, R. González Mazarío 1, L. Gonzalez Puig 1, E. Labrador Sánchez 1, I. Martínez Cordellat 1, R. Negueroles Albuixech 1, J.E. Oller Rodríguez 1, F.M. Ortiz-Sanjuán 1, E. Vicens Bernabeu 1, D. Hervás Marín 1, J.A. Román Ivorra 1, Rheumatology Department, HUP la Fe, Biostatistics Unit, IIS La Fe, Valencia, Spain

Background: In the management of rheumatologic patients treated with intravenous therapies, its regular monitoring is recommended in order to ensure its safety. The Nursing Consultation for monitoring rheumatologic patients treated with Intraversal Therapies (NCIT) represents a major support to patient caring for it provides patient monitoring before treatment administration and prior to rheumatologist consultation.

Objectives: To analyze number and types of incidents detected in the NCIT.

Methods: A cross-sectional longitudinal, observational study of data from patients followed-up in the NCIT (which was initiated in 2012) was performed. We have collected data of gender, diagnosis, drug administered, incidents detected previously to the drug administration, and if the incident was detected by telephone (one day before drug administration) or by personal interview. Biostatistical analysis with R (3.3.2.) was performed.

Results: We analyzed 7809 drug infusions corresponding to 545 patients (73% women). 48.25% of patients were diagnosed with osteoporosis (OP), 30.1% rheumatoid arthritis (RA), 5.7% ankylosing spondylitis (AS), 4.2% systemic lupus erythematosus (SLE), 2.9% psoriatic arthritis (PsA) and 8.3% had other diagnosis. The intravenous therapies were antieporeptic drug (7.6%) and biological and immunosuppressive treatment, being the most common drugs tocilizumab (38.89%), infliximab (31.9%) and abatacept (18.05%). In the 7809 treatment infusions, 477 incidents (4.1%) were registered, 33 of them related to the antieporeptic therapies and the other 444 incidents (93%) occurred in the biological therapies. The 63.7% of the incidents were detected by telephone one day before drug infusion. Statistical analysis showed that SLE patients exhibit higher tendency to incidents (4.8% of incidents in the 392 treatments for SLE patients; P=0.026) than other autoimmune diseases. On the other hand, RA and AS patients have incidents detected mainly by telephone (P=0.047 and P=0.029 respectively). We also observed a high number of incidents in the intravenous administration of TCZ (P=0.009).

Conclusions: The NCIT has performed the follow-up of more than 500 patients with only 6% of incidents, contributing to an improvement in the patients' health and in its caring. Moreover, the fact of identifying the incidents helps to reduce the number of personal consultations, avoids drug preparation in those cases where this suspension is induced, and in summary it improves management of hospital resources.

AB1081 INTEGRATING CASE FINDING AND INITIAL MANAGEMENT FOR OSTEARTHROPATHY, ANXIETY AND DEPRESSION INTO ROUTINE PRIMARY CARE NURSE-LED LONG-TERM CONDITION REVIEWS: RESULTS FROM THE ENHANCE PILOT TRAI C. Jinks 1, E. Nichols 1, J. Liddle 1, E.L. Healey 1, A.L. Evans 1, C.A. Chew-Graham 1, K.S. Dziedzic 1, V.A. Tan 1, A.G. Finney 1, M. Porcheret 1, S. Lawton 1, V. Cooper 1, M. Lewis 1, C.D. Mallen 1 on behalf of ENHANCE team, 1Research Institute for Primary Care & Health Sciences; 2Keele Clinical Trials Unit, Keele University, Keele, United Kingdom

Background: Co-morbide osteoarthrosis (OA), anxiety and depression are undermanaged in primary care yet have significant impact on pain, disability and outcomes of other long-term conditions (LTCs).

Objectives: To test the feasibility and acceptability of integrating case-finding and initial management for OA, anxiety and depression within extended primary care practice nurse (PN)-led LTC review consultations.

Methods: A stepped wedge pilot trial with process evaluation. PNs gave a study pack to patients age >45 years attending routine LTC reviews (asthma, COPD, hypertension, ischaemic heart disease, diabetes). The intervention included case finding questions (Generalized Anxiety Disorder (GAD2), Whooley 2-item depression, diagnosing OA clinically (hands, hips, knees or feet)) followed by further assessments (anxiety (GAD), depression (PHQ9), joint examination). PNs completed an electronic patient record and initiated management. Pre-determined success criteria were to recruit 4 practices; deliver training to 2 PNs per practice, recruit 50% of those invited, ensure 75% follow up (6 week, 6 month), and the satisfaction (GPAQ) of intervention patients to be at least as acceptable as that of control patients. 24 audio recorded consultations provided insight into fidelity of intervention delivery.

Results: Four practices were recruited. PNs were sequentially trained in practice prior to switching to intervention. Of the 474 people invited, 319 responded (207 control, 112 intervention) (67% response). 83% and 79% of patients returned week 6 and 6 month questionnaires respectively. Demographic characteristics, general health, pain intensity, anxiety and depression scores were similar across arms. Overall, self-reported health (EQ5DSL) was high (median 0.84; IQR 0.72, 0.94). 14% of participants reported moderate to severe depression (PHQ9). Median GPAQ scores were similar (control 1.00 (IQR: 1.00, 1.29), intervention 1.00 (IQR: 1.00, 1.14)). 96% of those in the intervention arm reported being asked about joint pain, 93% reported being asked about mood. Audio recordings revealed that case finding questions were used as intended in most consultations (joint pain 20/24 consultations, anxiety 15/24, depression 6/24). One referral to physiotherapy and none to primary care mental health services were recorded by the PNs.

Conclusions: Recruitment and follow up were good. However, to target those who may benefit from the intervention, changes to the target population and eligibility criteria are required. There was reasonable delivery of the case finding questions, but limited referral and signposting, highlighting areas to optimise ahead of a main trial.

AB1082 IMPACT OF ANKYLOSING SPONDYLITIS VERSUS NON-RADIOMIC SPONDYLOARTHRITIS ON EARLY RETIREMENT C. Cobilinschi, R. Ionescu, D. Opris-Belinski, Stanta Maria Clinical Hospital, Bucharest, Romania

Background: Axial spondyloarthritis include non-radiographic Spa (nrSpa) and ankylosing spondylitis (AS), suggesting the extent of sacroiliac involvement on imaging techniques (1). The influence of the two conditions on patients' physical condition and their impact on work capacity should be regularly assessed so that we can better establish integral and effective therapy. In fact, as an SpA (2), early intervention and optimal management may contribute to patient’s quality of life and working capacity.

Objectives: The present study aims to assess the differences between AS and nrSpa patients under anti-TNF therapy regarding disease related retirement (DR) and its contributing factors.

Methods: Over a period of eleven months 136 patients diagnosed with AS or nrSpa on current biological therapy were included. Demographic data and working status were assessed. Statistical analysis was performed with SPSS 20.0.

Results: In the study cohort 69% of patients were males. The predominant age group was situated between 30 to 40 years old (29.8%), while 20.2% were over 50. Of the study group, 66% confirm they are active in their work field with a minimum of seven hours per day, whereas 4.3% reached their retirement age. 29.8% of patients were granted a disability retirement and the majority (42.9%) belonged to the 40–50 age group. Surprisingly, 6.8% of early retired patients were under 30. Out of the DR category, 92.9% were diagnosed with AS, while the rest of 7.1% had nrSpa. The interval from diagnosis to the initiation of biological therapy was 72±85.1 months for AS patients and 64±71.2 for nrSpa. 23.2% of patients applied for early retirement before biological therapy and only 3.1% resumed work after anti-TNF introduction. Patient gender did not influence the working capacity. At the time of study inclusion, 12% of patients with AS and 4% of patients with nrSpa still exhibited signs of highly active disease, according to ASAS/CRP assessment.

Conclusions: Almost a third of patients in the study group were offered early retirement due to axial SpA. The vast majority of disease related retirement patients were known with AS, thus emphasizing the extent of disability brought on by this entity. However, a significant percentage of patients suffered from nrSpa, raising doubts as to whether clinicians can promptly diagnose this entity and offer early, appropriate treatment so that inability no longer occurs.

WORK IMPAIRMENT IN PATIENTS EXPERIENCING MUSCULOSKELETAL PAIN

N.M. Higgins 1, A. Cochrane 1, C.J. Rothwell 1, O. FitzGerald 2, P. Gallagher 2, J. Ashton 3, R. Breen 4, A. Brennan 5, O. Corcoran 6, D. Desmond 1.

School of Nursing and Human Sciences, Dublin City University; 4. Physiotherapy Services, Beaumont Hospital; 5. Royal College of Physicians in Ireland; 6. Physiotherapy Services, AMNCH, Dublin.

Background: Many individuals with musculoskeletal disorders (MSD) continue to have pain and limitation despite adequate treatment. Little is known about those who remain occupationally active relative to those who are on sick leave, despite the clear potential for reduced productivity or work ability, and associated downstream effects.

Objectives: To assess self-reported work impairment and its associations with psychosocial risk factors amongst workers seeking care for musculoskeletal pain.

Methods: Recruitment took place in five Irish hospitals. Self-report questionnaires were used to assess risk of progressing to long-term sick leave and work disability (Órebro Musculoskeletal Pain Screening Questionnaire; ÖMPSQ), work ability, work impairment (WPA) and work performance (WRFQ).

Results: 155 patients (53.5% females; mean age 46.50 years; range 20 to 71) completed the questionnaire. 25.2% (n=39) were at high risk of progressing to long-term sick leave and work disability according to the ÖMPSQ. 62.6% (n=97) were classified as functioning poorly according to the WRFQ; 52.3% reported having poor work ability (n=81). Higher work role functioning was associated with higher pain self-efficacy (β = -0.385). Presenteeism was associated with higher pain self-efficacy (OR =0.650) and higher return to work expectancy (OR =1.179). Presenteeism was associated with higher pain intensity (β =0.295) and lower pain self-efficacy (β = -0.385).

Conclusions: MSDs affect many individuals ability to work effectively. While all participants have managed to stay at work despite increased levels of work ability and functioning, approximately a quarter are at high risk of progressing to long-term sickness absence. Interventions that attempt to improve mutable factors, such as pain self-efficacy, may help reduce the likelihood of work disability.

AB1084 CONTRIBUTION OF CLINICAL TRIALS TO THE EFFICIENCY OF ARTHRITIS RHEUMATOID MANAGEMENT

Rheumatology Department, HUP la Fe, Valencia, Spain.

Background: Treatment and management of Rheumatoid Arthritis (RA) results in a high cost to the Health system such as the Spanish Health System. During the last 5 years a total of 31 clinical trials (CT) the sponsor is the one that pays for the direct healthcare costs of the patients, which leads to savings to the National Health System (NHS).

Objectives: To estimate the economic impact of conducting clinical trials (CT) for the NHS terms of avoided costs.

Methods: A retrospective observational study was conducted using information from the clinical trials performed at the Clinical Research Rheumatology Department in the HUP la Fe from 2011 to 2015. Also a Cost-analysis was performed according Health System perspective. We calculated the length of stay in the CT for each patient included in the RA diagnosis. Afterwards, we also calculated the total number of weeks of treatment for the total number of patients. In order to evaluate the economic impact in terms of avoided costs, economic evaluation included direct healthcare costs (rheumatologist visits, nurse care, laboratory tests and pharmaceutical treatment), and it was compared to the cost of the best alternative treatment in the market.

Results: A total of 35 CT were analyzed in this period, 14 of them focused on RA. Two observational studies and one CT (premature closure by the sponsor) were discarded. Therefore, 11 were considered in this study and a total of 76 patients with RA were analysed which add together 2609 weeks of treatment.

Distribution of biological drugs: 49 (49%) adalimumab, 20 (20%) ustekinumab, 18 (18%) etanercept, 6 (6%) golimumab, 3 (3%) tocilizumab, 2 (2%) secukinumab, 1 (1%) certolizumab. The treatment was self-administered in 61 patients. Only 30 (30%) patients had undergone previous biological treatment. At present, 43 patients had some additional treatment, 36 with methotrexate and 5 with lefunomide.

SAFETY ASSESSMENT OF THE BIOLOGIC TREATMENTS TO MANAGE RHEUMATOID ARTHRITIS

1. Rheumatology; 2. Internal Medicine, Uludag University, Bursa, Turkey.

Background: Today, the immunosuppressive treatment agents became important for the therapy of rheumatoid diseases. Theoretically, the use of these agents may result in complications in patients that infected with Hepatitis B (HBV) and Hepatitis C (HCV) virus.

Objectives: To aimed the studies the reactions during treatment and prevalence of HBV and HCV infections in rheumatology patients who are using immunosuppressive treatment.

Methods: The records of a total of 1146 patients who were taking an immunosuppressive treatment for a rheumatoid disease were reviewed retrospectively. The hepatitis serology, type of immunosuppressive treatment, the duration of treatment, liver function tests, complete blood count, HBV – DNA and HCV – DNA and antiviral agents and time of use (if patient is infected) were recorded.

Results: There were 682 (59.5%) women and 464 (40.5%) men, the mean age was 45.0±13.13. Arkylosing spondylitis (AS) was diagnosed in 453, rheumatoid arthritis (RA) in 365, psoriatic arthritis in 151, systemic lupus erythematosus in 13, vasculitis in 39, Behcet disease in 28, sarcoidosis in 9, juvenile rheumatoid arthritis in 7, SJogren Syndrome in 7, Still Disease in 3, familial mediterranean fever in 6, retroperitoneal fibrosis in 1 and mixed connective tissue disease in 1 patient. The rate of HbsAg positivity was 1.8% in AS and 2.2% in RA; the rate of HCV positivity was 0.7% and 1.9% respectively.

Discourse of Interest: None declared.

POVERTY, POOR NEIGHBORHOODS, AND SLE OUTCOMES: THE PATIENT’S PERSPECTIVE

E. Yelin, J. Yazdany, L. Trupin. University of California, San Francisco, San Francisco, United States

Background: Studies have shown that persons in poverty experience worse outcomes of SLE and that the effect of poverty on outcomes is exacerbated for those living in neighborhoods with a high proportion of households in poverty. We report the results of a project to explore the viewpoint of SLE patients on how income and neighborhood affect disease outcomes.

Objectives: To explore the perspective of SLE patients with SLE on the effect of income, neighborhood, and stress on outcomes: 1) How does presence or absence of money affect care for SLE and in dealing with disease? 2) What role, positive or negative, does neighborhood play in SLE care and outcomes? 3) What are specific stresses that make dealing with SLE difficult?

Methods: We recruited SLE patients for qualitative interviews from a national longitudinal study of SLE conducted between 2003 and 2015. Subjects were selected to highlight the effects of income (those in the highest and lowest income quintiles), neighborhoods (living in neighborhoods with a high proportion of households in poverty), and geographic diversity (four regions of the U.S.: urban, suburban, and rural residents), and range of SLE outcomes. An ethnographically informed conducted hour-long semi-structured interviews were recorded, transcribed, and analyzed using grounded theory methods.

Results: 28 qualitative interviews were completed; 11 from the highest income group and 17 from the lowest (11 from poor neighborhoods). 3 were men, 20 members of racial/ethnic minorities, and mean age was 49, range 22–70. Among the poor, none cited lack of money as limiting their access to care, but all stated that it necessitated choosing which pressing needs to focus on, with food and housing a higher priority than dealing with their SLE. Among the more affluent, financial resources were used to provide help in daily chores or to withdraw from work to reduce stress, and allow for more time to manage their disease. Among the poor, none cited a positive benefit of neighborhood in finding health care resources or in mitigating how they dealt with disease but all stated that they did not need it since starting the biologic.

USE OF NATURAL LANGUAGE PROCESSING TO ENHANCE RETRIEVAL OF RHEUMATOID ARTHRITIS DISEASE ACTIVITY OUTCOMES MEASURES IN US VETERANS

G.W. Cannon 1, S. Mehrotra 2, B.C. Sauer 2. 1Rheumatology; 2Salt Lake City Va Medical Center, Salt Lake City, United States

Background: Rheumatoid arthritis (RA) disease activity measures in the Veterans Affairs RA (VARA) registry are extracted automatically through natural language processing (NLP). While this system is very effective at extracting data when templated notes are properly used, it lacked an error detection and feedback mechanism. Accuracy of the registry is essential for credible epidemiological research and patient care. We report a new automated approach with an active error monitoring and reporting system to alert providers of missing or potentially erroneous elements that can be easily corrected using standardized addendums available in the electronic medical record. The automated NLP system was revised to identify, extract, and integrate these updates to support the calculation of DAS28 and other composite outcome measures for the VARA database.

Objectives: 1. To describe the systems to identify needed corrections of VARA data.
2. To outline the procedures that allow providers to easily use addendums to enter corrections into the medical record to be automatically captured and loaded into the VARA database.

Methods: Procedures were developed and tested at a single pilot VARA site using data available in the Corporate Data Warehouse (CDW) from 01/01/2016 to 12/31/2016. A Java program was designed to retrieve Rheumatology notes, and correspond to an “local” addendum. These addendums were then processed to extract defined elements of RA disease activity listed in the table below. After each scheduled NLP run the system generates a log file that provides a summary, and patient-level report of completed and missing data elements. Providers receive the report and are asked to review the clinical notes of patients with missing elements and follow simple procedures that correct or add missing data elements when template violations occur. Addendums are used to flag and request for review when the items are not available in the notes. Updating the VARA database from addendums occurs during the next NLP run.
Results: During the pilot testing phase the automated system processed 516 notes and identified 489/516 (94.8%) as successful loads, and 27/516 (5.2%) were flagged as problematic since one or more data elements were missing. Misapplication of the template occurred in 21/27 (77.8%) of notes flagged by the monitoring system and corrected with addendums. An additional NLP run produced 510/516 (98.8%) completed assessments with calculated DAS28 scores. Specific elements recovered using this process are presented in table below.

Conclusions: The addition of this error monitoring system provides an efficient data correction system and is expected to motivate and reinforce the use of RA templates. The implications of which may be profound as we transition from traditional epidemiological research to a more active learning healthcare enterprise. This pilot study established “proof of concept” and the next challenge is to adapt the technology to other VARA and non-VARA sites. This technology and framework could enable collaborative clinical research networks that are committed to large-scale pragmatic and observational effectiveness studies.

IS THERE AN ETHNIC VARIATION IN ACCEPTANCE OF BIOLOGIC THERAPY? A UNIVERSITY HOSPITAL EXPERIENCE

H. Selvaskandan, H. Al-Ani, A. Moorthy. Department of Rheumatology, University Hospitals of Leicester, Leicester, United Kingdom

Background: Ethnic variation in drug adherence & preference is well documented (1). While usually a reflection of patient autonomy, the issue takes significance if it impedes the provision of effective evidence based care. Indeed, race affects rheumatological disease outcomes (2), likely for both biological & psychosocial reasons. Studies from United States of America found ethnic minorities were less likely to be on a biologic for a rheumatological disease compared to Caucasians, even after adjustment for education & insurance (3). Studies in the United Kingdom found similar results (4), although few investigated the disparity in the acceptance of biologics between ethnicities. Leicester, a midland UK city has an ethnically diverse population, where identifying and addressing such disparities is crucial in delivering effective & equal care.

Objectives: To determine any disparity in acceptance of biologic therapy, when offered in person, in a healthcare system free at the point of access, between White British and other ethnicities.

Methods: Data was collected from nurse led Biologics therapy clinics, from October 2016 to December 2016. All patients referred were deemed suitable for a biologic as per NICE guidelines by a Rheumatologist, and were attending the clinic for counselling, assessment & consenting. Proformas were piloted, and improved proformas with information including demographic, disease & treatment details, as well the outcome of the consultation (biologic accepted or rejected) was used to collect data. The collated data were then analysed using EXCEL spread sheet.

Results: Data was collected from 55 patients. Interestingly, sex distribution was nearly equal (54%, female). 57% of the total sample was White British (WB). The remaining 43% included; Indian, Bangladeshi, Pakistani, White Other, Asian, African Caribbean & Any other mixed race. The most common disease necessitating referral for a biologic was rheumatoid arthritis (53%). 16% of patients rejected a biologic drug, of which 66% were ethnic minorities. The rejection rate among ethnic minorities was thus 24% compared to 10% in the WB cohort. The highest rejection rate was within the Any Other Mixed Ethnicity cohort (100%), followed by the Bangladeshi cohort (50%). Of note, all patients who rejected biologic therapy from an ethnic minority background did not speak English as their first language. Rejection rates were highest in the Spondyloarthropathies (21%).

Conclusions: Our results demonstrate a disparity between the White British population and other ethnicities in the acceptance of biologics, despite one to one counselling. This can have detrimental impacts on treat to target concept and disease progression, and thus will be further investigated & addressed.

HIGH ACCEPTANCE RATE IN RA, AS AND PSA PATIENTS WHEN BEING STARTED ON BIOSIMILAR TNF OR BEING SWITCHED FROM THE ORIGINAL TNF MAB (REMICADE, ENBREL) - A SINGLE CENTER EXPERIENCE

H. Kellner, Schwerpunktpraxis für Rheumatologie und Gastroenterologie, München, Germany

Background: Biosimilar TNF Mab (BioTNF) have become available in most of the European countries in the last few years. They are labeled to be used in the most common rheumatic diseases, like RA, AS and PsA. Controlled studies have shown comparable efficacy and safety of BioTNF and original TNF (Remicade, Enbrel). BioTNF are allowed to be used in TNF naive patients as well as in TNF pretreated patients (switchers). Prescriptions in different countries may vary due to local most often cost driven restrictions.

So far, little is known about the awareness, acceptance and possible obstacles which may influence patients willingness to accept therapy with BioTNF instead using the original compounds.

Objectives: The study was conducted and designed to get a deeper insight in what may influence patients decision making and willingness to accept treatment with BioTNF firsthand or accept switching.

Methods: Between February 2015 and December 2016 41 patients (BioINF n=29, BioETA n=12) were introduced to BioTNF therapy. 9 Patients (Bio-INF n=3, Bio-ETA n=6) received TNF therapy the first time, in 32 patients (Remicade n=23, ETA n=8) were switched from the originator TNF compound to BioTNF. All patients received comprehensive information on BioTNF in verbal and written form.

A standardised questionnaire was used to ask patients on their awareness, acceptance and about possible obstacles for the usage of BioTNF Mab.

Results: 6 out of 9 TNF naive patients agreed after their first information on BioTNF to start therapy with BioINF (n=3) or BioETA (n=3). Another 2 patients accepted BioETA therapy on their second visit. Only one patients asked to be started on the originator TNF Remicade. In patients being ask to switch from Remicade to BioINF 19 patients accepted promptly to be switch in and patients with Enbrel therapy 6 out of 9. Finally only 1 patient on Remicade TNF therapy denied even after a third visit to be switched. Mayor concern to deny the use of BioTNF were possible lack of efficacy (30%), safety (32%) and missing longterm experience (35%).

The main motivation to switch was patients believe to save money and that they were asked to switch to BioTNF Mab on short notice from their health care insurance company.

Conclusions: There is a high acceptance rate in patients with chronic inflammatory rheumatic disease to be started on or switched to BioTNF (~90%). There are little concerns in patients accepting BioTNF with regard to safety or efficacy of BioTNF. Patients are aware of BioTNF as a less costly way to treat their rheumatic condition. Physicians should be aware of this willingness and offer BioTNF therapy if it is appropriate. Using BioTNF is a cost saving way to use biologics in rheumatic therapy with equal efficacy and safety compared to the originator compounds.

SATISFACTION AND BELIEF REGARDING TREATMENT WITH INTERSTITIAL LUNG DISEASE AND RHEUMATIC DISEASES IN MULTIDISCIPLINARY OUTPATIENT CLINIC

J. Jung 1, S. Jung 1, S. Kim 2, J.R. Choi 3, H.-S. Kim 1, Internal medicine, the Soonchunhyang University Seoul Hospital, Seoul; 2Internal medicine, Gangneung Asan Medical Center, Gangneung; 3Internal medicine, Pohang Saint Mary's Hospital, Pohang, Korea, Republic Of

Background: Among rheumatic disease-related lung disease, interstitial lung disease (ILD) is the most prevalent and contributing to the mortality and morbidity. Increasing numbers of reports dealing with ILD with rheumatoid arthritis (RA). Sjögren's syndrome (pSS) and systemic sclerosis (SSc), multidisciplinary discussions (MDDs) have been growing interest for diagnostic accuracy with dedicated service. There was little evidence indicating that multidisciplinary outpatient clinic resulted in improvements in clinical outcomes including satisfaction and belief.

Objectives: We have designed validated a scale of evaluating coping strategies about satisfaction and belief in patient of ILD and rheumatic disease with multidisciplinary approach.

Methods: From December 2015 to September 2016, we evaluated 20 patients of rheumatoid disease with ILD and 20 patients of idiopathic pulmonary fibrosis. Patient perceptions of illness, treatment beliefs, and moods were measured via the multiple choice questionnaires presenting brief illness perception questionnaire, beliefs about medicines questionnaire, and patient health questionnaire for comparing the effectiveness of MDDs and routine ILD management.

Results: Univariate analysis, beliefs in necessity of treatment and adherence differed significantly in high multidisciplinary outpatient clinic for people with ILD (intentional or unintentional). When controlling for other factors that may impact medication nonadherence, more belief in necessity of medication and higher MRCI (OR 1.1, p<0.019) were associated with high adherence. Table 1 shows significant univariate associations with MDD status for the treatment of ILD patients.

Conclusions: The treatment of ILD was quite successful with achievement of the therapeutic target in 66% of cases and ‘unhappy’ in only 15%.

ASSOCIATION BETWEEN USE OF TRADITIONAL CHINESE MEDICINE AND MEDICATION ADHERENCE AMONG CHINESE-AMERICAN RHEUMATOLOGY PATIENTS

K. Sun 1, H. Tian 2, Y.J. Chang 3, L. Lee 1, J.C. Leng 4, L.A. Mandl 1. Hospital for Special Surgery; 2New York University School of Medicine; 3Mount Sinai Beth Israel; 4Memorial Sloan Kettering Cancer Center, New York, United States

Background: Chinese-Americans (CA) are a fast-growing US immigrant group with high utilization of Traditional Chinese Medicine (TCM) and worse SLE and RA outcomes than Caucasians (1,2). The effect of TCM use on adherence to prescribed western medications for systemic rheumatic diseases is unknown.

Objectives: To evaluate whether TCM use is associated with adherence to western medicines prescribed for systemic rheumatic diseases among CA patients.

Methods: Patients with systemic rheumatic diseases were recruited from 2 rheumatology clinics that serve a predominantly CA immigrant population. Inclusion criteria were speaking Mandarin or English and having medication(s) prescribed by the rheumatologist. TCM use, adherence, Patient-Reported Outcomes Measurement Information System (PROMIS) domains, and other variables were assessed using validated instruments available in English and Chinese. Adherence was classified as high or medium/low based on the 8-item Morisky Medication Adherence Scale (3). Medication complexity was assessed using the Medication Regimen Complexity Index (MRCI) (4); higher score indicates more complexity.

Results: 177 enrolled, mean age 54 (range 20–97), 62% female, 73% high school education, 75% Medicaid (subsidized insurance), and only 18% spoke English. Diagnoses were RA (43%), SLE (17%), SjS (10%), pSS (8%), gout/CPPD (6%), and other (10%). 49% reported TCM use in the past year, most commonly turina massage (48%), acupuncture (47%), and herbs (39%). 27% reported low adherence. Table 1 shows significant univariate associations with high adherence. In multivariate analysis adjusting for all variables in Table 1, only TCM use (OR 2.6, p=0.027) and higher MRCI (OR 1.1, p=0.019) were associated with high adherence.

<table>
<thead>
<tr>

<tr>
<td>PROMIS Fatigue, T-score (SD)*</td>
<td>49 (11)</td>
<td>52 (10)</td>
<td>0.03</td>
</tr>
</tbody>
</table>

*Lower score is better.

Conclusions: Among poorly integrated and low socioeconomic status CA rheumatology patients, TCM use was statistically significantly associated with high adherence to western medication, as was higher MRCI. TCM use does not appear to represent an alternate but rather complementary approach to disease management in these patients. Future studies should evaluate whether TCM use is associated with disease activity and outcomes over time.

AB1095 EARLY DIAGNOSIS AND TREATMENT OF CHRONIC DISEASES: NATIONAL REVIEW AND GUIDELINES - RA AS AN EXAMPLE

L. Euler Ziegler on behalf of the High Council for Public Health (HCSP), Rheumatology Department, Academic Hospital and University of Nice, Nice, France

Background: Managing the increasing burden of chronic diseases is a major public health problem. Are early diagnosis and management a key point for their optimal care and outcomes?

Objectives: Assessing early diagnosis and management of chronic diseases was the aim of a study carried out by the High Council for Public Health (HCSP), independent national body gathering experts nominated by the Minister of Health, to provide health authorities with expertise on development of national public health goals, assessment of achievement and contribute to their monitoring.

Methods: A multidisciplinary working party run within the HCSP a review of scientific data supporting early intervention benefits, as well as frequency, impact and mechanisms of delayed management on individuals and society, in order to produce national guidelines. A huge amount of data were analyzed and considered contributions from national Professional organizations and Patient Professional organizations and Patient associations, literature analysis, audition of national agencies representatives.

Results: Early stages of chronic diseases are less studied than later ones. Nevertheless, there is a strong evidence that delayed diagnosis and management are frequent and often adversely affect patients and society. The frequency, length and burden of delayed care were analyzed, varying with each disease, availability of efficient treatments and guidelines, socio-economic context. Optimal time for adequate management from symptom onset was reviewed, as well as medico-economic studies.

Rheumatologic disorders appeared as models, notably Rheumatoid Arthritis (well-established window of opportunity, international guidelines for early diagnosis and management, including T2T and patient active implication). Evidence for early treatment benefit was also found for spondyloarthritids, osteoporosis, obstructive sleep apnea syndrome, chronic obstructive pulmonary disease, renal insufficiency, autism spectrum disorders, bipolar disorders, ... Ethical considerations may arise: in Alzheimer’s disease, a diagnosis source of marked anxiety, there is no effective pharmacological treatment but non pharmacological treatments are quite helpful for patients and family and therefore recommended by health authorities.

Obviously, the benefit of early intervention must be strongly assessed. When this benefit is proven, too many patients are facing delays, often long, with adverse consequences and increased burden for society. The mechanisms of such delayed management are multiple and often intricate: we analyzed the barriers to optimal care linked with professionals, patients, family, health system and society, in order to identify the ways to optimize the outcomes and therefore improve the global health status of the population.

Finally the HCSP established a set of guidelines, in 3 axis

- disseminate widely the available knowledge among professionals, patients, the general public, taking into account the social poor perception of chronic diseases
- implement effectively change in practice toward early intervention, when appropriate: timely coordination between professionals and patient, fair diagnosis announcement, early patient implication, fight against social health inequalities
- develop research on early stages of chronic diseases, diagnosis, management and outcomes.

Conclusions: From a national public health perspective, early diagnosis and management, in the chronic diseases where their benefit is proven, should be better known and effectively implemented.

AB1096 TIMED UP AND GO TEST (TUG) FOR SARCOPENIA SCREENING

Ll. Filipin 1, V.O.N. Teixeira 2, N.C. Oliveira 3, D.D. Berwanger 3, F. Mignaga 1

1 Program Post-graduat Saúde e Desenvolvimento Humano, Centro Universitário la Salle, Canoas/RS, Canoas; 2 Post-doctoral Fellow, Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre; 3 Physiotherapy Graduate; 4 Physical Education Graduate, Centro Universitário la Salle, Canoas/RS, Canoas, Brazil

Background: Sarcopenia is a multifactorial syndrome characterized by a decrease of muscle mass and force with functional performance impairment. Sarcopenia has been described as an independent predictor of health adverse outcomes such as falls, decreased quality of life, enhanced risk of death and higher treatment costs. However, there are just a few screening tools of low cost and easy applicability to detect sarcopenia. In this context, a standard mobility assessment such as the TUG test has recently been described as a predictor of sarcopenia.

Objectives: To evaluate the performance of timed up and go test (TUG) as a screening tool for sarcopenia in the elderly.

Methods: This is a cross-sectional home study with 211 elderly participants in the South Region of Brazil. Sarcopenia diagnosis criteria was based on the European Working Group on Sarcopenia in Older People (EWGSOP). Individuals that presented low muscle mass (women: ≤ 6.37kg/m2 and men: ≤ 8.90kg/m2) added to decreased handgrip strength (women: ≤ 20kgf and men: ≤ 30kgf) and/or walking speed (≤ 0.8m/s) were considered sarcopenic. TUG test quantifies functional mobility through the task of getting up from a chair, walking 3m and come back to sit on the chair.

Results: Based on EWGSOP criteria for sarcopenia, 17.1% (n=36) received the sarcopenia diagnosis. A ROC curve was constructed to evaluate the discriminatory power of TUG (AUC: 0.73 [IC 0.67 – 0.78; p=0.0001]). TUG test presented high sensitivity (88.9%) and negative predictive values (93.2%), with a cutoff point of 7.5 seconds (figure 1).

Conclusions: Detecting the beginning of sarcopenia could allow for early interventions and slow the syndrome process, preventing further hospitalizations and economic burden. In this context, TUG is an easy, fast and low-cost test with high sensitiveness for sarcopenia detection that could be used as screening tool for this syndrome.

AB1097 PATIENTS’ EXPERIENCES OF REMOTE MONITORING OF RHEUMATOID ARTHRITIS USING A SMARTPHONE APP

L. Austin 1, C. Sanders 1, W. Dixon 2, 1 Centre for Primary Care, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre; 2 Arthritis UK Centre for Epidemiology, Centre for Musculoskeletal Research, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom

Background: The care of patients with Rheumatoid Arthritis (RA) is guided by monitoring changes in disease activity. However, whilst a number of patient-related outcome measures (PROMS) exist 1, they are not collected on an on-going basis. Consequently, there are few objective measurements of disease activity, between clinic visits, to inform treatment decisions. In response to this, the REMORA study (REMOTE Monitoring of Rheumatoid Arthritis) is developing a smartphone app, to capture data on disease activity and integrate it directly into the electronic patient record. The project explores whether on-going collection of electronic patient-reported outcomes (ePROMS) between clinic visits can enhance clinical care, support patient self-management, and provide a sustainable source of data for research.

Objectives: To describe patients’ experiences of remote monitoring of their disease activity, and the perceived value in relation to clinical consultations and self-management.

Methods: A diverse sample of 20 patients with RA entered data into the app over...
a three month period in response to daily, weekly and monthly question sets (table 1). An optional diary component was included, but not integrated into the EPR. The ePROs had been determined during earlier interviews with rheumatology patients, practitioners and researchers. Qualitative interviews were conducted with patients at the end of the three month period. Two previously expressed patients’ views on the components of the app, and perceived implications for self-management and clinical care. Interviews were transcribed and analysed thematically.

Results: Qualitative analysis of the data identified a number of themes including; the benefits and limitations of using scales to reflect changes in symptoms experienced, the value of the diary for providing contextual information and an “outlet” for feelings, and the impact the data made to their clinical consultation and self-management. Overall, the collection of longitudinal data was seen as useful by patients. Successful integration with the EPR allowed data to be displayed graphically during clinical consultations. Reviewing remote monitoring data detected changes which may otherwise have been missed such as flares in disease, or gradual improvements in response to new treatments. Data therefore facilitated “a shared conversation” and decision making around treatment plans.

Additionally, being able to self-reflect on data recorded enabled patients to identify triggers and alleviators in relation to their disease activity and take steps to self-manage their RA; for example, by recognising when they needed to rest as opposed to “just carrying on” when their symptoms were more severe.

AB1098 | TEMPORARY WORK DISABILITY CAUSED BY MUSCULOSKELETAL DISEASES AT THE HOSPITAL CLINICO UNIVERSITARIO DE VALLADOLID: 6 MONTHS EXPERIENCE

M.D. Sánchez González 1, C.C. Macía Villa2, C. González-Montagut Gómez 1, J. Medina Lueves 1, "Rheumatology, Hospital Clínico Universitario de Valladolid, Valladolid; 2Rheumatology, Hospital Universitario Severo Ochoa, Leganés (Madrid), Spain"

Background: Musculoskeletal diseases are the leading cause of disability in the world and have a huge impact on direct (health) and indirect (labor) costs. Labor casualties in Spain, when temporary, are known as temporary work disability (TWD). Since 2013, follow-up of patients with TWD (when the origin of the disease is a musculoskeletal condition) is being carried out in a monographic consultation within the external consultations of the Rheumatology Service of the Hospital Clínico Universitario de Valladolid.

Objectives: To describe the experience of the last 6 months in the consultation of temporary musculoskeletal incapacies (TWDMSDs) of the Hospital Clínico Universitario de Valladolid.

Methods: The TWDMSDs consultation is operational 2 days a week. The referral system is direct from Medical Inspection via email (1st part confirmatory work leave). The patients come from 7 Health Centers (population 82,000 people). The agenda is configured daily according to the emails sent, contacting the patients by telephone, excluding those with trauma, surgeries, pregnancies, non-localized, rejection or discharge. The assessment of the patients in consultation, corresponds to usual clinical practice. A medical report is issued (medical history, physical examination, completed or requested tests, recommendations and treatment).

The data are collected in SPSS, proceeding to its subsequent analysis.

Results: During the last six months of follow-up, 354 emails have been received. A total of 106 patients were evaluated, with the following characteristics: 54.3% women and 45.7% men, mean age 43.4 years, 95% performed physical work. Axial pathology was observed in 67.8% of cases and peripheral in 32.2%. The patients evaluated with some rheumatic pathology reached 96%. The average delay from the start of the work leave to the email was 12.2 days, and from the start of the work leave to the first consultation of 6.7 days (including weekends). 65.4% of the patients were discharged from the TWDMSDs agenda in the 1st consultation, without requiring interconsultations or requests for diagnostic tests, with an infiltration of 8% of the patients, arthrocentesis at 2%, ultrasonat at 28% and Exercise guidelines were given to 76% of patients. The mean number of consultations up to discharge was 1.3. The mean time from onset of discharge to discharge was 21.1 days and from the first consultation until discharge by Rheumatology was 6.6 days.

Conclusions: The TWDMSDs consultation makes possible the early detection of rheumatologic musculoskeletal pathology, allowing an early action that minimizes the number of requested tests and interconsultations generated and achieves an early diagnosis and treatment of patients, with the consequent benefits that this entails. The patients evaluated in consultation are mainly of average age, with physical work, mechanical pathology, resolution of the problem that causes the TWD and reintegration to the working life of early form. In the discharge report, recommendations are included to minimize future casualties (work refocus, orthotics, exercises, treatment regimens in the event of a recurrence of symptoms) and explain the importance of being actively involved in their pathology to prevent progression.

DOI: 10.1136/annrheumdis-2017-eular.6552
Conclusions: This survey suggested that CTD have a major impact on FP and family size, possibly mediated by the increased rate of miscarriages as compared to CA. Concerns about reproductive issues could be positively overcome by adequate counselling. Rheumatologists should implement the discussion about FP and the compatibility of pregnancy in the management of young women with RD, especially those with CTD for whom contraception and pregnancy have particular implications.

AB1100  PATIENT SELF-MANAGEMENT APPS AS ONE MODULE OF AN INTEGRATED TIGHT-CONTROL CONCEPT BASED ON THE EXAMPLES OF THE DIGITAL APPLICATIONS RHEUMALIVE UND AXSPALIVE

M. Feuchtenberger, 1 S. Kleinert, 2 F. Schuch, 2 S. Spåhlting-Mestekemper, 3 C. Kuhn, 2 M. Wecker, 1 1 Rheumatology, Schwerpunktpädis für Rheumatologie, Burghausen; 2 Rheumatologie, Rheumatologische Schwerpunktpraxis, Erlangen; 3 Rheumatologie, Rheumapunkt München-Pasing, München; 4 Rheumatologie, internistische Schwerpunktpädis am Ludwigsplatz, Karlsruhe; 5 Rheumatologie, MVZ für Rheumatologie Dr. Martin Wecker, Planegg, Germany

Background: Medical Applications have the potential to support physicians and patients to document the course of the disease and optimize therapies. We describe the linkage and integration of patient reported outcomes (PROs) into existing medical office software and rheumatologic documentation systems by means of the digital applications RheumaLive and AxSpaLive. RheumaLive is certified as medical product class I, and certification for AxSpaLive is in preparation.

Methods: RheumaLive and AxSpaLive are applications that can be downloaded free of charge from the common app-stores (Android, Apple) and installed on mobile devices (smartphones, tablets). A freeware version for PCs is also available (Windows- and Mac OS X-Version). A diary functionality allows to document the medication uptake (partially filed, memory-functionality for medication uptake available), validated scores like VAS, SJC, morning stiffness, FFBh (comparable to HAQ), BASDAI, RADAI, etc. and days of sick leave (+/− related to the rheumatic disease). All App-versions are password-protected, which is provided by the treating rheumatologist (relationship patient-physician).

The patient reported outcomes are stored locally on the respective device. For the subsequent visit, they can be printed or sent encrypted to the treating physician via internet in a prespecified interval. A specific software allows to integrate the data into the existing medical office software.

In daily practise, data entered by patients into RheumaLive can be screened and compared with collected clinical data and laboratory measures, because of it’s certification as medical product. In case of an increasing disease activity the patient can be rapidly contacted and medication can be modified, if necessary. Regular F2F-appointments remain integral part of the medical care, even in case of good controlled disease activity. But in case of F2F-appointments, PROs can be delivered by patients, saving time and resources.

The PROs can be made available to rheumatologic documentation systems like RheuDoc via predefined interfaces.

Results: In a first pilot phase 54 patients in 4 rheumatologic specialised practices were documented. In the next phase the number of patients and participating practices/centres should be increased.

Further studies are necessary to show if the integration of PROs which are collected via electronic application can lead to an improvement of rheumatologic diseases.

Conclusions: The integration of PROs collected with RheumaLive and AxSpaLive into existing rheumatologic documentation systems allows a close monitoring of disease courses and therapies according to the “tight control” principle. RheumaLive and AxSpaLive were developed by Starhealth GmbH on behalf of UCB Pharma GmbH.

AB1102  LOW BONE MINERAL DENSITY IS A MAJOR CONTRIBUTOR IN THE EUROPEAN HEALTH BURDEN DUE TO ROAD TRAFFIC ACCIDENTS IN PEOPLE AGED 50 YEARS AND ABOVE

N. Wilson 1, L. Sanchez-Riera 2, D. Prieto-Alhambra 3, C. Cooper 4, K. Drehmöller 5, A. Woolf 6, L. March 7, P. Halbout 1 1 Institute of Bone and Joint Research, University of Sydney, Sydney, Australia; 2 University Hospital Bristol NHS Foundation Trust, Bristol; 3 Oxford NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford; 4 MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, United Kingdom; 5 Center for Musculoskeletal Surgery, Charité Universitätsmedizin, Berlin, Germany; 6 Institute of Health Research, University of Exeter Medical School, Exeter, United Kingdom; 7 International Osteoporosis Foundation, Nyon, Switzerland

Background: Road traffic accidents (RTAs) are the second leading injury health burden and cause of death in Europe, after falls (1). A significant but as yet unmeasured proportion of such burden is potentially due to low bone mineral density (BMD), especially among older people, through its relationship with fractures.

Objectives: To measure the percentage of deaths, years lived with disability (YLDs) and years lived with disability (YLDs) due to RTA in people aged 50 years and above attributable to low BMD in the European population for the year 2015.

Methods: The estimates followed the Counterfactual Risk Assessment Methodology used in the GBD study (1). Systematic review was performed seeking population-based studies with femoral neck BMD (FNBM) measured by Dual-X-Ray-Absorptiometry in people 50 years and over. Age- and sex-specific prevalence of low BMD (T-score <−2.5SD) was extracted from eligible studies, and this was used as the exposure variable. The age and sex-specific 99th percentile from non-Hispanic whites in National Health and Nutrition Examination Survey (NHANES) 2009–2010 was used as the population-level-risk to estimate the potential impact fraction (PIF) of FNBM for fractures. Relative risks of low BMD for fractures were obtained from a previous meta-analysis (2). Attributional deaths due to RTA-related fractures were obtained through coded hospital data. Disability levels were established by applying disability weights to each type of fracture. Then, PIFs were applied to obtain attributable deaths and disability due to low BMD.

Results: In the European population aged 50–69 and 70 years and above, 10.8% (95% CI: 8.9–12.4%) and 30.9% (29.1–32.4%) of RTA-related deaths, respectively, were attributable to low BMD. In the age group 50–69 this was the second most important risk factor following alcohol use and in those 70 years and above became the most important risk factor, with double the weight of alcohol use. This represents 2,537 and 5,460 absolute deaths in those aged 50–69 and 70 years and above, respectively. The percentage of health burden and disability caused by RTAs attributable to low BMD grow steadily from the ages of 50 and onwards.

Conclusions: This data shows the previously-reported important role of low BMD as a preventable risk factor for European RTAs' health burden in population 50 years and over, which requires urgent attention.
AB1103
THE IMPORTANCE OF ADEQUATE SCREENING TO AVOID FALSE-POSITIVES IN THE DIAGNOSIS OF RHEUMATOID ARTHRITIS

P. Santos-Moreno 1, D. Gomez 1, E. Castillo 1, R. Giraldo 1, G. Ballesteros 1, L. Villarreal 1, D. Buitrago-Garcia 1, J. Bello 1 2

Background: The lack of expertise and skills in the diagnosis of in rheumatoid arthritis (RA) in primary level of Colombian medical centers can cause misdiagnosis of rheumatic diseases. Due to this issue in a specialized center in RA we established a multidisciplinary model and a strict disease management algorithm to diagnose properly our patients; as a consequence we have achieved the accurate diagnosis of great proportion of patients that were false positives diagnosed initially as RA.

Objectives: The aim of this study was to show effectiveness and accuracy of a screening method to avoid false-positive diagnosis of RA in a cohort of patients with supposed diagnosis of RA.

Methods: During two years we evaluated patients with presumptive diagnosis of RA. We conducted a cross-sectional study; we included patients who were referred from primary care centers to a RA specialized center in a 24 month period with presumptive diagnosis of (RA). Each patient was evaluated to confirm or rule-out diagnosis of RA as follows: a rheumatologist fulfilled a complete medical record, including joint counts; it was assessed rheumatoid factor and anti-CCP antibodies, as well as other laboratory tests. Then, if the diagnosis was corroborated, the patient was referred to rheumatology; if not, the patient was referred back to primary care center.

Results: Between 2015 and 2016 6813 patients were evaluated in our specialized center, in 76% of cases RA was confirmed, the remaining 1933 patients (24%) had a wrong diagnosis of RA; of these misdiagnosed patients, (87%) were female, and 205 (13%) male, with an average age of 62±12 years. Between differential diagnosis which were found in this cohort of misdiagnosed patients: osteoarthritis in 849 patients (63.3%), Sjögren syndrome (7%) Systemic lupus erythematosus (6%) the remaining 30% of patients had conditions such as gout, psoriasis, osteoporosis, myalgia, soft tissue diseases among others. The majority of patients with wrong diagnosis took DMARDs (23%), calcium (11%), biologics (10%) acetaminophen (9%), neuropathy medications (7%), acetaminophen plus ibuprofen (5%), antidiabetes medications (5%), antibiotics (4%), glucosamine (4%), diacerein (3%), the remaining patients took medications such as NSAID, glucosamine, antigout agents, gastritis drugs, among others.

Conclusions: The results of this program show that almost 25% patients with presumptive RA diagnosis are misdiagnosed; this is evidence that can be extrapolated to primary care centers in Colombia. The most important confounding diagnosis was osteoarthritis and many patients were receiving DMARDs for treatment. For this reason there is an urgent need of education strategies for primary care physicians and the implementation of centers of excellence in RA, in order to conduct a proper diagnosis and avoid clinical and health economics consequences of misdiagnosis.

AB1104
COST-EFFECTIVENESS ANALYSIS OF TNF INHIBITORS USE COMPARED TO DMARDS IN THE FATAL AND NONFATAL ACUTE CORONARY ISCHEMIC EVENT

R.K.S. Gomes 1, J.Y.K. Viscondi 1, M.R.C. Nobre 2 1 Center of specialty of the municipality of Blumenau and Brusque, Blumenau; 2 São Paulo University, São Paulo, Brazil

Background: Epidemiological studies have established that rheumatoid arthritis is associated with an increase in cardiovascular disease. The evaluation of tumour necrosis factor inhibitors (TNFi) on the reduction of the risk of acute myocardial infarction and death due to cardiovascular causes has shown promising results. The economic evaluation for these outcomes are not established yet.

Objectives: To evaluate the cost-effectiveness of TNFi versus disease-modifying antirheumatic drugs (DMards) to avoid a new case of acute ischemic heart disease and death in rheumatoid arthritis patients.

Methods: A cost-effectiveness analysis (CEA) was performed using a Markov model 6-month transition cycle, with time horizon of 30 years, under the Brazilian public healthcare system perspective. Costs are expressed in 2015 Reais and effectiveness measures are new cases of acute ischemic coronary disease and cardiovascular death.

Results: The average cost in 30 years of DMards and TNFi was 14,291,105.28 and 96,151,873.86 Reais, respectively. The incremental effectiveness was 2.69 cases of coronary artery disease and consequent incremental cost-effectiveness ratio (ICER) of 30,527,502.27 Reais per new cases avoided, while for cardiovascular death, incremental effectiveness was 1.33 and an ICER of 61,634,231.69 Reais per new cases avoided. The univariate analysis identified that the most relevant parameter in the ICER on both outcomes was the TNFi drug. The sensitivity analysis established that, in order to reach the amount of willingness to pay (WTP) per semester to avoid an acute myocardial infarction, the average cost of TNFi should be 1,337.47 Reais per case avoided and the average cost for the cardiovascular death avoidance would be 954.22 Reais. All the analyzes performed evidenced an unfavorable relationship of the drug treatment strategy with TNFi.

Conclusions: The findings of the CEA among patients with rheumatoid arthritis for cardiovascular outcomes when compared to the strategy of TNFi drug treatment with the dominant strategy DMards after the first 6 months of exposure point out an unfavorable relationship, surpassing the amount of expenses recommended by the Ministry of Health of Brazil in the year 2015.

1Correlation coefficient (p value); 2F-test (p value).

subjects had lower levels of hope compared to Non-Hispanic White subjects (difference between means -0.05). Associations between subject characteristics and their experience of taking the verbal education were measured in the multivariable regression model (including education, difficulty paying for medications, medication beliefs, trust, hope and worry), hope was associated with perceived importance of taking the medication in all three ethnic groups. Additional findings differed by race, with medication beliefs in Non-Hispanic White subjects; difficulty paying for medications in Non-Hispanic Black subjects, and worry in Hispanic subjects being associated with perceived importance of taking the medication.

Conclusions: Our findings confirm the important influence of emotion on decision making, and suggest that while hope is universally associated with perceived importance of taking a medication, other factors differed, highlighting differences in the decision making process across ethnic groups.

AB1106 VERBAL PATIENT EDUCATION ON VACCINATION IN ADULTS WITH AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES: IS IT ENOUGH TO IMPROVE VACCINATION RATES?

P. Magro, M. Rogers, F. Camilleri. Rheumatology, Mater Dei Hospital, Msida, Malta

Background: Patients suffering from autoimmune inflammatory rheumatic diseases (AIIRD) are at increased risk of infections, due to the underlying condition and its treatment. A study on vaccination in AIIRD carried out at Mater Dei Hospital, Malta in 2015 showed that 37.9% of the patients received the influenza vaccine in the previous year and 8.3% had received the pneumococcal vaccine ever. Only 38.3% knew that they had an increased risk of infection because of their condition.

Objectives: The aim of the current study was to establish whether verbal education on vaccination, influenced patients’ vaccination rates in the following year. A further aim was to determine whether the patients had a better understanding of their increased infection risk following verbal education.

Methods: The initial study carried out in 2015 consisted of a short face-to-face interview with 60 patients who suffered from autoimmune inflammatory rheumatic diseases. Following the interview, verbal information was given to the patients on their increased risk of infection, and the importance of vaccination, in particular the influenza and pneumococcal vaccine. After 1 year, the patients were contacted by means of a telephone call. They were interviewed with regards to their vaccination history and knowledge of their infection risk. Of the 60 patients, 2 had passed away. Therefore 58 patients were included in the study.

Results: The study included patients with a variety of AIIRD including rheumatoid arthritis, ankylosing spondylitis and psoriatic arthritis. 60.3% were females and the mean age was 63.1 years (range 25 to 82 years). Influenza vaccination rates in the previous year improved from 37.9% in 2015 to 41.4% in 2016 (p=0.704). Pneumococcal vaccination rates improved from 6.9% to 17.2% (p=0.086). On questioning the patients regarding their knowledge of increased infection risk, there was no improvement following the verbal education. In fact 37.9% of patients questioned in 2015, and 34.5% in 2016 knew that they were at increased risk of infection because of their condition. 33% of patients studied in 2016 could recall that they had been advised to take vaccination because of their underlying condition or treatment. This improved from 7% in 2015, and 34.5% in 2016 knew that they were at increased risk of infection because of their condition. 33% of patients studied in 2016 could recall that they had been advised to take vaccination because of their underlying condition.

Conclusions: Compared to the initial study, there was no improvement following the verbal education. In fact 37.9% of patients that had complete data on all required variables. A list of Read Codes relating to inflammatory arthritis, compiled by a rheumatologist and a GP, were searched for in primary care medical records of consenting respondents. Period of enrolment was from date of first ever PMR diagnosis in the medical records until survey mail-out.

Results: 704 eligible patients were identified and sent a questionnaire, with 550 (78%) responding. Responders and non-responders did not differ significantly by age or gender. Medical records could be obtained for 385 patients, of whom 310 completed the questionnnaire fully and were included in the analysis. IA score ranged from -8.4 to 2.5, with 21 (7%) patients being classed as having a positive IA score. 8 out of 310 patients had at least one inflammatory arthritis Read code recorded from date of first diagnosis of PMR in their medical record, although only 2 of those were predictive of IA. IA score was calculated in these patients that had complete data on all required variables. A list of Read Codes relating to inflammatory arthritis, compiled by a rheumatologist and a GP, were searched for in primary care medical records of consenting respondents. Period of enrolment was from date of first ever PMR diagnosis in the medical records until survey mail-out.

AB1108 HANDLING OF DE NOVO ARTHRITIS IN ADULTS BY GENERAL PRACTITIONERS: A SURVEY IN A FRENCH COHORT

S. Lecauchois 1, S. Gentille 2, P. Champaussay 3, J.-P. Mattei 4, L. Dillinger 2, V. Goeb 2, S. Guis 2, 3, 4, Aix Marseille Université, AP-HM, Marseille Cedex 9, France; 2Public Health; 3Radiology; 4Rheumatology, Aix Marseille Université, AP-HM, Marseille Cedex 9; 5General Practitioner, Aix-en-Provence; 6Rheumatology, CHU Amiens, Université de Picardie Jules Verne, Amiens; 7Crmemb-Cemerem UMR 7339, CNRS, Aix Marseille Université, Marseille, France

Background: A guide of good clinical practice regarding de novo arthritis in adults has been edited.

Objectives: The aim of this work is to identify whether the diagnostic and therapeutic tools proposed by general practitioners (GPs) to adults with a de novo arthritis is in line with the corresponding recommendations.

Methods: A questionnaire regarding the characteristics and the handling of de novo arthritis in adults has been submitted to 300 GPs chosen randomly from a French cohort database. The study period was from February 2015 to February 2016. Fifty seven GPs participated in the study (19%).

Results: No particular specificity was identified in the GP group. The age of patients ranged between 40 and 75 yo. The prevalence of arthritis was less than 5% among the GPs patients. The relative number of each category of arthritis was distributed as follows: Osteoarthritis (22%), Rheumatoid arthritis (22%), Psoriatic arthritis (14%), PPR (8%), other kinds of microcrystalline arthritis: chondrocalcinosis, (38.4%), gout (11.6%). Joints with mechanic degenerative effusion related to osteo-arthritis might be misdiagnosed as an inflammatory arthritis.

The knee was the most frequently involved joint in arthritis. The initial paraclinical
ABSTRACT

DOSE DESCALATION IN A SPECIALIZED OUTPATIENT CLINIC ON BIOLOGICAL THERAPY: COST MINIMIZATION OBSERVATIONAL STUDY

Background: To estimate the annual cost in the use of biological therapy (BT) in patients with different rheumatic diseases when dose modifications are undertaken in daily clinical practice in a specialized outpatient clinic during 2016 and to compare the results with data obtained in 2013.

Methods: Design: Cost minimization observational study under conditions of clinical practice. Patients: Patients with different rheumatic diseases who come to a specialized outpatient clinic on BT in the Rheumatologic department at a tertiary Spanish hospital (with tight follow-up) that was treated with BT under reduced doses during 2016 were collected. Protocol: Reductions in treatment dose or dose frequency were established empirically and were carried out by their rheumatologist in those patients who were in remission (DAS 28 ≤ 2.6) for at least 6 months without steroids. Main outcome: Reduction of annual average cost in euros/annum in BT used patients who are in dose reduction in clinical practice in 2016. Secondary outcome: Differences in annual costs reduction in 2016 compared with 2013. The cost reduction was calculated by comparing the actual expenditure (after modifying treatment dose in clinical practice) with the theoretical costs (official price) in case you had not made the adjustment. Statistical analysis: Sample descriptive analysis. Reducing annual absolute costs and by treatment after tapering down doses in clinical practice in 2016 and the differences found between 2013 were calculated.

Results: During 2016, the dose of the BT of 168 patients (94 Subcutaneous BT and 74 intravenous BT) were modified in clinical practice after reaching clinical remission: mean of DAS 28 (mean±SD)=2.31±0.76 or BASDAI (mean±SD)=2.15±1.39 without radiographic progression. Most patients were women (n=113;67%) and had rheumatoid arthritis (n=103;62%) and the rest were distributed among: spondyloarthritides (n=26;17%), psoriatic arthritis (n=22;13%), juvenile idiopathic arthritis (n=10;5.5%) and Systemic Lupus Ermethematosis (n=5;3%). No patients treated with certolizumab or anakinra was modified treatment doses. During this period, 5 patients discontinued BT (3 remissions and 2 minor adverse events). Table 1 shows the number of patients by type of BT and costs. The BT dose reduction in clinical practice during 2016 represented a saving of 676,501.67€ and a greater efficiency of treatments while in 2013, only 86 patients (30 etanercept, 15 adalimumab, 16 Infliximab (Remicade), 15 Tocilizumab IV and 55 Rituximab) had a modified dose of BT in clinical practice assuming a saving of 396,995.46€. The difference in the annual cost reductions in 2016 compared to 2013 meant a saving of 279,506.21€ more in the last year. Table 1.

Conclusions: In rheumatic diseases we may do a dose de-escalation of BT in patients who go into remission and therefore we could reduce the associated costs of BT and being more efficient with the treatments. We believe that it is important to create specialized outpatient clinics on BT where a tight-control management of these patients and an individualized treatment are carried out.

AB1111  A PROSPECTIVE COHORT STUDY MEASURING COST-BENEFIT ANALYSIS OF THE OTAGO EXERCISE PROGRAMME IN COMMUNITY DWELLING ADULTS WITH RHEUMATOID ARTHRITIS

1School of Nursing, Midwifery and Social Work and MAHSC; 2School of Medical Sciences; 3School of Nursing, University of Manchester, Manchester; 4University of Glasgow; 5University of Manchester, Manchester, United Kingdom

Background: Falls are one of the major health problems in adults with Rheumatoid Arthritis (RA). Interventions, such as the Otago Exercise Programme (OEP), can reduce falls in community dwelling adults by up to 35%. The cost-benefits of such a programme in adults with RA have not been studied.

Objectives: To determine healthcare cost of falls in adults with RA, and estimate whether it may be cost efficient to roll out the OEP to improve function and prevent falls in adults living with RA.

Methods: Patients with Rheumatoid Arthritis aged ≥ 18 years were recruited from four rheumatology clinics across the Northwest of England. Participants were followed up for 1 year with monthly fall calendars, telephone calls and self-report questionnaires. Estimated medical cost of a fall-related injury incurred per-person were calculated and compared with OEP implementation costs to establish potential economic benefits.

Results: 535 patients were recruited and 598 falls were reported by 195 patients. Cumulative medical costs resulting from all injury leading to hospital services is £374,354 (US$540,485). Average estimated cost per fall is £1,120 (US$1,617). Estimated cost of implementing the OEP for 535 people is £116,479 (US$168,504) or £217.72 (US$314.34) per-person. Based on effectiveness of the OEP it can be estimated that out of the 598 falls, 209 falls would be prevented. This suggests that £234,583 (US$338,116) savings could be made, a net benefit of £118,104 (US$170,623).

Conclusions: Implementation of the OEP programme for patients with RA has potentially significant economic benefits and should be considered for patients with the disease.

AB1112 DATANETWORK RHEUMA 4.0 – REAL WORLD DATA FROM PRIVATE PRACTICE

S. Kleinert1, F. Schuch1, S. Späthling-Mestekemper2, M. Feuchtenberger3, C. Kuhn4, M. Welcker5, 1Rheumatologie, Rheumatologische Schwerpunktpraxis, Erlangen; 2Rheumatologie, Rheumapraxis München-Pasing, München; 3Rheumatologie, Schwerpunktpraxis für Rheumatologie, Burghausen; 4Rheumatologie, Internistische Schwerpunktpraxis am Ludwigswaldrat, Karlruhe; 5Rheumatologie, MVZ für Rheumatologie Dr. Martin Welcker, Planegg, Germany

Background: The datanetwork Rheuma 4.0 (DNR_4.0) is a consortium of 5 internistic-rheumatologic specialized practices. Patient data that were collected routinely will be pooled pseudoonymized (e.g. via RheumaDock) and will be made available to answer numerous healthcare- and scientific research questions.

Methods: The participating centres document the following data in specific management data documentation systems (RheumaDock, Emily, DokuMed.ru). These data will be routed automatically to the data base of the DNR_4.0 via a prespecified interface and can be used for certain research areas: Diagnosis (by rheumatologist (R), anamnesis (R), medication (R), morning stiffness (R, patient (P)), scores like RADI (R, P), DAS28 (R), BASDAI (P), BASFI (P), quality of life (R, P). Also prespecified laboratory measures (R) like ESR, CRP etc. can be collected automatically.

Patient reported Outcomes (PROs) that were entered via mobile applications like RheumaLive and AxSpALive can be collected in certain intervals and be sent encrypted onto the medical data base. The data entered by patients will be screened by the rheumatologist or nurse and will be stored in the underlying data base. Clinical data that are collected during regular P2F-appointments will be stored together with the PROs according to a specific period of time.

Results: The datanetwork Rheuma 4.0 (DNR_4.0) is an association of 5 internistic-rheumatologic specialized practices.

Conclusions: The german biologic registry Rabbit and the “Core documentation” data base deliver valid data about the safety and efficacy of rheumatologic medication. The datanetwork Rheuma 4.0 will make a valuable contribution – especially in conjunction with apps of patient’s self management like RheumaLive and AxSpALive – to health care research, therapeutic strategies and clinical questions from daily practice.

Acknowledgements: RheumaLive and AxSpALive were developed by Starthealth GmbH on behalf of UCB Pharma GmbH.

AB1113 PATIENT PARTICIPATION IS CRUCIAL WHEN INTRODUCING NEW DEVICE TECHNOLOGIES IN THE MANAGEMENT OF CHRONIC ARTHRITIS: APPLYING THE PARKER MODEL, A QUALITATIVE 3-STEP APPROACH

T.S. Jørgensen1, L. Klokker1, M. Skougaard1, H. Asmussen1,2, A. Lee3, I. Mønstein1, H. Gudbergsen1, L.E. Kristensen1, The Parker Institute, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen; Communication IKH, Roskilde University, Roskilde; 3NATION, Copenhagen; 4University of Southern Denmark, Odense, Denmark; 5UCB Pharma, Brussels, Belgium

Background: Patients’ participation in design, development, and implementation of new device technologies is essential to ensure added value in patients’ disease management.

Methods: To explore the applicability and relevance of ava® , an electromechanical device (e-Device), as an alternative method for subcutaneous administration of certolizumab pegol.

Results: The Parker Model is an innovative 3-step qualitative research approach, which combined concept mapping (CM), participatory design (PD), and stakeholder evaluation (SE) to evaluate the development and implementation of a new device technology (ava® , Figure). CM was applied through workshops, with the participation of patients, using a structured group process focusing on relevant themes to identify issues and concerns with the e-Device. Patients used this information in a series of iterative PD sessions; patients participated in 3 interactive sessions to create a personal e-Device prototype in
cooperation with a designer and a medical expert. This was followed by a common group session. Finally, SE was performed based on semi-structured group and individual interviews with patients and disease-management stakeholders.

Results: The study included 9 rheumatoid arthritis (RA) patients, 4 psoriatic arthritis (PsA) patients, 1 ankylosing spondylitis (AS) patient, 2 doctors, 2 nurses, 1 medical rheumatologist, and 4 key public servants involved in the disease management of the selected rheumatic diseases. Saturation was reached after 3 CM patient workshops, generating 121 statements, which were organized by the participants into themes. Through content analysis of the results from the 3 workshops, 4 concepts were generated: technical usability, physical design, concerns, and enthusiasm. These data were used in the iterative PD sessions, resulting in 4 new prototypes. Finally, SE demonstrated that the identified concepts were pivotal for both facilitating and hampering device implementation, thus creating value when introducing the new e-Device.

Conclusion: Patient participation in the 3-step qualitative Parker Model identified important aspects to consider when designing and implementing an innovative device for the treatment and management of RA, PsA, and AS. This is the first time a composite, qualitative research model has been applied when introducing a new device to support these disease areas. The responses from patients and disease-management stakeholders indicated that it is key to include patient input in the design and adaptation of devices alongside education and communication with stakeholders. These resources can help ensure added value when developing devices for the management of RA, PsA, and AS using biologic medicines.

AB1114 PATIENT’S SELF-MONITORING OF DISEASE ACTIVITY OF RHEUMATIC DISEASES VIA WEBAPP – STUDY DESIGN, PATIENT’S PERSPECTIVE AND RECRUITMENT IN THE FIRST 11 MONTHS OF THE SWISS MULTICENTRE, LONGITUDINAL COMPASS II STUDY

V.K. Jaeger1, P. Schiffer2, P. Zufferey3, L. Pichler1, A. Badaracco4, M. Walder5, J. Dudler5, D. Frey6, F. Müller1, U.W. Walker1, 1University Hospital Basel, Basel; 2Praxis beim Rathaus, Zofingen; 3Lausanne University Hospital, Lausanne; 4Studio Medico Badaracco Cattaneo, Lugano; 5Praxis Walder, Dübendorf; 6Hospital Cantonal Fribourg, Fribourg; 7Praxis Frey, Basel, Switzerland

Background: The management of patients with rheumatic diseases is guided in part by asking patients about their medical history at each clinic visit. Patients often find it difficult to accurately remember the course of their symptoms between these appointments as they are often months apart. Regular app-based patients’ self-monitoring of disease activity (with our without feedback to the rheumatologist) between clinic visits might provide a possible solution for this. The COMPASS II study [1] demonstrated that RA patients’ self-assessments of disease activity via App correlate strongly with rheumatologists’ assessments. Following up on this, the Swiss based COMPASS II study is embedded in the Swiss rheumatology registry (SCQM) and hence allows the linkage of data obtained via the COMPASS II App from the patients with routine clinical data collected in the registry. The main aims of the COMPASS II study are to assess if continuous self-monitoring of the disease by patients optimises disease management and outcome in rheumatic diseases, and to assess the fluctuation of disease activity between clinic visits.

Objectives: The objectives of this abstract are to describe the set-up and the recruitment of the COMPASS II study in the first 11 months.

Methods: The COMPASS II App questionnaire consists of the RAPID3 score, a validated, commonly used PRO to self-assess disease activity. Additionally, patients are asked about their therapy compliance and cortisone dose. At inclusion, interested patients with RA, axSpA and PsA are electronically randomized into 3 study arms (Figure 1). In arm 1 patients and rheumatologist are displayed the self-assessed disease activity over time, the patient directly via the App and the rheumatologist via the SCQM registry. In arm 2 only the patients are displayed their disease activity chart and in study arm 3 neither sees the recorded data. Patients are encouraged to fill in the App weekly.

Results: The COMPASS II App went online on the 15/02/2016. In the first 11 months of COMPASS II, 272 patients were enrolled by their rheumatologist. 64% of patients used the WebApp (32% in arm 1, 38% in arm 2 and 30% in arm 3); 82% of patients filled in the questionnaires for longer than a months, the longest follow-up was 11 months. On average patients use the App every 2 weeks. Patients found the App easy to use “The COMPASS II WebApp is so easy to use, it doesn’t even take me 2 min.” and received feedback included “Now my rheumatologist sees how I was since the last appointment instead of me trying to remember how I was half a year ago.”.

Conclusion: The COMPASS II study will validate the utility of app-based patients’ self-assessments in enhancing disease control in a treat to target approach and deliver numerous additional scientific data.

AB1115 THE FEASIBILITY OF UTILIZATION OF MOBILE DEVICES TO ENHANCE PATIENT REPORTED OUTCOMES MEASURES (PROMS) IN RHEUMATOLOGY PRACTICE

V. Ogenovski1, K. Burger3, K. Weiss2, K. Esser4, D. Khanna1, 1Division of Rheumatology, University of Michigan, Ann Arbor, United States; 2Rheumatology Clinic, So Cyril and Methodius Faculty of Medicine, Skopje, Macedonia, The Former Yugoslav Republic of; 3Information Technology, University of Michigan, Ann Arbor, United States

Background: Patient reported outcome measures (PROMs) are accepted modalities of gathering patient-reported health status such as physical, mental and social well-being. In addition to research applications, in some countries such as the United States, some of these measures are being considered as metrics for quality of care. The advent and wide spread use of the electronic medical record (EMR) in the United States has enabled providers (and patients) to collect PROMs electronically via patient portals (1). At the University of Michigan, the patient medical record is maintained by MiChart- an EPIC® software which interfaces with the Patient Reported Outcomes Measures System – PROMIS (2) - an NIH funded project for development of assessment tools for collecting and analyzing patient health status. Our initial effort focused on integrating the PROMIS questionnaires into the patient EMR for two domains: Adult Physical Function and Pain Intensity Scores into patient portals (electronic patient-physician communication tool), thus enabling patient to complete questionnaires from home computers. Our collection rate of completed PROMs questionnaires via patient portals was about 5-10%.

Objectives: The aim of our project was to examine/enhance collection rate of PROMs with the utilization of portable devices/tablet based PROMs at the time of check-in the clinic by the patient.
Epidemiology, risk factors for disease or disease progression

**AB1116 PREVALENCE OF POLIAUTOIMMUNITY AND FAMILY AUTOIMMUNITY IN MEXICO**

A. Arellano-Martinez, V. Gonzalez-Diaz, S. Cerpa-Cruz, S. Gutierrez-Ureña, J. Reyes-Rueda, K. Garces-Vela, G.E. Martinez-Bonilla, Rheumatology Service, Hospital Civil Fray Antonio Alcalde, Guadalajara, Mexico

**Background:** Autoimmune diseases share pathophysiological mechanisms, genetic factors and certain environmental triggers. Its frequency is reported up to 24% in the United States for the 10 most frequent autoimmune diseases. Familial autoimmune diseases account for 30% to 50% of cases of autoimmune diseases. It is unknown in our population.

**Objectives:** To identify the prevalence of polyautoimmunity and family autoimmunity in a Rheumatology Service of a third level hospital in Mexico.

**Methods:** Observational, descriptive, cross-sectional study. Consecutive outpatients who attended the Rheumatology Service of the Hospital Civil de Guadalajara “Fray Antonio Alcalde” during the 2 months were entered in a questionnaire to obtain demographic data, autoimmunity and risk factors. Descriptive statistical analysis was done.

**Results:** Of 1,208 patients, 484 (40%) had autoimmunity, of these 58 (12%) had polyautoimmunity and 6 (1%) with Multiple Autoimmune Syndrome (MAS). In the Mas group of 35 autoimmune diseases registered were: RA 42%; SLE 17%; AS 6%; SSc 5%; SS 4%; PsA 3%; JIA 3%; autoimmune hypothyroidism 3%; APS 2%; Dermatomyositis 2% and Psoriasis 1%. In the group with polyautoimmunity SLE was present in 26 (45%) patients, SS in 13 (22%) and autoimmune thyroid disease in 14 (24%). In the MAS group autoimmune thyroid disease in 5 patients. Patients with polyautoimmunity developed first: SLE (14%) and RA (14%). In the patient with MAS autoimmune thyroid disease in 33%. Of the 58 patients with polyautoimmunity 31 (53%) have familial autoimmunity, of which SLE is the most frequent in (22%), followed by autoimmune thyroid disease (17%) and RA (10%). All 6 MAS patients had familial autoimmunity. Referent to risk factors: 154/484 reported active smoking. Of the 58 patients with polyautoimmunity, only 23 (40%) had or are current smokers. Of the 6 patients with MAS 50% presented this risk factor:158/484 (33%) patients had periodontal disease. In patients with autoimmune disease 54% were overweight (28%) or obese (26%). Of the 58 patients with polyautoimmunity 48% were overweight and 21% obese; of patients with MAS 50% were overweight or obese. Only one patient had ASIA syndrome with GCA diagnosed.

**Conclusions:** The search of polyautoimmunity is required in all patients with autoimmune disease and convenient to consider that these patients will have a higher frequency for familial autoimmunity. Smoking and periodontal disease are widely known risk factors that are not taken seriously by patients.

**AB1117 LATENT TUBERCULOSIS INFECTION AND TUBERCULOSIS IN PATIENTS WITH RHEUMATIC DISEASES UNDER TREATMENT WITH ANTI-TUMOR NECROSIS FACTOR DRUGS**

A.L.B. Morsch 1, G. Garziera 2, F. Otsesikwe 3, F.L. Staub 4, P.E. Malinoskins 1, C.V. Brenol 3, D.R. Silva 1,2,4, 1 Servico de Reumatologia; 2 Programa de Pós-Graduação em Ciências Pneumológicas; Hospital de Clínicas de Porto Alegre; 3 Faculdade de Medicina, Universidade Federal do Rio Grande do Sul; 4 Servicio de Pneumologia, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil

**Background:** The introduction of biological agents, especially the tumor necrosis factor inhibitors (anti-TNF) for the treatment of rheumatic diseases increased the risk of developing tuberculosis (TB). Screening for latent TB infection (LTBI) is strongly recommended before starting therapy with anti-TNF agents.

**Objectives:** This study aimed to identify the prevalence of LTBI and TB among patients with rheumatic diseases on anti-TNF drugs.

**Methods:** In a cross-sectional study, the electronic medical records of all adult patients (>18 years old) undergoing anti-TNF treatment at Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil, were reviewed. Every patient underwent Tuberculin Skin Test (TST) before starting anti-TNF therapy.

**Results:** In total, 176 patients were included. The mean age was 51.9±12.4 years, 34.7% were males, and 90.9% were white. The underlying diseases were rheumatoid arthritis (RA) in 50.6% (N=89), ankylosing spondylitis (AS) in 27.8% (N=49) and psoriatic arthritis (PsA) in 17.6% (N=31). Anti-TNF agents started after TST were: infliximab (22.7%, N=40), adalimumab (48.9%, N=86), etanercept (23.7%, N=43), and golimumab (1.1%, N=2). The prevalence of positive TST was 29.5%. Household contact with TB was significantly associated with a positive TST (p<0.02). RA patients had lower TST reactions than AS patients (p=0.022).

There were six cases of TB (3.4%) diagnosed during anti-TNF therapy.

**Conclusions:** We demonstrated a high prevalence of positive TST (29.5%) among patients with rheumatic diseases in a region with high TB prevalence. Our data corroborates the ACR's recommendation that patients who live in high risk TB incidence settings should be tested annually for LTBI.

**AB1118 REVIEW OF METHODS FOR ASSESSING THE RELATIONSHIP BETWEEN WEATHER AND CHRONIC MUSCULOSKELETAL PAIN**

A. Beukenhorst 1, J. McBeth 1, D. Schultz 2, J. Sergeant 2, W.G. Dixon 2

1 Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, 2 Centre for Atmospheric Science, School of Earth and Environmental Sciences, University of Manchester; 3 NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom

**Background:** People with chronic pain commonly believe that their pain is affected by the weather. Despite a century’s worth of research, there is no scientific consensus on the existence of a relationship between weather and chronic pain.

**Objectives:** A systematic literature review to (1) gain an overview of existing research on the weather-pain relationship, and (2) summarise the methodologies, methodological rigour and risk of bias in published studies of patients with musculoskeletal conditions.
Methods: Systematic search strategies were developed for 5 databases (Medline, Embase, Psycinfo, Scopus, Web of Science) to retrieve studies that investigated the relationship between weather conditions and chronic pain. Original articles describing observational studies that related chronic pain (primary outcome) to weather conditions (exposure), were included. Study characteristics, methodology (e.g., sample size, and weather variables) aspects of statistical analysis, and data on risk of bias (validation of participants’ exposure and diagnosis, coverage of weather variation, correction for confounders) was extracted. Methodological rigour was summarised by mapping the methodological variability among studies and ranking these from least to most rigorous.

Results: The search yielded 16,081 articles. After removing 3090 duplicates and excluding 12726 articles during title screening, 265 abstracts were assessed for eligibility. Of 64 observational studies that met the inclusion criteria, 30 (47%) investigated pain associated with musculoskeletal conditions, 24 (38%) investigated headache and 10 (16%) investigated pain associated with other conditions such as sickle cell disease and dental pain. After full text assessment, 10 of 30 papers on musculoskeletal conditions were excluded because they investigated risk of acute pain episodes rather than chronic pain symptoms (n=6), or investigated multiple conditions (n=4). The 20 included studies investigated rheumatoid arthritis (6, 30%), osteoarthritis (6, 30%), fibromyalgia (6, 30%) and low back pain (2, 10%). A total of 15 studies (75%) reported some effect of weather on chronic pain, and this was clinically significant (consistent and sufficient size of effect) in 6. Participant numbers varied from 19 to 2491. 1 study was cross-sectional and 19 longitudinal follow ups ranging from 1 week to 3.5 years, with participants scoring their pain daily or weekly for 1 to 12 months. Pain was measured with a Visual Analog Scale or Numerical Rating Scale in 17 (85%). Weather conditions were retrieved from local weather stations, with most studies assuming that participants stayed in the area/city (65%) or postcode area (20%) where they lived.

In 12 (60%) studies, participants were blinded to the study hypothesis. Methods for correcting for confounders were highly variable, with 7 studies not addressing any, and the remaining addressing one or more of 32 confounding variables.

Conclusions: Methodological variability of studies investigating the relationship between weather and chronic musculoskeletal pain is high. This methodological review will inform best research practice for those investigating the relationship between the weather and chronic pain.

AB1119 A DESCRIPTIVE STUDY OF GOUT PATIENTS IN A MULTI-ETHNIC SOCIETY

C. Chua1, P. Cheung2, A. Santosa2, A. Lim2, G.G. Teng1, 1Internal Medicine Residency; 2Division of Rheumatology, University Medicine Cluster, National University Health System, Singapore, Singapore

Background: Gout is a common inflammatory arthritis with rising global prevalence and health burden, especially in the Asia-pacific regions. Ethnicity may play a significant role suggesting lifestyle and/or genetic predisposition, but such data are limited in Asia-pacific region.

Objectives: Our study sought to assess the demographic and clinical factors of gout in the multi-ethnic Singapore and describe the burden and treatment pattern in our patients.

Methods: 282 adults with rheumatologist-diagnosed gout were recruited from rheumatology clinics of an academic medical centre in Singapore. Data on demographic and lifestyle features, medical conditions, gout severity and treatment were obtained.

Results: 282 subjects were recruited and 92.6% were men. There were 77% Chinese, 18.6% Malays and 2.5% Indians, compared to Singapore’s population median of 73%, 13% and 9% respectively. Mean age at recruitment was 52.6 years (SD 16.1) while age at gout onset was 42.5 years (SD 16.7). 34.4% received primary or no education; 67.0% were employed and 20.7% retired. 22.7% were current alcohol drinkers while 50.7% were teetotallers. 23.4% were current smokers. Mean body mass index (BMI) was 28.1±6.0kg/m2 while 69.9% had BMI ≥30kg/m2. Prevalence of hypertension was 56.7%, diabetes mellitus 18.8%, dyslipidemia 48.2% and chronic kidney disease (CKD, defined as glomerular filtration rate <60ml/min/1.73m2) 32.4%. Malays had significantly less alcohol intake (1.9%) but higher proportions of diabetes (32.1%), CKD (50.9%) and obesity (52.4%), compared with Chinese subjects (26.3%, 16.1%, 28.6% and 19.8% respectively, all P<0.05). Gout severity was rated moderate by 30.9% and severe in 50.4%; 69.3% suffered ≥3 attacks in 6 months. Mean SU was 477.8μmol/L (SD 130.8). 80.1% were on allopurinol. Subjects (32.3%) who achieved serum urate (SU) <360μmol/L, when compared to those with SU >360μmol/L, were more likely to be on urate lowering therapy (82.5% vs. 60.7%, P=0.001), on higher mean allopurinol dose [337 mg/d (SD 166) vs 233 mg/d (SD 140), P<0.001] and statin [54.8% vs 33.3%, P=0.003]. There were no significant differences among ethnicities for SU levels, gout severity and number of attacks.

Conclusions: Gout has substantial health burden in Singapore. Hypertension, dyslipidemia and obesity are more prevalent in our gout subjects compared to our population. Despite notably less alcohol intake compared with other cohorts4,5, Singapore Malays seemed to suffer higher prevalence and comorbidities of gout.

Majority of patients had moderate to severe disease but less than 25% achieved target SU levels highlighting suboptimal management of gout locally.

AB1120 COMPARISON OF NON-RADIOGRAPHIC SPONDYLOARTHRITIS VERSUS ANKYLOSING SPONDYLITIS PATIENTS UNDERGOING BIOLOGICAL THERAPY

C. Cobilinschi, D. Opris-Belinski, R. Ionescu, Stanta Maria Clinical Hospital, Bucharest, Romania

Background: Axial spondyloarthritis include non-radiographic spondyloarthritis (nr-SPA) and ankylosing spondylitis (AS); they reveal the extent of sacroiliitis assessed by conventional x-ray or MRI (1). The natural history of nr-SPA follows various evolution patterns; smoking, male gender, high levels of inflammatory markers, initial radiographic lesions are among predictor factors of progression to AS (2).

Objectives: The objective of the present study was to compare features related to progression of nr-SPA patients versus AS patients undergoing biological therapy with an anti-TNF agent.

Methods: This was an observational, cross-sectional study including 94 patients with nr-SPA and AS under continuous anti-TNF therapy for at least six months. SPSS 20.0 was used to analyze data with a P value of 0.05.

Results: Out of the selected study group, 69 patients were diagnosed with AS having a mean age of 44.8±10.8, while 25 patients had nr-SPA. Patients with nr-SPA were aged 32.1±6.6 years old and 40% of them were women, a rate significantly than in the AS group (P=0.05). Mean age at disease onset was 30.7 years for the AS subgroup versus only 23.8 years for patients with nr-SPA (P=0.001). AS patients presented a significantly higher value of the BMI compared to nr-SPA (27 versus 24.7 kg/m², P<0.001). 91% of patients had positive HLA B27 and 7.4% had a positive family history of SpA, with no significant differences between the two subgroups. A higher level of CRP was noticed in AS patients (P=0.038).In the study cohort the time interval from symptom onset to establishing a diagnosis was of 39±55.6 months, with a mean delay interval of 2.32 years for patients with nr-SPA and higher, of 3.5 for patients with AS (P<0.01).

Conclusions: The nr-SPA group had a considerably higher percentage of females compared to the AS subgroup. AS patients presented higher values of CRP at follow-up visits as opposed to nr-SPA patients. There were no significant differences between nr-SPA and AS patients regarding BASDAI or PIGA scores, smoking status or frequency of uvette. The presence of HLA B27 did not differ between the two subgroups, thus it might not be a reliable predictive factor of progression.

AB1121 TRABECULAR BONE SCORE COMBINED WITH CLINICAL RISK FACTORS CAN PREDICT INCIDENT FRACTURE IN RHEUMATOID ARTHRITIS PATIENTS

D. Kim1, S.-K. Cho 1, H.-R. Park1, Y.Y. Choi2, Y.-K. Sung1, 1Rheumatology, Hanyang University Hospital for Rheumatic Diseases; 2Nuclear medicine, Hanyang University Hospital, Seoul, Korea, Republic Of

Background: Fracture is one of the most common and important comorbidities associated with rheumatoid arthritis (RA) patients, especially patients who use glucocorticoids (GC). However, bone mineral density (BMD) by dual-energy x-ray absorptiometry (DXA) which is the gold standard of diagnosing and monitoring osteoporosis is not a useful tool for predicting new fracture in RA patients. Previous studies suggested the possibility of trabecular bone score (TBS) as a useful predictor for incident fractures.

Objectives: We aimed to evaluate the accuracy of TBS combined with clinical risk factors or BMD for prediction of new fracture in patients with RA.

Methods: A total of 100 female RA patients were enrolled with assessment of TBS, BMD, and clinical risk factors for fracture. During follow-up period, we...
AB1122 ALL-CAUSE OF HOSPITAL MORTALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND LUPUS ERYTHEMATOSUS IN A UNIVERSITY HOSPITAL DURING 1998 TO 2014

D. Vega-Morales, J.A. Esquivel Valerio, A.C. Arana-Guajardo. Rheumatology Service, Hospital Universitario Dr. José Eleuterio González, Monterrey, Mexico

Background: All-cause and cause-specific mortality is increased in patients with systemic lupus erythematosus (SLE) and Rheumatoid Arthritis (RA) when compared to the general population. Mortality can be attributed to the disease per se, side effects of drugs and effect of comorbidities. The survival of patients has improved over the past years when compared to historical controls.

Objectives: The objective is to describe all-case of mortality in patients with SLE and RA in a university hospital.

Methods: This is an observational, descriptive, and cross-sectional study. We included all patients with SLE and RA hospitalized during 1998 to 2014. The cause of death was obtained from medical records and classified according to International Classification of Diseases (ICD)-10. We made a descriptive analysis of all-causes of mortality in both diseases.

Results: We analyzed 1,330 medical records, of which 215 died in hospital. The respiratory insufficiency was the most common mortality diagnosis in both diseases (RA 29%, SLE 24.1%), followed by sepsis (RA 25%, SLE 20.4%). The all-cause mortality of SLE and RA are shown in Table 1. Of the 467 RA hospital admissions, the 5.1% died, and of the 863 SLE hospital admissions, the 22.1% died.

RA: Rheumatoid arthritis, SLE: Systemic Lupus Erythematosus.

Conclusions: Advances in the diagnosis and treatment of SLE and RA, have decreased the morbidity and mortality of the two diseases. Infectious and cardiovascular pathologies were the most frequent causes of death.

AB1123 POOR ASSESSMENT OF RISK OF OSTEOPOROSIS AFTER A FOREARM FRACTURE IN WOMEN: A HEALTH INSURANCE DATABASE STUDY IN THE LOIRE VALLEY REGION (FRANCE)

E. Cattelain-Lopez1,2, D. Chu Moow Lin1, P. Goupille1,2, A. Happe3, E. Lespesailles4, F. Jacquot2, P. Tavauroen2, E. Ruch5,6, E. Oger2, D. Mulleman1,2,3, Rheumatology, Université François Rabelais de Tours;
2Rheumatology, CHRU de Tours, Tours; 3Pharmaco-epidemiology, Université de Rennes 1, Rennes; 4Rheumatology, CHR d’Orléans, Orléans; 5Health Economy, Université François Rabelais de Tours; 6Health Economy, CHRU de Tours, Tours, France

Background: Bone Mineral density (BMD) assessment is a useful tool to evaluate bone fragility and is largely recommended in patients at risk of osteoporosis. We have previously reported in 250 women aged 50-year-old or more that only 10% of them had a BMD assessment after a forearm fracture.

Objectives: Herein, we evaluated BMD assessment and prescription of anti-osteoporotic drugs after a forearm fracture in women after 50-year-old in a large population database.

Methods: We identified all forearm fractures in women aged 50 years old or more in the “Centre-Val de Loire, France” area between 01/01/2011 and 31/12/2012, using the National Health Insurance database which cover both private and public sectors of the whole population. We analyzed the reimbursement and determinants of BMD assessment such as age, consumption of drugs inducing osteoporosis, anti-osteoporotics drugs and long term illness.

Results: We identified 414 patients with a forearm fracture during the study period. Among them, 546 (13.25%) had a BMD assessment performed at a median time of 4 months after the fracture. Women who had had a BMD were significantly younger than those who had not (67.44 years versus 74.63 years: OR: 0.941 CI95% (0.902–0.98)). Anti-osteoporotic treatment was positively associated with BMD assessment (OR: 3.233 (CI95%; 1.976–5.290)) while corticosterone was not (OR: 0.866 (CI95%; 0.601–1.247)). Among the women who had a BMD assessment, 168/546 (30.77%) had an anti-osteoporotic drug initiated after the forearm fracture, versus 231/3574 (6.46%) in those who had no BMD performed (Fisher test p.<0.05).

Conclusion: In this large population database, more than 15% of women over 50 year-old have a BMD assessment after a forearm fracture. BMD assessment was associated with anti-osteoporotic drugs initiation.

AB1124 EFFECT OF SARCOPENIA, SUBCUTANEOUS ADIPOSE TISSUE AND ABDOMINAL VISCERAL FAT ON MORTALITY RISK OF COMMUNITY-DEWLLING OLDER ADULTS: A POPULATION-BASED PROSPECTIVE COHORT STUDY IN BRAZIL

F.M. Santana, D. Domiciano, M. Gonçalves, L.G. Machado, C.P. Figueiredo, J.B. Lopes, V. Caparbo, L. Takayama, R.M.R. Pereira. Department of Rheumatology, University of São Paulo, São Paulo, Brazil

Background: Body composition changes resulting from ageing (decreased muscle mass and increased fat tissue) are frequently not accompanied by bone fragility and is largely recommended in patients at risk of osteoporosis. We sought to investigate the relationship between body composition and risk of all-cause of mortality among community-dwelling older adults in Brazil.

Objectives: The current study was designed to describe the association between body composition (skeletal muscle mass, subcutaneous fat mass, visceral fat mass) and all-cause of mortality risk in a large population-based prospective cohort study in Brazil.

Methods: In a large population-based prospective cohort study in Brazil, we identified 839 community-dwelling subjects (516 women, 323 men), ≥65 years, who were assessed by questionnaire on clinical data, laboratory exams and body composition (DXA) at the baseline and followed for 4 years. The mortality was recorded during 4 year-follow-up. Multivariate logistic regression analysis was used to compute odds ratios for all-cause and cardiovascular mortality.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.33982
Results: Over a mean 4.06±1.07 years of follow-up, there were 132 (15.7%) deaths. In men, after adjustment for age, BMI, smoking, physical activity, alcohol, diabetes, dyslipidemia, cardiovascular event, recurrent falls, 25(OH)D and PTH, the presence of sarcopenia (OR 11.36, 95% CI: 2.11–61.83, p<0.004) and visceral fat mass (OR 1.99 95% CI: 1.38–2.87, p<0.001, for each 100g-increase) significantly increased cardiovascular mortality risk while FMI was associated with decreased mortality risk (OR 0.48, 95% CI: 0.33–0.71, p<0.001). Similar results were observed for cardiovascular mortality in men: sarcopenia (OR 14.84, 95% CI: 5.15–47.72, p<0.001), visceral fat mass (OR 1.66, 95% CI: 1.31–2.10, p<0.001) and FMI (OR 0.57, 95% CI: 0.43–0.76, p<0.001). In women, only sarcopenia was a predictor for cardiovascular mortality risk, while FMI was associated with cardiovascular mortality (OR 74.54, 95% CI: 9.72–571.46, p<0.001).

Conclusions: Sarcopenia and fat distribution are associated with all cause and cardiovascular mortality risk in elderly, and they are different according to sex. Visceral fat and subcutaneous fat have opposite roles on mortality risk in elderly men, and this is distinct from what is observed in young adults. These findings point to the risk of encouraging weight loss in the elderly aiming young adult goals. Furthermore, DXA seems to be a promising tool for evaluation risk of mortality in elderly, since it is easily applicable in clinical practice.

AB1125 PREDICTION OF CHRONIC DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS BY USING MACHINE-LEARNING MODELS
F. Ceccarelli 1, M. Sciardone 2, C. Perricone 1, G. Galvan 1, F. Morelli 2, L.N. Vicente 3, I. Lecce 1, L. Massaro 1, E. Cipriano 1, F.R. Spinelli 1, C. Alessandri 1, G. Valesini 1, F. Conti 1, “Lupus Clinic, Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Roma; 2Dipartimento di Ingegneria dell’Informazione, Università di Firenze, Firenze, Italy; 3Dipartmento di Matematica, Universidade de Coimbra, Coimbra, Portugal

Background: The increased survival in Systemic Lupus Erythematosus (SLE) patients implies the development of chronic damage, occurring in up to 50% of cases after a follow-up of 10 years. Its prevention is a major goal in the SLE management. During the last years, it has been suggested that Artificial Neural Networks (ANNs) could be a useful prediction tool in medical scenarios, by using patients’ data as inputs and the specific outcomes as outputs. The International Conference on Advanced Computing and Communication Systems in 2015 underlined the possible application of sophisticated data analysis tools, such as machine learning methods, in SLE patients, in the light of their potential application to diagnostic and prediction purposes.

Objectives: In the present study, we aimed at predicting chronic damage in a large monocentric SLE cohort by using neural networks.

Methods: For the present analysis, we used data from 413 SLE patients (1997 ACR criteria; M/F 20:393; mean age ± SD 48±11.9 years; mean disease duration ± SD 174±112.4 months; mean follow-up period ± SD 63±30.7 months). At each visit, the patients underwent a complete physical examination and clinical and laboratory data were collected in a standardized, computerized, and electronically filled form. All the patients were evaluated at least twice per year. Autoantibodies and complement serum levels were also registered. Chronic damage was assessed by the SLICC/ACR Damage Index (SDI). We applied Recurrent Neural Networks (RNNs) as a machine-learning model to predict the risk of chronic damage. The clinical data sequences registered for each patient during the follow-up were used for building and testing the RNNs. We used 27 clinical and laboratory items as inputs for the mathematical model.

Results: At the first visit, 35.8% of patients had an SDI>0, with a mean±SD value of 1.7±1.1. For the RNN model, two groups of patients were analyzed: patients with SDI=0 at the baseline, developing damage during the follow-up (N=38), and patients without damage (SDI=0), in whom no damage occurred. We used all the visits before the development of damage, and in the second group, we considered patients with at least 5 visits and a follow-up of 2 years. We created a mathematical model with an AUC value of 0.77, able to predict damage development. A threshold value of 0.35 (sensitivity 0.74, specificity 0.76) seems able to identify patients at risk to develop damage.

Conclusions: We applied RNNs to identify a prediction model for SLE chronic damage. By using longitudinal data, including laboratory and clinical items, we created a mathematical model able to identify patients at higher risk to develop chronic damage.

AB1127 HEALTH LOCUS OF CONTROL IN SYSTEMIC LUPUS ERYTHEMATOSUS – A CROSS-SECTIONAL ANALYSIS OF THE LULA-COHORT IN GERMANY 2013
G. Chehab 1, J.G. Richter 1, R. Brinks 2, E. Zoico 3, F. Fischer-Betz 1, B. Winkler-Rohlfing 1, M. Schneider 1, 1 Policlinic of Rheumatology and Hiller Research Unit Rheumatology, Medical Faculty, Heinrich-Heine-University, Duesseldorf; 2German Lupus Self-Help Community, Wuppertal, Germany

Background: Health Locus of Control (HLC) is the degree to which individuals believe that their health is controlled by internal (self-responsibility) or external (fate-luck) factors. This condition might affect different disease aspects, especially in chronic diseases.

Objectives: Our objective was to assess the influence of HLC on different disease aspects in a representative sample of German systemic lupus erythematosus (SLE) patients.

Methods: The LuLa-Study is a longitudinal study on a multitude of SLE associated factors that is being conducted annually by means of a self-reported questionnaire among members of the German LE self-help community since 2001 and is ongoing. Inclusion criteria are a diagnosis of SLE and returning the self-reported paper questionnaire by the LE via the internet. The questionnaire takes place in several normal cellular processes, including introducing the failure of the plant cell wall, degradation processes in the cytoplasm, and the vital role of autophagy, and is being conducted annually by means of a self-reported paper questionnaire by the LE via the internet. The questionnaire takes place in several normal cellular processes, including introducing the failure of the plant cell wall, degradation processes in the cytoplasm, and the vital role of autophagy.

Results: There were 50 patients in the sub-group with ACPA positivity and RF negativity, 5 of them were smokers (39%, n=13). There were 97 patients in the sub-group with ACPA negativity and RF positivity, 28 of them were smokers (29%, n=97). There were 130 patients in the sub-group with ACPA negativity and RF negativity, 28 of them were smokers (21%, n=130). The highest prevalence of smokers was in the sub-group of patients with ACPA and RF positive rheumatoid arthritis (39%) and ACPA positive and RF negative rheumatoid arthritis (38%). The prevalence of smokers in ACPA negative sub-groups of patients with rheumatoid arthritis is significantly lower.

Conclusions: We confirmed that prevalence of smokers is significantly higher in the sub-group of patients with ACPA positive rheumatoid arthritis than in the sub-group with ACPA negative rheumatoid arthritis. Quitting smoking is highly recommended especially to these patients in order to achieve a favorable effect on the course of the disease.

AB1128 CITRULLINATION OF PROTEINS, SMOKING AND RHEUMATOID ARTHRITIS
G. Belakova 1, V. Manka 1, P. Racyz 2, E. Zanova 3, 1MEDMAN s.r.o.; 2Biochemistry Department/Comenius University, Martin; 3Department of Rheumatology, Piestany, Slovakia

Background: Rheumatoid arthritis (RA) is an inflammatory disease characterized by chronic synovitis and erosive destruction of articular cartilage and bone ultimately leading to joint deformities, disability, loss of quality of life and work loss. There are multiple risk factors, both environmental and genetic, that may predispose an individual to RA. Cigarette smoking is the most important risk factor. Citrulline contained within proteins is created post-translationally by the action of the enzyme peptidyl arginine deiminase on the aminoacid arginine. Citrullination takes place in several normal cellular processes, including introducing the failure of the plant cell wall, degradation processes in the cytoplasm, and the vital role of autophagy, and is being conducted annually by means of a self-reported paper questionnaire by the LE via the internet. The questionnaire takes place in several normal cellular processes, including introducing the failure of the plant cell wall, degradation processes in the cytoplasm, and the vital role of autophagy.
Results: Patients with a high internal health locus of control (HLCint 13.1 vs. 9.1) had less pain (numeric rating scale 0–10), less flares, a better mental and physical health related quality of life, lower disease activity and less fatigue. Patients with a high internal ‘doctor’-related health locus of control (HLCdoc 10.7 vs. 7.2) were older, had more co-morbidities, more disease damage and received more frequently an immunomodulatory therapy. No significant differences were found between the patients with a high external ‘doctor’-related HLC compared to the lower scoring patients (HLCcha 11.1 vs. 6.3). Participants with a high external ‘doctor’-related HLC had a more threatening view on their illness and a better adherence to medication (high adherence in 78.6% vs. 59.4%). Participants with a high internal HLC perceived their disease significantly less threatening. Higher education levels (school education, further education) went along with a decrease of external ‘doctor’-related HLC (HLCdoc).

Conclusions: Health locus of control has a significant impact in patients with SLE. The different disease characteristics, treatments, levels of medication adherence and illness perception were noticed. Holistic care needs to consider the impact different HLCs may have. The direction of causality cannot be proved beyond reasonable doubt in this cross-sectional analysis. Hence additional longitudinal studies are necessary.

**AB1128 HELICOBACTER PYLORI IN SYSTEMIC LUPUS ERYTHEMATOSUS AS ITS ASSOCIATION WITH ENDOCOPIC AND HISTOPATHOLOGICAL FINDINGS**

I. Arroyo Prado1, J.A. Velarde Ruiz Velasco2, C.E. Gomez Lopez1, S. Gutierrez Ureña1, G. Martinez Bonilla1, V. Gonzalez Diaz1, J.I. Espejo Pasencia1, S. Cerpa Cruz1, 2 Rheumatology. 3 Gastroenterology. 4 Pathology. Fray Antonio Alcalde Hospital, Guadalajara, jalisco, Mexico

Background: Helicobacter pylori (Hp) is a Gram-negative bacteria and cause of most of the chronic gastric infections and its prevalence is above 50% worldwide. This infection is a well-known risk factor to gastric MALT lymphoma but also could be the trigger of several autoimmune diseases such as immune thrombocytopenic purpura and systemic lupus erythematosus

Objectives: To determine the frequency of H pylori in systemic lupus erythematosus patients (SLE).

Methods: A cross-sectional study was done in patients who fulfilled the 2012 SLICC criteria for SLE and were willing to sign the informed consent to be subjected to endoscopic procedure. The sample size was analyzed by pathologist. We used mean and standard deviation to describe the data, to compare both groups Student t test was done and for continuous variables we used chi-square; the correlation analysis was performed with Spearman correlation. The frequency of Hp infection was determined by histopathological evaluation of the endoscopic samples.

Results: Twenty two SLE patients were included and we chose a control group from database of endoscopic clinic with diagnosis of functional dyspepsia. The age range was 21–78 years and 14/22 were female. Two patients were excluded due to Hp infection and the control group was 12/20. We performed 27 endoscopic biopsies in SLE patients and 9 in control group. We found a high frequency of H pylori infection in patients with SLE. Metaplasic and dysplastic changes were also more prevalent in the SLE group. Our data support that Hp infection took place in early stages of disease.

Conclusions: Hp is an immune reactive agent in patients with SLE. It may play a role in SLE pathogenesis. Further research is needed to determine the real role of Hp in SLE.

**AB1130 RELAPSE RISK ASSESSMENT IN YOUNG APS PATIENTS WITH AN AUTOIMMUNE DISEASE: AN EXPLORATORY STUDY TO DETERMINE THE PREVALENCE OF SLE IN A YOUNG POPULATION**

I. Arroyo Prado1, J.A. Velarde Ruiz Velasco2, C.E. Gomez Lopez1, S. Gutierrez Ureña1, G. Martinez Bonilla1, V. Gonzalez Diaz1, J.I. Espejo Pasencia1, S. Cerpa Cruz1, 2 Rheumatology. 3 Gastroenterology. 4 Pathology. Fray Antonio Alcalde Hospital, Guadalajara, jalisco, Mexico

Background: Seropositive Antiphospholipid Syndrome (APS) is crucial in young adults (less than 50 years old) [1]. Young adults affected by APS are at increased risk of thrombotic events. The most frequent manifestation of arterial thrombosis in patients affected by APS is ischaemic stroke, especially in young adults (less than 50 years old) [1]. Young adults affected by APS are at increased risk of thrombotic events.

Objective: To determine, through a systematic review and meta-analysis, the prevalence of back pain (BP) and spondylarthritis (SpA) in the adult general population and explore the heterogeneity between studies in and out Latin America (LATAM).

Methods: MEDLINE, Embase, BIREME, LILACS and Web of Science were searched using a strategy combining key words and related database-specific subject terms to identify relevant cross-sectional studies based on COPCORD methodology published since 2006. Included articles were assessed for risk of bias and quality based on the STROBE statement. Prevalence figures for BP and SpA (European Spondyloarthropathy Study Group criteria) were analyzed according to female percentage of sampled individuals, mean age and sample size. A mixed effect model was used to obtain the combined prevalence and a meta-regression to estimate the effects of these variables. Prevalence stratified values were obtained according to its geographical location.

Results: 44 out of 127 papers in English, Spanish or Portuguese were selected. Of them, 16 contained BP or SpA prevalence data. Estimates for any SpA prevalence ranged from 0.1% to 2%, with an average of 0.3% (95% CI: 0.01%–0.05%). The random-effects pooled prevalence was 0.18% (0.06%–0.36%). The prevalence of BP was 6.54% (3.8%–9.2%) with a pooled value of 5.24% (2.6%–8.7%). In both cases the heterogeneity was significant (P<0.01). No effect was associated to SpA heterogeneity, but an increase in the prevalence of BP was associated to sample size (random effect coefficient: 0.045, p=0.04). The stratified analysis did not show differences in terms of heterogeneity or prevalence for BP (Pooled prevalence for BP: 5.4%; 2.9%–8.5%, p=0.9); on the contrary, for SpA, for non-LATAM studies, the pooled proportion was significantly bigger (prevalence in LATAM 0.05%, 0.01%–0.012%; non-LATAM: 0.35%, 0.09%–0.78%, p=0.02).

Conclusions: We found significant variations in prevalence across this review. In particular, they related to sample size of BP studies. Similarly, there was a significant variation between LATAM versus other latitudes respect to the prevalence of SpA. The limited number of studies included in this meta-analysis however, prevents clear explanations of the mechanisms underlying these results.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.3916

**AB1139 A SYSTEMATIC REVIEW ON PREVALENCE OF BACK PAIN AND SPONDYLOARTHRITIS BASED ON COPCORD STUDIES**

J. Moreno-Montoya1, J. Rodriguez-Amado2, R. Burgos-Vargas3, I. Peltz-Ballestas1, 2 Universidade del Bosque, Bogota, Colombia, 3 Research Associate of South Florida, Miami, United States; 2 Rheumatology Unit, Hospital General de Mexico, Mexico, Mexico

Objectives: To determine, through a systematic review and meta-analysis, the prevalence of back pain (BP) and spondylarthritis (SpA) in the adult general population and explore the heterogeneity between studies in and out Latin America (LATAM).

Methods: MEDLINE, Embase, BIREME, LILACS and Web of Science were searched using a strategy combining key words and related database-specific subject terms to identify relevant cross-sectional studies based on COPCORD methodology published since 2006. Included articles were assessed for risk of bias and quality based on the STROBE statement. Prevalence figures for BP and SpA (European Spondyloarthropathy Study Group criteria) were analyzed according to female percentage of sampled individuals, mean age and sample size. A mixed effect model was used to obtain the combined prevalence and a meta-regression to estimate the effects of these variables. Prevalence stratified values were obtained according to its geographical location.

Results: 44 out of 127 papers in English, Spanish or Portuguese were selected. Of them, 16 contained BP or SpA prevalence data. Estimates for any SpA prevalence ranged from 0.1% to 2%, with an average of 0.3% (95% CI: 0.01%–0.05%). The random-effects pooled prevalence was 0.18% (0.06%–0.36%). The prevalence of BP was 6.54% (3.8%–9.2%) with a pooled value of 5.24% (2.6%–8.7%). In both cases the heterogeneity was significant (P<0.01). No effect was associated to SpA heterogeneity, but an increase in the prevalence of BP was associated to sample size (random effect coefficient: 0.045, p=0.04). The stratified analysis did not show differences in terms of heterogeneity or prevalence for BP (Pooled prevalence for BP: 5.4%; 2.9%–8.5%, p=0.9); on the contrary, for SpA, for non-LATAM studies, the pooled proportion was significantly bigger (prevalence in LATAM 0.05%, 0.01%–0.012%; non-LATAM: 0.35%, 0.09%–0.78%, p=0.02).

The limited number of studies included in this meta-analysis however, prevents clear explanations of the mechanisms underlying these results.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.4186
Methods: The analysis included 80 APS patients (≤50 years old) who presented a previous stroke event (patients who experienced cerebral venous sinus thrombosis were not included in the analysis). Clinical and laboratory data were retrospectively collected. Treatment was based on physician’s opinion according to the current guidelines. The aGAPSS was calculated for each patient by adding the points corresponding to the risk factors, based on a linear transformation derived from the β regression coefficient as follows: 3 for hyperlipidaemia, 1 for arterial hypertension, 5 for aCL IgG/IgM, 4 for anti-β2glycoprotein I IgG/IgM and 4 for LA. Relapse was defined as the recurrence of thrombotic event and/or progression of known ischaemic lesions detected with MRI.

Results: Results pointed out that patients with relapse of thrombotic events and/or progression of known ischaemic lesions were 39 out of 80 (48.7%) and patients without relapse were 41 out of 80 (51.3%). Significantly higher aGAPSS values were observed in relapse group when compared to the non-relapse group [mean aGAPSS 9.08 (S.D. 4.7) Vs. mean aGAPSS 7.22 (S.D. 3.3); T test; p=0.05]. Distribution of aGAPSS values among the two groups is illustrated in Graph 1.

Conclusions: Our analysis suggests that aGAPSS could represent an effective tool to stratify the risk of relapse of thrombosis and/or progression of ischaemic lesions in young APS patients with clinical history of stroke. This data could also aid developing different therapeutic approaches, especially for patients at higher risk of relapse.

AB1131 HIGHER RATES OF OBESITY AND ASSOCIATIONS WITH POORER CLINICAL STATUS IN PATIENTS WITH RA, OA AND SLE: A CROSS-SECTIONAL STUDY FROM ROUTINE CARE

I. Castrejon, N. Shakoor, J.A. Block, T. Finchus. Rheumatology, Rush University Medical Center, Chicago, United States

Background: Obesity is a risk factor for many chronic rheumatic diseases. In rheumatoid arthritis (RA), obesity is associated with increased comorbidities, higher medical costs, disease activity, and poorer physical function.1 In OA, obesity is a risk factor for both incidence and progression, and has a negative impact on outcomes2. In systemic lupus erythematosus (SLE), obesity is associated with more severe renal involvement, lower quality of life, and increased cardiovascular risk3.

Objectives: To assess associations of obesity with patient self-report multidimensional health assessment questionnaire (MDHAQ) scores and physician global assessment scores in patients with RA, OA, and SLE seen in routine care.

Methods: All patients at one academic center complete a MDHAQ, which includes a 0–10 scale for physical function (PF), 0–10 visual analogue scales (VAS) for pain (PN) and patient global assessment (PATGL), compiled into a composite score (MDHAQ). Patients complete a VAS for patient global (PATGL). Body Mass Index (BMI) was calculated from the medical record as weight (kg)/ height (meters)2. Patients were classified by BMI as normal (18.5–25), overweight (25–30), or obese (>30) according to the WHO guidelines. Demographic and clinical MDHAQ data were compared in the 3 diagnostic groups according to BMI groups using ANOVA and chi-square tests.

Results: 396 patients with RA, 425 with OA, and 306 with SLE were studied. Obesity was reported by 40% of RA and SLE patients, and 59% of OA patients. More than 10% were higher than matched individuals in the general population in the same region (30.8%). Obesity was higher in African-American patients (48% in RA, 70% in OA, and 53% in SLE). Education level, gender, and age did not differ significantly across the groups. Obesity was associated with poorer physical function, poorer patient global and higher pain in all 3 diagnostic groups, with higher depression scores in OA and SLE (Table). DOCGl was significantly higher only in OA (data not shown).

Table 1. MDHAQ scores and physician global assessment according to BMI groups

Conclusions: Obesity is more prevalent in patients with rheumatic diseases compared with the general population. Obese patients had poorer status on most MDHAQ scores, particularly physical function and pain. Obesity is an important comorbidity in patients with rheumatic diseases.

HIGH CONSUMPTION OF SEAFOODS OR VEGETABLES NEGATIVELY CORRELATES WITH DISEASE ACTIVITY OF RHEUMATOID ARTHRITIS

1Department of Rheumatology and Clinical Immunology, Graduate School of Medicine; 2Department of the Control of Rheumatic Diseases, Graduate School of Medicine; 4Department of Human Health Sciences, Graduate School of Medicine; 5Department of Diabetes, Endocrinology and Nutrition, Graduate School of Medicine, Kyoto University, Kyoto; 6Department of Health and Nutrition, Osaka Shoin Women's University, Osaka; 7Department of Food and Nutrition, Kyoto Women's University, Kyoto, Japan.

Background: Food intake is one of the important environmental factors of various diseases, and possibly influences the pathogenesis of RA. However, we have little knowledge about the impact of food intake on the pathogenesis of RA. Because each country has its own food culture, the study focused on the dietary habit in Japan is essential in order to clarify the clinical impact of food intake in Japanese RA patients.

Objectives: The aim of this study is to clarify the relationship between the dietary habit of RA patients and their disease status.

Methods: We took the questionnaire survey about dietary habit in 2015, in KURAMA (Kyoto University Rheumatoid Arthritis Management Alliance) cohort as an essential dietary status was also examined in this cohort. These data were combined and statistically analyzed.

Results: 563 RA patients were enrolled from KURAMA cohort; female: male 4:1, age 63 years old, disease duration 15.5 years, DAS28-ESR 2.8 on average. Multivariate analysis showed that the intake frequency of vegetables had statistically significant negative correlation with DAS28-ESR (β=-0.17, p<0.01), SDAI (β=-0.15, p<0.01) and MMP-3 (β=-0.13, p<0.01). The intake frequency of frozen foods had positive correlation with MMP-3 (β=0.12, p<0.01). The intake frequency of juice had positive correlation with DAS28-ESR (β=0.11, p<0.01) and SDAI (β=0.11, p<0.01) and MMP-3 (β=0.11, p<0.01). The "vegetables and fruits", "meat and fried foods", "vegetables and fruits", "meats and processed foods", and "processed foods" were associated with the development of ILD. There are many patients who are not diagnosed as definite connective tissue disease (CTD) patients. These patients may have undifferentiated connective tissue disease (UCTD).

Conclusions: This study implicates that the disease activity of RA may be alleviated by high consumption of vegetables and fruits, or seafoods. Disclosure of Interest: None declared

CHARACTERISTICS OF AUTOIMMUNE FEATURED INTERSTITIAL LUNG DISEASE IN KOREAN PATIENTS

J.-H. Kim, J. Jae Hyun, Y.H. Seo, S.J. Choi, G.G. Song. Inmeanal medicine, Korea University Medical center, Seoul, Korea, Republic Of

Background: Interstitial lung disease (ILD) includes a heterogeneous group of disorders that result in diffuse parenchymal lung disease, with overlapping clinical, radiographic, and physiologic manifestations. Several rheumatologic conditions are associated with ILD. Interstitial lung disease is increasingly recognized in many patients who are not diagnosed as definite connective tissue disease (CTD). These patients may have an undifferentiated connective tissue disease (UCTD).

Objectives: The aim of this study was to compare the prevalence and characteristics of patients with CTD-ILD, UCTD-ILD and idiopathic pulmonary fibrosis (IPF) in Korean patients.

Methods: We studied the prevalence and characteristics of patients with connective tissue disease-associated interstitial lung disease (CTD-ILD), undifferentiated connective tissue disease-associated interstitial lung disease (UCTD-ILD), or idiopathic pulmonary fibrosis (IPF) between January 2016 and June 2016 in Korea university guro hospital. Clinical characteristics, laboratory tests, and high-resolution CT images were analyzed and compared among three groups.

Results: CTD-ILD was identified in 13.0%, UCTD-ILD in 18.2%, and IPF in 68.7% among 307 patients. Female and younger age patients were dominant in CTD-ILD group. Pulmonary symptoms were more common in IFP, while extra-pulmonary symptoms were more common in CTD-ILD and UCTD-ILD group. Patients with CTD-ILD had more abnormal antibody tests than those of UCTD-ILD and IFP. Usual interstitial pneumonia pattern was dominant in HRCT images among three groups.

Conclusions: CTD-ILD is not able to be diagnosed accurately in ILD patients. A systematic evaluation of extra-pulmonary symptoms and serologic tests in patients with ILD can identify CTD-ILD, UCTD-ILD, and IFP.

AB1135 ALLOPURINOL AND THE RISK OF INCIDENT PERIPHERAL ARTERIAL DISEASE IN THE ELDERLY AMERICANS: A U.S. MEDICARE CLAIMS DATA STUDY

J. Singh, J. Cleveland. University of Alabama at Birmingham, Birmingham, United States

Background: Recently we found that use of allopurinol, the most commonly used xanthine-oxidase inhibitor therapy, was associated with a reduction of the risk of myocardial infarction and stroke, acute manifestations of CAD. Given that both PAD and CAD are manifestations of atherosclerosis and a similarity of disease pathophysiology between them, an obvious question was whether allopurinol use would reduce PAD. To our knowledge, no previous studies have examined whether allopurinol use reduces the risk of PAD.

Objectives: To examine whether new allopurinol use is independently associated with a reduction of the risk of incident peripheral arterial disease (PAD) in the U.S. elderly.

Methods: We used the 5% random Medicare sample from 2006–2012 to examine the association of allopurinol use and its duration with risk/hazard of incident PAD, in a retrospective cohort study. Multivariable Cox regression models were adjusted for demographics, comorbidity, cardiac medications and cardiac conditions. Hazard ratios (HR) and 95% confidence intervals (CI) were calculated

Results: A total of 25,282 incident allopurinol use in 3,167 beneficial, of which 3,167 allopurinol use episodes (12%) ended in incident PAD. In multivariable-adjusted analyses, allopurinol use was associated with HR of 0.89 (95% CI, 0.81, 0.95) for incident PAD, as was female gender, 0.84 (95% CI, 0.78, 0.90). In a separate multivariable-adjusted model, compared no allopurinol use, durations of incident allopurinol use were associated support from: HR: PAD; 181 days to 2 years, 0.88 (95% CI, 0.79, 0.97) and >2 years, 0.75 (95% CI, 0.63, 0.89). Other factors significantly associated with a higher hazard of PAD were age 75–85 and >85, female gender, higher Charlson index score, and black race. Sensitivity analyses adjusting for cardiac conditions and medications, confirmed these findings with minimal to no attenuation of hazard ratios.

Conclusions: New allopurinol use was independently associated with a lower risk of PAD in the elderly. Longer allopurinol use durations seemed more protective. Mechanisms of protective effect need to be studied in future studies.

THE AGE OF ONSET OF RHEUMATOID ARTHRITIS CORRELATES WITH AIR POLLUTION AND HEART EXPENDITURE: RESULTS FROM MULTINATIONAL DATABASES

J.D. Castilho-Ortiz1, A. Barajas-Ochoa1, I. Pelayo-Ballestas2, A. Ramirez-Gomez1, F.J. Aceves-Avila1,2,3, J.J. Castaneda-Sanchez1, C. Ramos-Remus1, I. Unidad de Investigacion en Enfermedades Cronico-Degenerativas, Guadalajara; 2Hospital General de Mexico, Ciudad de Mexico; 3Hospital General Regional 46, IMSS; 4Universidad Autonoma de Guadalajara, Guadalajara, Mexico.

Background: Environmental variables contribute up to half of the variation in the rheumatoid arthritis (RA) susceptibility. We have recently reported that the age of RA onset (RAo) varies across latitudes around the world, starting younger around the Tropic of Cancer (1). Latitude gradients have been used as a surrogate for studying the influence of the environment on the risks of disease in order to generate regionalization. The development of the GEO-RA database between January 2016 and June 2016 in 41 countries.

Objectives: This is an exploratory study to assess whether the age of RAo correlates with tropospheric pollutants (2), electromagnetic fields, Inequality-adjusted Human Development Index (I-HDI) and Health Expenditures as per national census of participating countries.

Methods: The age of RAo was obtained from the GEO-RA group database that involves 2,481 patients from 41 countries. Information of the tropospheric pollutant PM10 (particulate matter 10µm), the I-HDI, and Health Expenditures per capita was obtained from the World Health Organization’s reports. The average of each country’s electromagnetic fields (nanotesla, nT) from the past 50 years was calculated using geographic coordinates per country through the magnetic field calculator of The National Centers of Environmental Information. Pearson’s correlation and linear regression were used to evaluate the correlation of these environmental variables with the age of RAo by country.

Results: Complete data sets were available in 35 of the 41 countries. Overall, the mean age of RAo was 44±4.8 years, the annual average of PM10 of 57.5±39.3 (µg/m³), the Health Expenditure per capita of US $22,127±2,742, and the electromagnetic fields of 41,900±8,720 nT. The age of RAo was younger in countries with high PM10 levels (r=-0.81, p<0.01), high inequality (I-HDI, r=0.59, 2010;188(2):143–9.

The role of social determinants on the prevalence of rheumatic diseases in Latin America. A multilevel copcord study

AB1137
THE ROLE OF SOCIAL DETERMINANTS ON THE PREVALENCE OF RHEUMATIC DISEASES IN LATIN AMERICA: A MULTILEVEL COPCORD STUDY

To determine the impact of individual and regional variables on the geographic distribution of RD across six Latin American countries.

Methods: This is a secondary multilevel analysis of the cross-sectional data of COPCORD studies that investigated the prevalence of RD in Argentina, Ecuador, Colombia, Mexico, Peru, and Venezuela. Individual factors were sex, age, comorbidities, job status, and Health Assessment Questionnaire (HAQ) score. Contextual level variables were country and subject's identification as indigenous. RD predictors, including individual and regional variables, particularly indigenous status were identified with logistic regression models. The effect of contextual variables was estimated with median odds ratio’s (OR) estimation.

Results: Most individuals included in this analysis came from urban areas (62.40%); their mean age was 43.12 years (95% CI 43.01–43.35); and 56.0% of COPCORD studies that investigated the prevalence of RD in Argentina, Ecuador, Colombia, Mexico, Peru, and Venezuela. Individual factors were sex, age, comorbidities, job status, and Health Assessment Questionnaire (HAQ) score. Contextual level variables were country and subject's identification as indigenous. RD predictors, including individual and regional variables, particularly indigenous status were identified with logistic regression models. The effect of contextual variables was estimated with median odds ratio’s (OR) estimation.

Results: Most individuals included in this analysis came from urban areas (62.40%); their mean age was 43.12 years (95% CI 43.01–43.35); and 56.0% of COPCORD studies that investigated the prevalence of RD in Argentina, Ecuador, Colombia, Mexico, Peru, and Venezuela. RD predictors, including individual and regional variables, particularly indigenous status were identified with logistic regression models. The effect of contextual variables was estimated with median odds ratio’s (OR) estimation.

Conclusions: The most common diagnosis was arthritis (40% type unspecified, 19% rheumatoid arthritis), followed by fibromyalgia/chronic widespread pain (24%) and ‘other pain diagnosis’ (23%). We identified four clusters of engagement: high (14%), moderate (22%), low (39%) and tourists (25%). Median days of data entry ranged from 1–175 (IQR: 0–175) for the tourist and high engagement clusters, respectively. Those in the high and moderate clusters (n=2249, 35%) engaged on at least 50% of days in the study (high: 79%; moderate: 50%). Highly engaged participants were older (median 56 [47–63]) when compared to those who were low engagers (47 [39–57]) or tourists (49 [40–58]). A lower proportion of tourists were women (76% [95% CI: 74–78]), than in any other cluster (high: 82% [80–85], moderate: 84% [82–86], low: 81% [79–82]).

Conclusions: There are common factors associated to the prevalence of RD in the region, however, the estimation of its impact varies in significant way across countries and related to the fact of belong to an indigenous group indicating an increase in the estimated ORs.

AB1138
ENGAGEMENT IN A UK SMARTPHONE STUDY EXAMINING THE ASSOCIATION BETWEEN WEATHER AND PAIN: PRELIMINARY RESULTS FROM CLOUDY WITH A CHANCE OF PAIN

K. Druce, J. McBeth, S.N. van der Veer, D.A. Selby, B. Wijdenes, K. Georgatzis, A.M. Chowdry, L. Rakhsmimaranayana, D.M. Schultz, C. Sanders, J.C. Sergeant, W.G. Dixon. 1Arthritis Research UK Centre for Epidemiology, University of Manchester; 2NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust, Manchester; 3Department of Statistics, University of Warwick, Coventry; 4Oxford Internet Institute, University of Oxford, Oxford; 5School of Informatics, University of Edinburgh, Edinburgh; 6uMotif, London; 7Centre for Atmospheric Science, School of Earth and Environmental Sciences; 8Medical Sociology, Division of Population Health, Health Services Research and Primary Care, University of Manchester, Manchester, United Kingdom

Background: Smartphones can facilitate collection of temporally-rich self-reported data and have proven to enable large recruitment. However, their viability to support epidemiological research is uncertain due to concerns about selection bias and unsustained engagement.

Objectives: To examine the characteristics and engagement of participants in the first six months of Cloudy with a Chance of Pain, a UK smartphone-based study investigating the link between the weather and chronic pain.

Methods: Between 20th of January and 29th of February 2016, we recruited UK residents 17 years or older with chronic pain (>3 months) who owned a smartphone. Participants received prompts from an app developed by uMotif, which they needed to daily report the severity of ten pain-related symptoms (5) for at least 50% of days in the study (high: 79%; moderate: 50%). Highly engaged participants were older (median 56 [47–63]) when compared to those who were low engagers (47 [39–57]) or tourists (49 [40–58]). A lower proportion of tourists were women (76% [95% CI: 74–78]), than in any other cluster (high: 82% [80–85], moderate: 84% [82–86], low: 81% [79–82]).

Conclusions: Smartphones can facilitate collection of temporally-rich self-reported data and have proven to enable large recruitment. However, their viability to support epidemiological research is uncertain due to concerns about selection bias and unsustained engagement.

Methods: Between 20th of January and 29th of February 2016, we recruited UK residents 17 years or older with chronic pain (>3 months) who owned a smartphone. Participants received prompts from an app developed by uMotif, which they needed to daily report the severity of ten pain-related symptoms (5) for at least 50% of days in the study (high: 79%; moderate: 50%). Highly engaged participants were older (median 56 [47–63]) when compared to those who were low engagers (47 [39–57]) or tourists (49 [40–58]). A lower proportion of tourists were women (76% [95% CI: 74–78]), than in any other cluster (high: 82% [80–85], moderate: 84% [82–86], low: 81% [79–82]).

Conclusions: Cloudy with a Chance of Pain recruited a large sample of people with chronic pain, of whom one in three participants engaged in smartphone-based symptom reporting for at least 50% of days in the first six months. Smartphone studies require quick mass participation with sustained daily data entry, providing unprecedented volumes of daily data. While there may be selection bias towards older females in our study, younger men are also less likely to participate in studies using traditional data collection methods. Our study suggests that smartphones could provide a viable alternative to traditional data collection methods.

AUTOANTIBODY AGAINST COMPLEMENT COMPONENT 1Q SUBCOMPONENT IS ASSOCIATED WITH THE PATHOGENESIS OF RECURRENT PREGNANCY LOSS

AB1139
AUTOANTIBODY AGAINST COMPLEMENT COMPONENT 1Q SUBCOMPONENT IS ASSOCIATED WITH THE PATHOGENESIS OF RECURRENT PREGNANCY LOSS

K. Ohmura, K. Oku, T. Kitaiotai, M. Kono, S. Tanimura, E. Sugawara, R. Hisada, H. Nakamura, G. Shimamura, Y. Fujieda, M. Kato, T. Bohgaki, O. Amengual, S. Yasuda, M. Sugura-Ogasawara, T. Atsumi. 1Division of Rheumatology, Endocrinology and Nephrology, Hokkaido University Graduate School of Medicine, Sapporo; 2Department of Obstetrics and Gynecology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan

Background: In recurrent pregnancy loss (RPL), the pathogenesis of the majority of cases remains to be explained. Antiphospholipid syndrome (APS) is one
of the disorder responsible for causing RPL and its overwhemled complement activation recognized as a major pathogenic mechanism. Autoantibodies against complement component 1q subcomponent (aC1q) have been shown to associate with complement activation in primary APS, but the relevance of aC1q in RPL is still unclear. We hypothesized that aC1q would be associated with the pathogenesis of RPL in patients with or without APS, especially in RPL of unknown etiology.

**Objectives:** The aim of this study was to explore the significance of aC1q in RPL.

**Methods:** As a clinical study, we conducted a retrospective cross-sectional study comprising a total of 134 patients with RPL of unknown etiology. 27 with obstetric APS (OAPS), 14 parous patients with connective tissue disease (CTD) without historical obstetric/thrombotic complications and 17 parous healthy controls (HC). Serum levels of aC1q were measured using a solid-phase ELISA (Buhmann Laboratories AG, Switzerland) and defined as positive using cut-off value of more than 15 U/mL according to the manufacturer. In murine model, 8–12 week-old female BALB/c mice were mated with isolated males and the presence of vaginal plug was defined as day 1 of pregnancy. Mice were treated with intravenous injections of anti-mouse C1q monoclonal antibody (JL-1), isotype control IgG2b or PBS. To block C5a receptor (C5aR), mice were intravenously pre-treated with anti-C5aR antibody, 30 minutes before the injection of JL-1 on day 8. Mice were sacrificed on day 16 of pregnancy and fetal resorption ratios, weight of fetuses and placentas, serum levels of C3a and immunohistochemical staining of complement components on placental tissue were compared among each group.

**Results:** Among RPL, OAPS, CTD and HC, 47 (35%), 8 (30%), 3 (21%) and 2 (12%) were positive for aC1q, respectively. In RPL patients, aC1q was more prevalent (p < 0.05) and its titer was significantly higher than in HC (median and interquartile range [IQR] 12 [8–21] vs. 0 [0–4.3], p < 0.001) (Figure 1). In murine model, fetal resorption ratio was higher (p < 0.01), weight of fetuses and placentas lower (p < 0.05), and serum levels of C3a higher (p < 0.01) in mice treated with JL-1 than in control mice. Immunohistochemical findings showed that complement components were more deposited on plaencta in JL-1 treated mice than in control mice. Furthermore, the additional blockade of C5aR cancelled the pathogenic changes in JL-1 treated mice.

**Conclusions:** Clinical findings showed that aC1q could be relevant to RPL. Moreover, we have established aC1q induced pregnancy loss model mouse. Our study indicates that aC1q has a pathophysiologic role in RPL and that anticomplement therapy might be effective for at least some groups of patients with RPL for whom specific treatment remains to be established.

WHO DISABILITY ASSESSMENT SCHEDULE 2.0 IS RELATED TO UPPER AND LOWER EXTREMITY SPECIFIC QUALITY OF LIFE

K.S. Park, Y.-H. Cheon. Gyeongsang National University, Jinju, Korea, Republic Of

**Background:** Musculoskeletal complaints influence disability, but the relative contribution of concurrent upper and lower extremity health-related quality of life (HRQOL) on patient perceptions of disability is unclear.

**Objectives:** We evaluated whether two disease specific quality of life instruments (DASH and WOMAC) reflect a patient’s perception of general disability using the WHO Disability Assessment Schedule 2.0 (WHODAS 2.0) and determined whether disability components are explained by upper and lower extremity HRQOL.

**Methods:** We recruited 421 randomly chosen participants 50 years or older without stroke, cancer, or history of surgery for musculoskeletal disease who participated in the Namgang Cohort. Upper extremity HRQOL was determined with the DASH score and lower extremity HRQOL with the WOMAC, as a measure of disability to obtain “HRQOL. Multiple regression analysis was used to assess the relative contributions made by upper and lower extremity HRQOL to disability.

**Results:** Most patients reported knee pain (61.0%), shoulder (17.1%), elbow (28.5%) and hand (56.1%). Mean WHODAS 2.0 total score was 28.06 (SD=14.2), corresponding to mild to moderate disability and WOMAC and DASH scores were 23.2 (SD=22.1) and 22.4 (SD=19.3). When adjusted for age, sex, level of education, spouse, self rated health, hypertension, DM and depression, the DASH total score was correlated with the getting around (r=0.137, p=0.032) and social participation (r=-0.226, p<0.001) and the WOMAC total score was correlated with the getting around (r=0.362, p<0.001) and social participation (r=0.289, p<0.001)

**Conclusions:** We found that in a community-based population, perceived activity limitation and social participation were associated with upper and lower extremity HRQOL. Since the WHODAS 2.0 does not target a specific disease (as oppose to the DASH, WOMAC), it can be used to compare disabilities caused by different diseases.

PREVALENCE OF LONG-TERM STEROID THERAPY: FRENCH DATA

L. Couvaras, S. Trijau, G. De Lamotte, V. Pradel, T. Pham, P. Laforgue. APHM, Marseille, France

**Background:** Corticosteroids are widely used for various diseases, from chronic respiratory conditions to auto-immune disorders. However, there are few epidemiological data about long-term steroid therapy in southern Europe (1, 2, 3).

**Objectives:** To describe chronic glucocorticoid prescriptions in a large cohort.

**Methods:** Information was collected from a national public health-insurance database that covers 4.1 million individuals and 83% of the population, in our geographic area of Provence-Alpes-Côte-d’Azur and Corsica, from September 1, 2009 through August 31, 2011. We identified subjects aged of 15 years and over starting glucocorticoid therapy. Chronic glucocorticoid therapy was defined as ≥7.5mg of prednisone equivalent per day during at least 90 days consecutive. We identified the incident cases of long-term glucocorticoid therapy, defined as those prevalent cases who did not fill glucocorticoid prescriptions during the first 6 months of the 24-month study period.

**Results:** We identified 32,812 patients who were prescribed glucocorticoid therapy, yielding 0.97% prevalence. Of these 32,812 patients, 14,205 (43.3%) met our definition of incident cases, yielding an incidence of 0.42% for 18 months in the overall population aged at least 15 years, corresponding to an incidence of long-term glucocorticoid therapy of 2.8/1000 inhabitants/year. Among the incident cases, the most currently prescribed glucocorticoids were prednisolone (64%) and prednisone (32%). Thirty-six per cent of patients received only one type of glucocorticoid while 33% received two and 5% received 3 or more of them. The average treatment duration was 270.9 days (CI 95% 267.7 – 274).

**Conclusions:** Long-term corticosteroid therapy is frequent in France, its description is close to what is already known in Europe.

AB1142 VITAMIN D LEVELS AND ASSOCIATION WITH DISEASE ACTIVITY IN PARAGUAYAN SLE PATIENTS

L. Román 1, G. Avila Pedretti 1, M.E. Acosta 2, M. Melo 1, M.T. Martínez 1, D. Margárit 1, I. Acosta Colman 1, 1Facultad de Medicina- UNA; 2Producción, Instituto de Investigación en Ciencias de la Salud, Asunción, Paraguay

Background: Systemic Lupus Erythematosus (SLE) is a systemic inflammatory disease associated with genetic, environmental, hormonal and immunological factors. Vitamin D levels are nowadays considered as one possible factor associated with disease activity. Therefore, previous studies have analyzed vitamin D to the severity of SLE.

Objectives: To assess the Vitamin D status in paraguayan SLE patients and its association with disease activity.

Methods: An observational Trial has been performed on individuals diagnosed with SLE. Epidemiological, clinical and biochemical data have been recorded for each patient to study the association between vitamin D concentrations, the phospho-calcium metabolism parameters and disease activity. Quantitative determination of Vitamin D was performed using chemoluminescence ARCHITECT assay. Vitamin D status was interpreted as follows: deficiency <20 ng/ml and insufficiency 21–29 ng/ml. The statistical association tests were performed using linear (SLEDAI activity index) and logistic (inactive/Mild vs Moderate/Severe) regressions. The epidemiological, clinical and biochemical variables were used as explanatory variables in these models.

Results: We included 77 SLE patients, of whom 94.8% (73/77) were female. The average age of patients at the time of the study was 30.7±10.3 years. All patients received calcium supplements associated with vitamin D. The average vitamin D concentration was 32.2±12.1 ng/ml. 29.9% (23/77) of patients had vitamin D insufficiency and 13.0% had vitamin D deficiency. 94.8% (73/77) of the population had normal serum calcium and the total population had a normal phosphoraemia. As for the dosage of PTH, it was found that 27.3% (21/77) have high values of PTH. 20.8% (16/77) of the patients had positive anti-DNA. Low C3 complement was observed in 30/77 (39%) and low C4 in 50/77 (64.9%) patients.

The mean value of SLEDAI at the time of the study was 2.32±2.83. When we study the distribution of vitamin D concentration according to the disease activity (SLEDAI) a clear pattern is observed linking lower vitamin D concentrations with higher disease activity. (OR 0.93, 95% CI 0.88–0.99; P=0.001). The prevalence of erosions increased with longer disease duration. Patients who were CCP+ had higher rates of prevalent erosions than those who were CCP– with similar disease duration.

Conclusions: Erosions were common in this cohort of patients, and prevalence of erosions increased with longer disease duration. Patients who were CCP+ had higher rates of prevalent erosions than those who were CCP– with similar disease duration.

AB1143 THE IMPACT OF ANTI-CYCLIC CITRULLINATED PEPTIDE SEROPOSITIVITY ON EROSION PREVALENCE AMONG PATIENTS WITH RHEUMATOID ARTHRITIS OF VARYING DISEASE DURATION

L. Harrold 1, K. Price 2, H. Litman 3, S. Connolly 2, E. Alemao 2, S. Rebello 3, W. Hua 4, J. Kremer 4, 1University of Massachusetts, Worcester; 2Bristol-Myers Squibb, Princeton; 3Corrona, LLC, Southborough; 4Albany Medical College and The Center for Rheumatology, Albany, United States

Background: Little is known regarding the prevalence of erosive disease in a contemporary cohort of patients with RA and whether erosive disease prevalence differs by disease duration and seropositivity to anti-citrullinated protein antibodies (ACPA).

Objectives: To characterize the proportion of patients with RA with erosive disease by disease duration category and stratified by positive and negative serological status (anti-cyclic citrullinated peptide [anti-CCP], a surrogate for ACPA).

Methods: We identified patients with RA aged ≥18 years who were enrolled in the Corrona registry (October 2001–June 2016), with available disease duration, radiographic/MRI/ultrasound studies and serological status based on anti-CCP. Patients were grouped based on RA disease duration (0–2, 3–5, 6–10 and >10 years from diagnosis). Unadjusted prevalence erosion rates were calculated based on the proportion of patients with reports of erosions present on joint radiographs/MRIs/ultrasounds. Seropositivity was based on laboratory results (anti-CCP ≥20 U/mL) at enrolment in the Corrona registry. Chi-squared tests were used to assess differences in prevalence rates.

Results: There were 9759 patients who met inclusion criteria. Most were women (76%), middle-aged (mean [SD] 57 years [14]), with moderate disease activity (mean [SD] CDAI 14.7 [13.4]). Prevalence of at least one biologic or targeted synthetic DMARD had occurred in 41% of patients. Overall, the prevalence of erosive disease was 28.6%, with higher prevalence among CCP+ (35.4%) vs CCP– (20.1%) patients (p<0.001, chi-squared test). The prevalence of erosions increased with increasing disease duration (p<0.001; Table). For each disease duration group, the prevalence of erosions was higher in patients who were CCP+ compared with those who were CCP–.

Table 1. Prevalence of Erosions According to Disease Duration and Serological Status

<table>
<thead>
<tr>
<th>Disease duration (years)</th>
<th>CCP–</th>
<th>CCP+</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overall</td>
<td>19.3 (905/4699)</td>
<td>28.3 (475/1678)</td>
</tr>
<tr>
<td>Serological status</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CCP–</td>
<td>16.1 (359/2226)</td>
<td>22.7 (169/744)</td>
</tr>
<tr>
<td>CCP+</td>
<td>22.1 (546/2473)</td>
<td>32.8 (306/934)</td>
</tr>
</tbody>
</table>

Data are % (n/N).

Conclusions: Erosions were common in this cohort of patients, and prevalence of erosions increased with longer disease duration. Patients who were CCP+ had higher rates of prevalent erosions than those who were CCP– with similar disease duration.

AB1144 GOOD THERAPEUTIC RESPONSE WITH BIOLOGICS: REMISSION IS RELIABILITY. DATA FROM THE AUSTRIAN BIOREGISTRY

M. Herold 1,2, G. Eichbauer-Sturm 3, T. Nothnagl 4, R. Puchner 5, B. Rintelten 6, P. Spellitz 4, B.F. Leeb 2,3 on behalf of BioReg Austria. 1BioReg Austria, Vienna; 2Department of Internal Medicine VI, Innsbruck Medical University, Innsbruck; 3Rheumatologist in private practice, Linz; 42nd Department of Internal Medicine, Lower Austrian State Hospital, Stockerau; 5Rheumatologist in private practice,
Scientiﬁc Abstracts

1456
Wels; 6 Rheumazentrum Wien-Oberlaa, Vienna; 7 Karl Landsteiner Institute of
Clinical Rheumatology, Stockerau, Austria
Background: Remission or at last low disease activity is the aim of drug therapy
in patients with chronic inﬂammatory rheumatic diseases. We evaluated disease
activity in patients treated with biologics and using data of the Austrian biologic
registry.
Objectives: The aim of this evaluation was to elucidate disease activity in patients
with rheumatoid arthritis (RA), spondyloarthritis (SpA) and psoriatic arthritis (PsA)
at baseline and at control-visits every six months after inclusion in BioReg.
Methods: Data were extracted from the Austrian BioReg registry (http://www.
bioreg.at) which was initiated in 2009 to document patients treated with one of
the biologics approved in Austria. Patients with ongoing biologic therapy as well
as biologic-naïve patients starting biologic therapy can be included (baseline,
BL). Further documentation is recommended about every six months (V1,V2 up
to V11). Meanwhile, 1877 patients (rheumatoid arthritis (RA) n=1046, ankylosing
spondylitis (SpA) n=446, psoriatic arthritis (PsA) n=322, other disease n=63) have
been documented. Estimation of disease activity is done using DAS-28 as well as
RADAI-5 in RA, SASPA in PsA, and BASDAI in SpA.
Results: DAS-28 (median values of BL; V1; V2; V9; V10) of patients with RA
are 3,30; 2,51; 2,58; 2,52; 2,49, the respective RADAI-5 values are 3,2; 2,4; 2,2;
2.0; 2,3. BASDAI in patients with SpA were 3,60; 2,61; 2,45; 2,63; 2,20. Median
values of inﬂammation’s laboratory markers (ESR in mm/1st hour and CRP in
mg/l) were always within the normal range (ESR and CRP in RA 15; 12; 12; 12,5;
14 and 2,0; 2,0; 2,0; 2,0; 2,0; in SpA: 8; 6; 7; 8; 8; and 2,0; 1,4; 1,4; 1,1; 1,0 in
PsA 9; 8; 9; 7 (V7); 6 (V8); and 1,6; 1,5; 1,4; 1,9 (V7); 0,8 (V8)).
Conclusions: Our data conﬁrm the efﬁciency of therapy with biologicals. During
5 years of continuous treatment more than half of patients with RA reach and
keep remission with a DAS-28 below 2,6 and normal values of ESR and CRP.
Also patients with SpA and PsA show similar successful therapeutic response.

AB1145

GENDER, AGE AND PULMONARY FUNCTION IN DOMINICAN
PATIENTS WITH RHEUMATIC DISEASES

M.A. Santos 1 , E. Tavera 2 , C. Tineo 1 , E. Loyo 1 , J. Reyes 3 . 1 Rheumatology,
Hospital Regional Universitario Jose Maria Cabral y Baez; 2 Pneumologyst,
Union Medica Clinic; 3 Investigation, Pontiﬁcia Universidad Catolica Madre y
Maestra, Santiago, Dominican Republic
Background: Interstitial lung disease (ILD) is a frequent entity in patients with
rheumatic diseases, worsening the prognosis of those who suffer it (1). Previous
studies have used the GAP (Gender, Age, Pulmonary function) model stage
system to determine mortality at 1, 2 and 3 years (2). For stage I is 5.6% the
ﬁrst year, 10.9% second and 16.3% the third. GAP II has a mortality of 16.2%,
29.9% y 42.1% for the ﬁrst, second and third year. For stage III, 39.2%, 62.1%
and 76.8% respectively (3)
Objectives: To perform GAP model stage system in Dominican patients with
Interstitial Lung Disease (ILD) related to Rheumatic Diseases (RD).
Methods: This is an observational, cross sectional study, with 42 patients who
presented ILD related to RD. The GAP model stage system was determined by
using demographic variables and pulmonary function tests such as spirometry
and lung diffusion capacity (DLCO).
Results: 36 patients were female; the median age was 45±12 years. The mean
value for Forced Vital Capacity (FVC) was 72%, Forced expiratory volume in 1
second (FEV1) 73%, and the ratio FEV1/FVC 99%. The DLCO mean value was
66±23 ml/min/mmHg. 35 patients (83.3%) were in stage I, 7 patients (16.6%) in
stage II and none in stage III. The statistical signiﬁcant variables were the time
of diagnosis of the RD (p=0.013); with 4.9 years for those in stage I and 10.8
years for stage II; the time of the diagnosis of the ILD (p=0.003) with 2.1 years for
patients in stage I and 4.8 years for stage II and smoking (p=0.063).
Conclusions: These ﬁndings suggest that the GAP model system is an useful
tool to stage patients with interstitial lung disease related to rheumatic diseases. It
can also help us make changes in treatment based on the stage. Special attention
must be paid to those with a longer time of diagnosis of the RD, time of diagnosis
of the ILD and/or smoking.

Osteoarthritis Fundation International, Barcelona, Spain
Background: Osteoarthritis (OA) is the most prevalent joint disease and the
leading cause of disability from 60 years onwards. In fact, 14,8% of the Spanish
population has OA.
Objectives: This study aimed to analyze the indications and average doses
prescribed in the treatment of knee osteoarthritis in Primary Care in Spain.
Methods: The EMARTRO study was designed as an observational, multicenter,
transversal study to compare probability of suffering a comorbidities based
on presence of symptomatic knee OA visited by GPs. Sociodemographic,
anthropometric, clinical parameters and clinical variables of interest were recorded.
The prescribed medications and doses indicated in syntomatic knee OA were
analyzed in patients included in the EMARTRO study.
Results: A total of 1173 patients were included, of whom 646 had knee OA.
Patients with OA had a mean (SD) BMI of 30.9 (5.1), systolic blood pressure 132.8
(14.5) and diastolic blood pressure 77.9 (9.1) mm Hg. They also had a mean
of 4.3 (1.9) comorbidities, the most frequent were hypertension 358 (62.2%),
dyslipidemia 336 (58.3%), diabetes mellitus II 126 (21.9%), and gastroesophageal
reﬂux 110 (19.1%). As for the symptomatology, the patients presented a mean
(SD) pain in Huskisson’s VAS of 65.18 (15.27) mm and algofunctional Lequesne
score of 11.35 (4.86).
Patients were treated with a mean of 2,2 medications. The 45.5% of osteoarthritic
patients were treated as monotherapy, 35.5% were taking 2 medications for
osteoarthritis, 15.3% 3 and 3.7% 4 or more medications. It should be noted,
taking into account the high levels of pain, that 15% of the patients did not receive
any treatment.
Regarding prescribed medications for knee OA, 378 (58.2%) patients were treated
with paracetamol at a mean daily dose (SD) of 1,150.5 (1,815.5) mg; 232 (35.9%)
received NSAIDs, with metamizole being the most prescribed at doses 1,092
(538) mg, ibuprofen at doses 1,136 (528,8) mg and naproxen at doses 941,8
(238,5) mg. Next, 131 (20.3%) patients were treated with opioids, tramadol being
the most frequent at doses 102.7 (49.7) mg; 87 (13.3%) with SYSADOA being
chondroitin sulphate the most frequent at doses 758.7 (247.7) mg. Finally, 87
(13.3%) of the patients were treated with COX-2, mainly with etoricoxib at doses
of 69.3 (27.1) mg.
Conclusions: Although the patients presented many concomitant pathologies,
it is frequent to approach osteoarthritis in polytherapy. In addition, despite the
high symptomatology, patients are treated primarily with a mild analgesic such as
paracetamol at doses lower than those recommended. It is paradoxical the high
prescription of NSAIDs in a population with a high prevalence of cardiovascular
and gastrointestinal pathologies as well as an increase in the prescription of
opioids.

13
Centro de Salud Ingeniero Joaquín Belloch, Valencia, Spain
Background: Osteoarthritis (OA) is the most prevalent joint disease and the
leading cause of disability from 60 years onwards. In fact, 14,8% of the Spanish


population has OA. This study aimed to analyze the indications and average doses prescribed in the treatment of knee osteoarthritis in Primary Care in Spain.

Objectives: This study aimed to analyze the comorbidity profile of men and women affected by symptomatic knee OA and the differences between genders in terms of quality of life and mental health.

Methods: The EMARTRO study was designed as an observational, multicenter, transversal study to compare the probability of suffering a comorbidity based on gender with symptomatic knee OA visited by GPs. Sociodemographic, anthropometric, clinical, and laboratory parameters were collected. The probability of suffering a comorbidity based on gender OA was estimated using the Odds Ratio estimation with conditioned logistic regression models. Depending on the variable, comparisons between groups were done using t-Student, Chi-square and Mann-Whitney.

Results: A total of 646 patients were included, 71% were women. Mean (SD) age was 67.9 (6.6) years. Patients were obese without gender differences, with a BMI of 30.4 (4.4) and 31.2 (5.5) (p=0.0651) in men and women, respectively.

Men had a mean (SD) systolic blood pressure higher than women, 134.7 (15.0) vs 132.2 (14.5) mmHg (p=0.0453) and no differences were observed in diastolic pressure (p=0.5930).

As regards to the concomitant pathologies, no increase was detected in the likelihood of suffering comorbidities related to the gender [OR=0.607 (95% CI: 0.268; 1.397)] in men and OA. Men with OA were more likely to have angina pectoris [OR=4.493 (95% CI: 1.299–15.536) p=0.0176] and underwent coronary bypass [OR=3.706 (95% CI: 1.389-9.890) p=0.0089].

Osteoarthritic women elicited more pain in Huskisson’s VAS 62.8 (14.7) vs 56.6 (15.6) mm (p=0.0027) and worse function according to the Lequesne index 10.0 (4.9) vs 12.1 (4.7) (p<0.0001).

In terms of quality of life according to the EuroQol, women presented worse quality of life in dimension of mobility (p=0.0001) and in the dimensions of daily activities, pain/discomfort and anxiety/depression (p<0.0001).

Fatigue symptoms were more common in the Goldberg scale to detect psychological disorders (p<0.0001) and more cases of anxiety and depression according to the HAD scale (p<0.0001).

Conclusions: The results of the present study indicate that women with osteoarthritis of the knee, despite having the same diagnosis and a similar comorbidity profile to men, have a worse perception of health status regarding the symptoms of their osteoarthritis, their quality of life and their mental health.

INFODEMIOLOGY AND SEASONALITY OF SYSTEMIC LUPUS ERYTHEMATOUS USING GOOGLE TRENDS
M. Radin, S. Sciascia. Department of Clinical and Biological Sciences, Center of Research of Immunopathology and Rare Diseases- Coordinating Center of Piemonte and Valle d’Aosta Network for Rare Diseases, Torino, Italy

Background: People affected by chronic rheumatic conditions, such as systemic lupus erythematosus (SLE), frequently rely on Internet and search engines to look for terms related to their disease, and its possible causes, symptoms and treatments. “Infodemiology” and “infoveillance” are two recent terms created to look for terms related to their disease, and its possible causes, symptoms and treatments.

Methods: “Infodemiology” and “infoveillance” are two recent terms created to look for terms related to their disease, and its possible causes, symptoms and treatments. Infodemiology uses the large amount of data generated by Google Trends, a Big Data monitoring approach.

Results: We analyzed the large amount of data generated by Google Trends, considering “lupus”, “relapse” and “fatigue” in a 10-year web-based research. Google Trends automatically normalized data for the overall number of searches and presented them as relative search volumes, in order to compare variations of different search terms across regions and periods. The Mann-Kendall test was used to evaluate the overall seasonal trend of each search term and possible correlation between search terms.

AB1149 THE ABILITY OF THE HEALTH SYSTEM TO IDENTIFY THE BURDEN OF RHEUMATOID ARTHRITIS IN SERBIA: A EULAR SURVEY
M.J. Zlatkovic-Svenda1, R.M. Stojeanovic1, S.B. Sipetic-Grijić2, M.M. Radak-Petrović1, N.S. Damjanov1, F. Guillemin2, 1Institute of Rheumatology University of Belgrade School of Medicine; 2Institute of Epidemiology University of Belgrade School of Medicine, Belgrade, Serbia; 3INSEMER – Clínica 1433, University Hospital, and Université de Lorraine, EA 4392 Apemac, Nancy, France

Objectives: to estimate the rheumatoid arthritis (RA) prevalence in two urban regions of Serbia, covering the northern and the southern part, under the European League Against Rheumatism (EULAR) prevalence survey; to assess the ability of the health system to recognize and treat patients with RA.

Methods: The survey was conducted in four Serbian towns: Belgrade in the north and three towns in the south: Cacak (Moravichi region), Užice (Zlatiborski region) and Krusevac (Rasinski region), covering 36.5% of the total Serbian population with more than 99% Caucasians, mostly orthodox Serbs (83%), <4% Hungarian, Roms and Bosnians and a minority of other nationalities. The first-detection phase of the study comprised previously translated and validated telephone Questionnaire usage with 33 items covering signs, symptoms, self-reported diagnosis and classification criteria for RA (CAG 1987) (1). Diagnoses were confirmed by rheumatologists in a second-confirmation phase. Prevalence results were standardized for age and sex with regard to Serbian population (national census 2002). Confirmed RA cases were asked two more questions: “How long had you had symptoms before you were given the diagnosis of RA” and “How had you been treated for that period of time”.

Results: 6213 people were contacted and 63.6% answered the survey; joint pain was reported by 1,799 persons, and joint pain accompanied with joint swelling by 666 persons. A total of 23 RA cases were identified: 2 newly diagnosed. The standardized RA prevalence estimates were 0.30% (95% confidence interval [95% CI] 0.09;0.51) for the north, e.g. 0.09 (95% CI 0.08;0.26) for men and 0.49% (95% CI 0.19;0.79) for women. RA prevalence estimates were 0.42% (0.12;0.72) for the south; 0.28 (0.00;0.56) for men and 0.55% (0.09;1.00) for women, with
the female to male ratio 5.5:1 in the north and 2:1 in the south. Time period from the first symptoms occurrence to the RA diagnosis was 17.7 (13.2) months for the northern part and 25.0 (16.9) for the southern; 20.6 (14.9) for Serbia; in that period patients were mostly treated with NSAIDS (82%) and physical therapy (30%); short-lasting corticosteroids were given to 13%, peroral corticosteroids to 4% and no patients were treated with DMARDs.

Conclusions: RA prevalence in the southern and northern part of Serbia is in line (0.42% [95% CI 0.120.72] vs 0.30% [95% CI 0.090.51]), being more frequently presented in females as compared to males (five times more in the north and two times more in the south). Delay in diagnosis as compared to the first symptoms occurrence was 21 months and during that time no patients were treated with DMARDs.

AB1150 SLEEP HEALTH AND QUALITY OF LIFE IN PATIENTS WITH KNEE OSTEOARTHRITIS BEFORE AND AFTER TOTAL KNEE REPLACEMENT

M. Nurhez1, E. Nurhez2, J.M. Segur3, L. Lozano3, J. Montañana3, V. Segura3, M. Morillas2, A. Garcia-Romero2, S. Sastre2, X. Alemany2, X. Xarles1, 1Rheumatology and IDIBAPS Area, 1Hospital Clinic; 3SAP Suport Diagnostico i al Tractament, Institut Català de la Salut; 2Orthopedic Surgery and IDIBAPS; 4Rheumatology, Hospital Clinic, Barcelona, Spain

Background: Studies report that sleep disturbances are often associated with chronic musculoskeletal disease. There is no agreed definition of sleep health, but some characteristics, such as sleep duration (number of hours daily) and sleep quality or satisfaction (subjective evaluation of good or poor sleep) are used to evaluate sleep health. In a previous study in patients with severe osteoarthritis awaiting total knee replacement (TKR), patients reporting good quality sleep had better health-related quality of life (HRQOL) measured by the specific WOMAC and generic SF-36 questionnaires.

Objectives: To measure sleep health in patients included on a waiting list for TKR and 12 months after TKR.

Methods: Prospective study with a 12-month follow up. Sociodemographic and clinical variables were determined. Sleep health: hours of sleep and reparative sleep (RS) was examined using the question “How well do you usually sleep?” on a Likert scale (1=good [RS], 2=regular, 3=badly, 4=with medication/treatment (non-reparative sleep [NRS]). Function and pain were measured using the WOMAC and SF-36 questionnaires. Comparisons were made using t-tests (paired samples) and McNemar’s test. Linear regression models were used to analyze associations. Dependent variables: WOMAC and SF-36 pain and function dimensions; independent variables: sleep quality, age, sex, BMI, number of comorbidities, depression/anxiety.

Results: 105 patients (79% female, mean age 69.39 years [SD 8.3]) were studied. In statistical studies the main risk factors were defined. Pain, function and sleep duration (WOMAC and SF-36) were measured using the WOMAC and SF-36 questionnaires. In comparisons of patients with RS (p=0.029). Patients with RS had better scores in all quality of life dimensions (<10 points) than those with NRS (p<0.05) at baseline and at 12 months. Multivariate analysis showed RS was independently associated with pain and function (WOMAC and SF-36) (p<0.007).

Conclusions: Sleep health was associated with better HRQOL before and after TKR. Although many patients had RS after TKR, 60% of patients continued not to have sleep health. Although often undervalued clinically, sleep health is closely associated with the health status.

AB1151 MONTH OF BIRTH AFFECTS THE RISK OF RHEUMATIC DISEASES: A NATIONWIDE CASE-CONTROL STUDY

N. Koo, J. Lee, B.W. Lee, S.-K. Kwok, S.H. Park, J.H. Ju. Division of Rheumatology, Department of Internal Medicine, School of Medicine, The Catholic University of Korea, Seoul. Seoul St. Mary’s Hospital, Seoul, Korea, Republic Of

Background: There have been several studies which demonstrated the impact of birth on the risk of certain diseases such as asthma or cardiovascular diseases. However, rheumatic diseases have not yet been thoroughly investigated in terms of association with birth month.

Objectives: In this study, we sought to determine whether birth month or season could affect the risk of rheumatologic diseases.

Methods: The birth month patterns of patients with rheumatic diseases were compared to those of the general population. We utilized the claim data of Health Insurance Review and Assessment Service (HIRA) which covers nearly 90% of total population in Korea. The associations between birth month/season and 32 diseases were investigated using logistic regression.

Results: Our dataset included 17,247,458 (male 9,220,760; female 9,026,708) individuals from HIRA database from January, 1997 to August, 2015. Among 27 rheumatic diseases, 8 diseases including Crohn’s disease (CD), ulcerative colitis (UC), rheumatoid arthritis (RA), systemic lupus erythematosus, polymyalgia rheumatica (PMR), ankyllosing spondylitis (AS), multiple sclerosis, gout, fibromyalgia (FM) were significantly associated with birth month (p<0.05). In terms of seasonality, CD, UC, RA, Sjogren’s syndrome, PMR, AS, Gout, and FM showed significant difference. CD, UC and AS showed higher prevalence in individuals born in winter and lower prevalence in summer. On the other hand, people who were born in summer showed higher possibility to have gout and FM compared to those born in winter. In consistent with previous reports, type 1 diabetes is more prevalent in those born in winter. Angina and myocardial infarction showed higher prevalence in patients born in spring and lower in fall. This consistency reflects the relevance of our dataset and methodology.

Conclusions: We found significant impacts of birth month/year on various rheumatic diseases. Seasonal variation of infectious agent such as exposure or food ingestion during gestation or early infancy may explain the association between birth month/season and certain disease development.

AB1152 THE INCIDENCE OF HYPERSENSITIVITY TO NSAIDS IN THE GROUP OF PATIENTS WITH MUSCULOSKELETAL DISORDERS

O. Brzezińska-Pawłowska, A. Sztanka, K. Słodkowski, A. Lewandowska-Polska, J. Makowiecka, O. Brzezińska-Pawłowska

Background: Non-steroidal anti-inflammatory drugs (NSAIDs) are among the most common cause of drug hypersensitivity reactions (DHR). Recent studies show that the prevalence of hypersensitivity reaction to drug is particularly in Poland.

Objectives: To assess the frequency and the risk.od developing NSAID hypersensitivity in patients with chronic disorders of the musculoskeletal system.

Methods: The study group consisted of 200 patients (age 19–88 years - 54±14, women-161, men-39) hospitalized in the Department of Rheumatology in 2015-2016. All patients filled questionnaire regarding symptoms of DHR after ingestion of non-steroidal anti-inflammatory drugs. The presence of DHR, clinical pattern of the reaction, frequency of NSAIDs administration and comorbidities have been studied. In statistical studies the main risk factors were defined.

Results: Seventy-seven patients from study group (38.5%) reported symptoms that occurred within 24 hours after ingestion of NSAIDs ingestion. Symptoms characteristic for hypersensitivity reaction were reported by 40 patients (20%). Respiratory symptoms like dyspnea and/or cough were reported by 22 patients (11%). Cutaneous symptoms (urticaria/angioedema/dermal flush) were reported also by 29 patients (14.5%). Three patients experienced loss of consciousness. Thirty-seven patients reported isolated stomach cramps. The symptoms developed usually between 2–12 hours after drug intake. In 37 patients oral administration caused DHR reaction, moreover in 14 patients also topical application led to adverse reaction. In most of patients reaction appeared due to COX-1 inhibitor and interestingly in 3 patients reaction was evoked by celecoxib which is perceived to be safe alternative for patients with NSAIDs hypersensitivity. Chronic urticaria, asthma and systemic drug intake occurs the main risk factors of hypersensitivity.

Conclusions: Drug hypersensitivity reactions are reported very frequently in population of patients with chronic musculoskeletal disorders. Our studies suggest that patients taking protractedly NSAIDs are in group with high risk of drug hypersensitivity development.

AB1153 OSTEOPOROSIS RISK FACTORS IN PARTICIPANTS OF HEALTHY AGING ACADemy

O. Brzezińska-Pawłowska, A. Luczak, D. Stalmaich, A. Lentes, M.L. Kowalski, O. Brzezińska-Pawłowska

Background: Osteoporosis is a major cause of morbidity and mortality in elderly population. It is known that the mortality rate in European population within 1 year of hip fracture is about 30%, and another 30% of patients need long term nursing for the rest of their life. However, the prevalence and associated risk factors in the Polish elderly population have not been well documented. The aim of the
Background: Depression and suicidality are well-described comorbidities in psoriasis (PSO). The prevalence of these comorbidities in psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) is less well described.

Objectives: To assess the prevalence of depression and suicidality in PsA and axSpA in the recent literature, and compare rates to PSO.

Methods: For PsA and axSpA, we evaluated the recent English-language literature identified through a PubMed search; we used a recent review and performed a targeted review of the period since the publication in order to establish the rates for PSO for comparison. 5 Review articles were also examined to identify key publications.

Results: Rates of depression in PSO vary widely, depending on the outcome definition and method of ascertainment. Dowlatshahi et al. reported a pooled rate of 9.0–55.0%, with rates from the literature after the review period ranging from 9.0–39.8%. Rates for suicidality also varied widely, with 2.5–17.3% of patients (pts) reporting suicidal ideation. The limited data available provide ranges for depression in PsA of 3.4–28.6%, and in axSpA of 3.1–44.0%. The single study that differentiated between ankylosing spondylitis (AS) and non-radiographic (nr)-axSpA did not identify a difference between the two groups. 2 Very limited data exist on suicidality in PsA and axSpA. For PsA, the incidence rates (IR) of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 3 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 1000 person-years in the UK were 0.4, 1.3, and <0.001, respectively; 5 no prevalence data were identified. In a study in China, 2.5% of pts with axSpA reported a past suicide attempt, 4 while in Turkey, patients had higher rates of suicidal ideation, attempts, and suicide per 0.57% of patients with fracture and 0.43% supplemented vitamin D3. Also, 13% of patient with osteoporosis and in 23.1% bone density was within normal limits. The strongest risk factors for osteoporotic fractures were numerous falls per year (p<0.000) and frequent drinking of alcohol (p<0.008). The risk factors of fractures (sum of risk factors for falls and osteoporosis) among people with previous fractures vs. those without fractures were statistically significant (p=0.037). Only 13% of patient with fracture and 15% of all patients with osteoporosis and osteopenia were treated by antosteoporotic drugs (ibandronavion/aletromin). Calcium supplementation was received by 30% of patients with fracture and 43% supplemented vitamin D3.

Conclusions: The prevalence of osteoporotic fractures in population of relatively recent received by 30% of patients with fracture and 43% supplemented vitamin D3. Also, about endured fractures, osteoporosis risk factors, screening densitometry, treatment of osteoporosis, supplementation with vitamin D3 and calcium. Also, questions about classical risk factors for osteoporosis (loss of height (5 cm/year), family history, falls, loss of weight, treatment with steroids) were included to questionnaire.

Results: Fractures caused by fall from their own height were reported by 180 (27.9%). Moreover, 96 (14.88%) responders without fracture history declared more than 3cm decrease of height after their forties, what strongly suggest osteoporotic vertebral fractures. Forty three (24%) of the respondents had multiple fractures and single fractures were reported by 137 (76%) responders. The most common localization of fractures was forearm (57%), shin bones (10.4%) and foot bones (9%). Among subjects who underwent densitometry after the fracture 32% had the diagnosis of osteopenia; 19.4% were diagnosed with osteoporosis and in 23.1% bone density was within normal limits. The strongest risk factors for osteoporotic fractures were numerous falls per year (p<0.000) and frequent drinking of alcohol (p<0.008). The risk factors of fractures (sum of risk factors for falls and osteoporosis) among people with previous fractures vs. those without fractures were statistically significant (p=0.037). Only 13% of patient with fracture and 15% of all patients with osteoporosis and osteopenia were treated by antosteoporotic drugs (ibandronavion/aletromin). Calcium supplementation was received by 30% of patients with fracture and 43% supplemented vitamin D3.

Conclusions: The prevalence of osteoporotic fractures in population of relatively recent received by 30% of patients with fracture and 43% supplemented vitamin D3. Also, about endured fractures, osteoporosis risk factors, screening densitometry, treatment of osteoporosis, supplementation with vitamin D3 and calcium. Also, questions about classical risk factors for osteoporosis (loss of height (5 cm/year), family history, falls, loss of weight, treatment with steroids) were included to questionnaire.

Results: Fractures caused by fall from their own height were reported by 180 (27.9%). Moreover, 96 (14.88%) responders without fracture history declared more than 3cm decrease of height after their forties, what strongly suggest osteoporotic vertebral fractures. Forty three (24%) of the respondents had multiple fractures and single fractures were reported by 137 (76%) responders. The most common localization of fractures was forearm (57%), shin bones (10.4%) and foot bones (9%). Among subjects who underwent densitometry after the fracture 32% had the diagnosis of osteopenia; 19.4% were diagnosed with osteoporosis and in 23.1% bone density was within normal limits. The strongest risk factors for osteoporotic fractures were numerous falls per year (p<0.000) and frequent drinking of alcohol (p<0.008). The risk factors of fractures (sum of risk factors for falls and osteoporosis) among people with previous fractures vs. those without fractures were statistically significant (p=0.037). Only 13% of patient with fracture and 15% of all patients with osteoporosis and osteopenia were treated by antosteoporotic drugs (ibandronavion/aletromin). Calcium supplementation was received by 30% of patients with fracture and 43% supplemented vitamin D3.

Conclusions: The prevalence of osteoporotic fractures in population of relatively recent received by 30% of patients with fracture and 43% supplemented vitamin D3. Also, about endured fractures, osteoporosis risk factors, screening densitometry, treatment of osteoporosis, supplementation with vitamin D3 and calcium. Calcium supplementation was received by 30% of patients with fracture and 43% supplemented vitamin D3.
Prevalence of comorbidities in psoriatic arthritis: a cross-sectional study

Background: Psoriatic arthritis (PsA) is associated with important comorbidities: cardiovascular, gastro-intestinal, infectious, malignant, and psychiatric [1, 2]. However, they are less studied in PsA compared to other chronic inflammatory arthritis.

Objectives: The objective of this study was to calculate the prevalence of comorbidities and risk factors in a cohort of PsA patients.

Methods: This was an observational cross-sectional study, including consecutive, untreated PsA outpatients, patients treated with GS or PSL in 8 university hospitals in Romania.

Results: In all, 129 PsA patients were included: 77 (59.7%) women, mean age ± standard deviation 53.5±12.4 years, disease duration 7.7±4.8 years; 53 (41.1%) had peripheral arthritis, 33 (25.6%) dactylitis, 18 (14%) enthesis, and 24 (18.6%) current moderate/severe psoriasis. Most of them had low or moderate disease activity and almost a quarter of them (32; 24.8%) were taking a biologic. The most prevalent comorbidities were: dyslipidaemia 103 patients (79.8%), hypertension 87 (51.9%), obesity 44 (34.1%), diabetes 21 (16.3%) and ischemic heart disease 15 (11.6%). Almost a third of patients (42; 32.6%) suffered a cardiovascular event after their PsA diagnosis, of which heart attack 2 patients, stroke 4, cardiac failure 4 and peripheral arterial disease one patient. Cardiovascular events correlated with smoking (r=0.893, p<0.001) and current moderate/severe psoriasis (r=0.218, p=0.013).

Regarding infectious comorbidities: 11 patients (8.5%) had a history of tuberculosis after being diagnosed with PsA, 7 (5.4%) chronic viral hepatitis, of which 4 with B virus and 3 with C virus, and 5 patients (3.9%) developed severe infections. Five patients (3.9%) were diagnosed with neoplasia, but no correlation was identified with any of the clinical, biological or treatment related included variables. Only 11 patients (8.5%) were diagnosed with depression, but the prevalence is probably underestimated, since not all patients were screened to this end.

Conclusions: PsA is associated with a high prevalence of comorbidities, especially cardiovascular disease. This should be taken into consideration in the therapeutic and the global management of PsA patients.

AB1158 PREVALENCE OF MUSCULOSKELETAL DISORDERS AMONG GARMEN T INDUSTRY WORKERS IN BANGLADESH

S.A. Haq, N. Shazzad, S. Ahmed, A.Z. Al-Qadir, A. Shahin. Rheumatology, Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh

Background: Garment industry is flourishing in many developing countries. Attention is often not paid to ergonomics. It is plausible that the prevalence of musculoskeletal (MSK) pain may be high among garment workers.

Objectives: To estimate the prevalence of symptoms and disorders (MSD) among garment workers in Bangladesh.

Methods: This cross sectional study was carried out among 350 workers in two garment factories by face-to-face interview. The COPCORD (Community Oriented Program for Control of Rheumatic Disorders) methodology was adopted for the survey. The workers were classified into cutting, sewing, finishing and quality operators. Trained interviewers identified subjects with musculoskeletal pain. Trained internists and rheumatologists examined the positive respondents.

Results: The point prevalence of musculoskeletal pain was 61.7%. The parts commonly affected during the preceding 7 days of interview in the whole group were: shoulder (17.9%), lower back (15.2%), neck (13.8%) and knee (10.8%). The cutting operators suffered more from back (15.4%), neck (15.4%) and lower limb (11.5%); sewing operators from lower limb (12.4%), back (8.5%) and upper limb (7.7%); finishing operators from lower limb (50%) and quality control group from back pain (50%). Multiple regional pains were more frequent (n=155) among all operators. The sewing and cutting operators suffered from multiple regional pains more than other operators. The prevalence of Rheumatoid arthritis (RA) 0.9%, spondyloarthropathy (SpA) 1.42%, undifferentiated arthritis (UA) 1.1%, nonspecific low back pain (NSLBP) 4.6%, soft tissue rheumatism (STR) 3.7%, osteoarthritis (OA) 0.9% and lumbar spondylosis 1.1%. Nonspecific pain was the commonest condition (63.7%).

Conclusions: Rheumatic disorders are common causes of morbidity, disability, and work loss among the garment workers of Bangladesh where male and female workers are almost equally affected. Multiple regional involvement are common in this occupational group. Mechanical disorders are the commonest.

AB1159 HIGH DOSE GLUCOCORTICOIDS AS A RISK FACTOR OF SIGMOID DIVERTICULITIS PERFORATIONS IN AUTOIMMUNE DISEASES

T. Kuranobu, M. Ishitoku, T. Tokunaga, Y. Yoshida, S. Hirata, T. Nojima, E. Sugayama. Department Clinical Immunology and Rheumatology, Hiroshima university hospital, Hiroshima, Japan

Background: It has been reported that glucocorticoids (GCs) and non-steroidal anti-inflammatory drugs (NSAIDs) might increase sigmoid diverticulitis perforations (SDPs) for rheumatoid arthritis patients; however, there are few previous reports referring to the relationship between SDPs and GCs in patients with systemic autoimmune diseases. We investigate relationship between SDPs and GCs in patients with rheumatic diseases.

Objectives: To describe development of SDPs during high dose GC (over 50 mg/kg/day) therapy for systemic autoimmune diseases in our department, additionally reviewing previous reports with regard to the relationship between SDPs and GCs.

Methods: 187 patients hospitalized in our department from April 2015 to December 2016 were retrospectively reviewed.

Results: Among 187 patients, 61 took high dose GCs, 29 took moderate dose GCs (0.5–6.0mg/kg PSL equivalent), 53 took low dose (less than 0.5mg/kg PSL equivalent), and 29 didn’t take GCs. Four patients out of 61 who took high dose GCs developed SDPs (Table). Nobody developed SDPs in moderate, low and
not any dose GCs group. Case 1–3 took NSAIDs. Case 2 received mPSL pulse therapy (mPSL 1 g × 3 days). Case 1 and 2 developed SDPs within 3 months from initiating GCs. Case 1 recurred SDPs at 17 and 63 months from initiating GCs. Case 2 was prescribed Tacrolimus as a concurrent medication. All four patients were operated to remove the perforated segment, and case 2 and 4 were created artificial anus. Although they were clinically diagnosed as SDPs only case 4 clarified perforation in pathological findings.

Conclusions: We should take care of developing SDPs in patients described high dose GCs.

EPIDEMIOLOGY AND CLINICAL PRESENTATION OF OCULAR INOCULATION WITH NON INFECTIOUS UVEITIS

V. Venerito1, G. Lopalco1, L. Cantarini2, C. Fabiani3, M. Fornaro4, A. Vitale2, S. Guerriero2, R. Fava1, F. Cacciapaglia1, M. Galles2, G. Lapadula2, F. Iannone1.

Background: Uveitis is a sight-threatening inflammation which may involve different anatomical parts inside the eye. The prevalence of uveitis among the population is equal to approximately 0.7% and it may cause irreversible damages to the eye that predominantly affects people in their productive years, being one of the most common extra-articular manifestations in several rheumatic diseases.

Objectives: To describe the clinical features of ocular involvement in a population of patients affected with newly diagnosed Non Infectious Uveitis (NIU).

Methods: A total of 278 patients (mean age 42±18.18 years, range 4-87) from three specialized centres, all affected with uveitides, were enrolled; 158 were female, 120 male, all caucasian but one asiatic. Complete ophtalmologic examination was carried out in all of them, and medications, or any kind of medications were not prescribed. In addition blood tests, serum antibodies level evaluations and HLA haplotype typization were performed. Moreover instrumental tests were performed when a complete symptom complex was suspected. Uveitides were then classified according to the Standardization of Uveitis Nomenclature Working Group Criteria.

Results: 149 (53.6%) patients were affected with Anterior Uveitis (AU), 45 (16.2%) with Panuveitis, 16 (5.8%) with Intermediate Uveitis (IU) and 68 (24.5%) with Posterior Uveitis (PU). None of the patients had a systemic disease at the moment of the uveitis onset. HLA-B27 positivity was found in 15.8% of patients, whereas HLA-B51 positivity was found in 21.9% of patients. Behçet’s Disease (BD) was diagnosed in 39 (14%) patients: in particular AU was found in 9 out of 39 patients (23.1%), while PU in 16 out of 39 patients (41%). Ankylosing Spondylitis (AS) was recognized in 22 (7.2%) patients: AU was diagnosed in 16 out of 22 (72.7%) of them while 4 out of 22 (18.2%) were affected with Panuveitis. The cases of Psoriatic Arthritis (PsA) were found in 9 (3.2%); specifically, AU was recognized in 4 out of 9 (44.4%) of them while PU was found in 5 out of 9 (55.6%) of them. We also defined the most common form of uveitis in patients affected with either Juvenile Idiopathic Arthritis, or Systemic Lupus Erythematosus, or Sarcoidosis, or Vogt-Koyanagi-Harada disease or Inflammatory Bowel Diseases. The idiopathic form of uveitis, was diagnosed in 162 (58.3%) patients. Anti-nuclear antibodies (ANA) levels were assessed in 148 patients of whom 57 (38.5%) have been found ANA positive and 91 (61.5%) ANA negative. Notably 38 (66.7%) ANA positive patients were affected with AU.

Conclusions: Our study provides a depiction of clinical features and epidemiology of ocular involvement in a huge population of patients presenting newly diagnosed NIU. Notably, in our population, idiopathic uveitis was the most commonly diagnosed form; it took shape of AU in 56.6% of cases. The majority of HLA-B27 positive uveitides were also AU (68.2%), while, among HLA-B51 uveitides, PU (59.3%) and AU (37.7%) were recognized as the most common presentations.

PORTUGUESE ADAPTATION AND VALIDATION OF THE ANKYLOSING SPONDYLITIS QUALITY OF LIFE (ASQOL) QUESTIONNAIRE

A. Águeda1, A. Heaney2, S.P. McKenna2, A. Barcelos1, 1 Rheumatology, Centro Hospitalar do Baixo Vouga, E.P.E., Aveiro, Portugal, 2 Galen Research Ltd., Manchester, United Kingdom

Background: Ankylosing Spondylitis (AS) is a chronic rheumatic disease that affects mainly the axial skeleton and entheses. If left untreated, AS evolves with limited spine mobility and irreversible structural changes, with severe repercussions in patients’ quality of life. Throughout the years many instruments have been used in order to evaluate AS impact in patients’ lives, focusing predominantly on symptoms and functioning however, these instruments do not inform on the impact of the condition on quality of life (QoL). The ASQol is a patient reported outcome measure, specifically developed to evaluate QoL AS patients. It has been adapted to several languages worldwide, though a Portuguese version hadn’t been developed yet.

Objectives: Translation of the ASQol questionnaire into Portuguese and ascertain its psychometric properties.

Methods: Translation of the original UK English ASQol into Portuguese was performed by bilingual panel and then assessed by a lay panel. Cognitive debriefing interviews were performed with AS patients to assess face and content validity. Finally, a sample of AS patients were included in a test-retest postal survey, administered on two different occasions, two weeks apart, to investigate the reliability and construct validity of the new Portuguese adaptation of the ASQol. Nottingham Health Profile (NHP) was used as a comparator measure.

Results: The Portuguese version of ASQol proved to be relevant and easy to understand.

Validation of the ASQol included fifty-eight AS patients, with a mean age of 51 years (Range 25.0 – 80.0), with 55.2% males. The Portuguese ASQol had good internal consistency at Time 1 (α=0.90, p<0.001) and Time 2 (α=0.94, p<0.001). Correlation between ASQol scores and NHP was moderately strong with Spearman’s rank correlation coefficients between ASQol and NHP section scores, including the distress scale embedded within, all p<0.01. These results suggest that patient’s quality of life is influenced by many factors in addition to disease severity, including social skills and ability to adapt to physical limitations.

The Portuguese version of ASQol was able to discriminate between patients who differed on their perception of general health and presence of comorbidity, although there were no significant differences according to self-perception of disease severity.

Scientific Abstracts

AB1160

Validation of outcome measures and biomarkers
Conclusions: The Portuguese version of the ASQol performed well, demonstrating good psychometric properties for use in clinical studies and trials of patients with AS. The lack of significance in the analysis by self-perceived disease severity may be due to the relatively small sample size.

AB1162
RAPID3 SCORE CAN PREDICT DISEASE ACTIVITY IN PRIMARY SJÖGREN’S SYNDROME

B. Öz1, A. Karatas2, Z. Ömürçüoğlu3, O. Çatak4, N. Gozeli2, S. Cur2, E. Dönür2, S.S. Koca1, 1Rheumatology Department; 2Department of Internal Medicine; 3Department of Ophthalmology, Faculty of Medicine, First University, ELAZIG, Turkey

Background: Sjögren’s syndrome (SS) is a chronic autoimmune disease that causes salivary and lacrimal gland dysfunction, resulting in oral and ocular dryness. The European League Against Rheumatism (EULAR) SS disease activity index (ESSDAI) is a systemic disease activity index measuring disease activity in patients with SS. The ESSDAI includes 12 domains. EULAR SS patient-perceived index (ESSPRI) is used to evaluate dryness, fatigue, and pain symptoms, and their impact on the disease. Routine Assessment of Patient Index Data 3 (RAPID3) is used to evaluate disease activity in patients with rheumatoid arthritis which is another inflammatory disorder.

Objectives: This study aims to evaluate whether RAPID3 is useful in primary SS.

Methods: 30 patients with primary SS were enrolled in the study. ESSDAI, ESSPRI and RAPID3 scores were recorded. Chi-square, Mann Whitney U test and Pearson correlation analysis were performed for the statistical analysis.

Results: Demographically and clinical data were shown in the Table-1. Mean ESSDAI, ESSPRI and RAPID3 scores were 3.8±3.6, 5.8±1.7, and 14.8±5.2, respectively. RAPID3 scores were positively correlated ESSPRI (r=0.669, p<0.001). In addition, when we set the cut-off value to 12 on the RAPID3 score (>12 accepted as active, and ≥12 accepted as inactive), ESSPRI score was significantly higher in active patients (6.4±1.4 vs. 4.1±1.4, p=0.002). However, there was no relationship between RAPID3 and ESSDAI scores. Schirmer test was positively correlated with tear break up time (BUT) (r=0.573, p=0.007). Lissamine green score was negatively correlated with Schirmer test and BUT (r=–0.484, p=0.007, and r=–0.507, p=0.004, respectively). Despite there was high compliance among these three scales evaluating eye involvement, these scales did not appear to correlate with the ESSDAI, ESSPRI, and RAPID3 scores that assess global disease activity. The mean age was significantly higher in patients with Schirmer test ≤5 mm compared to the patients with >5 mm (55.6±6.9 vs. 47.6±8.5 years, p=0.044).

SS: Sjögren’s syndrome; WBC; white blood cell count, ESR, erythrocyte sedimentation rate, CRP; C-reactive protein, ANA; anti-nuclear antibody; HAQ; health assessment questionnaire, BUT; tear break up time.

Conclusions: In SS, it is not simple to detect disease activity. Comorbid psychosomatic diseases affect the set detecting global disease activity. On the other hand, the activity of glandular involvement and global disease activity are not with compliance. Therefore, new and easy tools are necessary in primary SS. In our study, RAPID3 score is correlated with ESSPRI. This result suggests that RAPID3 is useful to detect disease activity in primary SS.

ANTIBODIES BINDING SYNTETIC OLIGONUCLEOTIDES DISTINGUISH LUPUS FROM RHEUMATOID ARTHRITIS, SCLERODERMA AND SJÖGREN’S SYNDROME

C. Puttermann1, A. Gabrielli2, A. Balbir-Gurman3, R. Safer4, K. Jakobi-Brook4, R. Sorek4, T. Gluzman4, S. Wallace5, I.R. Cohen6. 1Division of Rheumatology, Albert Einstein School of Medicine, NY, United States; 2Istituto di Clinica Medica dell’Università di Ancona, Ancona, Italy; 3Rheumatology Unit, Rambam Health Care Campus and Rappaport Faculty of Medicine, Technion, Haifa, 4ImmuneArray LTD, Rehovot, Israel; 5ImmuneArray Inc, VA, United States; 6Weizmann Institute of Science, Rehovot, Israel

Background: The SLE-key® RuleOut iCHIP® antigen microarray-based test rules out a diagnosis of SLE with a sensitivity of 94%1.

Objectives: Here we report the use of the iCHIP® platform and a set of synthetic oligonucleotide antigens to distinguish between SLE subjects and those with a diagnosis of Rheumatoid Arthritis (RA), Scleroderma (SSc), Sjögren’s syndrome (SS), or healthy individuals (HC).

Methods: We examined IgM and IgG antibody binding to 22 synthetic oligonucleotides (44 features) in the sera of HC subjects (N=40); SLE (N=30); SSc (N=40); SS (N=20); or RA (N=30) patients. Univariate analysis (FDR adjusted p-values) was used to determine the ability of each feature to separate between SLE and the different classes of subjects.

Results: Table 1 shows that multiple oligonucleotides successfully distinguished SLE patients from other groups. All significant features were IgG antibodies, except for 1 IgM, Table 2 shows the impact of single nucleotide change on antigen binding. PolyG (G17) separates SLE from all but SS, T1G16 separates SLE from HC subjects, while G16T1 gave no significant separation. The addition of a G to the 5’ and 3’ end of T16 enhanced IgG antibody binding and improved separation between SLE and other autoimmune diseases with at least 10-fold improved significance as compared to T20. PolyG sequence length impacts the ability of the oligonucleotides to separate between SLE and the other groups (Fig. 1A). Unexpectedly, sequences either shorter or longer than G14 were effective in separating SLE from HC, RA, and SSc, while G14 was not effective. Furthermore, none of the polyG homopolymers could separate SLE from SS. Sequences rich in C or T were more effective at separating between SLE and SS patients (Fig. 1B).

Figure 1

Conclusions: Autoantibody binding to oligonucleotides can be used to differentiate SLE from other autoimmune conditions and healthy subjects.

• The structural basis for the differences in binding of antibodies from disease sera to the various oligonucleotides is not yet understood, but may be due to immunologically unique conformations and secondary structures of oligonucleotides of defined length and sequence.

• SSc can be differentiated from SLE based on particular antibody binding to epitopes of oligonucleotides containing C and T.

• RA can be differentiated from SLE more significantly than the other autoimmune conditions.

Figure 1
The CHIP® microarray technology is being further developed to generate a clinically useful test to rule in a diagnosis of SLE relative to other related autoimmune diseases.

RABIOPRED, AN INNOVATIVE THERAGNOSTIC TOOL FOR PRECISION MEDICINE IN RHEUMATOID ARTHRITIS PATIENTS

E. Schordan 1, M. Mehdi 1, S. Danilin 1, M. Coq 1, M. Schumacher 1, T. Huizinga 2, A. Aeschlimann 1, J. Angst 2

Background: Anti-TNF alpha biologicals are an important breakthrough in the treatment of Rheumatoid Arthritis (RA) patients. However, 30–40% of RA patients do not respond to these therapies. Therefore, there is an unmet need for a tool to predict treatment response that would help clinicians choose an optimal treatment for RA patients.

Objectives: Under the framework of Horizone2020 SME Instrument of European Commission, Firalis has identified and developed a panel of 2195 mRNA genes which can predict non-response to anti-TNF alpha therapy using the HTG EdgeSeq platform. As a predictive combination of a nuclease protection assay & next generation sequencing (NGS).

Methods: RABIOPRED assay is a proprietary panel of Firalis signatures, which also includes targets selected by the BTCure consortium, to predict treatment response of anti-TNF alpha biologicals. In total 2175 targets were selected for the development and 2159 are successfully included in the panel. Each oligonucleotide is a 100-mer comprising a 25-mer “wing” at the 5’ end and 3’ end, and a 50-mer sequence in between that is complementary to the target mRNA. QC is checked for secondary structure and absence of homology with other sequences. Analytical parameters are assessed and repeatability of the RABIOPRED assay is validated on both Paxgene and purified RNA samples. Sample input is set at 32 μl for Paxgene RNA blood and 25 ng for extracted RNA.

Results: Mean correlation factor for 12 samples on 8 replicates for Paxgene and RNA samples are R²=0.97 and R²=0.99 respectively. First analysis and predictive modelling shows an AUC over 0.95 for the prediction of non-response to anti-TNF alpha. In the present work, we disclose the performance of the CE-IVD RABIOPRED assay based on more than 200 samples obtained from the prospective clinical studies. PRINT and RA-TNF. The algorithm will be further validated within the ongoing RABIOPRED Proof-of-Performance study (ClinicalTrials.gov Identifier: NCT030216260) in 720 patients treated by anti-TNF alpha biologicals (5 originators and 3 biosimilars) launched in December 2016. First version of the CE-IVD RABIOPRED assay will be available during Q2 2017 and open for testing.

Conclusions: We are showing that we can accurately measure mRNA expression with RABIOPRED assay using HTG-EdgeSeq NGS platform. Preliminary performance of the assay shows that it can efficiently predict treatment response to anti-TNF alpha biologicals. The algorithm will be later on validated in a multi-centric proof-of-performance clinical study.

AB1165

THE MINIMAL CLINICALLY IMPORTANT DIFFERENCE (MCID) RAISES THE SIGNIFICANCE OF OUTCOME EFFECTS ABOVE THE STATISTICAL LEVEL

F. Angst 1, A. Aeschlimann 1, J. Angst 2

Background: In measurement of outcome effects, the patient's subjective perception to feel a change in health defines clinical effectiveness irrespective of statistical significance. Nevertheless, many – especially pharmacological – studies argue with statistical effects alone.

Objectives: To review, develop, illustrate, and discuss current and proposed new concepts of effect quantification and significance.

Methods: First, for determining minimal clinically important differences (MCIDs) were reviewed and further developed focusing on their characteristics and (dis)advantages. The concepts were illustrated by empirical rehabilitation effects (evaluation study) and a randomized controlled trial (investigative study) in knee osteoarthrosis.

Results: In controlled studies, empirical score differences between verum and placebo become statistically significant if sample sizes are sufficiently large. For example, a score difference of 5 points (scale 0–100) between the verum and the placebo effect becomes statistically significant, if the sample sizes are n=33 for each of both groups at a standard deviation=10 of the score differences (baseline to follow-up). MCIDs by contrast, are defined by patients' subjective score, which led to “anchoring” of effects by the “transision” item, where patients rate their change of health between baseline and follow-up in an evaluation study. The MCID for improvement by the “mean change method” is the difference of the mean change experienced by the “slightly better” group minus that of the “almost equal” group. The MCID can be expressed as absolute or relative score, as effects size (ES), standardized response mean (SRM) and standardized mean difference (SMD) (bivariate). It can further be adjusted by multivariate regression modeling. In our example of knee osteoarthritists, the MCID for pain relief was 8.74 (scale 0–100) and for baseline score by patient, SMD=0.469. This is consistent to the range of 0.30–0.50 for MCIDs reviewed in literature. After adjusting for potential confounders, the MCID was 7.09 score points or an increase of 2.9% per score point to feel better obtained by logistic regression.

Conclusions: Absolute and relative MCIDs are easy to interpret and apply to data of investigative studies. MCIDs expressed as ES/SRM/SMD reduce bias, which mainly results from dependency on the baseline score. Multivariate linear and logistic regression modeling further reduces bias by adjustment for possible confounders and increased precision. Anchor-based methods should use clinical/subjective perception to define MCIDs and should be clearly differentiated from distribution-based methods that provide statistical significance only.

QUANTUM BLUE® ADALIMUMAB: EVALUATION OF A POINT OF CARE RAPID TEST FOR THERAPEUTIC DRUG MONITORING OF SERUM ADALIMUMAB LEVELS

F.I. Bantleon, S. Kräuchi, T.B. Schuster, M. Schneider, J.M. Weber, Bühlmann Laboratories Ag, Schönenbuch, Switzerland

Background: Rheumatoid arthritis (RA) is a systemic autoimmune disease affecting approximately 1% of the population [1]. The pathogenesis of RA involves the overexpression of tumor necrosis factor alpha (TNF-α) and other cytokines [2]. Adalimumab (ADA) is a human monoclonal antibody directed against TNF-α and is highly effective in the treatment of RA. For efficient treatment trough levels of ADA need to be adjusted within a therapeutic window which is 5 to 10 μg/mL [3]. A rapid test allows faster reporting of trough levels, providing a great advantage over test formats that need samples to be sent to a central or service laboratory. Here we report on the technical performance evaluation of the Quantum Blue® Adalimumab test. RF showed no influence on correct measurement of ADA at all levels, with the lower limit of quantification between 0.1 μg/mL and 1000 μg/mL.

Methods: The sandwich lateral flow immunoassay uses a TNF-α coated gold label and a highly specific monoclonal antibody immobilized on the test membrane to detect ADA in diluted human serum samples. Sensitivity of the assay was determined by calculating limit of detection (LoD) and limit of quantification (LoQ) according to CLSI EP17-A2 guideline. Moreover, the assay was evaluated regarding cross-reactivity with other therapeutic antibodies targeting TNF-α, influence of rheumatoid factors (RF) and high dose hook effect. A method comparison was performed against a commercially available ELISA (RIDASCREEN® ADM Monitoring, R-Biopharm, Germany) to compare the trough level results of 40 patients treated with ADA. All statistical analyses were performed with Analyse-it for Excel.

Results: The Quantum Blue® Adalimumab test allowed analysis of serum samples within 15 minutes. The samples were diluted 1:20 in chase buffer before application onto a test cassette (volume 80 μL). The readout was performed with the Quantum Blue® Reader resulting in adalimumab concentration levels in the lower μg/mL range. The test exhibited a LoD of 0.2 μg/mL and a LoQ of 0.69 μg/mL. No high dose hook effect was detected for samples containing up to 1000 μg/mL ADA. The latter two data sets allowed a measuring range of 1 to 35 μg/mL of ADA in patient samples. Other therapeutic TNF-α blockers, like infliximab and golimumab, showed no cross-reactivity with the Quantum Blue® Adalimumab test. RF showed no influence on correct measurement of ADA at all tested concentrations. The method comparison to a well-established commercial ELISA method revealed a slope of 1.12 and a regression coefficient (R²) of 0.90 (by Passing-Bablok). A Bland-Altman analysis showed a bias of 1.9% confirming the overall excellent correlation of the two methods as well as the accuracy of our new developed rapid test.

Conclusions: The BÜHLMANN Quantum Blue® Adalimumab assay enables the quantitative determination of ADA trough levels over the clinically relevant range in serum with a time to result of only 15 minutes. The assay exhibits an excellent accuracy and correlation to a well-established laboratory reference
method. Hence, it represents a valuable tool for the clinician to assess the trough levels during ADA treatment follow up at the point of care.

**AB1167 AUTOACTIVE T CELLS TO CITRULLINATED HSP90 IN INTERSTITIAL LUNG DISEASE IN RHEUMATOID ARTHRITIS**

**J Chen**, S Song, Y Liu, Du Liu, S Ge, D Ascherman, R Rheumatology, Xiamen University; 2Rheumatology, The First Affiliated Hospital of Xiamen University; 3State Key Laboratory of Molecular Virology and Molecular Diagnosis, Xiamen University; 4Radiology, The First Affiliated Hospital of Xiamen University; 5State Key Laboratory of Molecular Virology and Molecular Immunology, Xiamen University, Xiamen, China.

**Objectives:** To address this issue we investigated the spontaneous T cell responses to the putative autoantigen citrullinated HSP90 (citHSP90) in different stages of RA-ILD.

**Methods:** In RA-no ILD (n=19), indetermine ILD (ILA1) (n=24), subclinical RA-ILD (ILA2) (n=20), clinical RA-ILD (ILA3) (n=4) and other connective tissue disease associated ILD (CTD-ILD) (n=14) patients. Cultures derived from whole blood or peripheral blood mononuclear cells isolated from patients with RA-ILD, clinical RA-ILD, ILA 2, ILA 3, and CTD-ILD were stimulated with citHSP90, citrullinated BSA, or no antigen. The concentration of 13 cytokines and chemokines in the plasma supernatant were then measured using Luminex xMAP technology.

**Results:** CitHSP90 induced significantly higher levels of IFN-γ levels in RA-ILD (ILA=2+3) groups compared to the RA-no ILD group (p=0.002), but did not stimulate the production of other cytokines (p>0.05). Furthermore, citHSP90 did not stimulate the production of IFN-γ or other cytokines stimulated those individuals with non-RA CTD-ILD (p=0.1039, IFN-γ).

**Conclusions:** The production of IFN-γ by T cells stimulated with citHSP90 during the activation of B cells may be involved in the pathogenesis of RA-ILD. The presence of autoreactive Th1-like cells in RA patients in conjunction with citrullinated autoantigens may indicate the involvement of this autoantigen in the pathogenesis of RA-ILD. Early targeting of the immune reactions in the lung might therefore be a new approach to modulate disease.

**AB1169 COMPENSATORY INCREASE IN FCERIIB EXPRESSION ON B CELLS IN PATIENTS WITH SYSTEMIC SCLEROSIS**

**N. Yag**, T. Matsushita, Y. Hamaguchi, K. Takehara. Department of Dermatology, Faculty of Medicine, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa, Japan

**Objectives:** We aimed to clarify how the abnormal activation of B cells involves inhibition FcεRI on B cells in SSc patients currently remain unknown.

**Methods:** Blood samples were collected from 76 SSc patients (38 limited cutaneous SSc [lcSSc], 38 diffuse cutaneous SSc [dcSSc]) and 59 healthy subjects. FcεRI expression was evaluated on FcεRIIB. Inhibition of immune responses, FcεRIIB is the only FcεRI that has an inhibitory function. Previous studies revealed that a decrease in the expression of FcεRIIB on B cells induced excessive immune responses and resulted in the development of autoimmunity. However, the expression levels of FcεRIIB on B cells in SSc currently remain unknown.

**Methods:** Blood samples were collected from 76 SSc patients (38 limited cutaneous SSc [lcSSc], 38 diffuse cutaneous SSc [dcSSc]) and 59 healthy subjects. FcεRI expression was evaluated on FcεRIIB.

**Results:** The expression of FcεRIIB on B cells was significantly stronger than that on the B cells of healthy subjects (Figure 1) (p<0.05 and p<0.001, respectively).

**Conclusions:** FcεRIIB mRNA expression on SSc B cells was also significantly stronger than that on the B cells of healthy subjects (p<0.01).

**Methods:** The expression of FcεRIIB on SSc naïve B cells and DN memory B cells was significantly stronger than that on the B cells of healthy subjects (p<0.01). The expression of CD80, CD86, and CD95, activation markers on B cells, was stronger in all B cell subsets, except for CD80 in switched memory B cells (CD19+IgD+CD27+). The mRNA expression of FcεRIIB was measured using real-time PCR. We examined the relationship between FcεRIIB expression and clinical features.

**Results:** The expression of FcεRIIB on SSc naïve B cells and DN memory B cells was significantly stronger than that on the B cells of healthy subjects (Figure 1) (p<0.05 and p<0.001, respectively). FcεRIIB mRNA expression on SSc B cells was also significantly stronger than that on the B cells of healthy subjects (p<0.01). The expression of CD80, CD86, and CD95, activation markers on B cells, was stronger in all B cell subsets, except for CD80 in switched memory B cells and plasmablasts. Patients with the stronger expression of FcεRIIB on DN memory B cells more frequently had interstitial lung disease than those with normal levels (p<0.05). Cyclophosphamide pulse therapy significantly reduced the expression of FcεRIIB on preswitched memory B cells and switched memory B cells (p<0.05 and p<0.05, respectively).

**AB1168 TOUCH STUDY: TECHNOLOGY AND OUTCOMES USED IN CLINIC IN A DAY HOSPITAL**

**L. Cunha-Miranda**, 1C Miguel, 1C Silva, 1F Barcelos, 1R Marques, 1R Trinca, 1A Cardoso, 1J Borges, 1S Fernandes, 1H Santos, 1A Faustino, 1Rheumatology; 2Nurse Day Hospital; 3Nutrition, Instituto Português de Reumatologia, Lisboa, Portugal

**Background:** Patient reported outcomes PRO are a key element in the global evaluation of patient care, especially those followed in day hospital. The use of touchscreen computers is one of the new features in the day hospital of Instituto Português de Reumatologia.

**Objectives:** To evaluate the transition from paper to touchscreen computer technology of the PRO in use in Reuma.pt
Conclusions: Our results suggest that SSc B cells exhibit compensatory increases in the expression of FcγRIIB in order to suppress the abnormal activation of B cells, and the expression of FcγRIIB may be an indicator of the clinical severity of SSc.

PREVALENCE OF ANTI-CARP ANTIBODIES IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: ASSOCIATION WITH CLINICAL, SEROLOGICAL AND HISTOLOGICAL ASPECTS

S. Colafrancesco1, G. Piacarelli1, A. Paceni1, T. Colasanti1, F. Spinelli1, C. Alessandri1, C. Barbati1, M. Vomero1, B. Cerbelli2, R. Priori1, G. Valesini1.

1Dipartimento di medicina interna e specialità mediche; 2Dipartimento di radiologia, Oncologia e Scienze Patologiche, Sapienza University of Rome, Rome, Italy.

Background: The presence of antibodies against carbamylated peptides (anti-CarP) has been associated with increased disease activity and severe joint damage in rheumatoid arthritis. Our group has demonstrated their prevalence in 27% of cases and an association with the presence of germinal centres (GCs). Thus, these antibodies have been proposed as a new tool for identifying SS patients with a more aggressive disease.

Objectives: To confirm the presence of anti-CarP antibodies in a large monocentric cohort of patients with SS and investigate their association with clinical, serological and histological features.

Methods: Serum samples from consecutive patients with SS (AECG criteria) were collected and stored at -20°C. Anti-CarP antibodies were detected by a modified ELISA. The mean ±3 times SD was used as cut-off. Minor paraffin embedded salivary glands were stained by H&E and IHC using lymphocytes T and B markers [anti-CD3, anti-CD20 (DAKO)]. GCs presence was defined by H&E and confirmed by identification of follicular dendritic cells [anti-CD21, DAKO]. Images were analysed as follows: focus score (FS) calculation, mean foci area, percentage of segregation, foci, GCs and lymphoepithelial lesions.

Results: Clinical and laboratory features of SS patients are shown in table. Serum anti-CarP were detected in 30/104 patients (28.8%) without association with any clinical or serological feature (Fisher’s exact test). Positive patients were more likely to present SF (P=0.024). No association was found with the presence of GCs or LELs. Anti-CarP titre correlated with the FS (P=0.045, r=0.304), the number of foci (P=0.008, r=0.347), mean foci area (P=0.028, r=0.331) and the percentage of SF (P=0.046, r=0.331) (Spearman’s test). Prevalence of anti-CarP was higher in patients with arthritis [7/15 (46.6%)] than those without [23/89 (25.8%)].

Conclusion: Anti-CarP titre was higher in patients with arthritis compared to those without (322.3±173.8 au/ml vs 279.5±171.1, P=0.004, respectively).

Conclusions: This is the largest cohort of SS patients screened for anti-CarP so far. Our results show a prevalence of anti-Carp antibodies in agreement with the literature; however, no association was found with any clinical or serological aspect. Anti-CarP do not seem to be associated with histological features predictive of lymphoma, i.e. GCs and LELs. Nonetheless, considering the titre correlation with the FS, mean foci area and percentage of segregation, higher serum levels of anti-Carp may reflect a severe tissue inflammation more prone to form organized infiltrates. This finding, in association with the evidence of higher levels in patients with arthritis, may support the idea that these antibodies are useful to measure the severity of systemic inflammation.

AB1171

ARTIFICIAL AND EXTRA-ARTICULAR DAMAGE INDEX ASSESSMENT IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS

S.M. El-Gamal, E.A.K. Elewa, M.M. Ashour. Rheumatology and Rehabilitation, Zagazig University Hospitals, Zagazig, Egypt

Background: Juvenile Idiopathic Arthritis is a broad term used to describe several different forms of chronic arthritis in children. Variable assessment tools can be used for assessment of JIA disease activity. JADI is composed of 2 parts (Viola et al., 2005).

Objectives: Assessment of the articular and extraarticular damage index in juvenile idiopathic arthritis patients.

Methods: This study was carried out on 60 JIA patients. Patients who had inflamed synovia related to trauma or malignant disease, septic arthritis, bone diseases, as dysplasia or osteomyelitis were excluded. Clinical assessment: sex, age at disease onset, JIA category, educational level, loss of school years and previous use of systemic corticosteroid and second-line drug therapies. Local examination: number of swollen joints, joints with pain on movement/tenderness, joints with limited range of motion, joints with active arthritis were recorded for every patient. Disease activity: was measured by using the (JADAS-27).

Functional ability: was assessed by (CHAQ). Laboratory assessment: included ESR and CRP. Radiographic assessment: scored according to the adapted Sharp/van der Heijde score. Damage assessment: was assessed using the Juvenile Arthritis Damage Index. The (JADI-A) and (JADI-E).

Results: Patient characteristics: 6 had systemic onset, 29 had polyarthritis, 14 extended oligoarthritis, 11 had persistent oligoarthritis and none of them had psoriatic arthritis. 38 females and 22 males (56.7%) percent of patients lost some years of education ranging from 0–3 years. Patients in remission were very few 5 patients only. According to the C-HAQ score (13.3%) of patients had no disability (11.7%) mild disability (41.6%) moderate disability and (33.3%) severe disability. 60% patients had articular damage and 35% patients had extraarticular damage. The wrist was the most frequently damaged joint. The growth failure, pubertal delay and leg length discrepancy were the most frequently reported extraarticular items. Correlation of JADI with other disease variables: showed that JADI-A is correlated with physician’s global assessment, CHAQ, radiological damage.

Conclusions: Ours is the first study that has used JADI to assess outcome in patients with JIA in Egypt. JADI has a good correlation with traditional outcome measures in JIA and may be a good tool to be used in clinical practice and is likely to increase current understanding of the natural history of the disease.

DOI: 10.1136/annrheumdis-2017-eular.6707
Background: The Leeds Assessment of Neuropathic Symptoms (LANSS) and the painDETECT questionnaire (PDQ) are two validated screening tools for neuropathic pain (NP). Recent evidence reported a low level of agreement between these tests in knee Osteoarthritis. Several studies have recently applied the PDQ in Rheumatoid Arthritis (RA), suggesting a NP component in these patients, although the application and performance comparison with LANSS is yet to be studied.

Objectives: Evaluate PDQ and LANSS performance for NP classification and investigate its optimal cutoff points in a RA cohort.

Methods: Observational, cross-sectional study was designed including RA patients followed at our Rheumatology department. Patients with diagnosed neuropathy or non-RA risk factors for NP were excluded. Selected patients were evaluated in a medical visit where LANSS and PDQ were applied. Agreement between the two questionnaires was evaluated using kappa coefficient analysis. Receiver operating characteristic (ROC) analysis was performed using each tool as gold-standard and cutoff points to optimize agreement were investigated. Non-concordant patients were compared with concordant patients using parametric and non-parametric analysis for significance level in NP classification.

Results: 112 RA patients were included, 86 (77%) were females, with a mean (SD) age of 55.1 (10.8) years and median disease duration of 13 years (range: 2–41), 102 (91%) were treated with DMARDs and 42% with a biologic DMARD. 48% patients had NP applying the LANSS (≥13) and 28% had NP in the PDQ (19 possible and 12 likely) and no demographic or clinical significant differences were found between these two groups. 82 (73%) patients had concordant NP classification (59 negative, 23 positive) by the two tests. Concordant group showed significantly higher mean score on PDQ than non-concordant group (14 vs 12 years and 8 vs 13, respectively, p < 0.05) with no other significant differences found. A moderate agreement ($\kappa = 0.41$) and linear correlation (r=0.58, p<0.001) were observed between the two tests. In the ROC curve analysis, PDQ (≥13) showed an area under the curve (AUC) of 0.80, 95% CI [0.71–0.90] with a specificity and sensitivity of 74% and 73%, respectively, using LANSS as gold standard. LANSS ($\geq$12) had an AUC of 0.80, 95% CI [0.71–0.90] and a sensitivity and specificity of 74% and 73%, respectively, using PDQ as gold standard. After ROC curve analysis, optimal cutoff for PDQ was 10, showing greater sensitivity (69%) but lower specificity (51%) with a slight increase in the agreement between the tests ($\kappa$=0.48). For the LANSS, the optimal cutoffs were the previous value or 13 (sensitivity 68% and specificity 78%) with a modest gain in the agreement ($\kappa$=0.42). Correction for both cutoff points resulted in a more substantial increase in agreement level ($\kappa$=0.51).

Conclusions: In this study, LANSS and PDQ had a moderate level of agreement, possibly because they capture different dimensions of NP. New possible cutoffs were studied to increase agreement between the tests. Further studies with other conditions and a validated gold-standard for NP are needed to confirm this data.

ORM2 AND APA2 SERUM LEVELS CAN PREDICT OA PATIENT RESPONSE TO CHONDROITIN SULFATE/GLUCOSAMINE HYDROCHLORIDE: RESULTS FROM THE MOVES STUDY

V. Calamari 1, M. Camacho-Encina 1, L. González-Rodríguez 1, P. Fernández-Puente 1, I. Rego-Pérez 2, M. Herrero 2, H. Martínez 2, C. Ruiz-Romero 1, F. J. Blanco 1, Grupo de Proteomic-PBR2-ProteoRed/ISCIII-Service de Reumatología; 2Grupo de Género, Service de Reumatología, Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUC), Sergas, Universidad de Coruña (UDC), la Coruña; 3Clinical R&D Area, Bioiberica S.A., Barcelona, Spain

Background: A shotgun proteomic analysis performed on sera from patients enrolled in the Multicentre Osteoarthritis interVention trial with Sysadona (MOVES) led to the discovery of a panel of putative protein biomarkers useful to stratify osteoarthritis (OA) patients into responders and non-responders, either to Chondroitin sulfate/Glucosamine hydrochloride (Droglican®), Bioiberica S.A., Barcelona, Spain or Celecoxib.

Objectives: To validate the sensitivity and specificity of a panel of six serum proteins useful to predict the patient response to Droglican treatment, in order to optimize therapeutic outcomes in OA.

Methods: We analyzed the serum levels of a panel of six putative predictive protein biomarkers by enzyme-linked immunosorbent assays (ELISAs): APAO2, APA2, APA1, APA4, CA4BP, ORM2. All the subject studied belonged to the MOVES cohort at baseline (Droglican sub-cohort, n=260). Non-parametric and multivariate analysis were performed to test the effects of the clinical variables, including gender, age, BMI, radiologic Kelgren/Lawrence (KL) grade and WOMAC score at baseline, as well as the serum levels of each of the six mentioned proteins, on the response to Droglican treatment according to the OMERACT-OARSI criteria and the WOMAC pain score (20%, 30%, 50% and 70% reduction) recorded at the end of the trial (after 6 months of treatment).

Results: Non parametric analysis showed decreased serum levels of ORM2 and APA2 in responders compared to non-responders, both for KL grade (ORM2, APA2; p<0.001), WOMAC (ORM2, APA2; p<0.001), and serum levels of the panel of protein biomarkers in responders. The best protein panels were obtained by the combination of APA2 and ORM2.

PHYSICIAN VISUAL ANALOG SCALE ESTIMATES FOR OVERALL GLOBAL ASSESSMENT, INFLAMMATION, DAMAGE, AND DISTRESS TO ASSESS PATIENTS AND SUPPORT DECISION-MAKING IN RHEUMATOLOGY CARE: ANALYSIS OF INTER-RATER RELIABILITY

T. Pinus, I. Castrejon, J. Chua, A. Kugasia, J. Schmukler, S. Weinberg, J.A. Block. Rheumatology, Rush University Medical Center, Chicago, United States

Background: A physician global estimate of patient status (DOGCL) was developed to quantify inflammatory activity in rheumatoid arthritis (RA) clinical trials. However, DOGCL may be affected by joint damage and/or distress (in fibromyalgia, depression, etc.). One approach to document the possible impact of these problems on DOGCL is to add 3 physician visual analog subscale (VAS) estimates for inflammation, damage, and distress. These subscales have been shown to be useful in patients with diagnoses other than RA (1) but inter-rater reliability has not been analyzed.

Objectives: To analyze inter-rater reliability between senior rheumatologists and trainees on 4 VAS estimates for overall DOGCL, inflammation (DOGINF), damage (DOCDAM) and distress (DOCSTR), in patients with various rheumatic diagnoses.

Methods: Patients seen in routine care were assigned 4 physician VAS estimates for overall DOGCL, and levels of inflammation or reversible symptoms (DOGINF), organ damage or irreversible symptoms (DOCDAM), and distress or symptoms not explained by inflammation or damage (DOCSTR). VAS estimates were assigned independently by a senior rheumatologist and a rheumatology trainee for the same patient at the same visit. Mean differences, correlations, and possible discordance of ≥2 units/10 between estimates of the senior rheumatologist and the trainee were analyzed.

Results: VAS estimates by the 2 physicians were analyzed in 64 patients with different rheumatic diseases, including osteoarthritis (16%), RA (14%), fibromyalgia (14%), and systemic lupus erythematosus (13%). Mean differences of scores assigned by the senior rheumatologists versus trainees were <0.43/10, less than 5% of the total scales, slightly lower for DOGINF, and slightly higher for the 3 other subscales (p<0.001) (Table). Mean estimates of both physicians for damage and distress were higher than for inflammation by 1.1 to 1.6 units (Table). Concordions of all 4 VAS between rheumatologists and trainees were significant (p<0.001) (Table). More than 70% of the estimates were concordant for DOGINF (75%), DOCDAM (78%), and DOCDAM (70%), while concordance was somewhat lower for DOCSTR (57%) (Table).

Conclusions: Good inter-rater agreement between two physicians is seen for VAS estimates, inflammation, damage, and distress. Mean scores for damage and distress were higher than for inflammation, indicating the complexity of rheumatology care. Quantitative scores can add to documentation of patient status and to support of clinical decisions for doctors, patients, and payers.

DECREASED AUTOPHAGIC ACTIVITY IN T LYMPHOCYTES
FROM PATIENTS WITH NEWLY DIAGNOSED SYSTEMIC LUPUS ERYTHEMATOSUS

X. Luo 1, Y. Liu 2, M. Yang 2, 1Department of Rheumatology; 2West China Hospital, Sichuan University, Chengdu, China

Background: Alterations in T-lymphocyte homeostasis have been suggested to play a key role in the pathogenesis of SLE. Autophagy is now emerging as a core player in the development and the functioning of the immune system.

Objectives: We investigated the autophagic behavior of T-cells from patients with SLE.

Methods: Thirty patients with SLE and twenty-five healthy subjects matched for gender and age were recruited. The levels of mRNA encoding ATG5, ATG7, Beclin-1 and LC3 were determined by quantitative real-time polymerase chain reaction (qPCR), and evaluated by flow cytometry. The number of autophagic structures was examined by TEM in T-cells from SLE patients and healthy controls.

Results: We documented a decreased level of mRNA expression of LC3 and Atg7 in T-cells from patients with SLE (t=2.282, P<0.027, t=3.573, P<0.001). A decreased percentage of autophagic cells was confirmed in T-cells from patients with SLE, as compared to healthy donors by flow cytometry (t=2.034, P<0.047). No significant correlations between autophagy levels in T-cells and the disease activity of patients were observed (P>0.05).

Conclusions: Our results indicate that autophagy activity in T-cells from SLE patients is decreased, which may contribute to the development of SLE, and thus that resetting autophagy activity may be an important therapeutic goal in this autoimmune disease.

Rehabilitation

THE COMBINATION OF PHYSIOTHERAPY AND BIOLOGICAL THERAPY FOR THE MANAGEMENT OF ANKYLOSING SPONDYLITIS

A. Sahimi, Y. Slimani, M. Messaoud, O. Bersaoub. Physical Medicine and Rehabilitation Department, University Hospital and Medicine Faculty of Sidi Bel Abbes, Sidi Bel Abbes, Algeria

Background: The management of the ankylosing spondylitis (AS) aims at relieving patient’s pain, restoring their joint mobility and preventing structural damage which results in progressive deformity, in order to improve the functional status and quality of life of these patients, using various pharmacological and non-pharmacological means. The importance of the physiotherapy in patients with AS under biological treatment was reported in some studies, but the literature on this topic is still scarce.

Objectives: Report the experience of our department of Physical and Rehabilitation Medicine, in the management of the AS, especially the effect of the combination of physiotherapy and biological therapy on pain, disease activity, spinal mobility, functional capacity and quality of life.

Methods: Prospective study on 20 patients diagnosed with AS, treated with tumor necrosis factor alpha inhibitors (TNFa inhibitors) and placed under physiotherapy for 3 months. At baseline and at the end of 3 months, we evaluated Bath AS Disease Activity Index (BASDAI), occupant-wall distance, Hertz index, Schober index, Bath AS Functional Index (BASI) and Visual Analog Scale (VAS) of patient’s quality of life.

Results: For the 20 patients (9 females), aged 38.4 years±10.24 [range 19–55], treated with TNFa inhibitors (Etanercept in 35% and Adalimumab in 65%) and included in a physiotherapy program of 3 months (3 sessions/week), comprising muscle relaxation, flexibility exercises for cervical, thoracic and lumbar spine, range of motion exercises of coxofemoral joints, muscular strengthening, straight posture and respiratory exercises.

After 3 months, all outcome parameters showed statistically significant improvements (P<0.05), as shown in the following table.

Conclusions: According to our results, the combination of physiotherapy and
biological therapy is an effective mean in increasing functional capacity and joint mobility, decreasing disease activity, improving quality of life for AS patients. Currently available data do not adequately address what role physiotherapy may have on patients with AS receiving biological drugs [1]. There are a few studies evaluating the effects of exercises in patients with AS receiving TNF inhibitors [2,3].

A PROSPECTIVE STUDY ON THE EFFECTS OF 3-MONTH COURSES OF TRADITIONAL PHYSIOTHERAPY AND YOGA IN PATIENTS WITH CHRONIC ARTHRITIS AND PRIMARY FIBROMYALGIA

C. Nalli1, L. Andreoli1, R. Avanzini2, P. Tipa2, M. Zanetti2, C. Milini3, S. Olivieri4, E. Abram3, R. Furfari3, R. Gorla3, A. Tancini1, N. Ruberti1, Rheumatology and Clinical Immunology Unit, Spedali Civili and University of Brescia; 2Physical Therapy and Rehabilitation Unit, Spedali Civili; 3Academia Esse, 3Associazione Bresciana Art disco Reumatologico (ABAR) Omlus, Brescia, Italy

Background: Physical activity is of fundamental importance for people with rheumatic diseases (RD). The traditional approach of Physiotherapy (PT) has been placed side by side with other physical programs, such as Yoga (Y), aimed at reducing chronic pain and improving the quality of life.

Objectives: To evaluate the effects of PT and Y on patients with inflammatory and non-inflammatory RD: Chronic Arthritis (CA) and Primary Fibromyalgia (FM).

Methods: Patients were enrolled in a prospective study including 3 months of PT and 3 months of Y (with a specific focus on the control of breathing - Ai-jutsu). Each activity was performed bi-weekly in a dedicated facility. Patients were randomly allocated to either the group starting with PT or that starting with Y. After 3 months they switched to the other activity. At the beginning and at the end of each activity patients underwent a medical assessment of their physical status and were proposed questionnaires: 1) HAQ for disability in everyday life; 2) ZUNG self-rating depression scale; 3) Tampa scale for Kinesiophobia assessing the fear and avoidance of movement. Patients with FM compiled also the FIQ for the impact of FM in everyday life. All patients rated their physical pain by VAS (Visual Analogic Scale) from 0 to 10.

Results: Thirteen patients with CA (77% female, median age 62 years, median disease duration 19 years) and 8 with FM (100% female, 56 years, 9 years) participated in the study. At baseline, there were no differences between CA and FM patients in terms of ZUNG, HAQ and Tampa scores. After 3 and 6 months of activity, all items had a tendency toward improvement, with a statistically significant reduction for VAS in both groups (nearly 30%). By intra-group comparison, between the beginning and the end of each activity, we observed that patients with CA had a significant reduction of ZUNG and HAQ scores (50 vs 40.5 and 0.600 vs 0.475, respectively) during PT activity, while FM patients had a trend toward the increase of Tampa score (24.5 vs 34.5). During Y activity, significant reductions were observed in VAS score for CA patients (5 vs 2.5) and in Tampa score for FM patients (34.5 vs 23.5). Overall, all items had a tendency toward improvement for FM patients during Y activity.

Conclusions: This pilot study involving both patients with inflammatory and non-inflammatory RD demonstrated benefit from an integrated program of sequential PT and Y and highlighted differences in patients’ needs according to their disease type. Particularly, PT seemed to bring more benefit to CA patients, probably because of the individualized work on joint movement range and muscular strengthening, while FM patients may have had a negative impact by this approach. A negative correlation between the beginning and the end of each activity, we observed that patients with CA had a significant reduction of ZUNG and HAQ scores (50 vs 40.5 and 0.600 vs 0.475, respectively) during PT activity, while FM patients had a trend toward the increase of Tampa score (24.5 vs 34.5). During Y activity, significant reductions were observed in VAS score for CA patients (5 vs 2.5) and in Tampa score for FM patients (34.5 vs 23.5). Overall, all items had a tendency toward improvement for FM patients during Y activity.

THE INTENSIVE EXERCISE PROGRAMME FOR NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS AND FOR ANKYLOSING SPONDYLITIS MAY IMPROVED QUALITY OF LIFE AND DISEASE ACTIVITY

M. Husakova1, K. Pavelka1, M. Spirtovic1,2, C. Abrilova1,2, Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague 2;2Charles University, Faculty of Physical Education and Sport, Prague, Czech Republic

Background: The therapy for axial spondyloarthritis (axSpA) is complex. Although anti-inflammatory medication is necessary for axSpA treatment, the exercise therapy is required to maintain mobility. The limited data are available to evaluate the effect of exercise therapy on quality of life in axSpA, particularly in patients with the non-radiographic form of the disease (nr-axSpA).

Objectives: To investigated the quality of life in axSpA subgroups, nr-axSpA and Ankylosing spondylitis (AS) in response to intensive rehabilitation programme

Methods: 46 patients with axSpA characterised according to criteria of Assessment of SpondyloArthritis国际社会 (ASAS) as nr-axSpA (n=23) and AS (n=23) by the increase disease and treatment underwent 24 weeks long intervention. The intervention consisted in twice a week outpatient group physiotherapy as exercise units of 60 minutes and a daily home-based exercise programme. All outcomes, disease activity (Bath AS Disease Activity Index, BASDAI and AS Disease Activity Index, ASDAS-CRP) and quality of life (AS quality of life, ASQoL and European quality of life, EuroQoL) as well as patients self-reported outcomes such as “patients global assessment” and “pain assessment” were measured at baseline and at the end of exercise programme.

Results: Altogether, 41 axSpA patients (AS, n=22 and nr-axSpA, n=19) finished complete six months programme. The disease activity was improved in all axSpA patients (ASDAS-CRP 2.08±0.12 to 1.83±0.11, p<0.01), particularly in nr-axSpA subgroup, ASDAS-CRP (1.98±0.19 to 1.71±0.15, p<0.05). There were no differences in the changes in ASDAS-CRP and BASDAI over the exercise training between groups (data not shown). After exercise therapy, positive changes of “Patients global assessment”, were evaluated by patients of both subgroups, nr-axSpA (33.42±5.13 to 23.68±4.11, p<0.01) and AS (35.22±3.94 to 25.22±2.92, p<0.01). The “assessment of pain during the last 7 days”, however, was improved only by patients in the nr-axSpA subgroup (34.7±4.58 vs. 21.05±4.71, p<0.05).

The quality of life, ASQoL was not changed after rehabilitation programme.
The EurQol was changed in all axSpA (0.74±0.21 to 0.77±0.18, p<0.05), but significantly was improved only in nr-axSpA subgroup (0.72±0.23 to 0.78±0.18, p<0.01), not AS. Similarly, the improvement of the assessment of “hodiernal health status” was found after an intervention only in the nr-axSpA subgroup (65.81±21.80 to 78.00±13.77, p<0.01).

Conclusions: Our study demonstrated beneficial effect of intensive exercise programme on disease activity and patients self-reported outcomes in nr-axSpA and AS patients. The patients suffering from nr-axSpA can profit at least similarly from the rehabilitation care as those with radiographie form. The exercise programme should be recommended for both subtypes of axSpA.

AB1181 LOCAL STEIOD AND INSULIN INJECTION IN MANAGEMENT OF CARPAL TUNNEL SYNDROME: A COMPARATIVE STUDY
M.H. Abu-Bozaid, S. El morsy, S.A. Hablas. Rheumatology and Rehabilitation, Faculty of Medicine Tanta University Egypt, Tanta, Egypt

Background: Carpal tunnel syndrome (CTS) is the most common focal nerve entrapment. Local corticosteroid (CS) injection has been widely used to treat CTS. Recently; Local insulin Injection in CTS has been studied as insulin has anti-inflammatory anti-edematous effects.

Objectives: To compare the effectiveness of local steroid and insulin injections in management of CTS.

Methods: Forty patients complaining of mild or moderate idiopathic CTS (diagnosed clinically & electrophysiologically and classified according to American association of neuromuscular diagnostic medicine monograph) divided into 2 equal groups.

Group I received two local injections of 10 IU NPH insulin into the affected carpal tunnel 2 weeks intervals. Group II: received single injection of triamcinolone acetonide (20 mg/0.5 ml) all procedures done after informed consent. Patient with severe or secondary type of CTS were excluded from this study. Evaluation of the patients was done at baseline, 2 and 4 months later clinically by measuring visual analogue scale (VAS), Phallen and compression tests and electrophysiologically by measuring motor and sensory nerve conduction studies of median and ulnar nerves using a standardized technique.

Results: There was significant improvement in all clinical parameters in both groups after 2 and 4 months from injection (p<0.01) including VAS, Phallen and compression tests with more improvement was noticed in group I. However the improvement was more in group I but the difference between results in both groups were statistically nonsignificant.

Conclusions: Local insulin injection is as effective as (or even better than) local steroid injection in management of CTS.

Education

AB1183 PATIENT’S EDUCATION IN THE ADMINISTRATION OF SUBCUTANEOUS DRUGS IN THE RHEUMATOLOGY DAY-CARE HOSPITAL UNITS
A. Erra, A. Fagil, L. López. Rheumatology, Hospital San Rafael, Barcelona, Spain

Background: Rheumatology Day-Care Hospital Unit (DHU) is defined as a hospital unit for a few hours with the objective to do diagnostic clinical trials and/or multiple test, patient education and treatments that cannot be done in the outpatient clinic, but which do not justify the complete stay in the hospital.

Objectives: Analyze the number of visits that one patient needs in the Rheumatology-DHU to learn the self-administration of a subcutaneous drug.

Methods: All patients who were prescribed a subcutaneous drug (except monoclonal) during the period January 2015 - December 2016 were referred to Rheumatology-DHU. The nurse gave instructions, she supervised the patient’s learning and she decided if the patients needed a new control in Rheumatology-DHU.

Results: The following data were recorded: sex, age, diagnosis, drug, number of visits each patient needed in Rheumatology-DHU. In patients who had already been discharged and adherence to treatment. None declared.

References:
The patient's education by nurse in Rheumatology-DHU is necessary for the right visits or more new referrals to Rheumatology-DHU. Therefore, age is not a limiting factor. In 9% of the patients, the education was done to a reference person and not to the patient himself. We analyzed PTH and MTX groups (because they had the highest number of patients) and we observed that in the PTH group 82% required education of the relative. This percentage was 77% in the MTX group. The number of visits in the Rheumatology-DHU were: 1 in 26 patients (MS of 66 +/- 19.6 years), 2 in 59 patients (MS 65 +/- 18); 3 in 13 patients (MS 64 +/- 13); 4 in 6 patients (MS 67 +/- 14); 5 in 2 patients (MS 68 +/- 17), 6 in 2 patients (MS 70 +/- 22), and in 9 in 1 patient (47 years). Adherence to treatment was 98.2%. A total of 238 visits were made in Rheumatology-DHU.

Individual semi-directed interviews, have been performed and their thematic content analysed with the QDA Miner program. A guide had been achieved by rheumatologists, psychologists and patient association representatives. The project has been approved by the ethical committee of the University of Katowice, Poland.

AB1184 - EDUCATIONAL NEEDS OF PATIENTS WITH RHEUMATIC DISEASES RECEIVING BIOLOGICS

Background: Biologics are still a challenge in patients receiving biologics. Most of the patients represent their experience with biologics as a new and partially enigmatic tool for management of rheumatic diseases.

Objectives: The study was designed to evaluate educational needs and sources of education in patients with rheumatic diseases treated with biologics.

Methods: Anonymous questionnaires were distributed in 23 Polish rheumatological centers involved in the treatment, 1231 questionnaires were used for analysis. Responses were received from 806 patients with rheumatoid arthritis, 427 with ankylosing spondylitis, 117 psoriatic arthritis, and 62 adult patients with juvenile idiopathic arthritis (in whom administration of the drugs had been introduced before they were 18-year-old), as well as 19 ones receiving the drugs due to other musculoskeletal disorders. The investigated group constituted one fifth of all rheumatological patients on biologics in Poland.

Results: Almost all the patients had learnt for the first time on biologics from the rheumatologist (93%). Few patients only had got such data from internet or from other patients. Likewise, most of the patients got majority of educational data on treatment with biologics from rheumatologist who was supervising the therapy (82%). Remaining sources included internet (8%) and other patients (5%). Relative low number of patients was educated by nurses (2%). Most of the patients (87%) were looking for more details on biological treatment. The patients with rheumatic disease lasting less than 10 years, were more interested in the management than those suffering longer. Most of the patients (94%) considered their rheumatologist as the main person responsible for their education on biologics. There was no difference between patients with various rheumatic diseases as well as no difference was found between female and male patients. Biological treatment attracted more interest in younger than older patients.

Conclusions: Education is still a challenge in patients receiving biologics. Most of the patients represented traditional attitude to health education, expecting almost all educational data to be provided by their physician. We were surprised that role of the nurses was found to be rather low. An increase in role of nurses seems to be the future aim of the educational efforts in Polish rheumatology.

AB1185 - REAL-LIFE EXPERIENCE AND MUTUAL EXPECTATIONS OF PATIENTS AFFECTED WITH CHRONICAL INFLAMMATORY RHEUMATIC DISEASES AND THEIR RELATIVES: CONSEQUENCES IN PATIENT EDUCATION: A QUALITATIVE STUDY BY THE PROXYRIC GROUP OF THE PATIENT EDUCATION DIVISION OF FRENCH RHEUMATIC DISEASE SOCIETY

P. Poirier1, A. Untas2, E. Boujot1, C. Voulaee3, C. Delanney1, L. Carton5, N. Legoupl1, G. Hayem1, S. Pouplin5, A.-G. Rat5, J.-S. Giraudet-Le Quintrec5, C. Beaussais1, C. Michet-Thionville, Metz; 2Institut psychiatrie Paris Descartes, Paris; 3Institut psychopathologie et processus de santé, Versailles; 4Cabinet Psychiatrie; 5AFAR; 6Service Rhumatologie A, Hopital Cochin, Paris; 7Service Rhumatologie, Hopital Ambroise Paré, Boulogne Billancourt; 8Service Rhumatologie, CHU, Rouen; 9Service Rhumatologie, CHU Saint Antoine, Paris, France

Background: Interaction with relatives has a significant role on patients’ health, and can also impair relatives’ health. Education processes need codification to enrol relatives in the programs.

Objectives: To create a patient education program for relatives and patient affected by rheumatic inflammatory diseases.

Methods: Individual semi-directed by 2 psychologists interviews, have been performed and their thematic content analysed with the QDA Miner program. A guide had been achieved by rheumatologists, psychologists et patient association representatives. The (patient/relative) dyad, has been first questioned together, and then individually.

Results: 20 patients, average age 59 years (27–79) affected with Rheumatic Arthritis (n=13), Spondyloarthrits (n=9) with an average disease duration of 12,8 years (1–39) and one of their relatives (being their spouse in 18 cases) have been recruited in 7 rheumatology departments in France. Common life duration was 27,5 years as an average (1,5–57). About 2/3 of patients and relatives have a common view on: relative’s role in bringing an emotional support but needs a knowledge on disease and treatments; emotional distress experienced by both patient and relative; the worries and relative’s feelings of not knowing how to do; the help brought by the relative in everyday’s life and his participation to care management. Only a few relatives talked about concerns, regrets of past life, and burden feeling of patient. Relatives also express unfairness feelings. 2/3 of patients and relatives report will of independence of the patient, who wants to manage alone, and does not express his difficulties. 50% of relatives think they anticipate patient’s needs, they are also directly requested by the patient. On the other side, the patients often report that they watch over relative’s health. 50% of patients and relatives mention the idea of complementarity and a “team”, but also tensions or conflicts. Patient Education contribution would be sharing and exchanging biological and medical information and patient’s data and relatives, who therefore would prefer group education (12/20). Relatives however more often mention a common education with patient, and patients prefer a separate education of relative. The main limit to this study is that participation to study has favored harmoniously functioning dyads, what may explain the weak rate of abandonment feeling.

Conclusions: Expectations on relatives’ role seem to be common in terms of practical and emotional support. Relatives sometimes mention the “positivation” of their role, but also emotional distress and helplessness feeling. Patients fear they are a burden and want to be independent. A specific educational management of relatives is more often suggested by patients than by relatives.

AB1186 - OPTIMISATION OF RHEUMATOLOGY UNDERGRADUATE TEACHING: SELF-DIRECTED DEVELOPMENT OF POWERPOINT PRESENTATIONS BASED ON THEORETICAL CLINICAL CASES

F.A.H. Coolens1, 2, R.L. Batten1, J. Stewart1, D. Cosny1, 1City Hospitals Sunderland NHS Foundation Trust, Sunderland, 2NIHR Newcastle Biomedical Research Centre based at Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle upon Tyne, United Kingdom

Background: One element of rheumatology undergraduate teaching in City Hospital Sunderland, UK traditionally involves “paper cases” delivered via small group learning and discussion. Although popular it has had poor feedback from both the students and the tutors at times especially when the tutor to student ratio is high (1:16). With limited numbers of tutors (Consultant Rheumatologists), this issue was becoming more frequent.

Objectives: We wished to explore alternative yet still interactive methods to highlight key learning points relating to common rheumatological conditions in a 60 minute teaching session and to make this fun and engaging.

Methods: 30 undergraduate medical students (January 2017) were given modified teaching material for a 60 minute teaching session a week later. This material involved a partially populated Microsoft Powerpoint slideshow including prompts about a theoretical patient’s clinical case in the notes section. This guided development of a clinical case presentation which covered diverse aspects of clinical care, including its effect on side effects and hand activity scores. Clinical cases addressed systemic lupus erythematosus, early rheumatoid arthritis (RA), ankylosing spondylitis and established RA. Students (groups of 2-3) received one case each were encouraged to use images and online teaching repositories to enhance their presentation. This provided the framework for a 20 minute teaching presentation which was given to their students peers at a formal teaching day 1 week later. A tutor was also present during these sessions (with a ratio of 1:10) to ensure adequate understanding of topics had been achieved and to answer any questions. Feedback was sought from the students and compared with previous “paper case” (non-modified) sessions.

Results: Feedback obtained (n=9) showed 55% of students rated the modified teaching session as “excellent” with the remainder rating it as “good”. Free-text comments included “good to have students do to the presentations so they cover relevant points” “very useful to have a quick 20 minute overview of different conditions & preparation was useful” and “lots of learning, interactive”. Additional comments included the wish for more time to cover the points in even more depth. Informal feedback from the tutors of these events was also favourable with tutors believing students had a developed a greater depth of understanding. These findings compared favourably with the previous years “paper-case” feedback (March 2016). Note only 23% (n=11) of students had rated the session as “excellent” as well as free text comments emphasising wishes for more time to read through cases and smaller group discussion.

Conclusions: Current “paper based” modalities can easily be utilized and “re-purposed” to optimize both self-directed and formal teaching components of undergraduate teaching. This can promote the understanding of complex rheumatological learning points in a relatively short period of time and allow students exposure to modalities, such as imaging, which may previously be excluded in a traditional “paper case” format.

AB1187 SURVEY ON GENERIC DRUGS (GE) AND BIO-SIMILAR DRUGS (BIO-S) OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA) AND THEIR DOCTORS - COHORT STUDY OF THE JAPANESE CLINICIAN BIOLOGICS RESEARCH GROUP

K. Funahashi1, T. Yoshitama2, T. Tetsu Oyama3, A. Sagawa3, K. Katayama3, “GO TRANS”: OUTCOME OF THE PROGRAM OF WORKSHOPS

Methods: 30 research group member facilities. It was an anonymous written survey. After informed consent document was signed, participants were asked to complete a survey back. The group was 78% female, the majority of whom were in their 60’s, and had most had disease history of more than 10 years. Those with a good impression of a GE, who prescribed them, and conducted a comparative study of patient’s and doctor’s awareness regarding these drugs.

Methods: The survey was carried out amongst 4151 patients being treated at 20 research group member facilities. It was an anonymous written survey. After the section on patient background (age, gender, disease history) was completed, participants were asked to fill in the answers of generic drugs, their attitudes towards changing to a generic, whether or not they had ever experienced an adverse effect with a generic drug, what knowledge they had regarding bio-similar drugs, and if they had any interest in or experience with using bio-similar drugs. We also asked 32% of patients if they trusted bio-similar drugs became possible in Japan in 2015, but the degree of knowledge that patients have regarding them is unknown.

Objectives: Therefore we carried out a patient survey about generic and bio-similar drugs, and at the same time, we also conducted a questionnaire for doctors, who prescribed them, and conducted a comparative study of patient’s and doctor’s awareness regarding these drugs.

were under immunosuppressive therapy and 60% of them received biological treatment. 20% of patients had clinical activity data. The average of global VAS was 12 (0–100) and the average of VAS pain was 0.9 (0–100). The average of initial PEDSQL 4.0 was 80.7 (0–100) and the PEDSQL 4.0 at three months was 74.4. At the end of the workshops, 100% of parents and patients would recommend other patients to attend it, more than 50% of patients think that they would be able to go to medical visits without their parents and 90% of them would take responsibility for their treatments. A 90% of patients think that workshops have helped to improve their relationship with their rheumatologist and 60% of them have improved their knowledge about the disease. Regarding to physical activity levels, 30% of age have increased it compared to baseline. More than 50% of parents have observed a positive attitude change towards the disease after the program.

Conclusions: Transition programs are important for the transfer to be effective throughout the involvement of adolescent, who takes responsibility for his/her disease and also to ensure their psychosocial needs are met. Rheumatologists must be ready to cover these needs with the support of other specialists. Our experience with the program was very positive since most of the patients improved their knowledge about the disease and its autonomy concerning their medical consultations and treatments, being very satisfied with the contents of the workshops.

AB1190 BEHAVIOR AND TRENDS IN COLOMBIAN PATIENTS WITH RHEUMATIC DISEASES RELATED TO THE TECHNICAL TOOLS IN CONSULTATION OF RHEUMATOLOGY

M.C. Letorre1, A.M. Ocaña2. 1Reumatología, Country Medical Center; 2Electronic Engineering, Oceotsft, Bogota, Colombia

Background: In the last decades the internet has changed the way of communication with patients using email, social media and other technological tools, as a complement to the consultation. The development of websites and electronic history are part of these tools that have come to change communication with the patient.

Objectives: To analyze the behavior and trends of Colombian patients with rheumatic diseases related to use electronic tools.

Methods: We analyzed 425 patients between September 2015 and December 2016, who attended to consultation at Country Medical Center. Everyone was provided the website http://www.dra-mc stomchangalorrequemologica.com/. This website was developed by Oceotsft (http://www.oceotsft.com/), company specialized in development of websites and software. In this website we have general information the clinic, access, schedules, glossary, news, medical information and can request online appointment.

Results: We included 425 patients with rheumatic diseases, 85.5% female, with an average age of 52.5 years old. 95% lived in urban areas. 92% had internet access. 80% had smartphone. They were stratified by educational level, finding that 70% had college level. And by age groups it was found that patients between 30 and 50 years old in 72% of cases used the electronic way to request the appointment or ask questions. Patients between 18 to 29 years prefer social media. Patients over 60 years old preferred to use the telephone. The reasons for using the online appointment were: easy access at any time 84% tool speed 10%. Difficulty for the use of the telephone at work 2%. Others 4%. When patients communicate via email 90% of the questions are related to requesting an appointment or ask questions. Patients between 18 to 29 years old prefer social media. Patients between 30–40 or –40–50 years had a higher score than those aged 30–40 or 40–50 years (5.8 vs 5.2 vs 5.1 respectively) but were similar in the 2nd test (6.5 vs 6.3 vs 6.8). By nationality, Spaniards had higher initial scores than foreigners (5.78 vs 4.91, p < 0.001). Men showed higher scorings than women in their 1st test (5.92 vs 5.56), but the difference was lost in the 2nd test (6.79 vs 6.47). Younger residents (ages 20–30 years) had a 1st higher score than those aged 30–40 or 40–50 years (5.8 vs 5.2 vs 5.1 respectively) but were similar in the 2nd test (6.55 vs 6.3 vs 6.4). For specialties, dermatology, internal medicine and RHB had initial scores higher than MFC (7.3 - 6.1 - 6.3 vs. 5.4), but in the second test there were no significant differences. Conclusions: The level of knowledge of rheumatology of the residents who start a training rotation in this specialty is moderate, with an average of 5.59 points out of 10 possible. At the end of the rotation their scores increased an average of 22%, which shows a significant improvement but still not very high. Several factors were related to basic knowledge scores but lost significance in the final test, reflecting appropriate improvements in knowledge in all subgroups.

AB1192 NATIONAL BAROMETER TO ASSESS THE EMOTIONAL ASPECTS OF PATIENTS WITH RHEUMATOID ARTHRITIS. OPINAR PROJECT

S. Castañeda Sanz1, M.A. Gonzalez-Gay2, E.F. Vicente1, A. Cugre de Miguel3, M. De la Hera4, V. Torrente-Segarra5, L. Merino-Meléndez6, A. Juan-Mas7, L. Alcaide8, A.I. Torralba9, J.L. Baquero10.

1Reumatología; 2Hospital General de Castellón; 3Servicio de Reumatología; 4Hospital General de Castellón; 5Reumatología, Hosp. Virgen del Rocio; 6Reumatología, Hospital Son Llatzer, Palma de Mallorca; 7Reumatología, ConArtritis; 8Reumatología, Hospital de la Santa Creu i Sant Pau, Barcelona; 9Reumatología, H.U Quirón-Dexeus; 10Reumatología, H.U. de la Princesa, Madrid.

Background: The WHO defines health as the state of physical, psychic and social well-being. In contrast, patients with rheumatoid arthritis (RA) frequently report that treatment is directed mainly at combating physical affection and hardly anything to emotional and social aspects.

Objectives: To assess the emotional impact and degree of satisfaction with the medical care received in the patient with poor prognosis RA.

Methods: National, structured, anonymous survey of 26 questions conducted between March and July 2016. Responses were counted as percentages or as means/medians of the score given on a Likert scale from 1 to 10 (minimum and maximum, respectively). Analyses were performed using Microsoft 2012: mean (m), standard deviation (SD), median (M), interquartile range (IQR) and statistical significance of differences (Student t test).

Results: The survey was completed by 100 of 122 enrollees, 75 by telephone and 25 via email; 83 women and 17 men, with a mean age of 49.4 years (SD 12.1); from all the Spanish Autonomous Communities. 52% were considered of poor
prognosis (participant’s own perception). 66.7% of self-perceived high-activity RA by patients exceeded the physician’s impression; and 31.03% of the intermediate-activity. The degree of knowledge and the importance given to certain aspects of the disease in relation to the poor prognosis ranged from 8 to 9/10 in the different items analyzed. The awareness of their seropositivity against FR and ACPA was 77% and 17%, respectively. 63% consider the physical aspects more disabling, but 52% gave more value to feeling good emotionally. The mean treatment score for physical aspects was 7.07 (SD 2.52), whereas for emotional aspects was 3.39 (SD 2.57). 51.9% of self-considered poor prognosis patients believed that biological treatment was delayed and 50% related that to poorer outcome. 97% wished to participate in the doctor’s decision and 95% declared they had no choice. There were no statistically significant differences between the prognostic groups.

Conclusions: More than half of the patients self-reported poor prognosis. Two-thirds estimated poorer health status than physicians if their RA was of high activity; 1/3 if it was intermediate. Patients considered all assessed aspects as determinants of poor prognosis (m = 8). The degree of knowledge of their condition was high, being lower for joint damage and activity and prognostic markers. The beginning of treatment with biologicals was perceived as delayed in more than half of those who declared themselves with poor prognosis and half of them related it to a worse evolution. A high percentage of patients showed low satisfaction with the emotional attention received. Most claim to be more involved in medical decisions, although more than 1/3 does not seem to be able to do so.

AB1193 DEVELOPING THE KOREAN EDUCATIONAL NEEDS ASSESSMENT TOOL (KOREAN-ENAT) IN RHEUMATOID ARTHRITIS: A CROSS-CULTURAL VALIDATION USING RASCH ANALYSIS

Y-K. Sung1, D. Kim1, S.J. Cha1, D. Yoo1, S.-H. Kim2, M. Ndosi3, S.-K. Che1, 1Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul; 2Department of Measurement and Evaluation of Physical Education, Chungbuk National University, Cheongju, Korea, Republic Of; 3Centre for Health and Clinical Research, University of the West of England, Bristol, United Kingdom

Background: The Educational Needs Assessment Tool (ENAT) is a 39-item patient-completed questionnaire designed to help patients identify and prioritize their educational needs. It was originally developed in the UK and validated in 7 rheumatic diseases including rheumatoid arthritis (RA).1

Objectives: This study aimed to undertake cross-cultural adaptation and validation of the ENAT in RA for use in Korea.

Methods: The study involved two main phases: (1) Cross-cultural adaptation of the ENAT from English into Korean and (2) validation of the Korean-ENAT. The first phase followed an established process of cross-cultural adaptation of self-report measures.2 For the second phase, patients with RA completed the Korean-ENAT at the outpatient clinic of a university hospital and Rasch measurement computer program, WINSTEPs, was used to analyze the data. Fit to the model was determined by the observed data Infit and Outfit statistics (≥0.50 and <1.50); where a value of 1.00 suggests a perfect fit to the model expectations. The unidimensionality of the scale was determined by item (and person) separation index ≥1.50 and reliability ≥0.80.

Results: An adequate conceptual equivalence was achieved following the adaptation process. A total of 123 patients completed the Korean-ENAT. Their mean ± SD age was 46.7±12.3, disease duration 53.7±71.2 months and the self-report measures.3

PHYSICAL ACTIVITY IN PATIENTS WITH INFLAMMATORY ARTHROPATHIES

Background: Inflammatory arthropathies are a group of diseases that have common characteristics, like unknown etiology, autoimmune or autoinflammatory pathogenesis, genetic predisposition and chronicity. These affect people of all ages and can cause physical, psychic, and social disability. Physical activity is essential to decrease symptoms of pain, fatigue and weakness, improving joint mobility, increasing muscle mass, flexibility and psychosocial health.

Objectives: To describe the physical activity in patients with inflammatory arthropathies.

Methods: In this transversal, observational study we evaluated all patients with inflammatory arthropathies treated with intravenous biologic therapy in a Day Hospital Unit (DHU) of a tertiary hospital. We collected the following data: demographics, indexes of disease activity according to each disease, fatigue questionnaire (FACIT), health questionnaire SF–12, physical activity questionnaire (PAQ), and fibromyalgia questionnaire (FIQ*F). This represents a cohort of patients that initiate an educational program on the importance of physical activity in the management of the disease.

Results: We included 222 patients (60.8% female), with a median age (SD; range) of 56.19 (12.89; 25–82) and a median disease duration (SD) of 16.54 (9.6). Of all included patients, 54.1% had rheumatoid arthritis, 39.2% had spondyloarthritis and 6.8% has psoriatic arthritis; 26.8% were in remission, 43% practice more than one sport. According to the IPAQ questionnaire, 19.8% performed high physical activity, 44.1% middle, 36% low physical activity, and 5.1% sedentary. Fortye five (20.3%) patients had fibromyalgia according to FIRST questionnaire. According to the IQPA questionnaire, 73% of patients considered that their diseases affect the performance of physical activity. 67% of the patients had none or very low daily physical activity, 80% would like to do more exercise. Among sports or physical activities performed by the patients, the most common was walking (65%), then swimming (12%), cycling and gym (8%) and running (6%). Of the patients who perform physical activity, 43% practice more than one sport.

In a multivariate regression logistic, only the gender and the age related with the physical activity, and not the disease; males (p = 0.024; Exp(B) 2.389; CI 95%: 1.124–5.059) and younger persons (p = 0.004; Exp (B) 0.959; IC 95%: 0.943–0.987) performed more physical activity.

Conclusions: Patients with inflammatory joint diseases perform low physical activity. The nurse plays a very important role in educating and informing the patients about their illness, and helping them in changing their lifestyle, encouraging increased physical activity with appropriate programs depending on the alterations that produce each disease, in order to improve their quality of life.

THE EFFECTS OF KINESIO TAPING ON PAIN, JOINT RANGE OF MOTION, MUSCLE STRENGTH AND DISABILITY IN IMPINGEMENT SYNDROME

A. Yildiz 1, Y. Buyuktepe2. 1Physiotherapy and Rehabilitation, Marmara University Health Sciences Faculty; 2Istanbul Education and Research Hospital, Istanbul, Turkey

Background: The impingement syndrome is common cause of shoulder pain. Physical therapy includes manual therapy techniques, electrotherapy modalities and exercises in this problem. The Kinesio Taping application is a definitive rehabilitative taping technique that is designed to facilitate body’s natural healing process while providing support and stability to muscles and joints without restricting the body’s range of motion.

Objectives: The purpose of this study was to determine the efficacy of kinesio taping (KT) on subjects’ pain, joint range of motion, muscle strength and level of disability in treatment of impingement syndrome (IS).

Methods: The study was conducted patients with IS. The subjects were divided into two random groups as general physical therapy applications group (GPTG) and kinesio taping group (KTG). GPTG was treated transcutaneous electrical nerve stimulation (TENS), hotpack and ultrasound for ten session. KTG’s therapy was contained shoulder kinesio taping application in addition to TENS, hotpack and ultrasound. KT was applied as “Y strip” to deltoid and supraspinatus muscles and was “I strip” to muscle of teres minor. The groups were evaluated before and after treatment in terms of pain, range of motion (ROM), muscle strength and scores of shoulder disability. Visual analog scale was used to assess of pain (night pain, rest pain, pain with motion and general pain), goniometer measurements was used to assess of shoulder ROM. Shoulder Disability Questionnaire and Disabilities of the Arm Shoulder and Hand were used to assess of shoulder disability.

Results: 54 patients with IS aged 18 to 65 years were recruited to the study. Demographic data were similar in the groups. When compared before and after treatment, the level of pain, night pain, rest pain, pain with motion and pain in functional use) was significantly decreased in both groups (p<0.05) (Table 1), also an improvement was seen in muscle strength (p<0.05), ROM (p<0.05) and in the scores of disability of shoulder (p<0.05) in both groups. In terms of overall pain relief the KTG scores better than GPTG. Internal and external rotation muscle
Active internal and external rotation ROM increased in KTG (p < 0.05). Functionality and disability scores improved in two groups. It was detected that there was no difference between the groups in terms of the values of muscle strength, functionality and disability scores.

**Conclusions:** The kinesiologic band can be used as a supportive therapy method in the early shoulder treatment program because it provides painless shoulder motion to clinicians. We consider that KT applications in addition to general physical therapy applications may have positive effects in the treatment of impingement syndrome.

**A PHYSIOTHERAPY-LED IN-PATIENT INTENSIVE REHABILITATION PROGRAMME FOR ANKYLOSING SPONDYLITIS: FOLLOW-UP OUTCOMES**

C. Clarke1, P. Taggart1, J. Monaghan1, J. McKnight2, A. Cairns3.

1Physical Therapy, 2Rheumatology, Musgrave Park Hospital, Belfast, United Kingdom

**Background:** Physiotherapy and exercise are highly important in the management of Ankylosing Spondylitis (AS). Physiotherapy is delivered to patients with AS in either in-patient or out-patient settings. Knowledge of the effectiveness of an in-patient delivered programme is useful for physiotherapists in assisting patients to achieve their goals.

**Objectives:** To assess the short-term effectiveness of an intensive rehabilitation programme using BASMI and EASI-QOL outcomes, and long-term patient satisfaction and physical activity behaviour and adherence to exercise plan.

**Methods:** Thirty-two AS patients (25 males and 7 females) admitted to an in-patient rheumatology ward underwent a 1 to 2-week physiotherapy-led intensive rehabilitation programme and were then discharged with a home exercise programme. Pre/post rehabilitation BASMI scores were available for 26 patients. The primary outcome measure was the proportion of patients achieving an improvement on BASMI scores at discharge. Secondary outcome measures included improvements in physical activity levels and adherence to home exercise programme for longer than 3 months which was obtained via a postal patient satisfaction and physical activity questionnaire achieving a response rate of 50% (n=16).

**Results:** Improvements in BASMI scores was achieved in 69% of patients (n=18) at the end of the in-patient rehabilitation period. Improvements in EASI-QOL were achieved in 83% of patients (n=15) at the end of the in-patient rehabilitation period. Ninety-four percent of patients (n=15) increased their physical activity levels after discharge, with 81% (n=13) of patients maintaining their home exercise programme for 3 months more. Thirty percent (n=7) of patients carry out at least 150 minutes of physical activity per week (National Recommended Physical Activity Guidelines is 150 minutes/week of moderate intensity).

**Conclusions:** This recent audit shows the effectiveness of an intensive physiotherapy-led in-patient rehabilitation programme for Ankylosing Spondylitis improving BASMI scores in 18 patients and improving physical activity behaviour over the long-term. Future work will aim to compare demographics and medical treatment differences between improvers and non-improvers.

**SELF-MANAGEMENT EXERCISE PROGRAM ASSOCIATED TO SPA THERAPY INCREASED THE PHYSICAL ACTIVITY LEVEL OF PEOPLE WITH SYMPTOMATIC KNEE OSTEOARTHRITIS: A QUASI-RANDOMIZED CONTROLLED TRIAL**

C. Gay1, C. Auclair2, N. Boisseau3, L. Gerbaud4, E. Coudrey1.

1Medical and Rehabilitation Medicine Department, Clermont-Ferrand University Hospital, Clermont-Auvergne University, INRA, Human Nutrition Unit UMR1019, Clermont Ferrand; 2Public Health Department, Clermont-Ferrand University Hospital, Clermont Auvergne University, PEPRADE, EA 4681; 3Laboratory of the Metabolic Adaptations to Exercise under Physiological and Pathological condition (AME2P), Clermont Auvergne University, ENS 3533, Clermont-Ferrand; 4Public Health Department, Clermont-Ferrand University Hospital, Clermont Auvergne University, PEPRADE, EA 4681, Clermont Ferrand, France

**Background:** Treating knee osteoarthritis (OA) in the medical phase is today well standardized. Guideline oriented approaches aiming at increasing physical activity (PA), improving pain and disability.

**Objectives:** To assess effectiveness of self-management exercise program associated to spa therapy at 3 month on the improvement of physical activity (PA) level, disability, pain, anxiety, fears and believes in symptomatic knee osteoarthritides (OA).

**Methods:** Prospective, multicentric, quasi-randomized controlled trial with alternate month design method (one month periods). People with symptomatic knee OA people (stage I-V, Kelgren and Lawrence scale) with low and moderate PA level were included in 3 spa therapy resorts. Intervention group (IG) received 5 self-management exercise sessions (1h30; education, aerobic, strength training, range of motion) + information booklet + 18 sessions (1h) of conventional spa therapy (STC). Control group (CG) received information booklet + 18 sessions of STC. The primary outcome was changes at 3 months in PA level (IPAQ short form) and secondary outcomes were WOMAC function, pain (VAS), HAD anxiety/depression, KOFBeQ fears and believes changes.

**Results:** 131 subjects were included. The mean age was 65.6 years [±6.7]. WOMAC function score was 22.1±6 [±11.3] and pain was 4.6/10 [±1.9] in inclusion. Both groups significantly increased PA level measured with continuous IPAQ total score (ME±minutes/weeks), with superiority for IG (+77.8%; p=0.0062) than CG (+50.7%; p=0.0099). There was no change in setting time. Disability (-11.3%; p=0.0370) and pain (-15.2%; p=0.0032) also decreased significantly for both groups. Anxiety (-11.6%; p=0.0195) and fears and believes (-18.2%; p=0.0146) decreased significantly only in intervention group. Other data will be presented later.

**Conclusions:** This study confirms the impact of STC on disability and pain and gives news data’s on physical activity level. Self-management exercise program improve anxiety, fear and believes. Complex educational strategies comprising information booklet with or without self-management exercise program can be proposed and adapted to OA phenotypes.

**COST EFFECTIVENESS ANALYSIS OF ABATCEPT COMPARED WITH TNF INHIBITORS IN PATIENTS WHO ARE POSITIVE FOR ANTI-CITRULLINATED PROTEIN ANTIBODIES BASED ON RESULTS FROM AN OBSERVATIONAL TRIAL**

S. Johal1, E. Alemdao2, 1PAREXEL International, London, United Kingdom; 2Bristol-Myers Squibb, Princeton, United States

**Background:** Anti-citrullinated protein antibodies (ACPA) are highly specific to RA and patients (pts) who are ACPA positive (+) tend to develop more severe, erosive disease than ACPA-negative pts. In an observational study exploring the clinical value of ACPA in RA, pts with ACPA+ response to abatacept (ABA) or a TNF inhibitor (TNFi), mean (SE) changes from baseline in CDAI at 6 months was –8.6 for ABA and –5.6 for TNFi initiators.2

**Objectives:** To evaluate the costs and benefits of treating pts with RA who are ACPA+ with ABA vs TNFi on background MTX.

**Methods:** An economic analysis was carried out estimating lifetime direct costs and quality-adjusted life years (QALYs) of ACPA+ pts with RA treated with ABA or TNFi from a UK National Health Service (NHS) perspective. QALYs are a measure of quality burden, adjusted to reflect quality of life lived. As data for the economic analysis were derived from a real-world study, an “average” pt was modelled, whose baseline characteristics were based on the observational study. CDAI changes at 6 months for each treatment were converted to HAQ changes, and disease progression was based on HAQ score changes over a lifetime. Continuation of therapy was based on rates from the real-world study. Mean long-term survival on treatment with ABA or TNFi was derived from the literature.3 In the base case, pts discontinuing ABA or TNFi moved to palliative care (MTX). Direct medical costs and quality of life scores were correlated to HAQ scores.4,5 Costs included hospitalizations, joint replacements and treatment costs. Estimates of different direct costs and QALYs between ABA and TNFi initiators were used to calculate an incremental cost-effectiveness ratio (ICER; cost per QALY gained). The annual cost of TNFi was calculated as an average of TNFi drugs in the UK (£ 9113). For ABA, an average cost of five biologics was used (£ 9244) to reflect a realistic cost to NHS UK. A sensitivity analysis examined the effect of varying the input parameters of efficacy, cost and utilities on costs and outcomes.

**Results:** Based on an “average” pt from the observational study, the total estimated QALYs for ABA and TNFi initiators were 6.4 and 6.27, respectively. Total lifetime costs were £ 41,378 and £ 40,627, respectively. The lifetime cost for
Caribbean metacarpal osteoarthritis (CMC-OA) is a common joint condition, with a prevalence of 13% in people aged 41 to 50 years, increasing to 68% in people between 71 and 80 years. In the absence of disease-modifying interventions, non-pharmacological approaches are considered as core treatments for hand OA, while surgical treatment is recommended for those with severe CMC-OA.

Objectives: To describe function and previous treatment in patients referred for surgical consultation due to CMC-OA.

Methods: Individually referred for surgical consultation due to their CMC-OA at three Norwegian departments of rheumatology were invited to participate. Those who agreed attended a clinical assessment and reported their symptoms, disability and functional limitations at the Quick-Dash; 38.6 versus 30.4, (p=0.006) and MAPHand; 2.0 versus 1.7 (p<0.001), for women and men, respectively. However, for finger range of motion, men had slightly more flexion deficit and less palmar abduction in their left hand compared to women.

Conclusions: Among patients referred for surgical consultation due to CMC-OA, women self-reported lower hand function and scored poorer than men in observer-based assessments. Even if conservative treatment is recommended before referral for surgery, only a few participants had received such treatment for their hand OA.

THU0728-HPR

OBJECTIVES: To explore the attitudes and needs concerning blended care of two Health Professionals like to go? self-management: Is this the way patients and professionals like to go? C. Bode 1, E. Taal 1, H. Vonkeman 2, F. Ben Allouch 1, K. Hohl 1, 1 Psychology, Health & Technology, University Twente; 2 Rheumatology, Medisch Spectrum Twente, Enschede, Netherlands

Background: Blended care, the integration of online and face-to-face care, promises to combine the best of two worlds.

Objectives: To explore the attitudes and needs concerning blended care of two key stakeholders: health professionals and patients.

Methods: Rheumatologists (8) and specialized nurses (5) were recruited in a Dutch hospital and patients with an inflammatory rheumatic disease (10) were recruited via flyers in hospitals and patient organizations in Germany. A semi-structured interview schedule was used to explore knowledge, experiences, needs and perceived (dis)advantages of a blended care format for fatigue self-management. Transcribed verbal data were coded with hierarchical coding schemes.

Results: Perspective of professionals: Blended care matches needs for psychosocial interventions in medical settings, has a patient-friendly and flexible format, reflects the active role of patients and can easily be imbedded in standard care. Reported barriers were low education and skills in technology use in patients, the lack of proven and safe interventions and costs for development/implementation. Patient perspective: Patients expected better communication, time saving and improved autonomy in self-management. They were concerned about loss of personal contact and in general, patients were very critical regarding online activities, privacy risks and guaranteed quality of eHealth products.

Conclusions: Health professionals and patients differ in their attitudes towards blended care. Professionals are better informed and have a more positive attitude, whereas patients’ attitudes towards blended care are mainly driven by their reservations towards the reliability and safety of the Internet in general. Results will be discussed on the background of attitudes towards eHealth in different countries.

*Measured in Newton using the GripIt. t* Numerical rating scale (NRS): 0–10; t= no pain. * Measured in degrees using the Pollexograph.
as age, gender, disease duration and hand dominance, were homogeneous at the beginning of the study. In both groups there was a reduction in hand pain with time (intragroup analysis). Pain in the functional group, expressed as mean ± standard deviation, was 6.82±1.72 and 4.77±2.45 at the beginning and end of the treatment, respectively, and the corresponding figures for the nighttime group were 7.29±1.63 and 5.12±2.58. The p values for both groups were p<0.001. There were no statistically significant differences in the majority of the parameters assessed between the groups, including the outcome pain. Three measures considered to be occasional, presented a significant difference between the groups: right palmar abduction p=0.023 and right tripod pinch strength p=0.006 with better results for the group that used the night splint; and time execution of the pick-up test with eyes closed to the right hand p=0.048 with more representative results for the functional (daytime) splint use.

Conclusions: There was no statistically significant difference between functional and night splint in terms of pain, function or any of the other parameters assessed in rhizarthrosis patients after one year of treatment.

THU0729-HPR PATIENTS AND CAREGIVERS PREFERENCES RELATED TO THE USE OF INFORMATIC TECHNOLOGY TOOLS FOR EDUCATION IN RHEUMATOID ARTHRITIS

S. Henao1, F. Rodríguez2, L. Villarral3, P. Santos-Moreno4, M. Cabrera5, D. Buitrago-García1, C. Calcedo6. 1Patient service; 2Patient Program; 3Psychology and processes; 4Rheumatology; 5Engineer and processes; 6Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota; 7Public Health, Universidad Nacional de Colombia, Bogota, Colombia

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease of the joints affecting more than 1% of global population, it is a long term condition that causes disability and affects the quality of life (1). It has been demonstrated that patient’s involvement with its treatment and disease management can be more effective than information only given by the physician or a health care professional (2).

Objectives: To describe patient’s preferences regarding information technology tools for education and RA management in a specialized center in Bogota Colombia.

Methods: We conducted a descriptive study where a survey was applied to a group of patients or caregivers attending to a patient-focused symposium in Bogota Colombia. Descriptive epidemiology was done, percentages and averages were calculated for qualitative variables.

Results: We included 452 participants, 80% were patients and 20% caregivers, only 25% referred to assist to informative activities regarding disease management, 41% reported to have information regarding RA, also between 29% and 45% of patients acknowledged the role of the health-care team in the disease activity management. Regarding technology information tools patients considered that WhatsApp was the most important tool to received messages to disease management (40%) followed by YouTube and websites. 70% reported to have a computer or a mobile phone with internet connection, 60% reported to use Facebook while only 30% reported to use easily websites and twitter.

Conclusions: It is important to know the preferences and access that patients and caregivers have to informatics technology in order to create self-care programs that really are going to be used in this population. This survey is evidence not only to start an educational program in our specialized center but to the health care professionals and stakeholders in Colombia.

THU0730-HPR CONTENT AND SUPERVISION OF GROUP EXERCISE THERAPY (GET) FOR AXIAL SPONDYLOARTHRITIS (AXS) IN THE NETHERLANDS; A NATION WIDE SURVEY

F. Van Der Giesen1,2, S. Van Weely3, L. Nopuhaa3, T. Vliet Vlieland2. 1Rheumatology, Haga Teaching Hospital, The Hague; 2Orthopedics, Leiden University Medical Center, Leiden; 3Dutch Arthritis Foundation, Amsterdam, Netherlands

Background: For axSpA patients exercise therapy is recommended in (in)ternational treatment guidelines. Apart from mobility exercises, muscle strengthening and cardio vascular training are recommended therapeutic modalities [1,2]. In the Netherlands 45 therapy groups (land based exercises; 1, hydrotherapy; 13, combination groups; 31) are organized by 17 local patient organizations exclusively for AxSpA patients. It is unclear if the treatment recommendations are followed and what the nature of the supervision in these exercise programs is.

Objectives: To describe the therapeutic modalities used and characteristics of the supervision in GET for patients with axSpA in the Netherlands.

Methods: A questionnaire was sent to the coordinating supervisors of GET from the17 local patient organisations involved in GET for axSpA with questions regarding the frequency and duration of group exercise programs and treatment modalities (mobility, strengthening and cardio-vascular exercises) used in land-based and hydrotherapy parts of the programs. In addition the questionnaire included questions regarding the number of supervisors involved in the supervision of GET, their professional background (physical therapist, other), years of experience with GET (<1yr, 1–5 yrs, >5yrs) additional education related to rheumatic diseases (yes/no) and rheumatology network membership (yes/no).

Results: All 17 coordinating supervisors of GET for axSpA returned the questionnaire. All exercise groups were performed once a week with a median (range) duration of 30 minutes (30–60) for the hydrotherapy and 105 minutes (45–180) for the combination therapy groups. Regarding land-based treatment modalities, active joint range of motion exercises and muscle strengthening exercises were used as was stated by 15/17 and 14/16 coordinators respectively. Given the frequency in combination therapy groups showed a wide variety, as did the program composition (water based/land and water based). Identifying considerable practice variation. The majority of the supervisors were physical therapists with long standing experience but only a minority had postgraduate rheumatology education. To ensure the quality of GET for patients with axSpA, reducing practice variation is a future challenge.

Education of GET supervisors might be important aspects and target of priority.

THU0731-HPR CAN A THREE WEEKS PROGRAM IN A REHABILITATION CENTER IMPROVE SYMPTOMS AND EXERCISE-FREQUENCY FOR RHEUMATIC PATIENTS?

G. Jarret, A. Orpina, Skogil Helse- og Rehabiliteringsenter AS, Lillehammer, Norway

Background: Rehabilitation for people with rheumatic disorders (15% of world-wide population) is a long term project (Stoffer et al. 2015). Rheumatic patients do not exercise as often as recommended (Holm et al. 2015). Intensive multidisciplinary interventions in rehabilitation-centers are in some countries an option – of which there is little effect knowledge. Perhaps data from a quality-management perspective can shed some prespective on this subject.

Objectives: Primarily to observe short and long term effects of a three weeks intensive multidisciplinary program for people with rheumatic disorders, and secondary to see if a correlation can be found between level of training frequency and levels of pain, stiffness, and self rated health.

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.5450
Methods: 738 patients (age 62.0±11.1, 84% women), followed a three weeks multidisciplinary program of individual and group sessions - with physiotherapy as main focus - during the period of August 2010 to September 2016 at Skgolli Health- and Rehabilitation Center, Lillehammer, Norway. 3-month follow-up: N=252 and 12-month follow-up: N=118. Data from self-report questionnaires at T1-T4 was gathered and Pearson product-moment correlation coefficients were used to analyze the data obtained, using IBM SPSS Statistics v.23.

Instruments:
- NRS-11 for pain and stiffness at baseline (T1), at discharge (T2), and at 3- (T3) and 12 months (T4) after discharge.
- Likert scale (1–6) for self-rated level of health at T1, T2, T3 and T4.
- Self-reported level of training frequency at T1, T3 and T4

Results: There was a clear mean improvement (p<0.0001) on all factors at T2 on all scales. At T3 there was a mean improvement (p<0.01) on all factors, except pain, of small/moderate effect size. There was a mean improvement (p<0.05) on self-rated level of health and training frequency at T4 of a small effect size. Worth noting is that the degree of stiffness and pain at T4 is back to T1-level.

There was a correlation (p<0.05) between level of training frequency and self-rated level of health (small at T1/T3, medium at T4), but no correlation between level of training frequency and level of pain or stiffness, at any time. This suggests that a higher training frequency is associated with a higher sense of health - regardless of symptom levels.

Conclusions: People with rheumatic disorders seem to have a very positive short term effect on all aspects after a three week intensive multidisciplinary program, but gradually return to pre-rehab levels during the following year - especially regarding symptoms like stiffness and pain. At the same time there seems to be a much slower decline in self-rated level of health – especially for those who regularly exercise. Properly randomized controlled trials are however needed to be able to draw any clear conclusions.

Implications: There might be a need for intensive multidisciplinary programs for rheumatic patients at intervals of less than a year, to be able to better keep the general health and function gained. Another possible implication is to implement a stronger focus on teaching rheumatic patients the necessity for an active lifestyle – including regular exercises – for them to be able to maintain their sense of general health, regardless of symptom levels.

THU0732-HPR

ENHANCED MANAGEMENT OF ANKYLOSING SPONDYLITIS THROUGH GUANGDONG INTERNET HOSPITAL IN CHINA: A RANDOMIZED, CONTROLLED TRIAL

H. Zhengping 1, L. Tianwang 1, H. Zhixiang 1, P. Xia1, Z. Lihua 2, H. Yukai1, 2, H. Koksvik2, K. Grønning 1, A. Steinsbekk 1.

Background: Ankylosing Spondylitis (AS) is a kind of common chronic disease. Guangdong Internet Hospital is China’s first officially recognized network hospital and the government encourage development of telemedicine in the country. Increasing research evidences support the efficacy of telemedicine in management of chronic diseases. However, there are still few researches about AS management by using telemedicine.

Objectives: We here conducted a 6-month randomized, controlled trial to evaluate the feasibility and efficacy of Guangdong Internet Hospital in AS management.

Methods: A total of 102 AS patients were randomly divided into two groups: standard care (ST) group or standard care with Network-Enhanced Management (ST-NEM) group. NEM enhanced disease management including cognition of the disease, medication management, behavioral management and psychotherapy. Individuals were assessed by using several tools at baseline and 6 months later: Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) for the disease activity, Ankylosing Spondylitis Functional Index (BASFI) for the functional limitation, the Zung Self-Rating Anxiety Scale (SAS) and the Zung Self-Rating Depression Scale Zung (SDS) for the psychological status. Pittsburgh sleep quality index (PSQI) for the sleep quality, and SF-36 for the general health status.

In addition, we made a satisfaction survey about the network platform in the management of the disease. Both group received the same medications during the period. There were no significant differences in baseline demographic and clinical characteristics between the two groups.

Results: After 6 month, 91 patients completed the trial. BASFI (1.75±0.73 vs. 2.04±0.69, P=0.026), SAS (28.12±1.22 vs. 39.56±6.81, P=0.022), SDS (26.5±1.34 vs. 32.12±3.64, P=0.031), PSQI (3.31±0.46 vs. 4.79±0.54, P=0.019) and SF-36 (SF-36: 54.24±16.66 vs. 61.41±8.56, P=0.014; SF-36: 63.42±11.08 vs. 68.98±10.46, P=0.032) were significantly lower in ST-NEM group than ST group after 6 months. There was no significant difference in BASDAI (2.66±0.91 vs. 2.75±0.75, P=0.068) between the two groups. Individuals assigned to the ST-NEM group reported significantly improved in functional limitation, psychotherapy (daily) and patient education. The control group received treatment as usual. The primary outcome measure was physical function assessed by the “30 second Sit to Stand test” (30sSTS, number of sit and stand during 30 seconds, higher score is better) and self-management/coping measured by the “Effective Musculoskeletal Consumer Scale” (EC17, higher score is better).

Results: Forty patients (mean age 27.5, 65% female) with IRD (intervention/control: 3:2 rheumatoid arthritis, 3:9 juvenile idiopathic arthritis, 4:5 psoriatic arthritis, 8:3 ankylosing spondylitis and 2:1 polyarthritis) were randomized. 19 out of 20 patients completed the intervention. At twelve months follow up there were 3 patients lost to follow up from the intervention group, and 2 in the control group. Patients in the intervention group had a significant improvement in the 30sSTS test 3, 6 and 12 months after completed intervention, compared to the control group (Table 1). The within group analysis showed that both groups improved at 6 and 12 months. The EC17 showed no difference between the two groups at 3, 6 or 12 months.

Conclusions: The results indicate that the intervention group significantly improved their physical function one year after the intervention compared to the control group, but there was no effect on self-management/coping. These results
might reflect that the focus of the intervention was mainly intensive exercise, and less on self-management / coping. This was a small study and the results should be interpreted with caution.

**ASSESSMENT OF LOCAL DISEASE ACTIVITY AFTER AN INTENSIVE HAND EXERCISE PROGRAM IN PATIENTS WITH RHEUMATOID ARTHRITIS MEASURED BY ULTRASOUND IMAGING: AN EXPLORATORY RANDOMIZED CONTROLLED TRIAL**

C. Bartholdy, M. Henriksen, E. Wæhrens, K. Ellegaard.1,1. The Parker Institute, Frederiksberg, Denmark

**Background:** In 90% of patients with rheumatoid arthritis (RA) the joints of the hand are affected, causing impaired hand function. In general, reduced strength and range of motion of the hand are seen in patients with RA. Studies have shown positive effect on pain and function after exercise intervention for the hand in patients with RA. However, it is unclear if the disease activity in the joints of the hand is influenced by an exercise program. Ultrasound imaging (US) is shown to correlate with other markers of disease activity in RA and can be used as a surrogate measure for inflammation in the joint, as US visualizes synovial hypertrophy and increased blood flow.

**Objectives:** To investigate if intensive hand exercise combined with joint protection education for the hand in women with RA can be conducted without a negative effect on the disease activity in the wrist and metacarpal (MCP) joints.

**Methods:** This is a sub-study of a randomised clinical trial investigating hand exercise therapy as add on to education in joint protection during activities of daily living (ADL) performance. The intervention group (IG) had both ADL education and exercise therapy and the control group (CG) had only ADL education. The participants were women with RA involving the hand who had been on stable medication for at least three month.

At baseline all participants were examined by a rheumatologist. The joints were examined, blood samples collected and pain and strength of the hand were measured. Patient's functional ability was assessed using the Assessment of Motor and Process Skills (AMPS). US examination of the wrist and MCP 2–5 joints was performed using a linear probe 10 MHz. The evaluated was made according to a validated scoring system sum. (1)

**Results:**

Eight withdraw during the study period, six from the IG and two from the CG. Thus, 22 from the IG and 25 in the CG were included in the final analysis. The mean age 63.6 (12.6) years and mean disease duration was 12.7 (11.3) years, baseline mean tender and swollen joint were 4.8 (4.7) and 1.3 (1.7), respectively. No differences in change from baseline in tender joint count, hand pain and strength and functional ability was seen between the two groups (data not shown). The mean score and change from baseline in US score and inflammatory marker (CRP) in the blood are seen in table below.

**Conclusions:** Women with RA of the hand experience no negative effect on the disease activity in the joints of the hand after eight weeks combined hand exercise and joint protection education.

**SHARED CARE OF RHEUMATOLOGIST AND NURSE CONSULTATIONS IN FOLLOW UP OF RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS OUTPATIENTS WITH LOW DISEASE ACTIVITY: A MONOCENTRIC, RANDOMIZED CONTROLLED TRIAL**

K. Claes1, A. Van Hecke1, P. Jacques1. 1Rheumatology; 2Centre of nursery and midwifery, University Ghent, Ghent, Belgium

**Background:** Due to national regulations, the role of nurses in the management of arthritis patients differs significantly in all European countries (1). In Belgium, regularized consultations conducted by a rheumatology nurse do not exist.

**Objectives:** The study investigated whether rheumatology nurse consultations alternating with rheumatologist consultations for RA or AS patients with low disease activity is non-inferior compared to the usual care by the rheumatologist. Primary outcomes were safety and disease activity. Secondary outcomes were fatigue, pain, functional index, patient satisfaction, the level of self-management and self-efficacy.

**Methods:** This is a monocentric randomized controlled trial. The intervention group received a consultation conducted by a rheumatologist alternating with a rheumatology nurse every 8 weeks. Patients in the control group received usual care: consultations performed by a rheumatologist every 8 weeks.

**Results:** Mixed method analyses were performed. No statistical significant between-group effects were found nor in the RA group nor in the AS group, although there was a clinical relevance towards disease activity by AS patient in the intervention group. DAS 28 dropped with a mean difference of 0.4 (-1.1 –0.2, SD 0.30). The ASDAS and BASDAI both decreased with 1.1 (-1.4 –1.3, SD 0.1 and -1.7 –1.4, SD 0.1 respectively). No safety signals from biochemical parameters such as SGOT, GOT and creatinine were detected. Inflammatory markers (ESR and CRP) remained stable in both groups. The secondary outcomes showed no significant between-group effects for both diseases. The self-efficacy outcome noticed a positive in-between-group effect by patients with RA in the intervention group.

**Conclusions:** In the follow-up of patients with RA or AS and low disease activity, outcome is not different when rheumatology nurse consultations alternating with rheumatologist consultations are compared to usual care. Implementing nurse consultations can positively influence the disease activity and patient self-efficacy.

Efficacy of different types of exercise programs in osteoporosis with high risk of falls

K. Kazár-Tóth 1, C.K. Karóczi 1, B. Monek 1, C. Gácserné 1, É. Kovács 2, G. Pópor 1, I. Miko 1, 1National Institute of Rheumatology and Physiotherapy; 2Semmelweis University, Institute for Applied Health Sciences, Budapest, Hungary

Background: While ageing the frequency of osteoporosis increases. The most frequent risk factor is falling and consequently bone fractures which in this population is associated with high mortality. According to WHO data, 28–35% of elderly 65 years falls at least once per year, which increases to 32–47% over 70 years.

Objectives: The purpose of this randomized control study was to investigate the efficacy of a land-based and water-based exercise program specifically targeting balance to reduce fall risk in patients over 65 years with osteoporosis. We assumed that water-based training program would develop balance efficiently even at elderly people with severe degenerative diseases. Coordination in water is possible to be developed efficiently.

Methods: The study was carried out in the National Institute of Rheumatology and Physiotherapy. 61 participants were randomized [n=20 sensorimotor training group, n=20 control group (CG)] in the land-based sensorimotor training program (SMT) and 21 people [n=7 At Chi group (AC), n=7 water adapted sensorimotor training group (WASM), n=7 control group] in the water-based training program (WBT). The control group did not participate in any training program. The exclusion criteria included: neurological, cardiovascular and musculoskeletal diseases, which contraindicated the participation in the training program. Functional Reach Test (FRC), Timed Up and Go Test (TUG), Star Excursion Balance Test (SEBT) and coordination test by stabilometer were used to measure static and dynamic balance. The measurements were performed before and after the training period. The results of the SMT were analysed with two-sample t-test, and the results of the WBT with non-parametrical methods. The results were defined with p<0.05 statistical margin by SPSS program.

Results: After 18-weeks of the SMT program significant improvement was experienced in the SMT group compared to the CG with the following parameters: FRC (p<0.001), TUG (p=0.01). In the Coordination test no significant difference was found between the SMT and the CG (p=0.09). After 8-weeks of the WBT programs significant improvement in the mediolateral direction of SEBT was detected in the WASM (p=0.028) and in the AC group (p=0.043) compared to the CG. FRC test was shown marginal significance (p=0.075) in the WASM group, while in the AC group remarkable improvement (p=0.043) was recognised compared to the CG. In the TUG test significant improvement was found in the CG and the WASM (p=0.026, p=0.043) compared to the CG.

Conclusions: The findings from this study support the efficacy of the land- and water-based exercise programs in improving balance in this sample. Our results pointed out that balance improved efficiently even at degenerative joint diseases. Limitations of our research was the small number of the participants and the short duration of the program. In the light of the promising outcome we will continue our research that would result in an efficient fall prevention in this population with high risk of falling.

Promoting physical activity in rheumatoid arthritis: developing a theory-based behaviour change intervention

L. Larkin 1, A. Fraser 2, S. Gallagher 3, N. Kennedy 1, 1Department of Clinical Therapies, University of Limenick; 2Department of Rheumatology, University Hospitals Limenick; 3Department of Psychology, University of Limenick, Limenick, Ireland

Background: Physical activity has numerous benefits for people who have RA, however interventions targeting physical activity behaviour in people who have RA have had limited efficacy [1].

Objectives: To develop a theory-based behaviour change intervention to promote physical activity in people who have RA.

Methods: Development was guided by the UK’s Medical Research Council Complex Interventions framework [2] and consisted of three components; 1. Narrative review which explored the use of behaviour change theory in previous interventions 2. Systematic review which examined the content and structure of previous interventions 3. Qualitative study which explored the preferences of key stakeholders (people who have RA and health professionals) about the design of the intervention.

Results: Previous interventions lacked consideration of behaviour change theory in design and delivery, and there was a large degree of variance in content, structure and delivery. Lack of knowledge of current physical activity recommendations. NSW Public Health Bulletin, Vol. 22(3–4): 78–83.

Experiences and appreciation of shared medical appointment of young adults with a rheumatic disease, in transition from child to adult care

L. Gossens 1, J. Ammerlaan 2, L. Cazemier 1, H. Bouwens 2, B. Formsmoa 3, J. van Laa 1, A. Kruize 1, 1Rheumatology and Clinical Immunology; 2Patient partner, UMC Utrecht, Utrecht, Netherlands

Background: Young adults with rheumatic diseases deal with questions and uncertainties since their disease and treatment affect both physical and socio-emotional development. As part of the transition from child to adult care, the UMC Utrecht offers a shared medical appointment (SMA). During a SMA, four to six patients are seen together in the presence of a doctor and nurse specialist. Compared to an individual consultation with a doctor or nurse, a SMA is offering extensive exchange of information and shared experiences focussed on everyday life, as sport, study, work and treatment. During a SMA, patients learn from each other how to support self-management. In practice, the care providers notice that young adults are reluctant to join a SMA, they hesitate to have a consultation in presence of their peers. When invited, most patients, however, do attend a SMA, and it is unknown how these young adults experience and appreciate the SMA.

This evaluation is a first step of a larger project. The results will be deepened and supplemented with the findings on interviews with SMA participants and adults who are not SMA participants, in order to give an advice for further development of the SMA in our clinic.

Objectives: Evaluating experiences and appreciation of SMA in transition patients in order to further develop the SMA in our clinic.

Methods: In the period of January 2014 till December 2016, patients in transition who participated in SMA were asked to fill in an evaluation questionnaire. This questionnaire focussed on expectations, quality of medical care compared to an individual consultation, information about disease and treatment during a SMA and the presence of other young adults. Data was analysed by the researchers and patient partners using SPSS and thematic analysis.

Results: Forty-five patients filled in the evaluation questionnaire, among them 35 women, with an average age of 19.6 years. The majority had a form of juvenile idiopathic arthritis (n=39); with average disease duration of 9.4 years and most were using a DMARD and/or biological (n=35). The results showed that participating patients were just as satisfied with the medical care in a SMA compared to a regular consultation; they indicate that more information was given in a SMA and the presence of peers was experienced as pleasant. Most appreciated were sharing experiences, individual stories and tips. Personal attention and lack of privacy were perceived as less pleasant, moreover young adults expressed to find it difficult to discuss personal issues.

Conclusions: Although it is difficult to motivate the young adults to attend the SMA, whenever they do attend, they appreciate a SMA in positive way, especially on benefits of sharing information and meeting peers, when offered in addition to individual consultations with doctor and nurse.

recommendations for people who have RA was highlighted in the qualitative study, and delivery preferences were identified. Intervention development was mapped to the Behaviour Change Wheel [3] and employed the Theory of Planned Behaviour as it’s theoretical basis. The proposed intervention is outlined in Table 1.

Conclusions: We have developed a theory-based intervention which considers the preferences of key stakeholders. Future research will determine the feasibility and effectiveness of this intervention.

THE PHENOMENON OF ALEXITHYMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

M. Ramkhelawon, R.A. Grekhoff, G. Suleymanova. Rheumatology, Research Institute for Clinical and Experimental Rheumatology, Volgograd, Russian Federation

Background: Alexithymia as a radical in the structure of premorbid personality is attracting the attention of researchers as one of the possible psychological risk factors in the development of psychosomatic disorders in rheumatic diseases. Clinical experience supports the evidence of the relevance of alexithymia as a conception in relation to the many somatic patients, who show a limited ability to describe and differentiate emotion and create fantasies, and hence indicate the role of alexithymia phenomenon in the pathogenesis of psychosomatic disorders in SLE.

Objectives: To study the relationship of the levels of alexithymia with other clinico-psychological characteristics.

Methods: 87 patients with systemic lupus erythematosus (SLE) was surveyed with the Toronto Alexithymia Scale (TAS).

Results: According to the results obtained, SLE patients demonstrated a high level of alexithymia (73.86±2.6 points). The results of the research showed that the level of alexithymia, on one hand, does not depend upon gender, age, character and activity of the pathological process (p>0.05). On the other hand, there was a significant inverse correlation between alexithymia and the level of the patient’s education (r = -0.42 p=0.031). Moreover, internality in interpersonal interaction (r = -0.44 p=0.028), and significant direct correlation with indicators such as, the disease duration (r = -0.46 at p=0.01), the intensity of neurotic disorders (asthenia (r = -0.42 p=0.033), depression (r = -0.52 p=0.006), anxiety (r =-0.43 p=0.028), hypochondriasis (r = -0.48 p=0.01), as well as psychological defense mechanism “Regression” (r =-0.42 p=0.022).

Conclusions: Therefore, between the development of alexithymia in SLE patients and certain clinico-psychological characteristics, a particular association exists which provides a definite step for psychotherapeutic interventions aimed at correcting alexithymia personality traits of SLE patients.

INFLUENCE OF BIOFEEDBACK THERAPY ON THE MICROCIRCULATION IN SYSTEMIC SCLEROSIS

M. Ramkhelawon, R.A. Grekhoff, G. Suleymanova, S.A. Kharchenko, Rheumatology, Research Institute for Clinical and Experimental Rheumatology, Volgograd, Russian Federation

Background: Microcirculatory disorders are one of the most important clinical symptoms of systemic sclerosis (SSc), therefore we found it feasible to evaluate the clinical efficacy of biofeedback (BFB) in the complex therapy of patients with SSc based upon analysis of nailfold capillaroscopy.

Objectives: To study the impact of the method of biofeedback therapy on microcirculation disturbances in patients with SSc.

Methods: The study included 40 patients with SSc under observation. Among the patients examined, 95% were women and 5% were men. The average age of the patients - 38±3.3 years, duration of illness - 14±2.6 years. Raynaud’s phenomenon (RP) was observed in all the patients. A severe form of RP was seen in 80% of the patients. The effectiveness of biofeedback therapy was analyzed by comparing the dynamics of the measures from the nailfold capillaroscopy and comparing the data obtained of patients from the main and control groups.

Results: It was found that, patients who were under biofeedback therapy, showed significant positive dynamics in the following signs of capillaroscopic picture: dilation of the capillaries (c2 = 8,643 p=0,026), morphological changes of the capillaries (c2 = 4,619 p=0,032), as well as the level of haemorrhage (c = 2 = 4,514 p=0,034). In the control group of patients, in only one indicator of capillaroscopy that a significant change was noted, particularly by the presence of dilated capillaries (c2 = 5,833 with p=0,016). These findings suggest that treatment results were significantly better in the main study group of patients with SSc.

Conclusions: The implementation of biofeedback therapy favors a decrease in reflex musculo-tonic syndromes, improvement of microcirculation and peripheral blood flow and significantly allows an amelioration in the results of SSc therapy.

PLACEBO AND NOCEBO EFFECTS INDUCED BY CONTEXTUAL FACTORS. A SURVEY ON BELIEFS AND ATTITUDES OF ITALIAN MUSCULOSKELETAL PHYSIO THERAPISTS

G. Rossettini 1, T. Geri 1, A. Palese 1, M. Piorio 2, A. Viceconti 1, M. Testa 1
1 Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, University of Genova, Savona; 2 Department of Biological and Medical Science, University of Udine, Udine; 3 Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Verona, Italy

Background: Context effects are well known and were described as integral part of the clinical setting (1). The conscious use of contextual factors (CF) has been recently proposed as an effective modality capable to influence the psychotherapy outcome by faciliation of placebo responses. (2) To date, the knowledge about CF adoption in clinical practice of physical therapists is absent. Objectives: The aim of this study was to investigate frequency of use, beliefs and attitudes about contextual factors among Italian physical therapists specialized in manual therapy (OMTs)

Methods: An invitation to participate in an online survey was sent to 906 OMTs through the database of the Master in Musculoskeletal Rehabilitation (MRDM) of University of Genova. Analysis of the survey was performed with the software SPSS. This likely correspond to more than 85% of the whole OMTs population in Italy. A 17 items questionnaire and two clinical scenarios assessed behaviour, beliefs and attitudes of OMTs about CF adoption in clinical practice and data were analysed by descriptive statistics.

Results: 906 OMTs were invited to participate in the survey and 558 responded (62%). The majority of OMTs uses CF in their practice frequently (52%). They believe that an actual effect of CF can occur in acute pain (57%), chronic pain (78%) and rheumatologic disorders (56%). OMTs consider the use of CF ethically acceptable when it exerts beneficial psychological effects and their effectiveness was shown during clinical experience (31%). They disagree on the adoption of CF when they are based on deception, undermine the trust between OMT and patients, create legal problems or produce side effects (17%). 38% of respondents do not communicate the use of CF to their patients and they adopt CF as addition to other physical therapy interventions with the aim of optimizing clinical responses (20%). Expectation and psychological mechanisms are believed to be the main aspects behind placebo and nocebo effects induced by CF (7%).

Conclusions: The use of CF is quite common among Italian OMTs and they mostly had positive attitudes towards their use and effectiveness.

A NEW AND ALTERNATIVE TREATMENT IN SYSTEMIC SCLERODERMA DIGITAL ULCERS

M. Muratore1, D. Carati2, L. Quarta1, A. Grimaldi1, E. Quarta1, M. Garzya1, D. Longo1, O. Casilli1, F. Calcagnile1, L.O. Reumatologia-PO “V. Fazzi” Lecce, LECCE, 1Research & development, Ekuberg Pharma, MARTIANO, Italy

Background: Digital ulcers (DUs) are a major clinical problem for patients with systemic sclerosis (SSc). Patients with DUs may suffer from severe pain and often undergo a limitation of daily life activities, thus resulting in a functional impairment with a significant impact on the patient’s health-related quality of life. Prevention of further complications and lesions is possible if the initial evaluation is performed early and correctly and if a treatment is started promptly.

Objectives: The primary objective is to demonstrate the effect of Lecoxen cream (Ekuberg Pharma, Italy) in comparison with another cream (Fitostimolino cream, DAMOR SpA, Italy) on the reduction of the number and size of DUs in patients with systemic sclerosis evaluating in addiction the reduction of pain dealing with ulcer symptoms.

Methods: In this single-blind randomized progressive trial 39 women, with confirmed digital ulcers present for at least 4 weeks with a surface area greater than 0.5 cm² but smaller than 2.5 cm², that follow Iloprost therapy (0,05mg/2 times/month), afferent to the Operative Unit (O.U.) of Rheumatology of the Local Health Unit (U.O.) of San Martino Hospital, Lecce, were randomized to receive the topical application of Lecoxen cream (group I: 20 women) or Fitostimolino cream (group II: 19 women). We took digital photographs to measure ulcer surface area and to draw the periwound area before the first cream application and after 30 days. Then an evaluation of DUs diameter and number was carried out. A
tailored questionnaire was administered as Visual Analogue Scale (VAS) during monitoring visits, to evaluate intensity of pain. Furthermore quality of life was monitored through Short Form (36) Health Survey.

**Results:** Mean age was similar in the two study groups with values of 45.4±5.6 years and 46.1±4.1 respectively. In the patients treated with Lecoxen cream, the reduction of lesion size was significantly higher (70%–75%) (p < 0.001) in comparison with those registered in group II (40–45%) (p < 0.05); a significant improvement was observed in levels of pain in Group I (30 days: p < 0.001), while in group II the results of reduction were not significant. The analysis of SF36 survey showed highly significant reduction (p < 0.001) of indexes in group I. At last visit, 32 ulcers were healed: 17 in the group I, 11 in the Group II (p < 0.01). Two-way analysis of variance (ANOVA) test was used to examine differences. Intragroup changes were evaluated with the paired Student t-test. A p-value of < 0.05 was considered to be significant.

**Conclusions:** Lecoxen cream showed the greatest effect on the mean reduction of the lesion size and pain levels. In the patients treated with Lecoxen cream the reduction of lesion size was 70%–75%; the reduction was smaller in the group II. At last visit, 32 ulcers were healed: 17 in the group I, 11 in the Group II. Data collected from SF36 surveys are very interesting, because they show a clear improvement in quality of life of scleroderma patients, who underwent different three treatments. In particular, a better subjective perception of tactile sensation and minor discomfort in the pathological skin have been reported. On the basis of the results, it could be argued that the medical device Lecoxen cream may be useful in the treatment of DUs in patients suffering from systemic sclerosis.

**ASSESSMENT OF ADALIMUMAB SUBCUTANEOUS INJECTION RELATED PAIN AND EFFECTIVENESS OF NURSE SUPPORT FOR PATIENTS WITH RHEUMATOID ARTHRITIS**

M. Fusama1, M. Suzuki2, T. Hirase3, M. Takemoto4, Y. Asano4, K. Higashi4, T. Takahashi4, K. Tanimura4, M. Natsumeda5, H. Nakahara6. 1Division of Nursing, NTT West Osaka Hospital, Osaka; 2PS Clinic, Fukuoik; 3Division of Nursing, Hokkaido Medical Center for Rheumatic Diseases, Sapporo; 4Division of Nursing, Sweet Hospital, Kurashiki; 5Hokkaido Medical Center for Rheumatic Diseases, Sapporo; 6Sweet Hospital, Kurashiki; 7NTT West Osaka Hospital, Osaka, Japan

**Background:** Subcutaneous injection of biologic agents gives more freedom and independence for patients with rheumatoid arthritis (RA) than intravenous injection. Despite this, patients with RA sometimes select intravenous injections due to concerns over self-injection, such as injection anxiety, including pain, and lack of confidence in giving a self-injection [1]. It is reported that one in five people are estimated to experience injection anxiety [2]. Therefore, an understanding of subcutaneous injection pain and anxiety and support for anxiety of patients with RA are important for appropriate usage of subcutaneous biologics.

**Objectives:** The aim is to evaluate pain and anxiety caused by adalimumab (ADA) subcutaneous injection and assess the effectiveness of nurses’ care.

**Methods:** Patients with RA using ADA self-injections were enrolled. In this study, it was assessed in 4 categories: general, needle insertion, drug injection, needle removal. Pain was evaluated using Visual Analogue Scale (VAS) scale. Effectiveness of support by nurses was also assessed using self-questionnaires and free-format comments. Statistical analyses were performed utilizing Wilcoxon’s signed rank test and Spearman’s rank correlation coefficient.

**Results:** Twenty patients (Male: Female, 4: 16) completed the questionnaire. Average age and disease duration were 68 and 12.6 years, respectively. Mean ± SD of Pain VAS were 34.9±28.1 mm (General), 30.3±30.6 mm (needle insert), 42.5±35.8 mm (drug injection) and 11.8±16.4 mm (needle removal). There were no statistically significant differences between general pain and needle insertion (p = 0.631), or general pain and drug injection (p = 0.121). However, statistically significant differences were found between general pain and needle removal (p < 0.001). Moreover, there were statistically significant differences between needle insertion and removal (p = 0.003), and needle injection and needle removal (p = 0.0048). General pain showed statistically significant correlation with needle insertion pain (r = 0.653, p = 0.0018) and drug injection pain (r = 0.615, p = 0.004). However, general pain was not correlated with needle removal pain (r = 0.137, p = 0.565).

Patients with RA answered that support by nurses is effective for relieving pain (30%), reduction of anxiety (35%) and improving treatment motivation (50%). According to the patients, nurses helped raise motivation by explaining that treatment prevents the progression of RA and allows many patients to feel better (30%), reduction of anxiety (35%) and improving treatment motivation (50%).

**Conclusions:** These data indicate that needle insertion and drug injection pain have great influences on general pain. Support by nurses is likely to reduce injection anxiety and pain, resulting in higher motivation toward self-injection treatment.

**A COMPARISON OF THE EFFECTIVENESS OF WHOLEBODY VIBRATION, PROGRESSIVE RESISTIVE EXERCISE AND HOME-BASED EXERCISE IN PATIENTS WITH KNEE OSTEOARTHRITIS**

M. Pekesen Kurtla1, U. Bas Aslan1, E. Kuyucu2. 1Physical Therapy and Rehabilitation, Pamukkale University, Denizli; 2Orthopedics and Traumatology, Medipol University, Istanbul, Turkey

**Background:** Knee osteoarthritis (OA) is the most common type of lower extremity OA. Systematic reviews of randomized controlled trials (RCTs) indicate that exercise therapy reduces pain and patient-reported disability in patients with knee osteoarthritis (OA), but to date, type and the optimal exercise regimen has not been identified.

**Objectives:** The aim of our study was to determine the effects of whole body vibration training exercise, progressive resistive exercise, home-based exercise used in osteoarthritis treatment on pain, muscle strength, functional status and quality of life.

**Methods:** Forty-five patients (mean age=53.86±5.33 years, 42 female, 3 male) diagnosed with bilateral knee osteoarthritis (Grade II-III, Kelgren & Lawrence) were included in this study. The assessments were performed at baseline, after three months when they completed the exercise programme and sixth months. Whole body vibration exercise training programme (Group-I), progressive resistive exercise training in Group-2; home-based exercise training in Group-3; were applied for three days per week, three months, totally 36 sessions. All the groups were included patient education programme at baseline. The pain was assessed according to Visual Analog Scale (VAS) and quadriceps muscle strength was evaluated by using handheld dynamometer. The functional status of the patients was evaluated by WOMAC (Western Ontario and McMaster Universities) index and health related quality of life was evaluated by Nottingham Health Profile (NHP).

**Results:** Significant improvement was found after treatment on pain, quadriceps muscle strength, functional status and quality of life in all groups (p < 0.05). When the groups compared by ANOVA it was found that outcome measures were not significantly different between Group-1, Group-2 and Group-3 (p < 0.05).

**Conclusions:** Supervised resistive exercises and whole body vibration exercises were more effective in strengthening lower extremity muscles when compared to home exercise training in patients with knee OA. However, the increase in muscle strength was not observed at long- term follow- up in both groups. Neither whole body vibration exercise training programme nor progressive resistive exercise and home-based exercise programme were found to be superior for the treatment of osteoarthritis. All types of exercises and programmes were beneficial for pain, functional status, quadriceps muscle strength and quality of life. Further studies with long-term follow-up are warranted.

**RHEUMATOLOGY NURSE SPECIALISTS AND DMARD PRESCRIPTION - WHERE ARE WE NOW?**

M.K. Nissar1, J. Begum2. 1Rheumatology, Luton & Dunstable University Hospital; 2Rheumatology, Luton, Luton, United Kingdom

**Background:** It is widely acknowledged that a multidisciplinary team approach is the best way to care for rheumatology patient group. The rheumatology nurse specialist (RNS) is an integral part of this multidisciplinary team. EULAR has published recommendations for their role in the management of chronic inflammatory arthritis (van Eijk-Hustings Y et al, 2012). The Department of Health also highlights the need for providing different models of care in a more cost effective way. It recognises that the nurse specialists’ role is the bedrock of an effective care providing team and can contribute to answering the challenge of effectively delivering DMARD education for patients. Methotrexate was accepted as index DMARD for the purpose of the exercise. A questionnaire

EFFECT OF DIFFERENT PHYSICAL THERAPY RECOMMENDATIONS ON PHYSICAL THERAPY INCREASING PHYSICAL ACTIVITY IN PEOPLE WITH A KNEE OSTEOARTHRITIS

E.O. Günaydın

Results: The between-groups results showed a significant improvement for the (p < 0.05), while there was no difference in 60 degrees/sec isokinetic quadriceps strength test in the Kinesio taping group and TUG test in the ESWT group.

Conclusions: The results of this study showed that; ESWT, Kinesio tape and exercise therapy are all effective in decreasing pain intensity, improving knee strength and functional status levels of patients with knee osteoarthritis (OA). A quarter of the cohort felt unprepared to impart the skills to peers (median experience 1 year).

In conclusion, there is wide variation in the training of rheumatology nurse specialists. This can potentially have a negative impact on a relatively young workforce. There is a need for improving training standards to help deliver good quality rheumatology care.

EFFECT OF DIFFERENT PHYSICAL THERAPY PROGRAMS ON PAIN, STRENGTH AND FUNCTIONAL SITUATIONS ON KNEE OSTEOARTHRITIS

O.E. Günaydın, V. Bayrakçı Tunay, Sports Physiotherapy, Hacettepe University, Ankara, Turkey

Background: Knee Osteoarthritis (OA) is one of the most common causes of disability with an increasing prevalence and incidence with age. Although there are studies in the literature that examine the efficacy of ESWT, Kinesio taping and exercise on knee OA, there is no study to compare these methods with each other.

Objectives: The purpose of this study is to compare the effects of Extracorporeal Shockwave Therapy (ESWT), Kinesio taping and exercise therapy on pain, knee strength and functional situations of patients with knee osteoarthritis (OA).

Methods: Forty eight female patients aged between 50–65 and previously diagnosed with a grade 1–3 (Kellgren-Lawrence scale) knee OA included in this study. Patients were assessed before treatment and after treatment at 6 weeks and at 12 weeks. Visual Analog Scale (VAS), (ISO9693/2000 D&R GmbH, Germany) isokinetic device, Timed Up and Go test (TUG) and WOMAC scale were carried out for assessing patients’ pain, knee strength and functional situations. After randomising the patients into 3 different groups, the first group received 1 session of ESWT per week, the second group received 2 sessions of ESWT per week and the third group was prescribed with an exercise program only.

Results: The between-groups results showed a significant improvement for the pain during night, pain during resting and WOMAC test in the exercise group (p < 0.05), while no difference was found for the other measurements (p > 0.05). The inter-groups results showed significant improvements in 3 of the groups (p < 0.05), while there was no difference in 60 degrees/sec isokinetic quadriceps strength test in the Kinesio taping group and TUG test in the ESWT group.

Conclusions: The results of this study showed that; ESWT, Kinesio tape and exercise therapy are all effective in decreasing pain intensity, improving knee strength and functional status levels of patients with knee OA and can be used as alternative approaches to treat symptoms of knee OA.

RECOMMENDATIONS ON PHYSICAL THERAPY PRESCRIPTION FOR AXIAL Spondyloarthritis in the netherlands

S. van Weely1, F. van der Giesen 1, N. Lopuhaa2, F. van Gaalen3, T. Vliet Vlieland1, Orthopaedics, Rehabilitation and Physical Therapy, Leiden University Medical Center, Leiden; 2Dutch Arthritis Foundation, Amsterdam; 3Rheumatology, Leiden University Medical Center, Leiden, Netherlands

Background: In national and international guidelines physical therapy, comprising exercise interventions and education, is recommended as a required treatment modality for the optimal treatment of axial spondyloarthritis (axSpA) [1-3]. However, specific details regarding referral for physical therapy and optimal content and dose of exercise interventions are lacking. Research showed large variation in the content of exercise therapy in axSpA patients, which reflects a great need for uniform guidelines.

Objectives: To develop practice recommendations on indications for referral, content, dose and safety aspects of exercise therapy for axSpA patients based on scientific evidence, expert opinion and patient values. The ultimate aim is improving the quality of exercise therapy care for people with axSpA.

Methods: The recommendations are based on scientific evidence, expert opinion and patient values and were formulated following a combination of literature review and three expert-group meetings (consisting of patients, rheumatologists, physical and exercise therapists, policy makers, scientists and special interest groups). In three consecutive expert-meetings clinically relevant questions, draft recommendations based on the scientific literature, and final recommendations including level of agreement were generated. Lastly, a field consultation among physical and exercise therapists, rheumatologists, scientists and special interest groups will be scheduled and an implementation strategy, comprising of an information intervention and directives, will be developed.

Results: In the first expert-group meeting 18 clinically relevant questions were formulated, on: indication and referral, assessment, content of treatment, evaluation and safety. In addition to recently published systematic reviews, additional literature reviews concerned assessment, safety and the dosage of exercise therapy. Related to the clinical questions, a framework for the therapeutic process and 12 draft recommendations were developed and discussed in the second meeting. In the third and last meeting the 12 recommendations regarding the delivery of physical therapy and exercise interventions were set and the level of agreement was determined.

Conclusions: The expert-meetings and literature searches led to 12 practice recommendations and a clear starting point for the development of the implementation strategy. Twelve practice recommendations regarding the delivery of physical therapy for patients with axSpA were developed, based on scientific evidence, expert opinion patient values. The field testing and development and execution of a dissemination and implementation strategy will be done in 2017.

INCREASING PHYSICAL ACTIVITY IN PEOPLE WITH A CHRONIC DISEASE: EXAMINING THE EFFECTIVENESS OF A MOTIVATIONAL AND A PLANNING INTERVENTION, THEIR INTERACTION AND VARIOUS POTENTIAL MODERATORS AND MEDIATORS

S. Hilberink1, G.-J.Y. Peters2

1 Allied Healthcare Centre for Rheumatology and Rehabilitation, Groningen; 2 Psychology and Education Science, Open University of the Netherlands, Heerlen, Netherlands

Background: Physical activity has many health benefits, especially in people with a chronic disease. Behaviour change interventions appear more effective than just advice when increasing physical activity. However, most studies that compare different interventions overlook interaction effects between methods and possible parameters for effective interventions.

Objectives: Present study examined the effectiveness of a motivational and an action planning intervention for increasing physical activity in patients with a chronic disease. Their interaction as well as various potential moderators and mediators were studied in order to identify which intervention is effective in which context.

Methods: In a healthcare centre specialised in the treatment of people with a chronic disease, participants whose physiotherapist would advise them to be more physically active were randomly assigned to one of four interventions in a factorial design: 1) a control condition with only advice, 2) a motivational intervention...
with information about health benefits and selecting personally relevant motives and social support sources regarding physical activity, 3) an action planning intervention in which participants specified which physical activities they would do, when, where and for how long and 4) a combination of these interventions. Prior to the intervention, participants’ leisure time physical activity in the past week was measured with items from the SQUASH. Also behavioural intentions, expected social support and planning behaviour with regard to leisure time physical activity were measured. Directly after the intervention, positive outcome expectations and self-efficacy were measured. After a week, physical activity measures were administered again.

Results: 298 participants (71% female; mean age 62 years; 40% with a rheumatic disease) completed the study. Figure 1 displays the average change in physical activity for each intervention. Multiple regression analyses showed that both the motivational intervention (β=0.22) and action planning (β=0.31) significantly predicted positive physical activity change and that these effects appeared additive as opposed to catalytic. The effects were not moderated by intention, expected social support or planning behaviour, nor mediated by outcome expectations or self-efficacy. The motivational intervention’s effectiveness was weakly correlated with the number of personally relevant exercise motives identified (r=0.22) and the action planning’s effectiveness was weakly related to the number of plans made (r=0.19) and to one’s outcome expectations after the intervention (r=0.21).

Conclusions: These data suggest that using a motivational or action planning intervention seems beneficial for increasing physical activity in patients with a chronic disease, independent of one’s intentions, expected social support and planning behaviour. The data also suggest that action planning is preferable over a motivational intervention and that the added value of a motivational intervention is minimal if action planning is used. This study was limited by only measuring physical activity after a week and by using self-report. Future studies should investigate longer term effects, other potential moderators and mediators and interaction effects between other promising behavioural change methods.

**THE EFFECTIVENESS OF THERAPEUTIC FOOTWEAR IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS**

M. Terten-Diepenmaat, M. Leeden van der, T. Vliet Vlieland, L.D. Roorda, J. Dekker,

1 Amsterdam Rehabilitation Research Center, Amsterdam; 2 Department of Rehabilitation Medicine, VU University Medical Center, Amsterdam; 3 Department of Orthopaedics, Rehabilitation and Physical Therapy, Leiden University Medical Center, Leiden; 4 Department of Epidemiology and Biostatistics, Amsterdam Public Health research institute, VU University Medical Center, Amsterdam, Netherlands

Background: Therapeutic footwear is recommended in guidelines for the treatment of foot problems in patients with rheumatoid arthritis (RA) and commonly prescribed and frequently used, especially in patients with established RA, foot deformities or erosions in foot joints.

Objectives: The objectives of this study were to summarize the effectiveness of therapeutic footwear on foot function, pain, physical functioning, health-related quality of life, adherence, adverse events and patient satisfaction in patients with RA.

Methods: All randomized controlled trials, randomized controlled cross-over trials, (quasi-experimental) clinical trials, and uncontrolled studies investigating the effect of therapeutic footwear in patients with RA related foot problems were included. Therapeutic footwear consists of custom-made or ready-made shoes. A literature search was conducted in The Cochrane Central Registry for Controlled Trials (CENTRAL), PubMed, EMBASE and PEDro up to January 19, 2017. Selection and inclusion of articles, data extraction (using a standardized template) and assessment of methodological quality (using a checklist for between-group and within-group comparisons) was conducted by two independent reviewers. Quantitative data analyses was conducted, when quantitative data analysis was not possible qualitative data analysis was performed.

Results: Thirteen studies were identified. In five studies, one of which was of high quality, between-group comparisons were reported. In six studies, in which two were of high quality, within-group differences were reported. Qualitative data-syntheses for the within-group differences of custom-made therapeutic footwear resulted in weak evidence for the reduction of foot pain and improvement of physical functioning. Qualitative data-analyses of the within-group differences of ready-made therapeutic footwear resulted in a medium to large effect for the reduction of foot pain (SMD -0.68, 95% CI -1.00 to -0.37; P=0.0001; 162 participants), and a small to medium effect for the improvement of physical functioning (SMD -0.32, 95% CI -0.62 to -0.02; P=0.04; 128 participants). Quantitative data-analyses of the between-group differences of ready-made therapeutic footwear resulted in inconclusive evidence for foot pain and physical functioning.

Conclusions: In within-group designs, there is weak evidence for the reduction of foot pain and improvement of physical functioning after wearing custom-made therapeutic footwear. Furthermore, in within-group designs there is a medium to large effect of ready-made therapeutic footwear on the reduction of foot pain, and a small to medium effect on the improvement of physical function. Controlled, between-group designs resulted in inconclusive evidence. A definite RCT is necessary to investigate the between-group effectiveness of therapeutic footwear in patients with RA.

**EFFECTIVENESS OF FOOT ORTHOSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS RELATED TO QUALITY OF LIFE AND PAIN. A SYSTEMATIC REVIEW AND META-ANALYSIS**

Nursing and Podiatry, University of Malaga, Malaga, Spain

Background: Foot pain and deformity is almost ubiquitous in RA and results in considerable physical and psychosocial impairment [1]. Epidemiological studies consistently suggest a 90% prevalence of foot pain despite advances in pharmacological therapy [2]. Mechanical and other non-pharmacological interventions such as orthoses and footwear, have an important role in managing foot pathology in patients with their systemic disease controlled [1,3]. The effectiveness of treatment with insoles, especially in early periods, was studied in a randomized controlled trial, which results suggested an immediate clinical improvement, reducing foot pain, disability and limited functionality [1].

Objectives: The aim of this study is the effectiveness of foot orthosis in patients with rheumatoid arthritis in terms of quality of life and pain.

Methods: A systematic review and meta-analysis was conducted of randomized controlled trials.

Participants: Patients with rheumatoid arthritis were included. The criteria of exclusion were Juvenile Rheumatoid Arthritis, analysis of gait.

Intervention: Studies had to compare foot orthosis

Comparison: Other type of treatments, other type of foot orthosis, sham

Outcomes: Evaluation of Pain or Quality of life with any tool that measure this outcome

The search was conducted in Cochrane, CINAHL, PubMed, EMBASE, LILACS, and Cumiden. An independent peer review was carried out. The Mesh term and fields used were foot, ankle, joint, rheumatoid arthritis, foot, orthosis, insole, foot orthosis.

Results: After the analysis of 21 studies, 4 were included for the systematic review. The 4 studies enrolled 285 participants. Follow-up periods varied from 6 to 30 months.

Only two studies were included in the meta-analysis [4,5], both of them with pain (measured with Foot Function Index) as the selected outcome.

A meta-analysis of the two trials showed that use of FO resulted in a non-significant improvement in disability compared with control (MD (95% CI): 4.37 (-6.24, 14.98); N=64) (Figure 1).

Conclusions: Foot orthoses showed improvements in pain and disability/quality of life, but no significant differences between groups were found. Future research needs to increase the number of RCTs in this topic because results are not conclusive.

HPR measuring health (development and measurement properties of PROs, tests, devices) —

THU0752-HPR
DEVELOPMENT OF THE “TREATMENT BELIEFS IN KNEE AND HIP OSTEOARTHRITIS (TOA) QUESTIONNAIRE”
1Rheumatology, Sint Maartenskliniek; 2Primary and Community Care, Radboud University Nijmegen Medical Centre; 3Orthopaedics, Sint Maartenskliniek, Nijmegen; 4Rheumatology, Sint Maartenskliniek, Woerden; 5Physical Therapy and Manual Therapy, Partnership Velperweg, Arnhem; 6Psychology, Utrecht University, Utrecht, Netherlands

Background: Use of non-surgical treatment modalities in osteoarthritis (OA) is suboptimal1, which might be influenced by patients’ beliefs about treatments. An instrument for measuring treatment beliefs in OA is not available yet.

Objectives: To develop a questionnaire assessing patients’ beliefs about treatment modalities of hip and knee OA; the “Treatment beliefs in OA (TOA) questionnaire” and to evaluate its clinimetric properties.

Methods: The item pool, drawn from two previous qualitative studies, comprised beliefs regarding 5 treatment modalities: physical activity, pain medication, physiotherapy, injections and arthroplasty. A draft questionnaire comprising beliefs on these 5 treatment modalities was developed (200 items, Table 1). Two samples of patients with knee or hip OA (N=840, N=700) were recruited from our hospital to test the clinimetric properties of the TOA questionnaire. Descriptive analyses, exploratory factor analyses (EFA; sample 1) and confirmatory factor analyses (CFA; sample 2) were conducted for each treatment module separately. Internal consistency was assessed with Cronbach’s Alpha (both samples). In order to examine test-retest reliability a subsample of sample 2 (N=67) was asked to fill out the final TOA questionnaire again after two weeks.

Results: 351 patients filled out the draft TOA questionnaire (sample 1), 289 patients filled out the final TOA questionnaire (sample 2), with a subsample (N=50) who filled out the final questionnaire twice. EFA yielded a two factor solution for each treatment modality. The factors were labeled “positive treatment beliefs” and “negative treatment beliefs”. The final TOA questionnaire comprised 60 items; items per treatment modality ranged from 9 to 14. CFA showed adequate fit indices for physical activities and physical therapy, while fit indices for the treatment modalities pain medication, injections and arthroplasty just failed to reach adequate cut-off values. Internal consistency was good to excellent for the subscale positive treatment beliefs (Cronbach’s α between 0.84 and 0.90), and mediocre to acceptable for the subscale negative treatment beliefs (Cronbach’s α between 0.66 and -0.79). Test-retest reliability was satisfactorily good with ICCs from 0.66 to 0.88 and SEMs from 0.17 to 0.52.

Table 1: Example items in the TOA questionnaire

<table>
<thead>
<tr>
<th>Items TOA-questionnaire</th>
<th>Items</th>
<th>Items</th>
<th>Items</th>
</tr>
</thead>
<tbody>
<tr>
<td>I think [doing physical activity] leads to risks</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>My quality of life improves through [using pain medication]</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>I think [physiotherapy] causes pain</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>I can do household chores more easily through [an injection]</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>I think [a joint replacement] is pervasive</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

Conclusions: The TOA questionnaire is the first questionnaire assessing positive and negative beliefs regarding five treatment modalities for knee and hip OA. The TOA questionnaire showed moderate structural validity and good internal consistency and test-retest reliability. The TOA questionnaire is useful for a better understanding of patients’ treatment beliefs. Future research will examine how treatment beliefs, in interaction with other variables, influence treatment choices.

THU0753-HPR
PREDICTING THE FUTURE DEVELOPMENT OF SPONDYLOARTHRITIS AMONG PATIENTS WITH IDIOPATHIC ACUTE ANTERIOR UVETITIS USING REAL-WORLD DATA
M. Haroon1, K.A. Betts2, F. Mu3, M. Skup2, J.K. Anderson3, A.D. Joshi3, 1Division of Rheumatology, University Hospital Kerry, Tralee, Ireland; 2Analysis Group, Boston; 3AbbVie Inc., North Chicago, United States

Background: Previous studies have suggested an association between idiopathic acute anterior uveitis (AAU) and spondyloarthritis (SpA), including showing that at least 40% of AAU patients have undiagnosed SpA. However, the clinical factors to predict the incident diagnosis or future development of SpA remain poorly recognized.

Objectives: The objectives of this study were: 1) to describe the patient characteristics of AAU patients with and without SpA diagnosis, and 2) to identify the predictive factors of SpA diagnosis among AAU patients using real-world data.

Methods: Adult patients with at least one diagnosis of AAU (ICD-9-CM: 364.01 or 364.02) were selected from a large US insurance claims database (01/01/2008–06/30/2015). The first AAU diagnosis was defined as the index date. Patients were required to have at least 6 months of continuous data availability before the index date. Patients with intraocular surgery, penetrating or blunt eye trauma, or a diagnosis of rheumatoid arthritis or SpA on or prior to the index date were excluded. Potential predictive factors for subsequent diagnosis of SpA included demographic characteristics, type of AAU (primary [first diagnosis] vs. recurrent), SpA-related comorbidities, and healthcare resource utilization prior to the index date. Factors predictive of SpA diagnosis were selected into a multivariable Cox proportional hazards model based on statistical significance and clinical relevance. Hazard ratios (HR) and p-values were estimated for each factor.

Results: A total of 48,822 patients with AAU were included, and among them, 1,032 patients were newly diagnosed with SpA during the follow-up period which was 24 months on average. Patients with SpA were younger (45.7 vs. 50.4 years), more likely to be male (52% vs. 42%), more likely to have recurrent AAU (44% vs. 29%), back pain (21% vs. 13%), SpA-related comorbidities, and healthcare resource utilization prior to the index date. Predictive factors in the final Cox model were: male vs. female (HR=1.55; p-value <0.01), age <45 vs. ≥45 years old (1.65; 0.01), recurrent vs. primary AAU (1.94; 0.01), back pain under age 45 vs. no back pain (1.90; <0.01), back pain above age 45 vs. no back pain (1.46; <0.01), psoriasis (5.16; <0.01), IBD (2.50; 0.01), joint pain (1.14; 0.19), imaging test use (1.03; 0.74), corticosteroids use (1.07; 0.33), and nonsteroidal anti-inflammatory drugs use (1.93; 0.40). Conclusions: There are significant differences among isolated AAU patients and AAU patients that developed SpA later. The most predictive factors of SpA diagnosis were male, age <45 years, recurrent AAU, back pain, and other extra-articular manifestations of SpA such as IBD and psoriasis. Since delayed diagnosis is common among SpA patients, identifying such predictive factors can help inform risk stratification.

WORK STATUS IN WOMEN WITH FIBROMYALGIA – A 12-YEAR FOLLOW UP STUDY
S. Johannesson1, L. Nordeman2,3, M. Joelson1, K. Mannenkorpi2, A. Bergenheim2,3, T. Nährhsoln rehabilitation centre, Region Västra Götaland; 1Institute of Neuroscience and Physiology/Physiotherapy, Sahlgrenska Academy, University of Gothenburg, Gothenburg; 2Östhammar Rehabilitation and Research, Primary Health Care, Region Västra Götaland, Sweden

Background: Fibromyalgia (FM) affects approximately 1–3% of the general population in the Western world and about 10% have been found to report Chronic Widespread Pain (CWP). The work ability is often affected in persons with FM and CWP. Previous research has shown a small improvement of symptoms over time in patient with FM and CWP. Sustain in work has been
Dietary protein intake and upper leg muscle mass and strength in older adults. Whether there is an independent association with lower muscle strength in patients with knee OA. To confirm this relationship, future research is needed to test this association in longitudinal and interventional studies in patients with knee OA.

**EUROPEAN QUALITATIVE RESEARCH PROJECT ON PATIENT-PREFERRED OUTCOMES IN EARLY RHEUMATOID ARTHRITIS (EPOERA): RATIONALE, DESIGN AND METHODS OF AN ONGOING MULTI-COUNTRY, MULTI-CENTER, MULTI-LANGUAGE, LONGITUDINAL QUALITATIVE STUDY**

K. Van der Elst 1, A. Bremander 2, A. De Groef 1, I. Larsson 3, E. Mathijssen 4, A. Van de Putte 1, J. Vriezekolk 4, R. Westhovens 1, Y. van Eijk-Hustings 5.

**Background:** Ample studies exist on outcome assessment from the patient perspective in Rheumatoid Arthritis (RA), but little is known about health and quality of life in persons with FM/CWP. There is lack of research about long-term follow-up of work status in FM and CWP. To enable patients with FM or CWP to sustain in work or return to work it is crucial to gain knowledge about which factors that can contribute to work status over time.

**Objectives:** To investigate change in work status and possible predictors of work status after 12 years of a cohort of women with FM and CWP.

**Methods:** In 2004, 166 women with FM and CWP participated in a randomized controlled trial in Sweden investigating effects of patient education and pool exercise. The women were invited to participate in a follow-up study in 2016 in which long-term effects on work status, aspects of health and physical function were investigated. 126 participated in the follow-up study of which 98 were >65 years of age (age of retirement in Sweden) and included in the present study of work status. Data was collected by a standardized interview, a battery of questionnaires and an examination including tests of physical function. Work status refers to percentage of full-time work divided into four categories: 0%/1–49%/50–79%/80–100%. Wilcoxon’s signed-rank test was used for comparisons of work status over time within the group.

**Results:** Multivariable forward stepwise logistic regression was used for analyses of predictors of work status after 12 years. The dependent variable was work status dichotomized into <50%/≥50% work. Independent variables were baseline values of age, work status, symptoms of stress, pain intensity, overall health status, leisure time physical activity, walking capacity, health related quality of life and depression.

**Conclusion:** The results showed a significant increase in work status (p<0.001) at the 12 years follow-up. Proportions of work status in category 1–4 at baseline were 56%/10%/22%/10% and at follow-up it was 36%/15%/23%/28%. The participants age, overall health assessed with Fibromyalgia Impact Questionnaire (FIQ) and health related quality of life assessed with SF-36 Physical component summary (PCS) at baseline predicted work status 10–12 years later. Age (years): OR 0.90 (95% CI 0.84–0.97), p<0.004, FIQ total score (0–100): OR 0.94 (95% CI 0.91–0.97), p<0.001, SF-36 PCS (0–100): OR 1.1 (95% CI 1.0–1.2), p=0.019.

**DIETARY PROTEIN INTAKE AND UPPER LEG MUSCLE STRENGTH IN PATIENTS WITH KNEE OSTEOARTHRITIS: DATA FROM THE OSTEOSTRITIS INITIATIVE**

A.H. de Zwart 1, M. van der Leeden 1,2, L.D. Roorda 1, M. Visser 3, M. van der A.H. de Zwart 1,2, L.D. Roorda 1, M. Visser 3, M. van der 1, H. Guney 1, S. Karahan 2, A. Ates 3, M. Turgay 3, G. Kinikli 3.

**Background:** Protein is an essential building block for muscle tissue. Adequate dietary protein intake is needed to preserve muscle tissue. In a part of the general older population, knee OA is common and is strongly related to more pain and activity limitations. Therefore, optimizing muscle function in patients with knee OA is important.

**Objectives:** To investigate the relationship between protein intake and muscle strength in patients with knee OA.

**Methods:** A total of 88 patients with RA participated to the study. Disease activity was assessed using the Disease Activity Score in 28 joints (DAS28). Functional disability was assessed using the Health Assessment Questionnaire-Disability Index (HAQ-DI). The Disabilities of the Arm, Shoulder and Hand Score (QuickDASH) was used to assess the upper extremity function. The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) was used to assess the lower extremity function. The Time Scale for the Knee Index (TSK) was used to assess pain-related fear of movement. The multiple stepwise linear regression model with R-square (R²) was used to compare across the models and explain the total variance.

**Results:** Eight independent variables namely, age (r=0.215; p=0.044), QuickDASH (r=0.504; p<0.001), HAQ-DI (r=0.315; p=0.003), WOMAC Pain (r=0.512; p<0.001), WOMAC Stiffness (r=0.419; p<0.001), WOMAC Function (r=0.398; p<0.001), WOMAC Total (r=0.429; p<0.001), WOMAC range (r=0.419; p<0.001), demonstrated significant correlations with TSK. There were correlations between two independent variables (QuickDASH, p=0.013; WOMAC Pain, p=0.034) and TSK (R²=0.293).

**Conclusion:** Health professionals should keep in mind that fear of movement was likely to cause poorer upper extremity functional disability and lower extremity pain levels in spite of varied drug therapies in patients with RA.

**PREDICTORS OF FEAR IN MOVEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS**

G.I. Kinki 1, H. Guney 1, S. Karahan 2, A. Ates 3, M. Turgay 3, G. Kinikli 3.

**Results:** After adjusting for age and gender, lower protein intake was still associated with lower muscle strength (B = -1.102, 95% CI -0.680 to -1.524, p<0.001) and was maintained after controlling for other relevant confounders.

**Conclusion:** Lower protein intake is independently associated with lower muscle strength in patients with knee OA. To confirm this relationship, future research is needed to test this association in longitudinal and interventional studies in patients with knee OA.

**APPLICATION OF THE EULAR RECOMMENDATIONS FOR PATIENT EDUCATION FOR PEOPLE WITH INFLAMMATORY ARTHRITIS IN SWITZERLAND**

K. Niedermann, C. Madelaine-Bonjour, R. Roffler, K. Kocher on behalf of Health Professionals in Rheumatology Switzerland. 1School of Health Professions, Zurich University of Applied Sciences, Winterthur; 2Rheumatology University Hospital, Lausanne; 3Swiss League Against Rheumatism, Zurich; 4Rheumatology, University Hospital, Bern, Switzerland

**Background:** The recently published EULAR recommendations for patient education (PE) in people with inflammatory Arthritis (IA) encompass two overarching principles and eight recommendations (1). The average overall agreement of PE experts with the recommendations is fairly high (at least 88% (SD+/-0.5) on a 1–10 Numeric Rating Scale NRS) (1, 2). The recommendations ought to be disseminated and implemented to establish a core standard for delivering PE and training for health professionals (HPs) in delivering PE across Europe.

**Objectives:** The Swiss HPs in rheumatology organisation, hrSwitzerland, aimed to evaluate the current standard of PE as well as the agreement with and application of the EULAR PE recommendations in Switzerland, in order to develop further implementation steps.

**Methods:** An online survey was conducted among HPs and rheumatologists in the major rheumatology clinics (n=28) of the German and French part in Switzerland. The current knowledge and skills in PE and the performance of PE in clinical practice were assessed by multiple choice questions. The agreement with the PE recommendations was assessed on a 1–10 NRS and their application in the rheumatology clinics on a 4-point scale ("applied"/"rather applied"/"rather not applied"/"not applied").

**Results:** A total of 57 HPs, among them 12 rheumatologists, 21 nurses, 15 physiotherapists, 6 occupational therapists, 2 medical assistants from 12 rheumatology clinics participated. Of these HPs, 31 (55%) worked for more than 6 years in rheumatology and 15 (27%) indicated to have a formal training in PE. They perceived that PE formed a substantial part of their work (33.5% on average), the most important element being "providing information" (48%), compared to 27% counselling and 25% behavioural interventions.

The average overall agreement with the PE recommendations was 7.0 (SD+/- 2.25). Recommendations 3 and 7 were well applied (72%) in the rheumatology clinics. Least applied were the recommendations 4 and 6 with 21% and 24% respectively. Recommendations 1, 2, 5 and 8 reached between 40–50% application rates.

Image/graph shows Agreement with and Application of the PE Recommendations in Switzerland

**Conclusions:** The overall agreement with the recommendations was high, although lower than the overall agreement of PE experts (1, 2). The application of most recommendations was found to be moderate to low in Swiss rheumatology institutions; however no comparisons with other countries are available. "Providing information" was reported as the most important PE element. This emphasises the need to implement the PE recommendations as well as to improve HPs' knowledge on delivering and evaluating effective PE, in order to provide beneficial PE interventions for people with IA in Switzerland.

**DOES PHYSIOTHERAPY AND REHABILITATION PROGRAM IMPROVE MOBILITY AND DAILY LIVING ACTIVITIES IN ELDERLY INPATIENT WITH OSTEOPOROSIS?**

M. Karapinar, T. Firat, N. Kirdi. 1Department of Physiotherapy and Rehabilitation; 2Hacettepe University, Ankara, Turkey

**Background:** Osteoporosis (OP) is a generalized skeletal disorder characterized by compromised bone strength and deterioration of bone quality, often leading to fragility. Elderly osteoporosis is being public health problem that highly affects people especially above 65 years. Physiotherapy and rehabilitation programs are...
important in the prevention and management of osteoporosis. Exercises improve mobility in elderly inpatient by increasing activity, muscular strength, flexibility, and reducing the risk of falls and length of stay in hospital.

Objectives: The aim of our study was to investigate the effects of physiotherapy and rehabilitation program on mobility, physical activity and quality of life in elderly inpatients.

Methods: A hundred and twenty four patient with OP (mean age: 73.03±5.9) participated in this study. A total of patients who were randomized as study and control group followed by Hacettepe University Faculty of Medicine Department of Internal Medicine, Division of Geriatric Medicine Department of Physiotherapy and Rehabilitation, Geriatric Rehabilitation Unit were, included to the study.

Assessment for cognitive function (Mini Mental State Test), functional mobility (De Morton Mobility Index), activities of daily living (Katz Index of Independence in Activities of Daily Living), quality of life (EuroQol-5D) were used at admission and discharge. Activities of Daily Living were measured by patient, and rehabilitation program including breathing, balance and coordination and strengthening exercises were performed by the intervention group under supervision of physiotherapist during the stay in hospital. Control group did not special exercise, they continued their activities of daily living. Exercise. Length of stay in hospital of all participant was recorded.

Results: Sixty two patients were randomly assigned to the each group. The groups were similar in sociodemographical feature (p>0.05), Improvements in mobility, quality of life and daily physical activity levels were found in the study group (p<0.05). There were no significant differences between control and intervention group in length of stay in hospital (p>0.05).

Conclusions: Our advice line gives patients easy access to specialist advice. Patient satisfaction is high. Responses are timely and fast. Multiple concerns are commonly addressed, such as advice regarding flare of disease and medication queries. This service will be

THU0761-HPR  BIOLOGICAL THERAPY SURVIVAL: MULTI-CENTRIC ANALYSIS IN REAL CLINICAL PRACTICE CONDITIONS

Background: Biological treatment (BT) has changed the evolution of rheumatic diseases. A way to product label, in clinical practice, in 3 Spanish hospitals.

Methods: Observational retrospective study, based on clinical history (CH) of patients with Rheumatoid arthritis (RA), Psoriatic Arthritis (PA), and Espondiloarthritis (EA) treated with BT.

CH standardization was performed by data collected since 2013 by rheumatologists thought MEDiades® RHEUMA tool.

Variables: age, gender, indication (RA, PA, EA); TB: Etanercept (ETN), adalimumab (ADA), certolizumab (CRT), golimumab (GOL), infliximab (IFX), abatacept (A), tocilizumab (TCZ), rituximab (RTX); Start and end date from 2002 to 2016

Exclusion criteria: Patients and/or treatment lines with incomplete data (lack data or n<15) were also excluded.

Descriptive statistics and Kaplan-Meier survival analysis were performed with r-project.com

Results: From initial 1155 patients, 76 patients were excluded because of incomplete data. Almost half of the patients (42.35%) were diagnosed with RA, 30.03% have EA and 18.07% PA. 10% were excluded because of other indications. 79.48% of patients with RA are women, as 96.36% of EA and 96.96% of PA; Most of the patients are over 55 years. In all indications, the range of 36–54 years is the one that present a higher percentage of patients.

For the Kaplan-Meier survival analysis, the complete set of BT that each patient had received was analyze independently, considering 1206 cases. Table 1 shows average time and percentage survival at 1 year and 5 years showed that the higher survival rates were for IFX in RA (94.4%) and PA (94.7%) and for ETN in EA (89.4%).

Conclusions: Our advice line gives patients easy access to specialist advice. Patient satisfaction is high. Responses are timely and fast. Multiple concerns are commonly addressed, such as advice regarding flare of disease and medication queries. This service will be

THU0760-HPR  PATIENT ADVICE LINE - THE POTENTIAL CLINICAL AND FINANCIAL BENEFITS TO A RHEUMATOLOGY DEPARTMENT
A. Mascó, C. Beever, J. Ledingham. Portsmouth Hospitals Trust, Portsmouth, United Kingdom

Background: EULAR recommendation 3 for the role of the nurse in the management of chronic inflammatory arthritis states that patients should have access to nurse-led telephone services to enhance continuity of care and to provide ongoing support (1). In the UK quality standard 6 of the National Institute for Health and Care Excellence guidelines for the care of rheumatoid arthritis (RA) recommends that people with RA and disease flares, or possible drug related side effects should receive advice within 1 working day of contacting the rheumatology service. In 2016 audit data from England and Wales show that 96% of trusts report being able to provide patients with a telephone advice line but no further detail on these services was available (2).

Objectives: Data from our patient advice line were collected over a 6 month period. The objective was to understand who was using the helpline, the speed of our response, how much of the workload could be managed by nursing staff and the clinical and financial impact.

Methods: All patient calls made to our patient helpline were recorded and data were collected retrospectively on patient demographics, disease, purpose of call, response time and the cost and revenue produced. Patient feedback was collected via a questionnaire. Data were collected from April 2016 to November 2016.

Results: 150 patient calls were responded to. 108 calls were from females and were 42 years. The majority of patients had RA (75%). Other conditions are displayed in the graph below. The majority of calls were regarding a flare of their condition or medication queries (79/180 and 39/180 respectively) with some patients calling for more than one reason. 83% of calls were answered within 24 hours. A clinical nurse specialist is available to respond to calls over weekends. Income generated from responding to calls by the department was £1 900 per month. The expenditure was £1 650 per month. Patient satisfaction was high with 130/150 stating the main reason for the call was answered to their satisfaction (7 stating no, 13 not stated).

Conclusions: Our advice line gives patients easy access to specialist advice. Patient satisfaction is high. Responses are timely and fast. Multiple concerns are commonly addressed, such as advice regarding flare of disease and medication queries. This service will be

STUDY OF MEDICAL ECONOMICS DISEASE MANAGEMENT (SSDM) MOBILE TOOLS: A POSSIBLE NEW AND EFFECTIVE WAY TO INCREASE PATIENT ADHERENCE TO MEDICAL ADVICE

G. Gremmha1, S. Arnesen2. 1Department of Public Health and General Practice, Norwegian University of Science and Technology, Trondheim; 2Department of Comparative Politics, University of Bergen, Bergen, Norway

Background: Lack of Patient adherence to medical advice (PAMA) are recognized as an era of interest for the last decades. There have been several initiatives to improve PAMA such as patient centred care, shared decision-making, introduction of e-health and m-health. Although they are proven better than usual care, neither of these initiatives is proven successful. Outcome of medical interventions depends on complex physiological and sociocultural factors of which many are uncontrolled by health professionals.

Objectives: In the present study we assess beliefs about priorities in public health care, and adherence to medical advice to establish a novel approach to improve PAMA

Methods: The Norwegian Citizen Panel (NCP) is an experimental survey. Respondents are randomized to answer similar questions with slightly different wording. NCP is currently about 5000 respondents based on random selection performed by the Norwegian people register. The present study is based on two question experiments from NCP addressing beliefs about priorities in public health care, and adherence to medical advice. The question on priorities in health care is divided in six groups (two control group, four experimental). The question on adherence is divided in three groups (one control group, two experimental). All questions are answered with a seven point Likert scale.

Question 1-4 is used to assess beliefs on health care systems priorities. Question 2 assesses aspects of potential new ways to increase patient adherence. All questions are answered using a 7-point Likert scale. Result is based on positive attitude regarding wording in the question.

* Question phrases refer to how the physician explains to the patient why the treatment is rejected.
Conclusions: This study is the first to use experimental survey to assess PAMA. The result indicates that healthcare priorities form a base of trust between health care providers and patients. It further indicates that PAMA might increase if the healthcare provider refers to national expertise and patient organisations beliefs of a given treatment. This finding is supported by psychological theories of self-monitoring [2]. Informing the patient about the views of the patient organisations and adherence in the reasoning for a given treatment, may improve patient adherence to medical advice.

THU0764-HPR WHAT MOVES THE RHEUMATOLOGIST? UNRAVELLING DECISION MAKING IN SSC REFERRAL – A QUALITATIVE STUDY
J.K. Stöcker 1,2, E. Cup3, R. Nijhuis-van der Sanden 3, B. Staal 2,3, M. Vork 2, F. van den Hoogen 1,3, E. van den Ende 1.
1 Sint Maarten'skliniek; 2 Research group Musculoskeletal Rehabilitation, HAN University of Applied Sciences; 3 Rehabilitation medical center, Nijmegen, Netherlands.

Background: Well-coordinated multidisciplinary non-pharmacological care is considered to be a cornerstone in the management of patients with systemic sclerosis (SSc). However, unmet information and healthcare needs are found to be common in patients with SSc [1]. In addition, referrals by rheumatologists do not always correspond with potential treatment goals as identified by health professionals [HP][2].

Objectives: The aim of this study was to gain insight in the perspective of rheumatologists about the referral process of SSc patients to non-pharmacological care and to identify starting points for its optimisation.

Methods: Semi structured in-depth interviews were held with 13 out of 24 rheumatologists, specialised in SSc management, from different Dutch university and regional medical centres. The qualitative data analysis used an inductive thematic analysis by moving through a process of coding in layers of abstraction and interpretation: familiarization with data, generating initial codes, grouping similar codes in categories, discussing categories, searching for themes among categories, reviewing themes, defining and naming themes, and producing the final report.

Results: One major theme was identified as influencing decision making: "beliefs" and its three sub themes: a) beliefs about one's own professional role; b) beliefs about the patients' ability to take an active role in managing the disease and c) beliefs about the added value of non-pharmacological care. We also found an additional theme reflecting the "needs" of the rheumatologists regarding professional multidisciplinary collaboration (Figure 1). Another remarkable finding to be further explored was the discrepancy we found between the reliance of rheumatologists on established routines with regard to when and to whom to refer and the low confidence in HPs competencies on the other hand.

Conclusions: This study gives insight that rheumatologists base their referral decisions on complex reasoning mindlines and beliefs about their own professional role, the patient's role and HP competencies.

THU0768-HPR PATIENT SATISFACTION AND SELF-MONITORING OF CHRONIC INFLAMMATORY ARTHRITIS
K. Grønning 1,2, E.K. Lyngvær 2, A.S. Magnussen 2, E. Rødevand 1, 1 Department of Public Health and Nursing, Norwegian University of Science and Technology; 2Rheumatology, University Hospital in Trondheim, Trondheim, Norway.

Background: Effective drug treatment for patients with inflammatory arthritides have brought a major proportion of patients in clinical remission. The need for regular follow-up intervals in specialized care is less; patients take greater responsibility for their own care, and patients request access to more flexible health care services. As a result of this development, the University Hospital, St.Olavs Hospital, Department of Rheumatology, has developed a on-demand pathway (PORS) for patients with inflammatory arthritis (RA, PsA and AS) in clinical remission or low disease-activity aiming for increased patient responsibility and flexibility.

Objectives: The aim of this study was to investigate patients' satisfaction with PORS regarding disease status, treatment, knowledge, responsibility, and cooperation with health care professionals.

Methods: We conducted a quest-back survey for patients included in PORS for ≥ 1 year in the period from June 2016 to October 2016. The survey contained 10 questions about the pathway. The response alternatives and scoring were: not at all = 1, to a small extent = 2, to some extent = 3, to a large extent = 4, to a very large extent = 5, and not relevant = 0.

Results: We identified 1048 eligible patients, 10 invitations were returned (unknown address), and 312 responded (30%). The descriptive analyses (see table) showed that the patients in general considered their disease activity to be in a stable phase. The cooperation with their general practitioner was good, they had to some or large extent sufficient knowledge to take responsibility for the blood test controls and adhere to prescribed medication. The patients were to some extent satisfied with the renewals of prescriptions and access to health professionals. The patients were less satisfied with the ‘promise’ of getting outpatient appointments within 14 days if needed. Finally, the patients would largely recommend PORS to other patients.

Conclusions: Patients with inflammatory arthritides in general were satisfied with a management pathway encouraging greater responsibility for managing their own care and the possibility for more flexible contacts with the health care services. However, fulfilling the promise of outpatient appointments within 14 days were not always possible to achieve.

Acknowledgements: We would like to thank the local Rheumatology fund for financing the project.

THU0776-HPR REFERRAL TO TELECARE. A NEW MODEL OF RHEUMATIC PATIENT FOLLOW-UP

Objectives: To analyze the medical ramifications that are made to the consultation
of telecare of Rheumatology Nursing (CTCER) of our hospital and health care activity generated by this.

**Methods:** Design: Observational study cross.

Patients: 301 patients for follow-up were derived to CTCER in a hospital of third level of January - November 2016. Our hospital serves a population of 600,000 people.

Protocol: We have a specific document for referral to CTCER where the rheumatologist specifies the reason for referral, the nurse review period and diagnosis. Nurse appoints the patient in its agenda for the telephone follow-up on the date indicated and recorded in the history of the patient efforts made the day of the appointment. The most common medical efforts making the nurse are preset by consensus with rheumatologists. Coming out than expected are reviewed with responsible for the patient's rheumatologist.

Variables analyzed: diagnosis, reason shunt type of FAME, adverse events, appearance of Comorbidities, nurse management, new problems after telephone consultation.

Statistical analysis: descriptive analysis of the main variables.

**Results:** Of the 301 patients, 68.4% were women. The diagnoses were: rheumatoid arthritis (RA) 116 (38.5%), spondyloarthropathy (SpA) 34 (11.3%), psoriatic arthritis (PsA) 45 (15%), systemic lupus erythematosus (SLE) (19.6%), vasculitis 1 (0.3%), arthritis juvenile idiopathic (AJI) 5 (1.7%), Still's disease adult 3 (1%), osteoporosis 4 (1.3%), 4 undifferentiated arthritis (1.3%). Them reasons of referral were: control to the month of home of FAME synthetic 120 (38.4%), control to the home of FAME biological 28 (9.3%), review consultations 110 (36.5%), control toxicity hepatic 17 (5.6%), control alteration hematologic 7 (2.3%), control alteration renal 1 (0.3%), control of security of treatment Mycophenolate 4 (1.3%), control of safety of Teriparatide 2 (0.6%), wish gestational 1 (0.3%), analytical control not performed in consultation 13 (4.3%) (Table1). The most derived synthetic FAME was methotrexate 174 (57.5%) and the most derived biological FAME was etanercept 16 (5.3%) (table2).

Nurse managed bypass autonomously 298 (99%) referrals, need help of the rheumatologist in 2 (0.7%) referrals and having only 1 shunt referred to 2017. 17 (5.6%) leads new problems with the call appeared: intolerance digestive 11 (3.7%), headache 3 (1%), worsening 1 (0.3%), moderate infection 1 (0.3%), poor adhesion 3 (1%), new comorbidity 3 (1%).

**Conclusions:** The inquiry of telecare is a collaborative work rheumatologist-nurse. The nurse can manage leads independently without having to go to your rheumatologist. This type of call nurse brings improvements in patient care, prevents displacement, decreased on-site visits and improves the safety of patients.

ADVANCED PRACTICE MUSCULOSKELETAL PHYSIOTHERAPY SERVICES: A NATIONAL EVALUATION

O. Fennelly, C. Blake, O. Fitzgerald, R. Breen, A. Brennan, J. Ashton, C. Cunningham on behalf of The National Clinical Programmes for Rheumatology and Orthopaedics, School of Public Health, Physiotherapy and Sports Science, University College Dublin; National Clinical Programme for Rheumatology, Royal College of Physicians; Department of Rheumatology, St. Vincent's University Hospital; Health Service Executive, HSE; Physiotherapy, AMNCH; Physiotherapy, Beaumont Hospital, Dublin, Ireland

**Background:** Patients with musculoskeletal (MSK) disorders may remain on lengthy hospital outpatient waiting lists to be reviewed by a consultant doctor, although medical or surgical intervention may not be required (1,2). In 2012, a waiting list initiative saw the introduction of Advanced Practice Physiotherapists (APPs) across 16 hospitals in Ireland. APPs triage and manage patients awaiting a consultant doctor appointment, who are deemed non-urgent or unlikely to require surgery on screening of referral letters. APP scope of practice generally involves some traditionally medical-controlled acts such as: administering injections, ordering investigations/imaging, surgical listing and onward referral to hospital specialties; and depending on consultant doctor availability, their input may be sought on clinical decisions if required.

**Objectives:**

- Profile the national APP patient caseload
- Establish the clinical outcomes of APP consultations

**Methods:** A national database was established with all APPs (n=22) submitting patient data for 2014. These data were analysed using descriptive statistics.

**Results:** Data showed that APPs assessed 13,981 new patients, who presented most commonly with MSK disorders of the knee (n=3,096), lumbar spine (n=2,926) and shoulder (n=1,945) (Fig. 1) and the median wait time was 167 days (IQR 91–316). Including an additional 2,596 return appointments, the most common clinical outcomes were physiotherapy and/or clinical investigations (Table 1), and clinical decisions were made independently by the APP in 77% (n=11,728) of recorded cases (n=15,189).

**Conclusions:** APP services provide a more efficient MSK clinical pathway and reduce demands on the Consultant Doctor services. Collection of National Data enables ongoing service evaluation and monitoring of key performance indicators.

**THU0768-HPR**

PHONE FOLLOW-UP PROGRAM ENHANCES TREATMENT SAFETY AND DRUG CONCORDANCE ON DISEASE MODIFYING ANTI-RHEUMATIC DRUGS (DMARDS) THERAPY FOR RHEUMATOLOGY PATIENTS

P.F. Lee, Y.S. Cheung, C.K. Lam, M.C. Leung, C.M. Chan, W.L. Ng. United Christian Hospital, Hospital Authority, Hong Kong, Hong Kong

**Background:** DMARDS are beneficial for a number of rheumatic conditions. However, treatment effect may take a few weeks. On the other hand, patients may experience adverse effects (AEs) early on and they may not be able to follow complicated dosage titration regimen. In order to enhance treatment safety and empower self-management, rheumatic disease patients requiring initiation or change of DMARDS were recruited to a rheumatology nurse phone follow-up program.

**Objectives:** (1) To evaluate the service outcomes of Rheumatology Nurse Phone follow-up Program and (2) explore the factors that may influence treatment adherence

**Methods:** Upon initiation of DMARDS therapy at out-patient clinic or before hospital discharge, patients and/or their caregivers will be counseled for the new treatment plan and self-management knowledge by rheumatology nurse. A telephone follow-up by rheumatology nurse will be arranged within 4 weeks to monitor patients’ condition. Treatment responses, AEs, drug concordance of patients and advice given in each phone consultation (PC) were recorded. Retrospective case review was performed.

**Results:** There were 1230 episodes of PC performed by rheumatology nurse in 2015. 180 episodes of PC involved 76 patients (56 female) were randomly selected. The average number of PC was 2.4 times per case. The mean age of patient was 58 (24–85) years. Disease categories mainly involved rheumatoid arthritis (60.5%), systemic lupus erythematosus (7.9%), spondylarthritids (5.3%) and gout (3.9%). The most common DMARDS prescribed were methotrexate (40.8%), hydroxychloroquine (27.6%), sulphasalazine (22.4%) and 39.5% of the study cases have received steroid courses. Among the 76 patients, 8 (10.5%) have taken wrong dosage and another 4 (5.3%) patients have not started therapy due to worries about potential AEs. Altogether 40 patients (52.6%) reported AEs after starting DMARDS. The most common AEs were rash, itchiness, dizziness, alopecia and oral ulcers. For non-adherence behaviour, 8 patients (10.5%) have self-stopped their medication and another 7 patients (9.2%) have self-adjusted the medication respectively. Eventually 90% of the cases were able to continue therapy with or without adjustment of regimes. Only 7 cases (9.2%) required interruption of current treatment or switching to other DMARDS due to AEs within the study period.
THU0770-HPR

COST SAVINGS BY FAVOURING INFliximAB BISIMILARS IN THE EASTERN REGION OF AUSTRIA

B. Reichardt1, G. Reiter1, T. Stamm1, R. Heaton1, P. Heaton1, 1Behandlungsökonomie, BGKK, Eisenstadt; 2Section for Outcomes Research, Care, Maastricht University Medical Centre, Maastricht, Netherlands

Objectives: Since April 2015, the availability of infliximab biosimilars offered a new potential for cost savings in limited financial resources of the healthcare system. In Austria, there is currently no open tendering for drugs dispensed at homecare providers were identified using the trust’s biologic database and clinic records. Information on biologic delivery quantities and schedule were provided by Homecare companies. Data was analysed used Microsoft Excel®; number (and cost in accordance with pharmacy tariffs) of doses “wasted” was calculated by referring the date of treatment cessation with the date and quantity of last biologics deliveries and patient stock levels as reported by the homecare company. Doses obtained from charge were excluded. Baseline delivery frequency was captured over a six month period. Four costs were calculated: (1) Total waste. (2) Wasted supply exceeding two months to assess whether an increase in delivery frequency to two monthly could reduce waste. (3) Waste from unopened deliveries to establish whether waste could be reduced by improved patient education around refusing deliveries in the event of treatment failure or intolerance. (4) Waste from the second biologic prescription issued as a result of stopping biologic at the three month review to assess viability of the proactive phone. A proactive patient phone call was then initiated and waste data captured for a three month period following this intervention.

Results: 27 patients stopped treatment during the 6 months baseline data collection. 23 patients had drug waste totalling £ 32,140.80. The total value of wasted stock exceeding two months supply was £ 5,414.36. Three patients accepted deliveries for further supply and stopped treatment before opening final deliveries, creating a waste total of £ 5,509.09. Four patients stopped treatment at their three month review, £ 4,572.22 of additional biologic was supplied and then wasted as a result. Following the pro-active phone call intervention, 21 patients were contacted before their second supply was due and supply subsequently limited for 8 patients, four of whom stopped treatment at their next consultant review. Limiting supply in the four patients saved £ 6,682.

Conclusions: Initiating a proactive phone call at three months following biologic initiation can reduce drug waste. Other initiatives such as patient education to refuse deliveries and increasing delivery frequency also appear viable waste reduction initiatives.

INCORPORATING SENIOR PHARMACIST INPUT IN TERIPARATIDE PATHWAY ENSURES ADHERENCE TO PRESCRIBING GUIDANCE - AUDIT/QUALITY IMPROVEMENT RESULTS FROM A DISTRICT RHEUMATOLOGY UNIT

W. Gan, L. Bromilow, S. Vasireddy. Bolton NHS Foundation Trust, Bolton, UK

Background: Teriparatide is licensed for up to two years to treat severe osteoporosis. It is the most expensive osteoporosis treatment available (around £ 3500 per year). Hence a locally adapted national NICE guidance is needed for prescribing in our department; but the previous level adherence was uncertain. In 2011, a directory of services was agreed for our metabolic bone clinic. At the time a Rheumatology senior pharmacist review with the prescribing senior clinician was agreed on our teriparatide treatment pathway, including pre-treatment DXA, and a specified bone profile screen before treatment and for repeat prescribing at specified intervals. The agreement also incorporated access for our patients to senior pharmacist advice if needed via the department’s secretarial team.

Objectives: Our objective was to assess the impact of the senior pharmacist input on our adherence to the agreed guidelines in our Teriparatide pathway, including assessing treatment completion and response.

Methods: Patients with osteoporosis who were started on Teriparatide between 2011–2015 were identified from pharmacy prescribing spreadsheets. A retrospective review of case notes of all patients were carried out. Data including age, gender, prior agents tried, pre-treatment bone profile, and pre and post treatment DXA, and treatment completion were collected on a Microsoft Excel 2010 spreadsheet for processing and descriptive analysis.

Results: 33 patients who were started on teriparatide treatment between 2011–2015 were identified (29 female and 4 male). Mean age was 76.2 (range 63–92). All had pre-treatment DXA, and 32 (97%) were compliant with recommendations for initiation of teriparatide treatment with respect to DXA (one patient borderline). All 33 patients had a pre-treatment bone profile within acceptable limits before start of treatment (adjusted Calcium, Serum Parathyroid Hormone, Vitamin D level, e-gfr). 28 (84.8%) patients tried one agent before initiation of Teriparatide treatment and 5 (15.2%) patients tried 2 agents. 24 (72.7%) patients completed the full course of recommended treatment. 11 out of 24 patients who completed Teriparatide treatment have had post-treatment DXA. 3 out of 24 patients who completed Teriparatide treatment had a fragility fracture after treatment.

Conclusions: This audit confirms the benefit of incorporating Rheumatology senior pharmacist review in our pathway from the excellent compliance with guidelines in initiating and managing Teriparatide noted in the results. This is likely to have also contributed to the high completion rate of the treatment course. However, only 11 out of 24 had post treatment DXA, and this needs improvement by the next audit cycle, through input of senior clinicians who are in charge of requesting DXA. We would, therefore, recommend incorporating senior pharmacist input for review in teriparatide treatment pathways routinely.

THE EDUCATIONAL NEEDS OF PATIENTS WITH UNDIFFERENTIATED SPONDYLARTHROPATHY

A. Bremender 1,2,3, E. Haglund 2,3, S. Bergman 1,3,4, M. Ndo 1, 1Department of Clinical Sciences, Section of Rheumatology, Lund; 2School of Business, Engineering and Science; 3Spenshult Research and Development Center, Halmstad; 4Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Primary Health Care Unit, Department of Public Health and Companionship Medicine, Gothenburg, Sweden; 5Department of Nursing and Midwifery, The University of the West of England, Faculty of Health and Applied Sciences, Bristol, United Kingdom

**Background:** The educational needs of people with undifferentiated spondyloarthropathy (USpA) have not been well studied. The educational needs assessment tool (ENAT) has been translated to Swedish and validated in other rheumatic diseases but not USpA. 1

**Objectives:** To validate the educational needs assessment tool (ENAT) in people with USpA and use it to study their educational needs.

**Methods:** A cross-sectional study recruiting a random sample of patients with USpA from a hospital register. USpA was diagnosed according to the International Classification of Disease, ICD-10 (M46.0, M46.1, M46.8, and M46.9). 1 The study was approved by the Regional Ethics Board and all included patients signed an informed consent. We used a postal survey to collect data on disease activity (BASDAI) and educational needs (Swedish version of the ENAT). 2 The data was then utilized to assess the construct validity, internal consistency, unidimensionality and response bias of the ENAT using Rasch analysis. Given fit to the Rasch model, we transformed the ENAT ordinal scores into interval logit-units and assessed differences between patient subgroups using the student’s t-test.

**Results:** Complete responses were derived from 77 patients (48 women), mean (SD) age 50 (12) years, disease duration was 16 (11) years, BASDAI 4.9 (1.9) and BASFI 3.1 (2.3). When used as a 7-subscale questionnaire, the ENAT satisfied the requirements of Rasch model (c²=11.488; p=0.119) including strict unidimensionality.

In general, the mean (SD) ENAT scores for patients with USpA were 86 (32). Women reported higher needs than men in the domains of pain, mean (SD) 13.1 (6.8) vs. 10.1 (6.0), p<0.05; movement mean (SD) 13.0 (5.5) vs. 9.9 (5.7), p=0.02 and self-help, mean (SD) 17.0 (5.8) vs. 14.1 (5.0), p=0.03. Higher disease activity (BASDAI >4) was associated with higher educational needs, mean (SD) 22.6 (31.9) vs. 17.3 (29.4), p=0.02. There was no significant difference in educational needs between age groups.

**Conclusions:** The Swedish ENAT has been validated in USpA thus enabling an accurate estimation of the educational needs of people with USpA in Sweden.
Our data suggest that women and patients with higher disease activity are likely to have high levels of educational needs and these groups should be targeted in educational interventions for people with USpA.

EFFECTS OF VIRTUAL REHABILITATION ON SHOULDER PERIARTHRITIS
B. Kapıçığ,1 Z. Sari,1 B. Kavılak,1 A. Ataş,2 A. Tamhan,1 1Physiotherapy and Rehabilitation, Marmara University Health Science Institute; 2Physiotherapy and Rehabilitation, Special Kızılay Medical Center, İstanbul, Turkey.

Background: The virtual rehabilitation (Nintendo Wii) program works with a 3-dimensional, computer-assisted, virtual reality creation system. The system creates a mirror effect and provides the smoothness of the movement of the adult. It keeps visual and sensory feedback during exercise. The avatar that appears on the screen detects motion and displays the result thanks to the control commander. The use of virtual reality practice in the exercise program is a new way of improving participation and motivation of participants.

Objectives: The aim of our study is to investigate the effect of virtual rehabilitation on kinesophobia and clinical fragility in patients with shoulder periartthritis.

Methods: Fifteen cases diagnosed with shoulder periartthritis were included in the study. In the study, we used Tama Kinesiophila Scale for kinesiophobia, VAS for pain severity, manual muscle test for muscle strength and goniometer for ROM. In addition to clinical fragility Scale for fragility and 4-item Quality of Life Questionnaire were used to assess quality of life. Finally, Shoulder Pain and Disability Index (SPADI) was used for shoulder disability. Eight of 15 patients were included in the control group (CG) and 7 in the virtual rehabilitation group (VRG). Both groups were treated with Therapeutic US, TENS and Cold Pack. In addition to these, the control group consisted of 15 sessions of active stretching (CG); they were given 10 MWT, 5x SST (sec) as performance tests. Each of the tests was performed twice, with a break between testing.

Results: Statistically significant reductions in Fragility, Kinesiophila, SPADI and VAS values were observed in the VRG analyzes; A statistically significant increase in the 4-item quality of life questionnaire, range of motion and muscle strength values was assessed (p<0.05). In the CG, there was a statistically significant decrease in kinesiophila, VAS and SPADI values; There was a statistically significant increase in joint range of motion and muscle strength evaluations (p<0.05). There was no statistically significant difference in the fragility evaluation of the CG (p>0.05).

Conclusions: Fragility and kinesiophila decreased in both groups after treatment compared to before treatment, but this decrease was found to be higher in VRG (p<0.05).

Methods: The study included 32 OA patients (27 F, 5 M) who undergone TKA surgery 6 months prior to the study. Mean age and BMI of the patients were 64±10.58 and 30.49±5.87, respectively. Participants performed the Timed Up and Go Test (TT), 1 Meter Walk Test (10MWT), Single Leg Stance Test (SLST), Functional Reach Test (FRT), 2 Minute Walk Test (2MWTT), Five Times Sit to Stand Test (5x SST) as performance tests. Each of the tests was performed twice with a

ANALYSIS OF LEFT VENTRICULAR FUNCTION WITH ECHOCARDIOGRAM IN PATIENTS WITH PSORIATIC ARTHRITIS AND NOT DIAGNOSED CARDIOVASCULAR DISEASE
P. Egea-Serrano 1, A.C. Haro-Martinez 1, A. Vidal 1, D. Palma-Sánchez 1, 1Cardiology; 2Rheumatology; Hospital Rafael Mendez, Lorca, Spain

Background: It is known that some rheumatological disorders may affect the cardiovascular system. In the last years, psoriatic arthritis (PsA) has been pointed out as one of these.

Objectives: The aim of this study was to analyze if there was any subclinical dysfunction sign in patients with PsA of whom no cardiovascular disease had been diagnosed.

Methods: Forty three patients with PsA were studied. A comprehensive echocar-
1-day interval. ICC models were used to determine the test-retest reliability. Berg Balance Scale (BBS) was used as the reference standard to establish concurrent validity.

Results: All tests showed good to excellent reliability (ICC > 0.94) except SLST which showed moderate to good reliability (ICC = 0.74). Three of the tests (SLST, 10 MWT, 5x SSS) found to have moderate to excellent validity (r > 0.75) and three (2 MWT, TUG, FRT) found to have moderate to good reliability (r > 0.69). Results are presented in details at Table 1 and Table 2.

Conclusions: TUG, 10MWT, SLST, FRT, 5x SSS and 2 MWT are reliable and valid outcome measures, and could be used to assess balance and fall risk in patients with TKA. MDC scores presented in this study can be used to evaluate change in performance over time or effectiveness of interventions. 2 MWT and 5x SSS were determined as the most reliable and valid methods among the investigated tests.

THE SOURCES OF PAIN IN ABDOMEN IN PATIENTS WITH RHEUMATOID ARTHRITIS

H. Palhuyeva1, A. Litviakov1, V. Shynkovski2, N. Podolinskay2. 1 Internal diseases, Vitebsk State Order of Peoples’ Friendship Medical University, Vitebsk, Belarus

Background: Systemic diseases of connective tissue associated with the early development of atherosclerosis [1,2]. It is well-known that the main cause of decrease the quality of life patients with rheumatoid arthritis (RA) is a chronic pain syndrome. The cause of pain can be joint inflammatory process, systemic manifestations of RA (vascular disease, pericarditis, pleurisy, perineuropathy) [3], complications of drug therapy, comorbid conditions. Pain in the stomach area may be associated with NSAID-gastroptropy, problems with spinal discs, and perhaps with atherosclerotic lesions of the abdominal aorta.

Objectives: To estimate atherosclerotic changes of arteries in patients with RA and to determine possible sources of pain in the abdomen by ultrasound-control palpation.

Methods: We included 75 patients with RA (age 38.7±7.4, males 93.3%) and 29 healthy subjects, matched for age and gender, without a history of cardiovascular diseases. An ultrasound investigation of the arterial wall with measurement of the intima-media thickness (IMT) of carotids was performed. To determine the source of pain in the abdominal cavity ultrasound-control palpation of duodenal bulb, gallbladder, lumbar discs, and abdominal aorta was done. Seventy of pain was assessed using the VAS.

Results: It has been determined, that in RA group IMT was 0.8 mm (0.7–0.9), compared with 0.6 mm (0.6–0.7) in control group. IMT positively correlate with the age, duration of disease, Ritchie index, C-reactive protein level. In 22 (29.3%) patients with RA we found atherosclerotic plaques lesion in carotids, aorta, and vessels of the lower extremities. Present of atherosclerotic plaques associated with disease duration (12 years (10–15) in group with plaques and 5 years (3–8) in group without plaques). The presence of atherosclerotic plaques is associated with rheumatoid factor (c=1.02, p=0.05), and systemic manifestations of RA (c=1.59, p=0.001).

In RA group 36 (48%) patients had indicated the presence of pain in the abdomen while performing ultrasound control palpation. In 15 (20%) cases was detected pain during palpation of the lumbar spine, VAS 48 (36–59). In 21 (28%) cases, patients indicated pain during palpation of the abdominal aorta, VAS 42 (31–65). In this group of patients we found signs of the atherosclerotic lesions of aorta, change in the contour of the vessel, the heterogeneous structure of the vascular wall. Atherosclerotic plaques in the abdominal aorta are founded in 21 (28%) cases.

Conclusions: Patients with RA had an increase thickness of IMT and atherosclerotic plaques, which appear in various vascular regions. During performing ultrasound-control palpation in 36 (48%) patients was detected pain, associated with vertebral changes 15 (20%), and with atherosclerotic changes of abdominal aorta – 21 (28%).

THE EXPERT, WE ARE THE SPECIALIST

J.E. Voorneveld-Nieuwenhuis, M.D. Kok, N. Basoski, M. Holtrop, D. Lopes Barreto. Rheumatology, Maasstad Hospital Rotterdam, Rotterdam, Netherlands

Background: Patient participation is known in the field of rheumatology research and is becoming more customary. The patient perspective can improve the care and line specific needs of the patient to the delivered care.Recently, our rheumatology department within the Maasstad Hospital introduced the Value Based Health Care principle in order to optimize the current healthcare system.
We thought to measure the value for patients we should let them participate in the project and asked them about what is of value for them and what are there goals. A good reason to start with a patient panel.

**Objectives:** For this reason we aimed to create a patient panel of rheumatology patients that are well informed and prepared to actively cooperate and participate in research, and co-design novel healthcare strategies.

**Methods:** Staff members (e.g. doctors and nurses) were asked to nominate patients that are expected to actively participate in the panel. Nominated patients were verbally approached and asked to participate. After mutual agreement a contract was signed were patients discretion was warranted, the capacity to handle confidential information was assessed and equality between members of the panel and staff was ensured. Enrollment of the panel is mainly staff-driven, but panel members are also invited to actively recruit other rheumatology patients.

**Results:** The initial enrolment period lasted for six months. Thereafter, meetings were organized were discussion were held on various themes such as goals and value for rheumatology patients. Additionally, a focus group of rheumatoid arthritis (RA) patients was assembled to evaluate a PROMs measurement tool. To date, a number of four panel discussion have been held. Currently, our patient panel consists of 54 patients with all kinds of rheumatic diseases. Their demographic and clinical data are presented in Table 1.

**CONCLUSIONS:** Our panel has been asked to participate in other (hospital-wide) programmes including the development and evaluation of a patient portal. We organize about three meetings for the whole panel every year and arrange focus group meetings to discuss specific subjects.

**Conclusions:** Panel members are very open and enthusiastic. Some quotes: “I’m happy to do something in return for the good care I receive.” and “I want to promote participation in scientific research.” Deployment of patient participation for co-creating innovations alongside research is an asset these days to connect changes to patients perception.

In real live involving patient as an expert is not an effortless action for both patients and the expert care takers, it leads to satisfaction and an effective treatment.

L. Renkers, S. N. T. Renskers, S. A. S. A. Rongen, S. Teerenstra, M. E. J. L. Hulscher, P. L. M. van Riel, 1,2, 1,2, 3Department for Health Evidence, Radboud Institute for Health Sciences, Radboud university medical center, Nijmegen; 2,3Rheumatology, Bernhoven, Uden; 4Department for Health Evidence, Radboud Institute for Health Sciences, Radboud university medical center, Nijmegen, Netherlands

**Background:** Since the disease activity of patients with RA tends to fluctuate between visits and disease flares are easily missed during regular visits, patients might benefit from a more closely spaced determination of disease activity, which could be realised by iMonitor. iMonitor is a Software Medical Device developed and funded by Pfizer. This online system allows patients to complete three kinds of patient-reported outcome measures (PROMs): the Health Assessment Questionnaire (HAQ), the Rheumatoid Arthritis Impact of Disease (RAID) and the Rheumatoid Arthritis Disease Activity Index-5 (RADAI-5). More often, PROMs results might contribute to identification of patients who need additional medical attention in between visits and reduction of visits for patients with stable disease activity.

**Objectives:** To determine the degree to which the PROM-scores in iMonitor are associated with DAS28. Moreover, PROM preferences and completion rates were studied.

**Methods:** Patients were recruited at Bernhoven (Uden, the Netherlands) by an announcement on the hospital website, leaflets and meetings. Instruction classes were organised in which researchers assisted patients in using iMonitor. Patients indicated which PROM(s) they want to complete in iMonitor and chose reminder email frequency (weekly, two-, four-, six, and eight-weekly). Descriptive analyses were used to describe characteristics of the study population. Scatter plots with regression equations were performed with DAS28 as dependent and PROM as independent variable to determine the association between DAS28 and PROMs. Moreover, PROM’s correlations were calculated. PROM-score within the fourteen day window before and after DAS28 assessment were included.

**Results:** In total 33 patients with RA were included, seventeen of them were female (52%). Mean (±SD) age was 56±11 years. Seventeen patients (52%) attended the instruction classes. Majority of patients (n=10) chose all three PROMs to complete, nine patients chose RAID+RADAI-5, seven chose HAQ+RAID, three chose RAID, two chose RADAI-5 and two chose HAQ+RADAI-5. From March 2016 until December 2016, 435 PROM-values, 329 DAS28-values and 222 HAQ-values were gathered. When taking PROM-values within the fourteen day window before and after DAS28 assessment, 159 DAS28-values could be coupled to 529 PROM-values. Regression analysis showed the following proportions of explained variance (R²): 0.17 for HAQ, 0.32 for RAID and 0.29 for RADAI-5. Pearson’s correlation coefficients were 0.41 for HAQ, 0.57 for RAID and 0.54 for RADAI-5. Most chosen reminder email frequency was four weeks (n=21). Completion rates (measured until December 31, 2016) were 65% for patients with one week PROM-frequency and for patients with two, four, six and eight week frequency completion rates were 39%, 24%, 30% and 0%, respectively.

**Conclusions:** RAID and RADAI-5 were moderately associated with DAS28 and showed highest proportions of explained variance. The association between HAQ and DAS28 was weaker. Patients receiving a weekly reminder email showed highest completion rates. This pilot study is a first step towards personalised healthcare and patient involvement in online remote monitoring.

**References:**

L.F. Perez, A. Martinez, M. Moreno, L. Silvera, Reumatologia, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico

**Background:** Anxiety and depression are often present in chronic rheumatic diseases. Recognition of these psychological disorders is fundamental for proper patient management. The absence of screening leaves more than 50% of patients with depression unidentified. Patient Help Questionnaire-9 (PHQ-9) and General Anxiety Disorder-7 (GAD-7) are two validated self-applied questionnaires that are appropriate to assess the prevalence of, depression and anxiety, respectively.

**Objectives:** 1) To assess the prevalence of depression and anxiety in a hospital based outpatient Rheumatology clinic and 2) To provide the attending physician with appropriate instruments that allow a rapid orientation on the psychological status of her/his patient.

**Methods:** Consecutive patients that attended our outpatient Rheumatology clinic from March to June 2016 were invited to participate in this cross-sectional study. Participants filled out PHQ-9 and GAD-7 in the waiting room. The prevalence and severity of anxiety and depression were calculated for the most prevalent diagnoses.

**Results:** A total of 410 patients were recruited; 339 (82.8%) were female. Overall, 191 (46.9%) patients reported depressive symptoms (PHQ-9 ≥ 5). Of them, 87 (21.2%) were classified as having moderate depression or higher (PHQ-9 ≥ 10). Prevalence of depression and anxiety among study participants according to each rheumatic disease is depicted in Table 1. Prevalence of moderate or severe depression was significantly different among various rheumatic diseases (p=0.001). Regarding anxiety symptoms, they were reported in 168 (40.7%) and 87 (16.2%) of them had moderate or severe anxiety.

**Conclusions:** This cross-sectional study shows that anxiety and depression are frequent in the Rheumatology clinic. We demonstrated that the use of a self-applied screening tool can help clinicians to properly detect depression and anxiety associated with diverse rheumatic diseases. Specia attention should be paid to patients with fibromyalgia and osteoarthritis.
**Does the Use of Technological Devices Improve the Reliability of Measuring the Active Cervical Range of Motion in Patients With Neck Pain? A Systematic Review with Meta-Regression**

A. Rondon1, G. Rossetti1, M. Strobe1, F. Gallo2, D. Ristori1, M. Testa1,
1Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, University of Genova, Savona; 2Department of Health Sciences, University of Genova, Genova, Italy

**Background:** Economic impact of neck pain shows an increasing trend. In order to limit the costs of spine disorders management, it is important to assess clinical efficacy and the cost-worthiness of new technological devices, recently introduced in physical therapist's clinical practice.

**Objectives:** This systematic review compares, in patients with non-specific neck pain, the reliability of measures of Active Cervical Range of Motion (ACROM) detected with technological devices with those assessed with low cost, commonly-used devices. As secondary outcomes, it was investigated if ACROM reliability depends on the plane on which the measured movement is performed.

**Methods:** The literature was carried out in Medline, Scopus, Embase, The Cochrane Library, CINHAL, PEDro, and other available databases until August 2016. Inclusion criteria were: reliability design, population of adults with non-specific neck pain, examiners of any level of experience, measures repeated at least twice and statistics indexes on reliability. Exclusion criteria were: other study designs, asymptomatic population or mixed population, single or none ACROM measure inadequate statistics. The risk of bias was assessed by OAREL. It was considered inexpensive a device that costs at maximum 500 euros. A Univariate, and a Multivariate Analysis, were performed by using the Linear Mixed-Effect Model

**Results:** Searching the databases yielded 35,151 records. Nine studies met all eligibility criteria. The OAREL mean score of the selected studies was 3.7 out of 11. No significant effect of the type of device (inexpensive versus expensive) on ICC was observed for intra-rater (ICC=0.93±0.01; p-value=0.89) and inter-rater reliability (ICC=0.80±0.07; p-value=0.99) [Table 1]. The plane of movement did not affect inter-rater reliability (p-value=0.11) while significantly influenced the intra-rater reliability (p-value=0.0001) assessed with low-cost devices. Intra-rater reliability significantly decreases (p-value=0.0129) in frontal plane movements (side bending) compared with movement on the sagittal plane (flexion-extension).

**Conclusions:** The use of expensive devices to measure ACROM in adults with non-specific neck pain problems not seem to improve the reliability of the assessment. The assessment of side bending showed the lowest level of inter-raters reliability. Since the quality of the analysed studies is low, the conclusion of the present study should be taken cautiously.

**The Effectiveness of the Lower Dose of Laser Treatment on Knee Osteoarthritis**

E. Ekiz1, K. Kapaci2, M. Korkmaz3, 1Physical therapy and rehabilitation, Alaşehir State Hospital, Manisa; 2Physical therapy and rehabilitation, Ege University, Izmir; 3Physical therapy and rehabilitation, AYONKARAHISAR State Hospital, AYONKARAHISAR, Turkey

**Background:** During knee osteoarthritis (OA) therapy; medications, physical therapy modalities, exercises and surgical procedures are used. In previous studies, the benefits of low level laser therapy (LLET) for pain in the low back, shoulder, elbow, and hand have reported.

**Objectives:** In this study we aimed to investigate the effectiveness of LLLT on pain, functional status, and quality of life in patients with knee osteoarthritis.

**Methods:** Patients with Kellgren-Lawrence stage 2–3 knee osteoarthritis were enrolled. It was planned as a prospective, randomized and double-blind study. Group 1 received active laser therapy and group 2 placebo laser therapy. Patients have been provided active/placebo laser therapy for two weeks (5 days a week, a total of 10 sessions). Patients were evaluated before, immediately after and 1 or 3 months after treatment. Outcome measurements included pain intensity at rest and at movement on visual analog scale, knee function using Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) scale, active/passive joint range of movement, quality of life using Short form 36 (SF-36), and 15-meter walking distance, painless walking distance.

**Results:** In this study, we observed improvements in knee pain, 15-meter walking distance, WOMAC pain, stiffness and function scores, Lequesne index, and SF-36 physical function and social function (p<0.05) in active LLET group. At all, significant improvements were detected in SF-36 physical role, mental health, vitality, and emotional role function in active laser group (p<0.05).

**Conclusions:** The present study demonstrated that LLET is safe and effective upon pain and functional parameters on knee osteoarthritis. However, we think future long-term studies should be completed to include more patients in order to determine the priority and effectiveness are required.

INVESTIGATION OF ASSOCIATION BETWEEN WRIST PAIN, FUNCTIONAL PERFORMANCE, GRIP AND PINCH STRENGTH IN CHILDREN AND ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS: CROSS-SECTIONAL STUDY

S.N. Arman1, E. Tarakci2, O. Kasapcopur3, 1Department of Physiotherapy and Rehabilitation, Faculty of Health Science; 2Medical Faculty of Cerrahpasa Department of Pediatric Rheumatology, Istanbul University, Istanbul, Turkey

Background: Juvenile idiopathic arthritis (JIA), among the most common chronic diseases of childhood, can be associated with pain. reduced range of motion, decreased muscle strength and functionality (1).

Objectives: The aim of this study was to assess the relationships between wrist pain and functional performance, grip and pinch strength in children and adolescents with JIA.

Methods: Cross-sectional study design was included 42 (36 female). 6 male children and adolescents with JIA aged between 8 and 18 years. Patients who have at least one affected wrist included in the study. Sociodemographic data and clinical features were assessed by physical therapists. Hand grip strength was assessed with Jamar dynamometer. Lateral, tip and palmar pinch strengths were assessed with Baseline pinchmeter. Wrist pain during the activity was evaluated with Numeric Rating Scale (NRS). A score of 0 indicated "no pain" and 10 indicated "extreme pain" for NRS. Functional performance of hands was assessed with "Jebson Taylor Hand Functional Test" (JTHFT). JTHFT consists 7 subtests: writing a 24-letter, card turning, picking up small objects and placing them in a container, stacking checkers, stimulated feeding, moving light objects and moving heavy objects. All tests except writing performed on both right and left hand for JTHFT.

Results: The mean age and duration of disease was 13.05±3.04 (age range 8–18) and 6.55±3.78 years. respectively. Patient population consisted of 28 patients with polyarticular arthritis. 14 patients with oligoarticular arthritis. 39 of 42 patient's wrists were affected bilaterally. Significant relationships were found between writing and right palmar pinch strength (r=-0.34 p=0.023), right hand grip strength and right stimulated feeding (r=-0.32 p=0.039), left hand grip strength and left moving heavy objects (r=-0.33 p=0.028). Also, significant relationships were found between right lateral pinch strength and stimulated feeding (r=-0.33 p=0.028) and right stacking checkers (r=-0.31 p=0.039). For right side, significant relationships were found between palmar pinch and moving light objects (r=-0.35 p=0.020), moving heavy objects (r=-0.32 p=0.039), stimulated feeding (r=-0.36 p=0.017), stacking checkers (r=0.36 p=0.017), card turning (r=-0.34 p=0.026) and JTHFT-total score (r=-0.33 p=0.028).

Conclusions: The results of our study showed that hand grip and pinch strengths considerably decreased in children and adolescents with JIA, according to the normal means of the grip strengths of healthy children and adolescents reported in the literature (2). Our study suggested that decreased hand grip and pinch strengths may result impairment daily functions but wrist pain does not effect on. The results of our study showed that hand grip and pinch strengths were associated with JIA. Althought patients with JIA had only one affected knee joint, hip flexion muscle strength was primary predictor of stair climbing performance. We suggested that stair climbing performance should be considered in patients with juvenile idiopathic arthritis. Thus, not only affected joint, but also all lower extremity joints should be assessed multidimensionally.

FEASIBILITY OF FOUR QUESTIONNAIRES TO EVALUATE PATIENT EDUCATION FOR PEOPLE WITH INFLAMMATORY ARTHRITIS

R. Røe1, K. Gronning2, L.R. Eriksson1, H.A. Zang3 on behalf of the Norwegian patient education expert panel. 1Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo; 2Dept of Public Health and Nursing, Center for Health Promotion Research, Norwegian University of Science and Technology, Trondheim; 3National Advisory Unit on Rehabilitation in Rheumatology, Dept. of Rehabilitation, Diakonhjemmet Hospital, Oslo

Background: No core set of outcomes to evaluate patient education (PE) programmes exists. Evaluation of existing outcome measures is recommended (4). A Norwegian expert panel comprising patients and health professionals experienced in patient education (PE) participated in a 3-round Delphi-process. The aim of the process was to obtain consensus about outcome domains that might be influenced by PE for people with inflammatory arthritis (IA). Six domains were identified: Understanding disease and treatment, knowledge about healthy life style, coping strategies, self-efficacy, empowerment and communication with health professionals. Through a systematic literature search and further Delphi-rounds, the expert panel identified four patient-reported outcome measures (PROMs) that might capture these outcome domains.

Objectives: To test the feasibility of four identified PROMs suitable to evaluate patient education programmes.

Methods: Arthritis Self-Efficacy Scales (ASES) for pain and symptoms, Effective Consumer Scale (EC-17), Health Education Questionnaire (heiQ) and Patient Activation Measure (PAM) were tested in 13 PE programmes for people with IA at six rheumatology departments in Norway. The PROMs were divided into two test-sets, set A (ASES, EC-17 and PAM) and set B (ASES and heiQ). Data were collected before, immediately after and 3 months after PE programmes. The instruments were tested for missing values, internal consistency (Cronbach’s α) and ability to detect change. Floor and ceiling effects were considered to be present if more than 15% of the patients achieved the lowest or highest possible score on each item.

Results: 104 patients answered the questionnaires before participation in a PE programme, 63 in group A and 41 in group B, respectively. 96 (92%) answered the questionnaires after intervention and 78 (75%) responded at 3-month follow-up. Missing values were few in all PROMs (range 0–1.7%). Cronbach’s α was acceptable in ASES pain (0.75) and ASES symptoms (0.81), EC-17 (0.91) and PAM (0.78). heiQ comprises eight separate subcategories; seven categories had acceptable Cronbach’s α (0.72–0.86). All PROMs showed statistically significant improvements after the PE programmes. At 3-month follow-up statistically significant changes were found only in EC-17 (p<0.01, SRM 0.4) and in four of eight heiQ subcategories: emotional distress (p=0.01, SRM 0.5), skill and technique acquisition (p=0.02, SRM 0.5) and health service navigation (p=0.02, SRM 0.5). There were ceiling effects in all PROMs at baseline, 10/13 items in PAM, 5/17 in EC-17, 3/11 in ASES and 14/40 in heiQ. No floor effects were detected in any of the PROMs.

Conclusions: Based on this pilot study in patients with IA, EC-17 and three of the heiQ subcategories were the most feasible PROMs in terms of internal consistency and ability to detect change. Although ASES did not exhibit significant changes at 3-month follow-up, it should be considered as an outcome measure, because it is the only instrument to measure self-efficacy.

CROSS-CULTURAL VALIDATION OF THE PORTUGUESE "RHEUMATOID ARTHRITIS IMPACT OF DISEASE" SCORE: CROSS-SECTIONAL STUDY

P. J. O. Ferreira,1,2 L. Gosecic,3 S. Hewlett4, C. Duarte1, 5, J. K. Nicklin1,6, J. A. P. da Silva1,6, M. Noddi1,7, 1Centro Hospitalar e Universitário de Coimbra; 2UCICoE, Escola Superior Enfermagem de Coimbra, Coimbra, Portugal; 3Paris 6 University, Paris, France; 4University of the West of England, Bristol, United Kingdom; 5Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal

Background: The Rheumatoid Arthritis Impact of Disease (RAID) score1 assesses 7 impact domains of interest for people with rheumatoid arthritis (RA). Its use in research and clinical practice has been growing, and it is already translated into over 70 languages2 but the cross-cultural validity of the Portuguese RAID has not been well established.

Objectives: To validate the Portuguese RAID for use in Portugal.

Methods: This was a single centre, cross-sectional validation study involving 2 phases: (i) cognitive debriefing with 38 patients to determine comprehension of the existing2 Portuguese RAID (ii) cross-cultural validation using data from adult patients who were willing and able to complete the Portuguese RAID unaided. Analyses included fit to the Rasch model (implying construct validity, reliability and statistical sufficiency), tests for unidimensionality and invariance across different patient subgroups i.e. age, gender, education background, disease duration, function and culture. To test invariance to culture, the Portugal dataset was compared with datasets from France (n=195) and the UK (n=205).3 RUMM2030 software was used in all analyses.

Results: Phase I led to minor changes in phrasing 3 items to enhance understanding and conceptual equivalence between the original RAID and the Portuguese version. In Phase II, 288 patients were included: mean (SD) age=60 (12) years, 82% females, 76% with disease duration ≥5 years, 30% on biologics.

The Portuguese RAID was shown to have adequate fit to the Rasch model and high internal consistency (Table 1). Unidimensionality and invariance to age, gender, disease duration and function were confirmed (data not shown). The scale was well targeted for patients with different levels of disease impact (Figure 1). Pooling the datasets from Portugal, France and the UK revealed no cultural response bias (Table 1). RAID was then calibrated into logit-based scores to enable parametric analyses and bias-free cross-cultural comparisons if desired (data not shown).

DF: degrees of freedom; *6 items for cross-cultural comparisons (items 2 ‘Function’ and 5 ‘Physical well-being’ combined).

Figure 1. Distribution of items and persons along the same scale (logit score) confirming good targeting of the RAID.

Conclusions: This study confirms the Portuguese RAID as a robust unidimensional tool for use in Portugal. The raw scores of the 7-item RAID can be used with confidence in clinical practice. Conversion charts are available to enable accurate cross-cultural comparisons across Portugal, France and the UK.

evidenced by Spearman correlation coefficients of ≥ .50 were hypothesized between IPAAQ-LF total or its subscales and the armband to conform construct validity (p<.05).

**Results:** IPAAQ-LF total PA (Median [IQR]: 16.71 (5.91–45.15) MET.hrs/day) was associated with Physical Activity Level (r=.434, p<.01), moderate to (very) vigorous PA (MET≥3.6, r=.432, p<.01) and inactive time (MET<1.8, r=.382, p<.05) obtained with the armband. Similar, IPAAQ-LF moderate PA (Median [IQR]: 10.39 (2.41–23.71) MET.hrs/day) was related with PAL (r=.492, p<.01), moderate to (very) vigorous PA (r=.456, p<.01), moderate PA (r=.444, p<.01) and inactive time (r=.491, p<.05). Also, IPAQ-LF sitting (Median [IQR]: 14.91 (10.89–20.80) hrs/day) was correlated to PAL (r=.461, p<.01), moderate to (very) vigorous PA (r=.391, p<.05), moderate PA (r=.386, p<.05) and inactive time (r=.496, p<.01). No relevant nor significant correlations were found for the other IPAAQ-LF subscales. Taken together, no hypothesis could be confirmed.

**Conclusions:** Even at a group level, the convergent construct validity of IPAAQ-LF in axSpA was not confirmed. Self-reported PA outcomes may provide important contextual information on PA, but perform poor at quantifying PA levels in axSpA. Future research on a feasible self-reported PA measurement tool for these patients is required.

# PAIN SPREAD AND PAIN INTENSITY IMPROVE OVER 1, 2, 3, OR 4 YEARS FOLLOWUP IN WOMEN WITH FIBROMYALgia AND CHRONIC WIDESPREAD PAIN. A 12 YEAR FOLLOWUP STUDY

**A. Bergenhelm** 1,2,3, S. Johannesson 1, L. Nordeman 1,2, M. Joelsson 3, K. Mannerkorpi 2, C. Kaplan 1, A. Postlethwaite 1, A. Ganguli 2, J. Wang 1.

**1**Närhälsan Research and Development Primary Health Care, Region Västra Götaland; **2**Institute of Neuroscience and Physiology/Physiotherapy, Sahlgrenska Academy, University of Gothenburg, Göteborg; **3**Närhälsan Rehabilitation Centres, Region Västra Götaland, Sweden

**Background:** In the Western world, the prevalence of chronic widespread pain (CWP) is about 10–15% while Fibromyalgia (FM) affects approximately 1–3% of the population. The ACR 1990 criteria define CWP as pain >3 months on the right and left side of the body, above and below the waist and axial skeletal pain. The 1990 criteria for FM are CWP in combination with pain in >11 of 18 tender points on manual palpation. Previous studies indicate that some patients with FM or CWP improve over time and the key to improvement is an important question in research and clinical practice.

**Objectives:** The primary objective was to investigate the change of pain intensity and pain distribution after 12 years in 166 women with FM or CWP. The secondary objective was to compare baseline values of health related variables between patients who fulfilled the criteria for FM/CWP at the 12 year follow-up and patients who did not.

**Methods:** In 2004, 166 women with FM or CWP participated in a randomized controlled trial in Sweden aiming to investigate effects of patient education and pool exercise. All 166 were invited to the present study in 2016 and 2012 women (75%) participated. Data was collected by a standardized interview, questionnaires of health related aspects and a physical examination. Primary, within-group changes were calculated for pain distribution (Bergman’s pain drawing 0–18) and the subscale for pain intensity (0–100 mm) included in the Fibromyalgia Impact Questionnaire (FIQ). Secondary, the group who fulfilled criteria for FM or CWP at follow-up were compared with the group who did not fulfill the criteria for FM or CWP, in overall health status (FMQ total), symptoms of stress (Stress and Crisis Inventory – SCI-93), walking capacity (6 min walk test), hand grip force (the Grippit) and self-reported physical activity (Leisure time physical activity instrument).

**Results:** Primary: The 126 women with FM or CWP improved in pain distribution: mean values at baseline 12.9 (SD 3.4) vs follow-up 11.4 (SD 4.7), p < 0.001 and pain intensity: mean values at baseline 69 (SD 18.5) vs follow-up 59 (SD 22), p < 0.001. Secondary: 18% (n=23) of the 126 women did not fulfill the 1990 criteria for FM or CWP at follow-up, and they showed significantly better health status, lower symptoms of stress and higher walking capacity in 2004, than the women who still had FM or CWP at follow-up. Baseline mean values FM/CWP (n=123) vs Not FM/CWP (n=23): FIQ total 66 (SD 16) vs 55 (SD 15), p = 0.006; SCI-93 80 (SD 23) vs 59 (SD 22), p < 0.001; 6 min walk test 502 m (SD 86) vs 542 m (SD 80), p = 0.028. No significant differences were found between the groups for baseline values of hand grip force and level of physical activity.

**Conclusions:** This study showed that distribution and severity of pain improved during 12 years in women with FM or CWP. The group that improved most (18%), reported better health status, lower stress and had better walking capacity 12 years earlier. This knowledge is important for health care professionals to motivate the patients to apply a variety of strategies, including physical activity, to improve their health and symptoms.

the development of accelerated atherosclerosis, leading to increased risk of cardiovascular disease (CVD), and increased mortality.

Objectives: This study aimed at examining changes in the risk of death, CVD and RA-related orthopedic surgeries between the patients treated with conventional synthetic and biologic disease modifying antirheumatic drugs (csDMARD and bDMARD) for RA during 1997–2011.

Methods: Two cohorts of severe RA patients and their matched controls were identified from National Health Insurance claims database. The csDMARD cohort was patients who had medication claim for cyclosporine >50 mg/day with concomitant use of >2 csDMARDs for >28 days within 56 days after cyclosporine use during 1997–2003 (N=1,569). After csDMARD cohort was determined, the bDMARD cohort was selected if patients had >1 claim for bDMARD during 2003–2011 (N=1,530). Adjusted hazard ratios (aHRs) for the risk of death, myocardial infarction (MI), stroke, and RA-related orthopedic surgeries were assessed between the two primary joint involvement and their controls, respectively, using Kaplan-Meier survival curves and Cox proportional hazards models.

Results: RA patients using bDMARD showed a markedly decreased risk of death (aHR=1.05; 95% CI=0.84–1.33) compared with RA patients using csDMARD (aHR=0.87; CI=0.74–1.03). Also, bDMARD was associated with a reduced risk of stroke (aHR=0.37; CI=0.22–0.62) compared with csDMARD (aHR=0.73; CI=0.51–1.05). For RA-related orthopedic surgeries, risks were slightly lower for bDMARD (aHR=0.41; CI=0.32–0.52) compared with csDMARD (aHR=0.57; CI=0.48–0.69).

Conclusions: The introduction of biologics in the treatment of RA has shown to have beneficial effects on improving clinical outcomes, including decreased risks of death, stroke and RA-related orthopedic surgeries.

FRIO758-HPR EVALUATION OF MUSCULOSKELETAL COMPLAINTS ASSOCIATED WITH SMARTPHONE USE AMONG UNIVERSITY STUDENTS AND RELATED RISK FACTORS

E. Tonga, B. Özgüüz, E. Tisman, M. Cııta, Y. Hasırri, M.G. Polat. Marmara University, Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Marmara University, İstanbul, Turkey

Background: Smartphone use for long periods in a static and unsupported arm position could bring about abnormal alignment of upper limb and could cause postural problems and musculoskeletal pain. There are very few studies in the literature that examine the effect of smartphone use on musculoskeletal problems and related factors.

Objectives: The primary aim of our study was to determine the musculoskeletal complaint associated with smartphone use among university students. Other purpose of the study was to investigate the relationships with smartphone type, smartphone use frequency, smartphone use posture, smartphone use addiction level and psychological characteristics. 

Methods: 349 university students (240 women, 109 men; mean age 20.79±1.35) were included to our study. We conducted a survey that contains questions about students’ smartphone usage patterns and habits. Nordic musculoskeletal Questionnaire was used to determine the musculoskeletal complaint associated with smartphone use. Working posture while using smartphone were evaluated with Rapid Upper Limb Assessment (RULA). Smartphone addiction level were determined with Smartphone Addiction Scale (SAS). Also we used the Beck Depression Inventory (BDI) to determine the psychological distress. Pearson correlation analysis was used to evaluate the associations between parameters.

Results: Our results showed that university students had a high frequency of smartphone use and that the frequency was related to the level of addiction (r=0.199 p=0.00). %43 of students were use their smartphones extremely more than 12 hours a day and they use smartphones often for messageing with smartphone applications (%66.5). The most frequent symptoms were found in the neck (%59.6), shoulder (%51.82) and upper back (%54.4) regions. Statistically significant relationship was found between daily frequency of smartphone use and RULA neck posture score (r=0.170, p=0.001). Also there were statistically significant relationships found between BDI score and upper limb (r=0.135, p=0.005) and upper back (r=0.152, p=0.004) postures while using smartphone.

Conclusions: Smartphone users complain at least one area (neck, upper extremity, upper back). The frequency of smartphone use and addiction level is associated with abnormal postures while using smartphones which associated with psychological distress. Consequently, musculoskeletal rehabilitation programs should include an analysis of preventive strategies which should be multifactorial with the team work of all health professionals.

References:
Steroid was used by 39.2% of patients with diabetes and hypertension. Cardiovascular events (ischemic heart disease and ischemic stroke) occurred in 2.2% of patients and 45.5% of patients with cardiovascular events were receiving concomitant steroid. Infections requiring hospital visit were recorded in 1.8% of patients; 77.8% of patients with infection were on biologic DMARD and 33.3% were receiving concomitant steroid. Out of Two hundred seventy six patients who underwent DXA scanning for estimation of bone mineral density, 48.6% were having decrease bone density (37% osteopenia, 11.6% osteoporosis).

Steroid use was significantly associated with decrease bone density.

Conclusions: Comorbid conditions are frequently associated with Rheumatoid arthritis as observed in our cohort of patients. Patient care should not be focused only on arthritis care. All RA patients should be screened for comorbidities and treated accordingly in order to avoid their deleterious effect on patient health.

Disclosure of Interest: None declared

FRI0759-HPR COLLABORATION BETWEEN GENERAL PRACTITIONERS AND RHEUMATOLOGISTS TO MANAGE CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS PATIENTS

J. Weijers1, S. Rongen-van Dargel1,2, M. Hulscher1, P. van Riel1,2, I.Q. healthcare, Scientific Institute for Quality of Healthcare, Radboud university medical center, Nijmegen; 2Department of Rheumatology, Bornewonh, Uden, Netherlands

Background: To reduce the risk of cardiovascular disease in rheumatoid arthritis (RA) patients, adequate cardiovascular risk management (CVRM) is necessary. CVRM implies assessment, treatment and monitoring of cardiovascular risk factors1. The updated EULAR guideline states that cardiovascular risk assessment should be considered at least once every five years in all patients with RA. A few studies show suboptimal risk management in daily practice in selected groups of patients.

Objectives: This study aims to describe current performance of the CVRM recommendation in a hospital based RA population in the South of the Netherlands. In this region, general practitioners (GPs) and rheumatologists closely collaborate into manage RA patients’ cardiovascular risk.

Methods: Due to the collaboration, CVRM is performed as a part of a transmural care program. The rheumatologist informs the GP when a patient has been diagnosed with RA. The patient is placed on a list for CVRM to be screened by a specialised nurse practitioner. As a part of the collaboration, laboratory results requested by the GPs and rheumatologists are collected in one digital patient record system. This system is used to check whether the RA patient’s lipid profile was determined in the previous five years. If not, a letter with the listed patient is sent to the GP a reminder for screening the patient. In this study, we checked six months later whether lipid testing was ultimately performed.

Results: In 70% (n=475) of all 679 RA patients (mean age 63 (SD 9 years), 68% women and median disease duration of 7 years (IQR 3–11)) a lipid profile was determined in the previous five years.

Of the 204 non-screened RA patients, 98 had been screened after sending the letter to their GP (+48%), see Figure 1. No differences in gender and disease duration were found between the screened and non-screened patients (p=0.46 and p=0.25 respectively). By contrast screened patients were 10 years older compared to the non-screened patients (66 year (SD12) vs 56 (SD 15) year; p=0.0001).

Conclusions: As a result of the collaboration between GPs and rheumatologists, 70% of all RA patients were screened for CVRM. A small intervention, sending a reminding letter to the GP, increased this percentage even further, to 84%. This collaboration can be seen as a good practice to provide care in line with the EULAR guideline.

FRI0760-HPR BIOSIMILAR USE AMONG EUROPEAN RHEUMATOID ARTHRITIS PATIENTS AND IMPACT ON PATIENT OUTCOMES

L. Channoy, F. Mboge, A. Wadiwalla. Therapy Watch, Research Partnership, London, United Kingdom

Background: Biologic agents have been shown to help control disease progression in rheumatoid arthritis (RA) and significant reduce joint damage. However, their considerable cost has limited their widespread use.

Objectives: Biosimilars offers the opportunity for significant cost savings for national health services and the aim of this research is to better understand their use among European rheumatologists and their potential impact on patient outcomes.

Methods: We used data collected as part of an online treatment survey conducted among a panel of 261 rheumatologists between January and December 2016 across 5 European markets (France, Germany, Italy, Spain and the UK). Physicians were sampled to provide a representative mix of practice types and regions. Our record form sample included 9,650 patient currently treated with a bDMARD, 297 of which received a biosimilar. We split the sample into 2 groups, biosimilar patients = those treated with Benevapi (etanercept), Remsima (infliximab), Inflectra (infliximab) and Flixbax (infliximab) and originator patients = those treated with Enbrel (etanercept) or Remicade (infliximab). We analysed patient demographic data along with current DAS, joint count, HAQ score and perceived disease severity to assess response to therapy over time.

Results: A total of 2.4% of our logistic sample with the greatest uptake of these agents reported in the UK (3.8%) and the lowest in France (1.6%). Use of biosimilars increased in patients who started their current biologic in 2016 (8.1%), with a marginally higher use seen in patients on their 2nd or higher line of bDMARD therapy vs. those on their 1st bDMARD (8.4% vs. 7.5%, respectively).

We saw no significant difference in the distribution of biosimilar and originator patients by age and gender although biosimilar patients appeared to have more severe disease. While a smaller proportion of biosimilar patients were perceived to have moderate/severe RA at diagnosis (73.1% vs. 88.4%) a greater proportion were thought to have moderate/severe disease at their latest visit (64.3% vs. 44.2%). The average DAS28 of biosimilar patients was higher at a directional level but their average HAQ score and tender/swollen joint count were non-significantly lower. Biosimilar patients were more likely to suffer from a comorbid condition (87.2% vs. 74.1%) and a autoimmune condition beyond their RA (17.2% vs. 11.6%). There were no significant differences in the proportion of patients unable to work due to their disease (4.3% on average from the total sample).

We analysed the data focusing solely on 1st line patients to reduce any bias introduced by previous lines of therapy but observed similar trends. A higher proportion of biosimilar patients were considered to have moderate to severe RA at their latest visit (67.9% vs. 43.0%) and a greater proportion of patients had a DAS28 ≥5.1 (23.3% vs.3.0%).

Conclusions: Our research suggests that biosimilar uptake remains limited amongst European rheumatologists with a directional trend towards 2nd line use. Our data did not clearly show any significant differences in the profile of biosimilar patient’s or outcomes. Increased governance from healthcare regulators and additional clinical data may be needed to further establish the efficacy and safety of these agents and drive their wider use, ensuring greater cost efficiency and the potential for wider access to biologic therapies for RA patients.

FRI0761-HPR CHRONIC WIDESPREAD PAIN PREVALENCE IN THE GENERAL POPULATION: A SYSTEMATIC REVIEW & META-ANALYSIS

P. Andrews, M. Steulfjens, J. Riskowski. Health and Life Sciences, Glasgow Caledonian University, Glasgow, United Kingdom

Background: Chronic widespread pain (CWP) is a worldwide health problem and a significant contributor to disability. Understanding the impact of individual-dependent (e.g., gender) and contextual-dependent (e.g., survey method, latitude) factors have on CWP prevalence may provide a foundation population-based strategy for addressing CWP.

Objectives: To determine a general population worldwide estimate of CWP prevalence and to examine the individual and contextual-dependent factors related to CWP prevalence.

Methods: A systematic review was undertaken using seven databases. Along with data extracted from the manuscripts, additional contextual data including WHO development status and region, human development index (HDI); measure

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.6598
of socioeconomic position), Gini coefficient (measure of inequality), and latitude were added. Methodological reporting quality was assessed using meta-
regression analyses.

Results: Thirty studies across 20 countries (630,654 participants) met the inclusion criteria. Studies varied in CWP diagnostic criteria, survey method, and reporting quality. Study CWP sample prevalence ranged from 1·4–24·0%, with CWP in men ranging from 1·1–15·3%, while in women it ranged from 1·7–22·1%. Estimated overall CWP prevalence was 9·4% (7·6–11·3%). By gender, the global CWP prevalence estimate in women was significantly higher than for men (10·9% [8·1–13·7%] v 6·7% [4·5–8·8%], p<0·01; Table 1). A meta-regression of the contextual factors showed the HDI was related to CWP prevalence (p=0·002), while other measures such as survey type, methodological reporting quality and Country induced showed no significant effect.

Conclusions: Globally CWP affects one in ten individuals within the general population, with women more likely to experience CWP than men. HDI was noted to be the socioeconomic factor related to CWP prevalence, with those in more developed countries having a lower CWP prevalence than those in less developed countries. There was a lack of data from countries with a lower socioeconomic position, and further CWP data in these areas can help determine if there are socioeconomic effects associated with CWP prevalence and can refine the CWP prevalence estimate.

Conclusions: Despite treatment, patients with PSS still experience a high disease burden. Here we have provided novel insights into the higher treatment cost and increased healthcare utilisation burden of PSS compared with the sicca-free cohort, in particular for patients with extra-glandular disease manifestations.

FR10764-HPR MORTALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND END STAGE RENAL DISEASE

S. Paudyal, J. Waller, A. Oliver, B. Le, N. Ziek, N. S. Nahman, L. Carbone, 1 Internal Medicine, School of Medicine, University of South Carolina, Columbia; 2Biostatistics; 3Medical College of Georgia, Augusta University; 4Charlie Norwood Veterans Affairs Medical Center, Augusta, United States

Background: Cardiovascular related mortality is higher in patients with rheumatoid arthritis (RA) compared to the general population, and accounts for more than half of all deaths in end stage renal disease (ESRD). The prevalence of ESRD is increasing and there are an increasing number of older patients with RA. Our recent study demonstrated approximately 1% of patients with ESRD have RA. The implications of ESRD on RA relative to the burdens of cardiovascular diseases, cardiovascular and all-cause mortality are not known.

Objectives: To determine whether patients with RA who have ESRD are at increased risk for cardiovascular disease (CVD) events, cardiovascular mortality and all-cause mortality compared to the general population of patients with ESRD.

Methods: Retrospective cohort study of adult patients (age 18 and older) with ESRD receiving renal replacement therapy (hemodialysis or peritoneal dialysis) in the United States Renal Data System (USRDS) who initiated dialysis between 2003 and 2008 looked for up to five years. Patients with an ICD-9 diagnostic code for RA on or before the start of dialysis and a 5% random sample of those without RA were included. Incident cardiovascular events, cardiovascular related mortality and all-cause mortality was determined in those with RA compared to those without RA.

Results: There were 2,824 subjects including 407 with RA and 2,417 without RA included in the analyses. There was no significant difference in the total number of incident CVD events by RA status (n=311 (76.4%) vs. n=1936 (80.1%) without RA) (p=0.09). 76 patients with RA (18.7%) died from a CVD related cause compared to 403 without RA (16.7%) (p=0.32). Overall mortality was significantly higher in those with RA (n=226 (55.5%)) vs. n=970 (40.1%) (p<0.01). Compared to those without RA, those with RA had a significantly shorter mean time in months from start of dialysis to any incident CVD event (17.5 (12.4) vs. 21.2 (14.1) (p<0.01), CVD death, (34.2 (12.5) vs.37.9 (12.6) p=0.02), or all-cause mortality (33.1 (13.0) vs. 37.8 (12.6) (p=0.01). In final adjusted models, RA was associated with an increased risk for both CVD related mortality (aHR=1.23 (95% CI 1.05–1.43)) and all-cause mortality (aHR=1.22 (1.05 – 1.42) within five years. Risk factors for CVD and overall mortality included older age, a higher Charlson comorbidity index, black race, needing assistance with ADLs and living in a nursing home. Black race and Hispanic ethnicity was associated with significantly less CVD and all cause-related mortality.

Conclusions: Physicians treating patients with RA and ESRD should be aware that patients with RA are at increased risk for cardiovascular related mortality and all-cause mortality compared with the general population of ESRD patients. Patients with ESRD and RA at higher risk for mortality can be identified by both demographic risk factors as well as overall health status.

FR10765-HPR PREVALENCE OF SARCOPENIA IN ELDERLY WITH OSTEARTHRITIS OF LARGE JOINTS

Y. Satonova, V. Tsurko, 1 Northwestern State Medical University named after II Mechnikov, Department of gerontology, Geriatrics and Nursing, St. Petersburg; 2 First Moscow Medical University named after I.S. Pavlov, Department of Hematology and Geriatrics, Moscow, Russian Federation

Background: Lean muscle mass and strength decline starting approximately at 40 years of age to become 25% of body weight at 75–80 years old [1]. Within the existing literature, sarcopenia is a highly prevalent condition in older people. The prevalence of sarcopenia increases considerably with age ranging from 5% to 15% in persons aged 60–70 years and 11% to 50% in persons aged 80 years and older. In older persons, sarcopenia is related to falls and physical disability leading to reduced quality of life [2]. The prevalence of osteoarthritis increases with age so that 30 to 50% of adults over the age of 65 years suffer from this condition [3]. Age-related factor that contributes includes to the development of OA include a decline in muscle strength. People with lower extremity OA had a two to five times increased incidence of falls than age-matched healthy controls [4].

Objectives: Conduct analysis of condition of muscle strength and muscle functioning in older persons with osteoarthritis.

Methods: Prospective study of 159 patients aged 74±13.3 years was held. Controls, normal 11% to 50% to LBM in accordance with criteria of sarcopenia EWGSP. Muscle strength was estimated by a hand dynamometer and muscle functioning was estimated on the basis of SPPB tests. Amount of pain was estimated by VAS.

Results: Sarcopenia was revealed in 31,45% of older persons with osteoarthritis. Cases of OA were observed in 28.30% (95% CI 21.5 - 36.0) in patients with osteoarthritis with sarcopenia (average number of falls – 1,93) and in 16,98% of patients without sarcopenia (95% CI 11.5 – 23.7) (average number of falls – 0.48). Level of pain in patients with osteoarthritis with sarcopenia amounted 3.16 times higher in patients without sarcopenia – 3.49 points (p<0.05). Muscle strength in patients with sarcopenia was 14.36 kg, in patients without sarcopenia was significantly higher – 18.53 kg (p<0.05). Common point of SPPB tests in patients with sarcopenia was 6.9, in patients without sarcopenia significantly higher – 7.85 (p<0.05).

Conclusions: Patients with sarcopenia in the presence of osteoarthritis were observed to have significant decrease of muscle strength and muscle functioning, increase of frequency of falls which raises risk of repeated falls and their frequency, and consequently, deteriorates condition of musculoskeletal system in older persons.

FR10766-HPR DOWNS ARTHROPATHY - CLINICAL AND RADIOLOGICAL FEATURES OF ARTHRITIS IN CHILDREN WITH TRISOMY 21

C. Foley, E. J. MacDermott, O. G. Killeen, OLCHC, Dublin, Ireland

Background: Down’s Arthropathy (DA) was first reported in the literature in 1984. Crudie estimates suggest higher incidence and prevalence rates of DA compared with Juvenile Idiopathic Arthritis (JIA), (JIA prevalence 1/1000, estimated DA prevalence 8.7/1000). Despite this fact, there remains a paucity of data on this condition. DA is rarely recognised at onset, & remains under-diagnosed. As a direct consequence children with DA are presenting with significant joint damage and disability at diagnosis.

Objectives: Perform a musculoskeletal examination on children with Trisomy 21 (T21) aged 0–20 years

Methods: Children with T21 were invited to attend a screening clinic. Screening involved completion of a health questionnaire & a comprehensive musculoskeletal examination. DA cases detected were investigated & managed as per normal clinical practice. Data on a convenience sample of 33 newly diagnosed children with JIA was collected to create a comparison group.

Results: 503 children with Trisomy 21 were included for DA, 22 new cases have been diagnosed. All of these children had poor language skills or were non-verbal. Only 11% of the parents suspected that their child may have arthritis prior to attending our screening clinics, and this was only after reading our recruitment literature. In total, we now have 33 children attending our centre with DA (combining cases attending pre-dating the start date of the study). This suggests the prevalence of DA in Ireland is 18–21/1000.

The majority of children presented with a polyarticular pattern of disease. No cases of uveitis have been observed to date. 88% of the DA cohort had small joint involvement of the hands, significantly higher than that observed in the JIA comparison group. Erosive changes were reported on X-Ray in 29.2% of the DA cohort (9.5% in the JIA Cohort). Methotrexate-associated nausea was a significant barrier to treatment with this DMARD in DA. There was a significant delay in diagnosis of DA, 1.7 years v 0.7 years in the JIA cohort.

Conclusions: Children with T21 are at increased risk of developing arthritis. There is a lack of awareness of this risk among health care professionals & the general public at large. This almost certainly contributes to poor recognition of the disease and a delay in diagnosis. The predominant pattern of disease is polyarticular small joint arthritis. Treatment with standard protocols used in JIA
is complicated by drug-associated side effects in children with T21. However, a good response to treatment with steroid intra-articular joint injections has been observed. Our study has raised a number of questions. Future research to accurately define this disease & identify best practice with regards to treatment would be invaluable. We advocate that all children with T21 should have annual musculoskeletal examination as part of their health surveillance programme.

PARTICIPATING IN A MUSCULOSKELETAL RANDOMISED CONTROLLED TRIAL: IDENTIFICATION OF EDUCATION TRAINING NEEDS BY OCCUPATIONAL THERAPISTS AND PHYSIOTHERAPISTS IN THE UK

J. Adams 1,2, P. Barratt 3, S. Bradley 4, S. Barbosa-Bouças 4, K. Hislop Lennie 5, P. White 2 on behalf of OTTER II Trial working group. 1Arthritis Research UK, Centre of Excellence Sport, Ex & OA; 2Faculty of Health Sciences, University of Southampton, Southampton; 3Occupational Therapy, Poole General Hospital, Poole; 4Department of Psychology, Buckinghamshire New University, High Wycombe; 5Health Sciences, University of Southampton, Southampton, United Kingdom

Background: There is an association between clinical teams engaging with research and impacts in the delivery of health services. Randomised controlled trials (RCTs) provide strong evidence to influence practice in musculoskeletal services. For occupational therapists (OTs) and physiotherapists (PTs) implementing RCTs is not yet commonplace. As part of a multi-centred clinical effectiveness and efficacy RCT of splints for thumb base osteoarthritis (OTTER II Trial) we established an education training programme to support clinical therapists deliver the trial across 15 UK hospitals.

Objectives: To evaluate the content of trial training to educate and support OTTER II Trial clinicians in undertaking clinical research roles.

Methods: Two trial training days were run in the North and South of England. Therapists provided details of their clinical trial experience. They were asked to identify one area in which they felt confident and one in which they were not confident in participating in a RCT. These perceived facilitators and barriers were summarised using descriptive statistics and content analysis.

Results: Thirty five clinicians (20 OTs,15 PTs) attended a training day, 13 (37%) had no previous experience with clinical trials; 19 (54%) had been involved with at least one previous clinical trial. Clinicians considered they were already confident in; delivering the trial standardised assessment and treatment to patients n=21 (60%); trusting the OTTER II trial team and their own hospital research departments to support their research role n=13 (37%); understanding the trial protocol and what needed to be delivered n=6 (17%) and, being convinced that the trial asked a relevant question 3 (9%). Areas in which clinicians considered they did not have confidence included; the logistics and time management of delivering a RCT in their own hospital n=18 (51%); the associated trial paperwork to be completed n=8 (23%); NHS computer access/win access for randomisation procedure n=7 (20%); recruiting participants to time and target n=6 (17%) and staff capacity to deliver a RCT in the NHS alongside clinical commitments n=5 (14%).

Conclusions: Well documented trial protocols and support from a trusted research team and local hospital research departments were identified as key areas that help clinicians become confident to engage with a national clinical RCT. Clinicians are less confident about managing the practical logistics, staff time and trial paperwork involved in delivering a national RCT. Clinicians identify that they perceive their confidence in clinical assessment and treatment skills that already equip them to recruit and treat patients as part of a national trial. The logistics of delivering a trial requires ongoing negotiation and support from clinical service managers and the clinical trial teams to ensure clinicians are supported to deliver the RCT to time and target.

MUSCLE WASTING IN OSTEOARTHRITIS MODEL INDUCED BY ANTERIOR CRUCIATE LIGAMENT TRANSECTION

Background: Osteoarthritis (OA) is a chronic joint disease characterized by progressive loss of articular cartilage and abnormal bone formation. Furthermore, there are changes in periaricular muscles, such as loss of muscle mass, strength and function. These features may contribute to functional impairment among patients.

Objectives: This study aimed to investigate the molecular pathways involved in muscle wasting in an animal model of OA induced by anterior cruciate ligament (ACL) transection in rats.

Methods: Female Wistar rats were allocated into two groups: OA (submitted to the ACL transection; n=9) and SHAM (submitted to surgical procedures without ACL transection; n=8) [1]. Spontaneous exploratory locomotion, nociception and body weight of animals were evaluated weekly. Twelve weeks after the disease induction, animals were euthanized and the right knee joints were collected for morphometric and histological analyses by histopathology, according to OARSI histologic scoring system [2]. Gastrocnemius muscle from the right hind paw were dissected and weighed. Gastrocnemius was used for evaluation of muscle atrophy [3] and protein expression of myostatin, MuRF-1, MyoD and myogenin. Data were compared by Student’s t test or ANOVA followed by Tukey’s test or ANOVA following Bonferroni–Winer’s U-test. The results are expressed as mean values ± standard deviation (SD) for symmetric variables and as medians with interquartile range for asymmetric variables. Significance was accepted at P<0.05.

Results: Histopathology of the right knee joints confirmed the development of the disease in animals from OA group. Gastrocnemius area of animals from OA group had a reduction of about 10% compared to animals from SHAM group. Protein expression of myostatin was increased in OA group, while myogenin expression was decreased. MuRF-1 and MyoD expression was similar in both OA and SHAM groups. Spontaneous exploratory locomotion, nociception, body weight and weight of gastrocnemius showed no difference between OA and SHAM groups.

Conclusions: Gastrocnemius atrophy in OA induced by ACL transection involves increased protein expression of myostatin and decreased protein expression of myogenin. In this model, muscle wasting may be linked to myostatin-induced deficits in satellite-cell differentiation due to decreased expression of myogenin.

EVALUATION OF THE EFFECTIVENESS OF DEEP WATER RUNNING FOR THE TREATMENT OF CHRONIC NONSPECIFIC LOW BACK PAIN

J.S. Arakaki, F.M. Jennings, S.R. Toffolo, J.C. Tamashiro, J. Natour. Rheumatology, Universidade federal de Sao Paulo - UNIFESP, Sao Paulo, Brazil

Background: Low back pain (LBP) is one of the most common musculoskeletal conditions and can lead to disability. Aerobic exercises have recently been suggested as important in the management of pain and physical disability of LBP patients, and there are studies that prove the efficiency of this type of exercise in the treatment of LBP. One proposed modality is Deep Water Running (DWR) which are aquatic conditioning exercises that simulate normal running on soil.

Methods: It was a randomized controlled trial with a duration of 16 weeks with evaluations performed before the intervention and 8 and 16 weeks after the beginning of the training. The population was composed of 60 patients aged over 18 years with diagnosis of chronic nonspecific low back pain. The intervention group performed 3 times a week aerobic exercises in a heated pool. The sessions had duration of 50 minutes and frequency of 3 times a week for 16 weeks and with 70% of the maximum heart rate, with 10 bpm less for the difference in the behavior of HR in aquatic environment. The control group underwent aerobic conditioning by treadmill exercise for 50 minutes, 3 times a week for 16 weeks, and also with 70% of maximal heart rate. Evaluation instruments: Visual analog pain scale (EVA) in cm; Likert Scale of pain improvement and worsening according to the patient and according to the evaluator; Functional capacity through the Roland-Morris questionnaire and 6-minute walk test; SF-36 for general quality of life; And absenteeism and anti-inflammatories used during the study period. Evaluations were performed by an evaluator who was unaware of the patient allocation group.

Results: The two groups were homogeneous regarding most clinical demographic characteristics, in the initial evaluation. The two groups showed statistically significant improvement in the variables Roland Morris, EVA for pain and Time up and go, but no statistically significant differences were found between groups. At the Likert scale, the 6-minute walk test and the amount of anti-inflammatories used during the study, no significant differences were found, the two groups remained unchanged. No adverse events were observed in either group during the exercise program.

Conclusions: Deep water running aerobic exercise is as effective as treadmill running in improving pain and functional capacity in patients with chronic nonspecific low back pain.
A BETTER WAY TO DECREASE KNEE SWELLING IN PATIENTS WITH KNEE OSTEOARTHRITIS: INTERMITTENT PNEUMATIC COMPRESSION – A RANDOMIZED CONTROLLED CLINICAL TRIAL

Z. San, O. Aydoğdu, I. Demirbüken, U.S. Yurdalan, G.M. Polat, Physiotherapy and Rehabilitation, Marmara University, Health Sciences Faculty, Istanbul, Turkey

Background: One of the most common symptoms of knee OA is swelling. Knee swelling negatively affects knee mechanics and muscle activity in patients with OA. Thus, knee swelling should be eliminated in the early period of rehabilitation. The utility of cold therapy for musculoskeletal injuries has been clearly established (1). It was shown that cold therapy may not be a statistically effective modality in improving range of motion, decreasing knee swelling (2), and improving clinical outcomes in patients with knee OA rather than cold therapy. Intermittent pneumatic compression (IPC), which has been used to treat limb edema, is a common option for patients with lymphedema and venous leg ulcers. Currently, IPC is primarily used in the prevention of deep venous thrombosis. It is also used for venous insufficiency, arterial occlusive disease, prevention of hematoma, etc (3). However, despite its widespread use, the literature on IPC in musculoskeletal injuries is limited. In particular, there is no report on whether IPC, which is known to have positive effects on circulatory problems, affects the knee swelling in OA.

Objectives: In this study, we hypothesized that IPC may have better outcomes on knee swelling. We also investigated whether IPC may contribute to better short-term patient outcomes in patients with knee OA rather than cold therapy.

Methods: This was a randomized, prospective, comparative clinical study. The study included 81 patients aged 18–65, who were admitted to the Cr – Ahşap Balat Hospital. The patients were randomly divided into two groups. One group (n=36) received ultrasound, transcutaneous electrical nerve stimulation, electrical stimulation, exercise, and cold packs. The second group (n=45) received ultrasound, transcutaneous electrical nerve stimulation, electrical stimulation, exercise, and IPC. The primary outcome was pre- and post- treatment follow-up was knee swelling. Secondary outcome measures included range of motion, muscle strength, pain intensity and disability. Results: Intermittent pneumatic compression significantly decreased knee swelling in patients with osteoarthritis (p<0.001). A significant difference between the groups was found in knee swelling in favour of the intermittent pneumatic compression group (p=0.028). We also found significant improvements in range of motion, muscle strength, pain intensity and disability in both groups (p<0.05). No significant differences in any of secondary outcome variables between the groups was found.

Conclusions: The mechanism of our hypothesis was that in opposite of cold therapy which has local effects, IPC may affect circulatory control. In conclusion, IPC may be an effective modality in improving range of motion, muscle strength, pain intensity and disability in patients with knee OA.

PREGNANCY AND DELIVERY IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS

A. Zbinden 1, S. van den Brandt2, P. Villiger1, M. Østensen 1, F. Förger1.
1Department of Rheumatology, Immunology and Allergology, Inselspital, University of Bern, Berne, Switzerland; 2Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands

Background: Inflammatory rheumatic disease do have an influence on pregnancy course and outcome. There is little knowledge about the comparison between two rheumatic diseases.

Objectives: To analyze pregnancy complications, pregnancy outcome and delivery mode in patients with rheumatoid arthritis (RA) and spondyloarthritides (SpA).

Methods: Patients with RA and SpA were compared with those of matched healthy controls (HC) with respect to pregnancy complications, pregnancy outcome and delivery mode. Patients and controls were prospectively followed at the University of Bern.

Results: We analysed 244 pregnancies, of which 96 pregnancies occurred in 86 RA patients. 78 in 70 SpA patients and 70 in healthy women. Pregnancy complications (gestational diabetes, preeclampsia, infection, preterm rupture of membranes) were more frequent in RA patients (11.5%) and in SpA patients (17.9%) than in HC (1.4%).

Pregnancy outcome of 174 pregnancies in RA and SpA patients resulted in 178 live born infants, 6 sets of twins, one stillbirth and one induced fetal demise. The induced fetal demise was performed in a twin pregnancy on a fetus with a congenital anomaly. Congenital anomalies occurred in 6 infants (3 in RA and 3 in SpA patients). All HC had live births. Median birth weight was lower in RA and SpA patients compared to HC (RA: 3100g, SpA: 3245g, HC: 3455g). RA and SpA patients had more often small for gestational age infants (birth weight <10th percentile; RA: 16.2%, SpA: 11.4%, HC: 1.4%) and preterm deliveries (RA: 18.8%, SpA: 11.5%, HC: 1.4%).

With regard to delivery mode, most women had vaginal deliveries (RA: 51.0%, SpA: 57.7%, HC: 72.9%). Birth by caesarean section (elective and emergency) was more frequent in RA and SpA patients than in the healthy controls (RA: 44.8%, SpA: 39.7%, HC: 27.2%). Emergency caesarean sections were indicated in 22.9% of pregnancies among RA patients, in 21.8% of SpA patients and in 14.3% of healthy women.

Conclusions: Pregnancy complications, caesarean section, and adverse child outcomes were more frequent in patients with RA and SpA compared to healthy women. However, no significant differences in pregnancy outcomes were observed between RA and SpA patients indicating comparable risks induced by the autoimmune inflammatory process.

INFLUENCE OF PATIENT GLOBAL ASSESSMENT ON THE DISEASE ACTIVITY ASSESSMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS: A METEOR CROSS-SECTIONAL STUDY

R.J.O. Ferreira1, M. Ndosi2, C. Duarte1, P. Carvalho1, A. Chopra3, K. Salomon-Escoto4, D. Vega5, D. van der Heijde6, P. Machado7, J.A.P. da Silva1 on behalf of METEOR investigators. 1CHUC, Coimbra, Portugal; 2UWE, Bristol, United Kingdom; 3CRD, Pune, India; 4UMMMC, Worcester, United States; 5HUANL, Monterrey, Mexico; 6LUMC, Leiden, Netherlands; 7UCL, London, United Kingdom

Background: Disease activity indices (DAI) are used to guide immunosuppressive therapy in rheumatoid arthritis (RA). The inclusion of patient global assessment (PGA) in these indices has been questioned as it conveys mainly disease impact rather than disease activity.

Objectives: To determine the influence of PGA on patient disease states and to determine PGA correlations with inflammatory parameters, disease impact, demographic, clinical and contextual factors.

Methods: The METEOR international database was used, namely data from patients’ first available visit with no missing values on PGA, tender and swollen joint counts (TJC28, SJC28) and C-reactive protein (CRP). Remission rates were compared according to the DAS28CRP4v vs 4v and ACR/EULAR Boolean remission vs near-remission (failing 1 of the 4 criteria) definition. We assessed the correlation of PGA with (predominantly) inflammatory (TJC28, SJC28, CRP) and disease impact (pain and HAQ) factors. We used hierarchical modelling to explain PGA by 4 blocks (B) of independent variables (B1: gender, age, disease duration; B2: biologic DMARD, Gross National Income; B3: pain, HAQ; and B4: TJC28, SJC28, CRP).

Results: Among the 18280 patients analysed, 1930 (10.6%) were in DAS28CRP4v remission, and 2197 (12.0%) in DAS28CRP3v remission. According to the Boolean definition, 1207 (6.6%) patients were in remission. PGA was the main obstacle to Boolean remission: 2090 (79.0%) of the 2645 near-remission patients (Table 1). A considerable proportion of patients with low inflammation perceived high PGA (Figure 1).

PGA correlated better with Pain (r p=.79) and HAQ (r p=.55) than with TJC28 (r p=.45), SJC28 (r p=.36) or CRP (r p=.25).

In the entire dataset, 60.2% of PGA variance was explained by Pain and HAQ, 1.8% by B1 and B2 of covariates and only 1.3% by B4 (TJC28, SJC28, CRP) (Table 2).

In near-remission patients, B4 did not contribute significantly to changes in the model.

Conclusions: Two thirds of patients that achieve TJC28, SJC28, and CRP ≤1 still perceive high PGA despite disease “inflammatory” control. The weight of PGA in DAI could lead to immunosuppressive overtreatment. In these patients, disease impact management, including non-pharmacological treatments delivered by Health Care Professionals, are more likely to be effective.

"AND SUDDENLY YOU ARE A PERSON AT RISK OF DEVELOPING RHEUMATOID ARTHRITIS!" DIFFERENT PERSPECTIVES OF INDIVIDUALS ON PREDICTIVE TESTING – RESULTS OF AN INTERNATIONAL QUALITATIVE INTERVIEW STUDY

1Section for Outcomes Research, CeMSiS - Center for Medical Statistics, Informatics, and Intelligent Systems, Medical University of Vienna, 2Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, 3Department of Rheumatology, University of Birmingham and Sandwell & West Birmingham Hospitals NHS Trust, Birmingham, United Kingdom; 4Rheumatology and Immunology, Department of Internal Medicine 3, Universitätsklinikum Erlangen, Erlangen, Germany

Background: People at risk of developing rheumatoid arthritis (RA) may be candidates for interventions aimed at preventing RA development [1]. The identification of such ‘at risk’ populations includes testing for genetic and other (e.g. autoantibody) biomarkers. However, little is known about the people’s perspectives on these tests, how they react and cope when identified as being a person ‘at risk’ and what their unmet needs are.

Objectives: To explore the perceptions about RA and predictive testing and to understand the various reactions and coping strategies used when identified as being at risk of developing RA from the perspective of those directly concerned.

Methods: As part of the EuroTEAM project, a qualitative interview study with people who were informed of being at risk of developing RA was conducted. An interview schedule was developed and pilot-tested. Interviews were audio-recorded, transcribed verbatim and analyzed using thematic analysis.

Results: A total of 34 individuals (with rheumatoid factor and/or ACPA positive) already informed of being at risk of developing RA participated in the study, from Austria (n=15), Germany (n=15), and the UK (n=4). In Vienna, people who had been tested within an expanded health exam participated in this study. In Birmingham and Erlangen, people with arthralgia were recruited from the outpatient clinics. Analysis of the interview data revealed five overarching themes related to perceptions in the context of predictive testing. There were differences between the perceptions of arthralgia patients and asymptomatic individuals. People suffering from pain were much more frightened and worried when informed of being at risk of developing RA. As a consequence, they modified their lives in a larger extent and had greater knowledge about RA than those without any symptoms who were rather surprised, kept calm and hardly changed their lifestyle after being tested positive. Almost all participants in this study would appreciate precise predictive tests in the context of RA. However, more than half of them would refuse synovial biopsy (even if this could help quantify risk more accurately) or preventive medication. Recommendations for an improved procedure of predictive testing in the field of RA were given, which could promote uptake of preventive strategies.

Conclusions: Participants showed large differences in views about predictive testing in the context of RA risk and offered specific suggestions that should be incorporated into service design and delivery in the context of future predictive testing programmes. These findings may also be relevant to prediction and prevention in the context of other diseases where multiple genetic risk factors interact with environmental risk factors to drive disease development.

LONGITUDINAL ANALYSIS OF RESPONSE, COSTS AND RESOURCE USE OF PATIENTS WITH RHEUMATOID ARTHRITIS INITIATING BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS (BDMARDS) IN TAIWAN USING THE NATIONAL HEALTH INSURANCE RESEARCH DATABASE

1Eli Lilly & Co., Shanghai, China; 2Eli Lilly & Co., Budapest, Hungary; 3Elyia Group Ltd., Taipai, Taiwan, Province of China; 4Eli Lilly & Co., Indianapolis, United States; 5Eli Lilly & Co; 6National Taiwan University; 7Taipei Medical University, Taiwan, Province of China

Background: Rheumatoid arthritis (RA) is an inflammatory disorder associated with a significant physical and psychological burden. Patients with RA experience a lower quality of life than patients without RA. This study utilizes Taiwan’s National Health Insurance Database (NHIRD) which is a claims-based database recording all interactions with the National Health Insurance (NHI) system.

Objectives: The objective of this study was to use the NHIRD to estimate the percentage of newly treated patients with inadequate response (IR) to biologic disease-modifying antirheumatic drugs (bDMARDS) as well as the costs and resources.

Methods: Data were from the catastrophic illness file within the NHIRD from 1/1/2009 to 12/31/2013. The index period spanned 2010 with a pre-index period consisting of the index date – 365 days, and patient follow-up was index date to 365 days post-index. Patients with a catastrophic illness card for RA were included in the study. Biologically-naive patients were included through the first time showed an IR to their treatment within a year. Patients with any symptoms who were rather surprised, kept calm and worried when informed of being at risk of developing RA. As a consequence, they modified their lives in a larger extent and had greater knowledge about RA than those without any symptoms who were rather surprised, kept calm and hardly changed their lifestyle after being tested positive. Almost all participants in this study would appreciate precise predictive tests in the context of RA. However, more than half of them would refuse synovial biopsy (even if this could help quantify risk more accurately) or preventive medication. Recommendations for an improved procedure of predictive testing in the field of RA were given, which could promote uptake of preventive strategies.

Conclusions: A significant proportion of patients with RA initiating a bDMARD for the first time showed an IR to their treatment within a year. Patients with an IR had increased resource utilization and higher non-medications costs than those with stable disease. This level of IR suggests an unmet need in the RA treatment paradigm.

EXPOSURE TO PASSIVE SMOKING AND RA RISK; RESULTS FROM THE SWEDISH EIRA STUDY

A.K. Hedström1, L. Klarekskog2, L. Alfredsson1.

1Institute of Environmental Medicine, 2Department of Medicine, Karolinska Institutet, Stockholm, Sweden

Background: Smoking has consistently been associated with increased risk of developing rheumatoid arthritis (RA). However, no studies have been performed investigating the effect of exposure to environmental tobacco smoke (i.e. passive smoking) on RA risk.

Objectives: The aim of this study was to estimate the influence of passive smoking on the risk of developing the two major subsets of RA, defined by anti-citrullinated protein antibodies (ACPA) status.
FAMILIAL RISKS OF RHEUMATOID ARTHRITIS: EVIDENCE FROM THE MALAYSIAN EPIDEMIOLOGICAL INVESTIGATION OF RHEUMATOID ARTHRITIS CASE-CONTROL STUDY

C.L. Too 1,2, L.K. Tan 3, A.F. Nurul Aain 3, S. Salsabili 3, H. Hesleyn 4, S. Wahhundan 5, I.S. Lau 5, S.C. Gun 7, S. Nor-Shuhaila 6, M. Eashwary 4, M.S. Mohd-Shahrir 6, M.M. Anon 4, R. Azimilah 4, O. Muhami 4, C. Hasliza 1, Y.A. Chong 4, L. Al-Faheski 4, M. Shahnaz 4, 5, *Allergy and Immunology Research Center, Institute for Medical Research, Kuala Lumpur, Malaysia; 6Department of Medicine, Rheumatology Unit, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden; 7Institute for Medical Research, Kuala Lumpur, Malaysia.

Objectives: We investigated the association between family history of RA and the risk of anti-citrullinated peptide antibody (ACPA)-positive and ACPA-negative RA in the Malaysian population.

Methods: Data from the Malaysian Epidemiological Investigation of Rheumatoid Arthritis (MyEIRA) population-based case-control study involving 1,055 early RA cases and 1,055 age, sex and residential area-matched controls were analyzed. Information from interview-reported family history of RA or rheumatic stiff back among first degree relatives was used to estimate the risk of developing ACPA-positive and ACPA-negative RA. The odds ratio (OR) with 95% confidence interval (CI) was calculated.

Results: In this study, 64% of the RA patients were ACPA-positive and 40% of the overall RA carried HLA-DRB1 shared epitope (SE) alleles. Family history of RA was significantly associated with an increased risk of developing RA in the Malaysian population (RA versus controls, 17.0% vs. 7.7%, OR 2.4, 95% CI 1.8–3.2, p < 0.0001). The association between positive family history and risk of RA was unadjusted for the presence of ACPA-positive RA (OR 2.5, 95% CI 1.8–3.3, p < 0.0001) and ACPA-negative RA (OR 2.3, 95% CI 1.6–3.2, p < 0.0001) subsets, respectively. A dramatically increased risk for ACPA-positive RA was seen in individuals who both were having positive family history of RA and carried HLA-DRB1 SE alleles (OR 14.7, 95% CI 7.7–27.8). We also observed a lesser risk magnitude in the ACPA-negative RA patients (OR 5.7, 95% CI 2.7–11.9).

Conclusions: Our data demonstrate that family history of RA remains an important clinical risk factor for RA. In addition, positive family history of RA was associated with an increased risk of developing both the ACPA-positive and ACPA-negative RA in the Malaysian population, suggesting that the two RA subsets are similar in genetic risk factor content and overlap with these diseases.

PATIENTS WITH RHEUMATOID ARTHRITIS – A NATIONWIDE CROSS-SECTIONAL STUDY

B. A. Esbensen 1,2, C. Flurney 3, K.V. Jensen 1, L. Andersen 1, N.M. Hammer 1, Rigshospitalet - Glostrup, COPECARE, Centre for Rheumatology and Spine Diseases & Research Unit, Glostrup; 2Department of Clinical Medicine, Faculty of Health and Medical, University of Copenhagen, Copenhagen, Denmark; 3Rheumatology Unit, Royal Bristol Infirmary, West England, Bristol, United Kingdom

Background: There is an increasing focus on how patients with inflammatory arthritis (IA) manage living with arthritis. There are a preponderance of women with RA (70%), thus previous research has overall focused on female patients and their management. Research in other long term conditions suggests men need their own health strategy. It is important to investigate whether there are gender differences in coping strategies and illness acceptance within chronic IA.

Objectives: To explore gender differences in IA as reflected by coping strategies and illness acceptance. Furthermore, to identify factors associated with high degree of illness acceptance.

Methods: The study was conducted as a nationwide cross-sectional study using online survey during 2016. Patients ≥18 with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) were invited to contribute through: The Danish Rheumatism Organization, local arthritis networks, diagnosis networks, and rheumatology departments across the country. The self-report online questionnaire comprised Socio-demographics, Diagnosis, Symptoms (pain, fatigue, global), Medications, Disease Activity, Functional Status, Coping (i.e. confrontation, avoidance and acceptance-resignation) and Illness Acceptance. As recommended by EULAR 2 patients with RA (KJ & LA; male and female, respectively), were included as equal research partners in all phases of the study. Descriptive statistics were applied to explore gender differences, and logistic regression analyses were performed to test for factors associated with illness acceptance.

Results: In total, 664 (85% women) were included in the study; RA 53%, PsA 27% and axSpA 20%. More men (40%) than women (30%) were treated with biological DMARDs (p=0.048). No significant gender differences were found in disease activity, symptoms and functional status. Overall, the total sample had high degree of illness acceptance and no significant difference was found between males and females. Regarding illness coping, women with IA tend to use avoidance as a coping strategy significantly more than men (p=0.015). In the final multivariable regression model, higher education (OR=1.46; 1.02–2.11), longer time diagnosed (OR=1.21 per 1 yr. increase: 1.01–1.05), lower physical function (OR=0.86, 0.76–0.95), better coping with fatigue (OR=1.13; 1.05–1.22), less avoidance (OR=0.93; 0.87–0.99) and acceptance-resignation (OR=0.62; 0.62–0.75) as coping strategies were significantly associated with high degree of illness acceptance.

Conclusions: No significant differences were found in illness acceptance among women and men with IA. However, women tended to use avoidance as a coping strategy more than men. High levels of illness acceptance may be explained by high education, longer disease duration, and better physical function, better coping of fatigue and less use of passive coping strategies.

GOTHENBURG NURSE LED TIGHT CONTROL STUDY - GOTTNET: A STUDY COMPARING "CARE AS USUAL" WITH NURSE LED CLINIC, TIGHT CONTROL AND PERSON CENTRED CARE IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) AND WITH MODERATE/HIGH DISEASE ACTIVITY  

U. Bergsten 1,2, K. Almehed 2, L. Jacobsson 3, 1 Department of Research, Development and Education, Region Halland; Varberg; 2 Rheumatology Department, Sahlgrenska University Hospital, Gothenburg; 3 Department of Rheumatology and Inflammation Research, Institute of Medicine, Gothenburg, Sweden  

Background: The treatment guidelines of EULAR recommend treatment according to “tight control” (TC), clear treatment goals (Treat-to-Target, T2T) and patient centered care. The treatment guidelines of EULAR recommend treatment according to “tight control” (TC), clear treatment goals (Treat-to-Target, T2T) and patient centered care would result in better outcome compared to care as usual. The treatment guidelines of EULAR recommend treatment according to “tight control” (TC), clear treatment goals (Treat-to-Target, T2T) and patient centered care would result in better outcome compared to care as usual. One way to overcome this could be nurse led clinics of RA patients, which for patients in remission have shown positive effects on patient’s pain, knowledge and self-efficacy. We hypothesized that a nurse-led clinic based on the above principles of TC, T2T and Person-centered care would result in better outcome compared to care as usual.  

Objectives: The aim of the study was to compare the effect of such nurse-led clinic with frequent visits and person-centered care with regular care of patients with established RA and a moderate to high disease activity.  

Methods: This was a randomized, controlled, blinded assessor study that aimed to compare the effect of nurse-led clinic with regular care of patients with the established RA. Inclusion criteria were: duration of RA >2 years, DAS28>3.8, age >85 years, and not having experience with all available csDMARDs and bDMARDs. Patient with any severe current comorbidity were excluded. Intervention Group (IG): intervention included two elements; 1) disease activity control every 6th week, with clear treatment goals (DAS28 >2.6) and escalation of pharmacological therapy according to existing Swedish guidelines, 2) a written person-centered care health plan with shared goal setting and decision making between patient and healthcare provider. Control Group (CG): Patients in the control group followed a protocol of care at baseline, 3 and 6 months and at 1, 2, 5 and 8 years. SOFI consists of 3 parts measuring hand, arm (upper), and leg (lower) function. One hand function is tested by 4 movements: cylinder grip (H1), pen grip (H2), pincer grip (H3) and opposition of the thumb (H4). Arm function is assessed by 3 movements: hand behind the head and the ability to touch the cervical spine processes with fingers (A1), elbow supination (A2) and elbow extension (A3). Leg function is tested by 4 movements: the ability to touch the opposite knee with the heel while sitting (A1), knee extension in supine position (L2), dorsiflexion of the foot standing on a balance board (L3), and the ability to stand on tip toes without shoes (L4). An assessor scores the patient’s ability to perform the different tests on an ordinal scale (0=normal, 1= partly impaired and 2= unable to perform). The range of SOFI scores is 0–44 (best to worst).  

Results: At baseline the mean (SD) SOFI was 7.2 (5.8), and at 1 year follow up the improvement was 2.75 (5.65), p<0.001. From 1 year to 8 year follow up the deterioriation was 1.5 (4.6), p<0.001. When studying hand, upper and lower function separately, the pen grip and the ability to stand on tip toes improves most during the first year. From 1 to 8 year the pincer grip and the ability to stand on tip toes improved with 0.5 (2.4) and 1.1 (2.7) respectively. The ability to touch the opposite knee with the heel while sitting and the ability to stand on tip toes without shoes improved with 1.8 (3.6) and 2.1 (4.3) respectively. The difference in the improvement was not statistically significant. Pre-study power calculation estimated group sizes to 60 patients in each group. Due to difficulties in the recruiting process the study was stopped preterm.  

Conclusions: This controlled trial suggest that a nurse-led clinic for RA patients with moderate/high disease activity may be effective. Although not shown, it likely to be cost-effective and possible to implement in clinical care.

THE EFFECT OF INSPIRATORY MUSCLE TRAINING ON AEROBIC CAPACITY, PULMONARY FUNCTION AND FUNCTIONAL STATUS IN PATIENTS WITH ANKYLOSING Spondylitis: A RANDOMIZED CONTROLLED STUDY

Background: In ankylosing spondylitis (AS) the chronic inflammatory process mainly affects the axial skeleton with ensuing pain and limitation of thoracic and spinal mobility. Most of the AS patients have the complaint of reduced exercise capacity due to cartilage and meniscus impairment, chest wall restriction, weak respiratory muscle performance, peripheral muscle weakness and deconditioning which have been reported as the hypotheses for reduced exercise capacity.

Objectives: The aim of this study was to evaluate the effects of inspiratory muscle training on exercise capacity, pulmonary function and functional status in patients with AS.

Methods: A total of 32 patients (18 female, 16 male; mean age: 37.3±10.4 years) were included in this study. The patients were randomized as two groups; Group I consisted of 16 patients, received inspiratory muscle training (IMT) in addition to conventional exercise (CE), Group II consisted of 16 patients, received only CE. All assessments were done before and after the training (8 weeks) for every patient. Standard pulmonary function tests were applied for pulmonary volumes. Maximum inspiratory pressure (Pilmax), maximum expiratory pressure (PEmax) were also measured as respiratory muscle strength. Six-minute walk test (6MWT) was used for the assessment of aerobic capacity. For the evaluation of functional status, the Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Metrology Index (BASMI) were used. CE training program consisted of 20 exercises: motion and flexibility exercises of the cervical, thoracic, and lumbar spine, myofascial stretching of the hamstrings, quadriceps, erector spine muscle, and shoulder muscles. IMT training load was based on 50% of the patient’s sustained maximum inspiratory pressure. The patients started performing ten loaded inspiration with a 60 second rest period between each inspiration for three sets every day. The exercises were performed as home program for five days per week, 40 minutes per session.

Results: After eight weeks follow-up, patients in Group I had a significant increase in Pilmax (p=0.001), PEmax (p=0.05), and 6MWT (p=0.041) compared with Group II (p=0.134, p=0.281, p=0.281 respectively). There were no significant differences of spirometric measurements. Comparison of the groups showed significantly superior results for group I in BASDAI (p=0.049).

Conclusions: Ankylosing spondylitis patients who performed eight weeks of inspiratory muscle training in addition to conventional exercise training, had an increased respiratory muscle strength, a better aerobic capacity, and disease activity than those who performed conventional exercise only. Inspiratory muscle training should be disseminated with these patients due to advantages.

SAT0730-HPR DIFFERENCES IN PERCEPTION OF THE DISEASE CONSTRAINTS BETWEEN THE CHILD AND PARENTS IN JIA

E. Ünal 1, P. Kısacık 1, G. Arion 1, N.B. Karaca 1, E.D. Batu 2, Z.S. Arici 2, E. Sönmez 2, Y. Bilginer 2, S. Ozen 2, 1Department of Physiotherapy and Rehabilitation, Hacettepe University Faculty of Health Science; 2Pediatric Rheumatology, Hacettepe University Faculty of Medicine, Ankara, Turkey

Background: Studies suggest that the perception of the child and family differ in juvenile idiopathic arthritis. This may pose a problem for the clinician’s assessment (1,2).

Objectives: The aim of this study was to evaluate the differences in perception of the disease constraints between child and parent in JIA.

Methods: 129 children with JIA were included in the study. The main complaint about the illness was requested to be expressed in writing by both the child and the family. Individuals’ expressions and demographic data were recorded. The main complaints were considered nominal. The correlation between the parent’s and child’s expressions were examined. The types of complaints were classified as none, functional, symptomatic, and both functional and symptomatic.

Results: The age range of children ranged from 6 to 21 (mean±SD; 12.86±3.68). When the complaints of the 129 children and the parents were compared, 45.7% were different, 20.2% were partially similar and 34.1% were perfectly similar complaints. When the answers of the 59 children and parents who differ in their complaints were examined, 67.8% of the children expressed a milder disease than their parents (Table 1). While the family mostly concentrated on the symptoms, the children were worried on functional complaints (Table 1).

Table 1. Results of the evaluations

<table>
<thead>
<tr>
<th>Group of complaint - Child</th>

<td>Function + Symptom n (%)</td>
</tr>
</tbody>
</table>

Conclusions: As a result of this study, there was a difference between parent’s and child’s perception of the disease. While children report functional complaints, parents focus on symptomatic complaints. Exercise approaches should focus on the child’s functional complaints and identify common goals with the family.

Families should be educated about the importance of the complaints that the child expresses.

SAT0732-HPR RESILIENCE AND POSITIVE AFFECT ARE RELATED TO THE EXPERIENCE OF FATIGUE IN PATIENTS WITH A RHEUMATIC DISEASE

E. Taal 1, K. Schreurs 2, L. Gudoff 1, C. Bode 1, M. van de Laar 3, 1Psychology, Health & Technology, University Twente; 2Rheumatology, Medisch Spectrum Twente, Enschede, Netherlands

Background: Fatigue is a common symptom in patients with a rheumatic disease. Resilience, the ability to bounce back or recover from stress, has been found to be related to lower fatigue in patients with cancer, traumatic brain injury, cardiac disease and fibromyalgia (see e.g. [1]).

Objectives: To study the relationships of resilience and the resilience related factors positive affect, acceptance and engaged living with fatigue in patients with rheumatic diseases.

Methods: 57 patients with a rheumatic disease (rheumatoid arthritis, 70%; osteoarthritis, 11%; others, 9%) completed an online questionnaire. Fatigue was measured with SF-36 vitality scale, pain with a VAS; Resilience with BRS and resilience related factors with PANAS (positive affect), AAQ-II (Acceptance) and ELS (engaged living). Data were analysed with hierarchical multiple regression analyses.

Results: Resilience, positive affect, acceptance and engaged living were multi-variate significantly related to fatigue ($R^2=0.54$; $P<0.001$). Resilience ($|b|=0.29$; $P<0.05$) and positive affect ($|b|=0.39$; $P<0.01$) were significant individual predictors of lower fatigue in multiple regression analysis. Acceptance and engaged living were not significantly related with fatigue in the multivariate model. The relationship between resilience and fatigue was partially mediated by positive affect. When pain was included in the model the relations of resilience ($|b|=0.27$; $P<0.05$) and positive affect ($|b|=0.34$; $P<0.05$) with fatigue remained significant.

Conclusions: Resilience and positive affect may be predictors of decreased fatigue in rheumatic patients. Further longitudinal studies are needed to examine the causality of these relationships.

SAT0731-HPR SYMPTOMS OF PAIN, FATIGUE AND SELF-EFFICACY IN YOUNG PATIENTS WITH SPONDYLOARTHITIS – A COMPARISON BETWEEN WOMEN AND MEN

A. Torell 1, A. Bremander 2,3,4, S. Bergman 3,4,5, E. Håglund 2,4, 1Department of physiotherapy, Ångelholms sjukhus, Ångelholm; 2School of Business, Engineering and Science, Halmstad University, Halmstad; 3Department of clinical Sciences, Lund, Section of rheumatology, Lund University, Lund; 4Sporshult R&D centre, Sweden, Halmstad; 5Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

Background: Spondyloarthritis (SpA) often has an early disease onset with inflammatory back pain debuting already in young adulthood. Studies have shown gender differences in disease specific areas but few studies have focused only on the younger subjects. Extended knowledge based on self-reported information can help to better understand the characteristics of these younger women and men with SpA.

Objectives: To study the differences between young women and men with SpA with regard to self-reported pain measures, disease activity, fatigue, self-efficacy and health status.

Methods: A cross-sectional population based cohort of 201 patients age 18–36 years with SpA identified through a health care register by searching for ICD-10 codes for SpA between the years 2003–2007. They all responded to a questionnaire survey in 2009, 29% were diagnosed with ankylosing spondylitis, 39% with psoriatic arthritis, and 32% with undifferentiated spondyloarthritids. The survey included questions concerning pain (NRS 0–10 and a pain mannequin), fatigue (NRS 0–10), self-efficacy (ASES 10–100, low-high), The pain mannequin was used to categorize patients into groups; no chronic pain (NCP), chronic regional pain (CRP) or chronic widespread pain (CWP). Self-reported disease activity (BASDAI), health status (EQ5D, 0–1) were used to describe the group. Characteristic symptoms are reported as mean, standard deviation (SD) and frequencies. T-Test and Chi2 test were used to study gender differences.

Results: The mean age (SD) was 30 (5) years, 60% were women. The group reported disease activity scores (BASDAI) of 3.8 (2.3), health status 0.75 (0.16), and a disease duration of 7.5 (5) years. One third were smokers or former smokers, and 69% reached WHO’s recommended level of health enhancing physical activity. 21% reported CRP, 41% CWP and the remaining 38% reported NCP. More women reported CWP pain than men, (48% vs. 30%, p=0.026). Women also reported worse pain compared to men, (3.9 (2.4) vs. 2.9 (2.1), p=0.001), worse fatigue (5.0 (2.6) vs. 3.9 (2.7), p<0.003), less self-efficacy for pain (53 (20) vs. 59 (21), p=0.040) and also for symptoms (59 (19) vs. 65 (20), p=0.038).

Conclusions: A significant proportion of both women and men reported symptoms consistent with chronic widespread pain already at young age. Women reported in general worse health compared to men, including pain distribution, pain intensity and pain management. This information could be valuable for clinicians in the care of young patients with SpA.

SAT0733-HPR A QUALITATIVE STUDY ON OBSTACLES AND MOTIVATIONS TO VACCINATIONS IN RHEUMATOID ARTHRITIS

F. Fayet, C. Savel, M. Rodere, M. Soubrier, S. Mathieu. Rheumatology department, CHU Clermont-Ferrand, Clermont-Ferrand, France

Background: Rheumatoid arthritis (RA) is characterized by an increased risk of infection, which is further enhanced by the associated treatments like corticosteroid therapy or biologics. To diminish this risk, influenza and...
pneumococcal vaccinations have been recommended prior to initiating treatment with biological agents. The COMEDRA trial, conducted in France, revealed the usefulness of a nurse-led consultation in the management of RA-associated comorbidities. Despite this, however, only 40% of patients were shown to be appropriately vaccinated (1).

Methods: This qualitative study was conducted at the rheumatology department by means of semi-directed nurse-led interviews lasting about 45 minutes, between July and November 2015. Four topics were analyzed: obstacles and motivations to influenza vaccination, obstacles and motivations to pneumococcal vaccination, post-vaccination follow-up, and information sources. The interviews were registered and transcribed within 45 hours post-interview, and were pursued using content analysis. The final data analysis was carried out by the nurse in charge of the interview, then by a second nurse, with the two analyses assembled according to the traditional concept of double reading. Differences between both analyses were thoroughly discussed, with a consensus sought by a third researcher, namely a rheumatologist, as necessary.

Results: Overall, 15 interviews were conducted involving 11 women and 4 men, with a mean age of 63 years (29–83). All patients were suffering from RA and undergoing at least one immunosuppressant therapy. Most (80%) were vaccinated against pneumococcus, but only 33% against influenza, with eight patients declaring having been affected by influenza and one by pneumococcus-related pneumonia.

The obstacles to vaccinations, revealed during the interviews, primarily concerned fears of unwanted effects in relation with the vaccinations, particularly concerning the influenza vaccination. The patients also reported anxieties in relation with the vaccines’ excipients, with overdoses, or with disease reactivation. Moreover, media impact, contradictory information, the fact that vaccinations were not always proposed, and the lack of traceability may also be considered obstacles against vaccinations. Influenza is often considered a benign disease, and the vaccine poorly efficacious. Patients with prior influenza were more motivated towards vaccination. The primary motivation reported by the patients, and especially as to the pneumococcal vaccination, was the protection provided by the vaccine. The perception of frailty and increased infection risk associated with the disease and its treatments were other sources of motivation, and particularly when vaccination was highly recommended by the physicians, and when there had been no public controversy.

Conclusions: The fears and motivations associated with these two vaccinations are not identical. Influenza vaccination appears to be poorer perceived, patients reporting more fears related to it. With respect to pneumococcal vaccination, we only collected a few comments, given that the vaccine is less well known, and thus better accepted.

THE EFFECT OF RHEUMATIC DISEASES ON WORK ABILITY: A STUDY OF SELF-ASSESSMENT OF SF-36 IN PATIENTS WITH SMART SYSTEM OF DISEASE MANAGEMENT (SSDM)

1Department of Rheumatology and Immunology, Dongguan People’s Hospital, Dongguan; 2The First Affiliated Hospital of PLA General Hospital, Beijing; 3Department of Rheumatology and Immunology, The First Affiliated Hospital of Harbin Medical University, Harbin; 4Shandong Provincial Hospital, Jinan; 5The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou; 6Department of Rheumatology and Immunology, Dongguan People’s Hospital, Dongguan; 7The First Affiliated Hospital of PLA General Hospital, Beijing; 8Department of Rheumatology and Immunology, The First Affiliated Hospital of Harbin Medical University, Harbin; 9Anhui Medical University Affiliated Provincial Hospital, Hefei; 10The First Affiliated Hospital of Nanchang University, Nanchang; 11The First People’s Hospital of Jinhong, Jinhong; 12TCM-Integrated Hospital of Shanghai Tongji Medical University, Shanghai; 13Medical Department, Shanghai Gothic Internet Technology Co., Ltd., Shanghai, China

Background: A variety of rheumatic diseases can significantly affect the patient’s quality of life and work ability. SF-36 is a commonly used tool to assess the quality of life and work ability in patients with chronic disease. In the past, most patients were guided by doctors/nurses to assess SF-36 in a paper form. At present, there is a lack of research on the quality of life in patients with rheumatic disease by using new mobile tools in the real world.

Objectives: To explore the effect to the life ability of rheumatic disease and the potential association between the disease activity and SF-36 in patients with rheumatic diseases (RA) using SSDM.

Methods: SSDM is a new smart disease management mobile tool, which includes physicians’ and patients’ application system. After entering the results of SF-36 assessment by patients, all data can be synchronized automatically to the mobile terminal of authorized rheumatologist. According to the scores of SF-36 (<12.5, 12.5–50 and >.50), the quality of life was divided into three levels: poor, moderate and good.

Results: From June 2016 January 2017, data were extracted online from the mobile terminals of 839 adult patients (284 male and 555 female) in 62 hospitals across China. All patients performed self-assessment of SF-36 for a total of 1,065 times. The mean age was 38.12±13.87 (18 to 81) years and the median disease duration was 20.60 (0 to 573) months. There are 25 kinds of rheumatic diseases involved, including RA (23%), ankylosing spondylitis (AS, 19%), systemic lupus erythematosus (SLE, 13%), osteoarthritis (OA, 11%), Sjogren syndrome (SS, 10%), polyarthralgia/dermatomyositis (PM/DM, 6%), mixed connective tissue disease (MCTD, 6%) and others (12%).

The 8 items of SF-36 index were averaged between 49.07 (General Health perceptions, GH) to 74.12 (Physical Functioning, PF). The overall mean score of patients with different rheumatic diseases was higher than 50. However, there were significant differences in the scores of 5 kinds of rheumatic diseases with average score of 5 items less than 50, including: MCTD, SS, PM/DM, AS and SLE in patients with GH score: 44.24, 44.60, 47.87, 47.93 and 49.16, PM/DM in patients with the Emotional Role functioning (RE): 47.52, Physical Role functioning (RP): 44.68 and AS patients with Reported Health Transition (HT): 49.64, respectively. In RA patients, 39% and 37% of patients reported that their ability to work were affected by disease and mood changes respectively. Bivariate correlation analysis showed that DAS28 was negatively correlated with the two items scores (RP and RE) of SF-36 index in RA patients, p<0.01.

Conclusions: SSDM can be used to assess SF-36 in patients with rheumatic diseases. The Quality of life scores in patients with MCTD, SS, PM/DM, AS, and SLE were more likely to be affected by rheumatic disease. The disease activity (DAS28) of RA patients was negatively correlated with the work ability (RP and RE of SF-36 score).

DOI: 10.1136/annrheumdis-2017-eular.4990
Background: Fatigue, sleep disturbances and pain, are symptoms of primary Sjögren’s syndrome (PSS). However, current clinical interventions predominantly focus on treating patients’ dryness symptoms. 

Objectives: To explore the experience of fatigue, sleep disturbances and discomfort in people with PSS, to investigate the impact of these symptoms on patients’ daily lives and to develop an intervention strategy to address them.

Methods: Qualitative focus groups with open-ended questions allowed participants to explore ideas together and focus on issues they perceived as being important. PSS patients (n=10) and spouses (n=3) took part in three focus groups divided into six sessions which were facilitated by two clinician researchers using a topic guide. Discussion topics included; the symptoms, strategies used by participants to explore ideas together and focus on issues they perceived as being important.

Results: Patient participants all experienced these symptoms. Symptom severity varied within individuals and flares occurred unpredictably. Fatigue, sleep disturbances and discomfort, all affected patients’ lives and those around them and sometimes felt overwhelming. Discomfort symptoms included oral and ocular dryness, tingling, nausea and difficulties tolerating light and noise. The invisible nature of these features meant patients often struggled to meet others’ expectations, which affected their mood and resulted in social withdrawal. Fatigue was a major barrier to engaging in work, productivity and leisure activities. Sleep disturbances further compounded the fatigue. Patients employed a range of strategies to self-manage their symptoms to varying degrees of success.

Participants expressed a need for tailored support from health care professionals which included information provision, access to peer support and professional support to apply symptom management information. A three stepped model of care was proposed. The model includes different modes of delivering intervention content, including written information, education groups, peer support, digital self-management and one-to-one therapy. Intervention intensity increased with each step in the model.

Conclusions: Symptoms of fatigue, sleep disturbances and discomfort all impact on PSS patients’ daily lives and individualised interventions are needed to support self-management. Care needs to be tailored as different patients require variable levels of support. A stepped model of future symptom management delivery is proposed.

with 15 patients with RA who had taken part of the tele-health follow-up. The selection of participants was purposive and participants with different sex, age, disease duration and severity were included. Age ranged from 28 – 77 years and disease duration from 4 – 41 years. The analysis of the interview transcripts was inductive with a constant comparative approach. First, we identified the main themes that could describe the participants’ experiences. Subsequently, we constructed patient types that could explain different perspectives on the tele-health follow-up.

Results: Five themes covered the participants’ experiences with PRO based tele-health follow-up: (A) flexible solution”, “Responsibility”, “Knowledge of RA”, “Communication and involvement” and “Continuity”. Two different types of perspectives were identified: “the keen patient” and “the reluctant patient”, representing opposite perspectives and preferences regarding the core value of and approach to the tele-health follow-up compared to usual out-patient care.

Conclusions: In general, the participants had positive perceptions towards the PRO based tele-health follow-up and saw this as a flexible, time and resource saving solution. Disadvantages were mainly related to the missing face-to-face contact with health professionals. The two types of perspectives, ‘the keen patient’ and ‘the reluctant patient’, contribute to the understanding of patients’ different needs, wishes and abilities to take part in tele-health follow-up. Thus, our findings call for more insight into how tele-health follow-up could be integrated in routine clinical practice with a special attention on how to support ‘the reluctant’ patient’.

PATINGTS’ PREFERENCES TOWARDS CHARACTERISTICS OF TREATMENT WITH BIOLOGICAL AGENTS DIFFER ACROSS EXPERIENCE WITH THEIR RHEUMATIC DISEASE AND TREATMENT RECEIVED OR PRESCRIBED: RESULTS FROM THE CARA STUDY

L. Sinigaglia1, P. Sarzi-Putini2, L. Laccaloni3,4, C.M. Montecucco5, R. Giacomelli6, G. Lapadula7, I. Olivieri7, A. Giardino8, P. Cortesi9, L.G. Mantovani1, L. Sacco University Hospital, Milano; 2Rheumatology Unit, L. Sacco University Hospital, Milano; 3University of Milano Bicocca, Monza; 4CHARTA Foundation, Milano; 5University of Pavia School of Medicine, IRCCS Policlinico San Matteo Foundation, Pavia; 6Rheumatology Unit School of Medicine, University of L’Aquila, L’Aquila; 7Rheumatology Unit, L. Sacco University Hospital, Milano; 8Rheumatology Institute of Lucania (IRel), the Rheumatology Department of Lucania, San Carlo Hospital of Potenza and Madonna delle Grazie Hospital of Matera, Potenza and Matera, and the Basilicata Ricerca Biomedica (BRB) Foundation, Italy, Potenza and Matera; 9MSD Italia, Roma, Italy

Background: The development of biologic therapies has created a more complex decision-making process to select the treatment option for patients. In order to optimize the decision of the decisions, it is necessary to be informed and aware of the preferences of the interested parties and the influence of their experiences on their preferences for the different treatments.

Objectives: To estimate preferences of relevant treatment characteristics valued by different patient subgroups involved in the management of patients with rheumatic diseases. This abstract focuses on patients’ preferences.

Methods: We involved patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) or psoriatic arthritis (PsA), who according to clinical practice, at the time of data collection had for the first time a prescription of (PsA), we constructed patient types that could explain different perspectives on the rheumatic disease and treatment received or prescribed: RESULTS FROM THE CARA STUDY.

Results: Four categories were revealed: (1) Feelings and thoughts related to significant others, where participants would feel like being someone’s burden, taking away opportunity, and express anxiety about how relationships and activities would function in the future. (2) The importance of physical contact, referring to the problematic and manageable impact RA could have on intimate live, as well as body contact in the form of hugging. (3) Getting the support you want, where participants distinguished getting help they had not asked for, from helping each other out. The first being experienced as a degradation, and the latter as feeling more involved in the activity. (4) Adaption of daily activities, referring to how the person and significant others consciously modified their activities and activity choices when needed.

Conclusions: Significant others can either be a barrier or facilitator for participation in daily activities, for persons with early RA. From a clinical point of view it is important to further involve significant others in the rehabilitation process, in order to enhance participation in daily activities for persons with RA.

PHYSICAL PERFORMANCE AND GAIT SPEED OF FALLER AND NON-FALLER ELDERLY PEOPLE WITH KNEE OSTEOARTHRITIS LIVING IN THE COMMUNITY

M. Karagin2, A. Abit Kocaman, N. Kirdi. Department of Physiotherapy and Rehabilitation, Hazettepe University, Ankara, Turkey

Background: Osteoarthritis (OA) is the most prevalent chronic degenerative joint disease in the elderly population. The main signs and clinical symptoms of this disease are pain, edema, stiffness, and articular instability. OA is considered to be an intrinsic risk factor for the occurrence of falls. Falls constitute one of the major public health concerns. They frequently have a negative impact on the daily activities of elderly people and could lead to an increase of dependence, fear of falls, fractures, immobility and death.

Objectives: The purpose of this study was to compare physical performance and gait speed among older people with knee osteoarthritis with and without a history of falls.
THE EFFECT OF A NEOPRENE KNEE SLEEVES ON KNEE JOINT PROPRIOCEPTION IN PATIENTS WITH TOTAL KNEE PROSTHESIS

M. Eymin¹, N. Narin¹, V. Karatosun². ¹School of Physical Therapy and Rehabilitation; ²Faculty of Medicine Surgery Medicine Department of Orthopaedics and Traumatology, Dokuz Eylül University, İzmir, Turkey, İzmir, Turkey

Background: Proprioception has been defined as the perceived sense of knee joint position (joint position sense) and movement (kineesthesia) (1). The sensory input from the joint capsule, muscles, ligaments, skin improve proprioceptive acuity. With total knee arthroplasty (TKA) surgery articular cartilage, meniscuses, articular ligaments are removed. Also articular effusion and hematoma formation increase following surgery. Therefore, proprioceptive acuity decrease after TKA surgery (2). The proprioceptive improvement might prevent patients with TKA from falling down and increase their sense of security during physical activities. The clinical effect of neoprene knee sleeves on knee proprioception has been evaluated by studies in both injured and uninjured populations (3). But there is not any study research on the effect of neoprene knee sleeves on knee proprioception in patients with TKA.

Objectives: The aim of this study was to determine the effect of the neoprene knee sleeves on joint proprioception in patients with TKA.

Methods: Sixty patients (50 female/10 male) with a median age 64.9±8.84 years were included in the study. Knee joint proprioception of all the patients was evaluated with and without a neoprene knee sleeves preoperatively and at discharge. Patients attempted to replicate target angles (in knee joint angle 15°, 30°, 60°) using active knee extension movements in sitting position. The average of the 3 repetitions of active joint repositioning test was recorded as position sense score. The angular displacements from the target angles (in knee joint angle 15°, 30°, 60°) at the end of the active reproduction tests were recorded as position sense deficit scores.

Results: Preoperatively (p<0.001) and after surgery (p<0.001) patients’ proprioceptive acuity measured with neoprene knee sleeves in knee joint angle 15°, 30°, 60°, had a significant improvement. When the proprioceptive acuity measured without neoprene knee sleeves before and after surgery were compared, had a significant decrease in proprioceptive acuity (p<0.001) in early stage after TKA. Multiple logistic regression analysis showed that age (odds ratio=12.5, p=0.011), body mass index (odds ratio=14.5, p=0.030), pain intensity (odds ratio=3.5, p=0.045), range of motion (odds ratio=9.8, p=0.012), and knee swelling (odds ratio=8.4, p<0.001) were independent risk factors for fear of falling among patients with knee OA.

Conclusions: We conclude that age, body mass index, pain intensity, range of motion and knee swelling influence the fear of falling. They are viewed as an important predictor of fear of falling in knee OA. Our results could be used to help select knee OA patients who should be enrolled in fall prevention programmes.

THE USE OF HEALTH ASSESSMENT QUESTIONNAIRE (HAQ) TO GIVE A PICTURE OF PATIENT EVERYDAY LIFE WITH RHEUMATOID ARTHRITIS

P. Toftegaard, I.M.J. Hansen, Department of Rheumatology, Svendborg Hospital, Svendborg, Denmark

Background: HAQ is used to monitor physical disability in patients with Rheumatoid arthritis (RA). At our department patients are planned to answer HAQ at every visit. The suitability for use in connection with ordinary clinical controls are questioned (1, 2) and furthermore we have the impression that the patients fill in the HAQ questionnaire because the staff wants it, and not because it make sense to the patients themselves.

Objectives: Evaluation of the HAQ from the patient perspective

Methods: A survey where all patients with RA who visited the outpatient clinic over a period of 3 weeks were invited to participate. Patients were asked to fill in a questionnaire to evaluate (20) in the HAQ on a scale from 1 – 10, 1 = no meaning and 10 = most meaningful. Values less or equal to five were evaluated as “no meaning”. Furthermore a literature review was done, afterwards a Critical Appraisal Skills programme (CASP) was performed on publications found

Results: 100 patients were asked to participate, in total 67 questionnaires were returned, twelve patients were excluded because of incomplete answers, twenty-one did not return the questionnaires or did not want to participate. Depending on which of the 20 questions, different fractions of the patients did not find any meaning in the questions: 18.6% (are you able to shampoo and wash your hair?) up to 40.4% (are you able to use the bathtub?)

In the literature (3, 4) we found several themes of importance for everyday life with RA seen from the patients’ perspective. Pain and impaired physical performance is of great significance for patients living with rheumatoid arthritis. It affects patients both physically, mentally and socially, as it may be necessary to cut back on social activities, to ask for help for ordinary everyday chores, changing or dropping work etc. This has implications for the role of the patient in the family. Powerlessness, frustration and uncertainty about the future affect the mood in form of anger and depressive thoughts.
Overall, it affects the patients' self-image and the patients' independence may be lost.

Conclusions: HAQ questionnaire is relevant in the term of defining the areas in everyday life, where the patients have problems. But the questionnaire does not contribute to elucidate the implications for the patient, which probably is the reason why many patients do not find the meaning of the questions. To evaluate the everyday living with and of treatment arthritis embedding the patient values, patient involvement in designing questionnaires is vital.

IMPACT OF AN INTERDISCIPLINARY INTERVENTION ON RA PATIENTS

I. Fortin1, H. Sylvain2, F. Banville3, B. Loisiv4, S.V. Rochefort1, 1Research, CISSS du Bas-Saint-Laurent/Hôpital Régional de Rimouski; 2Sciences infirmières; 3Research, Université du Québec à Rimouski, Rimouski; 4Rheumatology, CISSS du Saguenay-Lac-St-Jean/Hôpital de Chicoutimi, Chicoutimi, Canada

Background: Rheumatoid arthritis (RA) impairs patient function and quality of life (QoL) which, in turn, may lead to invalidity and chronicity of pain.1 Even though a variety of effective treatments are available, there is still a significant portion of patients not attaining remission, of whom many continue to report moderate to high pain and fatigue despite low levels of inflammation.1 Interdisciplinary interventions are promising approaches that may complement the medication effect on patient well-being and disease control, however previous studies on the effectiveness of interdisciplinary interventions seem conflicting.

Objectives: The primary objective is to compare the DAS28 response between patients receiving an interdisciplinary intervention (Intervention group) and patients followed under standard rheumatologic practice (Control group). Secondary objectives are to compare patient-reported outcomes such as pain, fatigue, general health, and patient empowerment between the two groups.

Methods: Prospective quasi-experimental, matched cohort (age, gender) study. Adult patients with a diagnosis of RA and DAS28 (CRP)≥2.6 are eligible for the study. The Intervention group (n=28) benefits from interdisciplinary team intervention with the following professionals: rheumatologist, nurse, physiotherapist, social worker, kinesiologist, occupational therapist, and nutritionist. The Control group (n=32) receives a conventional rheumatologist-nurse intervention. Both groups see the rheumatologist approximately three times over 12 months. Interdisciplinary meetings take place in the hospital setting with the patients at Month 0 and Month 12 and without them at Month 6. The following outcome measures are used at each visit to the rheumatologist: patient pain, fatigue (Multidimensional Assessment of Fatigue; MAF), disability (HAQ), quality of life (SF-36), patient empowerment (Patient Activation Measure; PAM13), and patient satisfaction (OSC-F; only in Intervention group at Month 12).

Results: A total of 28 patients were enrolled in the Intervention group and 32 in the Control group without any significant differences in demographics or disease parameters with the exception of disease duration which was significantly higher in the Intervention group (10.9 vs. 5.8 years; p=0.021). Within 6 months of treatment, clinically important and statistically significant (p<0.01) improvements in DAS28 were observed in both groups which were maintained until 12 months. Overall, at 12 months, DAS28 response was comparable between groups (68% vs. 63%; p=0.140). However, when looking at patients with established RA (≥2.6) on AS in ERA patients.120 patients with

TOWARDS MEASUREMENT OF PERSON-CENTERED CARE OUTCOMES IN OUTPATIENT NURSE-LED CLINICS

V. Bala1, 2, B. Fridlund3, B. Forsling4,5, B. Svensson6, P. Hagel7, 1Department of Medicine, Section of Rheumatology, Helsingborg; 2Department of Health Science, Lund University, Lund; 3School of Health and Welfare, Jönköping; 4Department of Clinical Science, Section of Rheumatology, Lund University; 5Department of Research and Education, Helsingborg's Hospital, Helsingborg; 6Section of Rheumatology at the Institution of Clinical Science, Lund University, Lund; 7The PRO-CARE Group, School of Health and Society, Kristianstad University, Kristianstad, Sweden

Background: Person-centered care (PCC) is increasingly emphasized as a key component of effective illness management and of developing high quality of care. Despite considerable progress of PCC in many areas of care there is currently a need and a need for means to assess PCC practice in outpatient care. In rheumatology, PCC is considered an unmet need and further development and evaluation of this approach to care is thus of high priority.

Objectives: To develop an instrument for measuring person-centered care from the perspective of the person with rheumatoid arthritis (RA) in nurse-led outpatient clinics.

Methods: A conceptual framework of PCC in the outpatient context and focusing on the meeting between the person with RA and the nurse and on the patient as an active care partner was undertaken. Based on this framework, qualitative interviews (1,2) and a literature review, a 35-item questionnaire was proposed and qualitatively tested regarding content validity and construct validity with patients attending RA with a nurse-led outpatient clinic. Two versions of the questionnaire were tested: one using four response categories (0 = Totally disagree; 3 = Completely agree) and one using two response categories (0 = Disagree; 1 = Agree). Content validity was estimated by calculating Content Validity Index of the individual items (I-CVI) and of the overall instrument (S-CVI).

Results: Respondents found the items easy to understand (77%) and relevant (93%). Seventy-three percent of the respondents preferred the questionnaire version with four response categories. This version took a mean (SD) of 5.3 (2.5) minutes to complete. I-CVI values ranged from 0.87 to 1.00 and S-CVI was 0.94. About 80% of the respondents considered some items to be redundant. This resulted in a reduced 24-item draft questionnaire that yield a total score between 0–72.

Conclusions: A preliminary 24-item patient-reported PCC questionnaire was developed. Psychometric testing is needed for validation of this tool before implementation.

Background: Patients with rheumatoid arthritis (RA) have higher incidence of cardiovascular disease (CVD) and prevalence of arterial stiffness (AS) due to TNFα. Whether inhibition of proinflammatory pathway or suppression of inflammation remains uncertain. While achieving Disease Activity Score in 28joints (DAS) remission was associated with significant benefits in articular disease, its effect on co-morbidities such as CVD risk is uncertain.

Objectives: To investigate the effect of achieving sustained DAS remission on AS.

Methods: This randomized control trial investigates the effect of 2 tight-control interventions: intensified, intensified disease activity suppression anti-TNF. We examined the difference in 2.minimal disease activity [DAS<2.6] vs 2.3 years on AS in ERA patients.120 patients with active disease (DAS>3.2), symptoms onset <2years and bDMARDs naive were recruited and received 1-year treatment.Treatment are adjusted based on the standardized protocol every 3months aiming at either 1 of the 2 targets. AS is measured by branch-ankle plethysmography wave velocity (bPWV) using a dedicated tonometry system (Omron VP-2000).

Results: In the interim analysis, results of 100 patients [male (23.0%); 52.8±13 years] completed 1year follow-up were analyzed. No significant differences between groups in clinical features, DMARD use and bPWV at month12
(M12) was observed yet significant improvement in disease activity was found in both groups. Hence, results from the 2 groups were combined to ascertain if achieving sustained DAS remission can prevent AS progression. The disease activity improved significantly [DAS: 4.8 (4.2-5.6) at baseline (BL) vs 2.38 (1.6-3.0) at M12, p < 0.001]. 57% patients achieved DAS remission at M12 and 36% patients achieved CR at M12 from interventions that focused on coping with pain and fatigue management, as well as those that raise awareness amongst employers.

No significant differences were found in disease activity, cardiovascular risk factors (CRF) and baPWV at BL between groups who can (CA) or cannot achieve (NA) sustained remission. At M12, no significant differences in CRF and baPWV were found between groups. However, the change in baPWV was significantly different between CA and NA group [-65.5 (-147.2, 44.0) cm/s vs 39 (-65.25, 124.75) cm/s, p = 0.005]. The differences remained significant in the change of baPWV [4.4 (-9.67-2.84) vs 2.51 (-4.34-10.28)%, p = 0.006]. In univariate analysis, association of change in baPWV and potential predictors included BL baPWV, blood pressure (systolic & diastolic) and sustained DAS remission was found. By multivariate analysis, achieving sustained DAS remission was an independent predictor for baPWV reduction.

**Table 1 – Changes in baPWV over a period of 12 months in patients who can or cannot achieve sustained DAS remission in 3 consecutive visits**

**WORKING WITH A MUSCULOSKELETAL DISORDER – A QUANTITATIVE STUDY OF WORKERS’ EXPERIENCES**

**Methods:** Semi-structured interviews conducted with 19 individuals who had attended musculoskeletal assessment clinics in three Irish hospitals within the preceding year with a confirmed diagnosis of non-inflammatory musculoskeletal disorder. Participants were only included if they had been in paid employment continuously for at least six of the previous 12 months. The interviews were audio-recorded and transcribed. Data were analysed using thematic analysis.

**Results:** Participants ranged in age from 21 to 50 years, most were female (n=16). Fifteen participants were continuing to work, while experiencing pain and some functional limitations. Job control emerged as a key factor in continued work participation. Specifically, being able to organise workload and make modifications to work practices enabled participants to maintain an acceptable level of work performance. The value of work, both personal and financial, motivated people to continue to work. While some co-workers and supervisors were considered to be helpful, interviewees were concerned that they could lose their job if they asked for assistance or took time off work. Fatigue had a considerable impact on participation in social activities.

**Conclusions:** While continuing to work was beneficial, negative spillover effects on performance and well-being were commonly reported. Workers with MSD may benefit from interventions that focus on coping with pain and fatigue management, as well as those that raise awareness amongst employers.

**SAT0749-HPR**

**THE RELATIONSHIP BETWEEN SPINAL MOBILITY AND STATIC AND DYNAMIC BALANCE IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

B. Unver, H. Yilmaz, F. Unver, Dokuz Eylul University, School of Physical Therapy and Rehabilitation, Department of Orthopaedic Physiotherapy, Izmir, Turkey

**Background:** Ankylosing spondylitis (AS) is a major chronic rheumatic disease that predominantly affects axial joints, determining a rigid spine from the occiput to the sacrum. The disease can lead to permanent spinal deformity and postural disorder during the later stages. Changes in axial mobility may lead to impaired postural control, with altered postural control being associated with increased fall risk and low-quality of life. Although correlation with AS has been rarely studied regarding postural control, both dynamic and static.

**Objectives:** The aim was to investigate the relationship between spinal mobility and static and dynamic balance of patients with mild to moderate AS.

**Methods:** The study included 137 (74 male and 63 female) patients with a mean age of 51.9 ± 10.72 (20–78) years who were diagnosed with AS according to the modified New York criteria. Patients were divided into two groups as tragus to the wall distance (TWD) > < 15 cm (Group I = mild AS, n=51) and TWD > > 15 (Group II = moderate AS, n=84). The mean duration of disease in Group I was 17.83±11.3 (1- 50) years and the mean duration of disease in Group II was 20.78±9.67 (2 - 48) years. Spinal mobility measurements (TWD, cervical rotation (CR), modified Schober test (MST), lumbar lateral flexion (LLF), intermeomeral distance (IMM), thoracic expansion (TE) tests) were compared with static and dynamic balance tests in the groups. Static balance was assessed with one-foot standing with eyes open and closed. Dynamic balance was assessed with timed up and go test and Berg balance scale.

**Results:** A statistically significant difference was found between spinal mobility measurements and Berg balance scale scores between the groups. Spinal mobility values of Group II were worse than Group I (p < 0.05). Berg balance scale scores were better in Group I vs Group II (p = 0.026). No statistically significant difference was found between the two groups in terms of static balance and timed up and go (p > 0.05). There was a weak and significant correlation between spinal mobility measurements (CR, MST, LLF, IMM, and TE) and static and dynamic balance in the positive direction (r=0.177-0.284, p < 0.05). There was no significant correlation between TWD and static and dynamic balance (p > 0.05).

**Conclusions:** In patients with AS, as the severity of the disease progresses, spinal mobility and dynamic balance worsen; however, the static balance does not change. These changes in the posture and balance can negatively affect patients’ participation in daily life and increase their risk of falling. For this reason, we think that detailed evaluation of balance, balance training and fall preventing approaches should be included in the rehabilitation programs for the patients with AS.

**“IS THIS REALLY THE WAY WE SHOULD GO?” – PATIENT PERSPECTIVES ON RHEUMATOID ARTHRITIS MANAGEMENT**

C.A. Lemay 1, K. Mazor 2, J. Kremer 3, W.B. Nowell 4, C. Bingham III 5, J. Curtis 6, E. Ruderman 7, L. Harrod 8, Orthopedics, University of Massachusetts Medical School; 2 Meyers Primary Care Institute, Worcester; 3 Albany Medical College, Albany; 4 Global Healthy Living Foundation, Upper Nyack; 5 Johns Hopkins University, Baltimore; 6 The University of Alabama at Birmingham, Birmingham; 7 Northwestern University Feinberg School of Medicine, Chicago; 8 University of Massachusetts Medical School, Worcester, United States

**Background:** Current rheumatoid arthritis (RA) treatment guidelines suggest aggressive management in order to minimize disease activity. To achieve this goal, clinicians will need to engage patients in shared decision making. Currently little is known regarding patient’s preferences and goals for treatment.

**Objectives:** To understand patient perspectives on their goals with regard to RA disease and flare management and the barriers to, and facilitators of achieving those goals.

**Methods:** Participants were interviewed utilizing open-ended questions focused on understanding their goals of managing their disease (both disease flares and remission) and the disease (as well as the barriers and facilitators of achieving those goals. We explored the following: disease impact; disease beliefs and behaviors; medication use; provider relationship and communication; availability of insurance coverage; and community resources. Interviews were recorded and transcribed. Data were categorized using content analysis techniques. Convenience sample of persons living with rheumatologist-diagnosed RA was recruited from rheumatology practices in 4 states to participate in telephone interviews.

**Results:** Twenty-seven participants completed an interview from March-August 2015. Mean age was 63 years; 82% were female and 82% Non-Hispanic White. Participants reported living with RA for an average of 12 years and 44% reported...
that their RA was not well controlled. The most common participant goal was to improve or maintain physical function. Barriers to RA and flare management included: 1) Patient Level- lack of knowledge of how to manage flares and a reluctance to change or use medications, related to concerns about potential side effects, and limited understanding of the potential benefits; 2) Provider Level- inadequate communication between patient and provider, specifically in relation to flare management and; 3) Health System Level- difficulty navigating insurance, handling coverage gaps, affording high medication costs. Facilitators of RA and flare management included: 1) Patient Level- successful use of non-medication approaches to disease management and the willingness to initiate conversation with their provider about changing medications; and; 2) Provider Level- a positive relationship with their provider, including having trust in the provider, easy access to the provider, and positive communication.

Conclusions: We identified patient-, provider and health system-barriers and facilitators experienced by RA patients achieving their treatment goals. A common theme that emerged was inadequate shared decision making between patients and their providers related to patient knowledge, inadequate communication, and mistrust.

SAT0751-HPR
THE RELATIONSHIP BETWEEN ANAEROBIC EXERCISE CAPACITY AND ISOMETRIC LOWER EXTREMITY MUSCLE STRENGTH IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

D. Bayraktar 1, S. Savci 2, E. Manci 3, O. Altug-Gucenmez 4, B. Makay 5, N. Ilcin 4, B.E. Umut 4 1Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir Karp Celebi University, 2School of Physical Therapy and Rehabilitation, 3Institute of Health Sciences, 4Faculty of Medicine, Division of Pediatric Rheumatology, Dokuz Eylul University, Izmir, Turkey

Background: Juvenile idiopathic arthritis (JIA) is a chronic disease that occurs before the age of 16 years. It was shown that anaerobic exercise capacity, which is important for most daily activities in children such as jumping, hopping and climbing was diminished in JIA. Previous studies showed that anaerobic exercise capacity was related to well-being level, functional status, and aerobic exercise capacity in JIA. However, no data is available about the relationship between lower extremity muscle power and anaerobic exercise capacity parameters in children with JIA.

Objectives: To determine the possible relationships between lower extremity muscle strength and anaerobic capacity.

Methods: Forty-six children with JIA (14 F, 32 M), with a mean age of 13.74±2.29 years (min-max: 9–17 years) were included in the study. Isometric lower extremity muscle strength was assessed with a hand-held dynamometer at the end points of knee flexion, knee extension, hip flexion and hip extension movements, which are generated from gross lower extremity muscles and important for anaerobic power. All the muscle testing was performed on the right leg. Anaerobic exercise capacity was measured performing a 30-second Wingate test. Both absolute and per kilogram values for peak power and average power were noted. The relationships between the parameters were determined with Pearson’s correlation coefficient.

Results: All children completed the assessments without any adverse effects. Demographics, average isometric lower extremity muscle strengths and parameters related to the anaerobic exercise capacity testing were shown in Table 1. Moderate to good correlations were determined between isometric muscle strength and anaerobic exercise capacity parameters r <0.001 (Table 2).

Conclusions: The results of the study suggested that lower extremity muscle strength might influence the anaerobic exercise capacity. Exercise regimes including lower extremity strengthening might help improving anaerobic exercise capacity in children with JIA.

SAT0752-HPR
THE MEASUREMENT OF PATIENTS’ EXPECTATIONS OF A MULTIDISCIPLINARY AND DEDICATED FIBROMYALGIA PROGRAM

D. Xhako, A.A. Borg, C. Mercieca. Rheumatology, Mater Dei Hospital, Swatar, Malta

Background: Fibromyalgia (FM) is a chronic and multidimensional condition impacting the physical health and psychosocial state of the individuals. In addition to performing clinical and psychological assessments, evaluating patients’ expectations may help address their specific needs and improve outcomes.

Objectives: The aim of this study was to assess the expectations of a cohort of FM patients participating in a multidisciplinary, dedicated fibromyalgia program.

Methods: This was a survey of 86 consecutive FM patients who were initiating a multidisciplinary program delivered by a rheumatologist, nurse, physiotherapist, occupational therapist, psychotherapist and GP with a special interest in FM. Patients were diagnosed using the 2010 ACR diagnostic criteria. Demographic data, Widespread Pain Index (WPI), Symptom Severity Score (SSS) were recorded. Patients filled in the self-administered questionnaires including the Revised fibromyalgia impact questionnaire (FIQR), Hospital Anxiety and Depression Scale (HADS) and a patients’ expectations questionnaire. The latter consisted of both open ended and closed questions using a five-point Likert scale (1=strongly agree to 5=strongly disagree) about the following domains: physical, psychological, coping and social aspects.

Results: Eighty-six patients (92% females) participated in the survey. The average age was 51.2 years (SD 10.60) and mean duration of symptoms 13.3 years (SD 11.17). The mean HADS-A was 11.6 (SD 4.37), HADS-D 8.67 (SD 3.47) and FIQR 55.9 (SD 21.64). In response to an open question about what was their main expectation from this program, just over half of the patients (52.3%) reported improvement of pain and fatigue as their most important outcome. This was followed by improved quality of life (19.3%), being able to cope better with ADLs, family and work (17.4%), obtain more knowledge about the condition (5.8%), while 15.1% did not have any expectations. When asked to rate their expectations for each specific domain: 64% expected significant improvement of physical symptoms, 74% to be able to cope better with family, hobbies and work and 66% expected an improvement of their psychological state, namely depression and anxiety. By the end of the program, 66% of the patients expected to have minimal or no symptoms. When asked to identify any lifestyle changes which could help, 30.2% mentioned a better work-life balance, 12.8% starting an exercise routine, 10.5% weight loss, 11.6% a mixture of house adaptations while 34.9% could not come up with any suggestions.

Conclusions: Expectations of fibromyalgia patients were high in all domains. This study highlights the need for multidimensional assessment and a personalised multidisciplinary approach in managing fibromyalgia. Moreover, it is very important to assess patients’ expectations in order to guide interventions and set realistic achievable goals which are acceptable to both patients and clinicians. Patients’ expectations are an important patient reported outcome measure, which need to be assessed.

**SAT0753-HPR** AWARENESS OF POSSIBLE SIDE EFFECTS OF NSAIDS AMONG THE ALBANIAN PATIENT POPULATION

E. Pistje, A. Themeli. Continuing Education, Medical Training Center Santa Maria, Lezhe, Albania

**Background:** No official published figures are available regarding the annual use of NSAIDs in Albania. Nonsteroidal anti-inflammatory drugs are used primarily to manage different pain conditions, less commonly they are used for their antiplatelet effect. Although generally well tolerated, conventional NSAIDs have been associated with a wide range of adverse effects. The most common of which are gastrointestinal tract (GIT) side effects like: dyspepsia, abdominal pain, heartburn, and the most serious life-threatening gastrointestinal (GI) ulceration.

**Objectives:** To investigate patient awareness of the proper use and frequency of side effects in nonsteroidal anti-inflammatory drugs (NSAIDs) patients in Albania. Methods: This was a cross-sectional study, a prospective 15 question interview of patients purchasing medications, during randomized 1 hour/day pharmacy visits over a one month study period (May 2015).

The study was conducted in 4 community pharmacies located in the city of Tirana (capital of Albania). Two hundred and ten patients were included in this study.

**Results:** Overall NSAIDs use during last year was 63%: ibuprofen and diclofenac was the most used NSAIDs. The majority of patients (58%) reported having side effects upon NSAIDs use; gastrointestinal upset was the most frequently reported side effect. Patients awareness regarding proper NSAIDs use was poor, and pharmacist role in counselling was inadequate.

However, user ability to discover the most common side effect to the drug seemed not to be affected.

**Conclusions:** Nonsteroidal anti-inflammatory drugs use awareness and knowledge of probable side effects and how to handle them was not adequate. This probably reflected on high incidence of side effects. Nonsteroidal anti-inflammatory drugs are available on prescription as well as over the counter drugs. Pharmacist involvement in education of patients using them is highly recommended and much needed to help decrease frequency of side effects. However this is a small scale study and further studies need to be done.

**SAT0755-HPR** VARIATION IN SLE-RELATED PAIN: A SEVEN YEAR FOLLOW-UP STUDY

E. Waldheim 1, S. Ajeanqova 1, S. Bergman 2, J. Frostegård 2, E. Welin Henriksson 2, 3, 1Karolinska Institutet, Stockholm; 2University of Gothenburg, Gothenburg; 3Linköping Universitet, Linköping, Sweden

**Background:** In a previous study we have shown that 24% of the SLE patients in our cohort reported high level of SLE-related pain, ≥40 mm on VAS (0–100 mm). These patients with high pain level also reported significantly more fatigue, anxiety and depression and reduced health-related quality of life compared to the SLE patients with low pain level, <39 mm on VAS.2

**Objectives:** To investigate the variation in self-reported SLE-related pain and its association with presence of chronic widespread pain (CWP) and patient-related outcomes after seven years of follow-up.

**Methods:** 64 of 84 patients agreed to participate in the 7-year follow-up and answered questionnaires on pain (VAS/mm), fatigue (MAF), HROQL (SF-36), anxiety and depression (HADS) and, in case of remaining pain – three months, marked painful body regions on a pain-drawing. Disease activity and damage (SLAM, SLEDAI, SLICC) were also captured. Nonparametric statistics were used to compare the different groups. Difference in measures (diff) between inclusion and follow-up was calculated.

**Results:** For patients with low degree of SLE-related pain the previous week (<39 mm on VAS) at inclusion, n=50, there were no significant differences at 7 years follow-up in pain, fatigue, anxiety, depression and all dimensions of SF-36, except for deterioration in physical function median diff (IQR) 0 (-10 to 5), p=0.024. Of these patients with low level of pain, 26% indicated chronic widespread pain on the pain drawing.

Among patients with high degree of pain (≥40 mm on VAS) at inclusion, n=14, half of the patients reported significantly decreased pain, diff (IQR) 45 (35 to 65), p=0.021, fatigue, 8 (8 to 17), p=0.018, anxiety, 4 (1 to 6), p=0.035 and depression, 4 (2 to 5), p=0.018 and improvements in all dimensions of SF-36 except for role emotional and social function at follow-up, p<0.05.

However, half of the patients with high degree of pain at inclusion reported no significant changes at follow up regarding pain, median diff (IQR) -13 (-20 to 28), fatigue, 5 (-0.3 to 6), anxiety, 2 (-1 to 3) and depression, 0 (3 to 2). These patients reported significantly deterioration in vitality in SF-36, diff (IQR) 20 (15 to 35), p=0.0018 but no significant changes in the other dimensions of SF-36. All patients with high levels of remaining pain indicated chronic widespread pain on the pain drawing. These patients with remaining pain had significantly higher SLAM at follow-up compared to the patients with decreased pain at follow-up, p=0.017 and the patients with low levels of pain at inclusion, p=0.006. No significant differences were found regarding SLEDAI and disease damage.

**Conclusions:** Self-reported level of disease-related pain remain low in most patients and in some patients also significantly reduced. However, half of the patients with high level of pain at inclusion still experienced high level of pain and pain-related problems including widespread pain after 7 years of follow-up. These results suggest a transition from SLE-related pain to chronic widespread pain, which requires different pain management.

**SAT0754-HPR** A NECESSARY INVESTMENT IN FUTURE HEALTH. PERCEPTIONS OF PHYSICAL ACTIVITY MAINTENANCE AMONG PEOPLE WITH RA PARTICIPATING IN AN OUTSOURCED HEALTH-ENHANCING PHYSICAL ACTIVITY PROGRAM

E. Swärdh 1, 2, B. Nordgren 1, 2, C.H. Opava 1, 3, I. Demmelmaier 1, 4. 1Department of Neurobiology, Care sciences and Society, Division of Physiotherapy, Karolinska Institute; 2Functional Area Occupational Therapy & Physiotherapy, Allied Health Professionals’ Function, Karolinska University Hospital, Huddinge; 3Department of Rheumatology, Karolinska University Hospital, Solna, Sweden; 4Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden

**Background:** Health-enhancing physical activity (HEPA) is an active treatment in rheumatoid arthritis (RA) that may be difficult for patients to maintain over time. A two-year HEPA program including twice-weekly circuit training at public gyms and 150 weekly minutes of moderately intense aerobic exercise was conducted in Sweden between 2011 and 2013. Regular peer support sessions were held to promote the maintenance of HEPA. Patient perceptions on maintained physical activity in RA have been minimally explored.

**Objectives:** To describe perceptions of physical activity maintenance during the second year of an outsourced 2-year HEPA-program among people with RA

**Methods:** A descriptive design with a qualitative inductive approach was used. Interviews were conducted with 18 participants with RA, including men and women differing in age, disease duration, activity limitation, perceived pain, levels of physical activity, training centers and peer support groups. Qualitative content analysis was used, and a pattern of theme, subthemes, categories, and subcategories was constructed based on the participants’ perceptions of the phenomenon.

**Results:** A main overarching theme and three subthemes were established, called ‘A necessary investment in future health through dedication, affinity and awareness’; which described participants’ experiences of maintenance during the second year of an outsourced 2-year HEPA-program. This was further described in eight categories with 16 subcategories. The categories described the participants’ ‘mindsets, habits, commitments, social support, PA contexts, monitoring, insights in PA, and health gains’. 

**Conclusions:** The findings are partly in line with the theoretically derived explanations for maintenance of behavior change formulated to date, such as maintenance motives (self-determination and identity), self-regulation (skills and processes, lapse, relapse and coping) habits, resources (psychological and physical) as well as environmental and social influences. The results of this study could also be transferable to similar groups of people with RA in similar settings and can be useful in designing future HEPA interventions to facilitate maintenance of behavior change.

**SAT0756-HPR** EFFECT OF NSAID INTAKE ON KINESIOPHOBIA IN PATIENTS WITH ANKYLOSING SPONDYLITIS

G.I. Kinkil 1, 2, S. Karahan 2, A. Ates 3, M. Turgay 2, G. Kinkil 1. 1Department of Physiotherapy and Rehabilitation, Hacettepe University Faculty of Health Sciences; 2Department of Biostatistics, Hacettepe University Faculty of Medicine; 3Department of Rheumatology, Ankara University Faculty of Medicine, Ankara, Turkey

**Background:** Spinal stiffness and loss of spinal mobility, explained byspinal inflammation and structural damage due to extensive osteoporosis, are characteristics of Ankylosing Spondylitis (AS). AS usually disables a person with severe back pain and, in later stages, remarkable spinal kyphotic deformity. The deformity may initially only be present as reduced spinal movement, thereby controlling the symptoms and progression of AS in early stages by effective medication is the main step in the management of AS.

**Objectives:** The aim of this study was to investigate the effectiveness of DMARD therapies on NSAID intake and kinesiophobia in patients with AS.

SIGNIFICANT IMPROVEMENT OF RHEUMATOID ARTHRITIS (RA) OUTCOME WITH REPEATED SELF-ASSESSMENT APPLYING SMART SYSTEM OF DISEASE MANAGEMENT (SSDM) MOBILES TOOLS: A COHORT STUDY OF RA PATIENTS IN CHINA

J. Yang 1, Y. Wang 2, F. Li3, H. Wei 4, J. Xue 5, H. Wang 6, J. Ru 7, R. Mu 8, J. Huang 9, X. Zuo 10, X. Xin 11, F. He 12, X. Shi 13, Z. Li14, F. Xiao 15, H. Xiao 15, Y. Liu 15, Y. Jia 15, Z. Li 15, 2Department of Rheumatology, Central Hospital of Meizhou, Yangjiang, Sichuan, China; 3Department of Rheumatology and Immunology, First Affiliated Hospital of BaoTou Medical College, Baotou; 4Department of Rheumatology and Immunology, The Second Hospital of Shandong University, Jinan; 5Department of Rheumatology and Immunology, The sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou; 6Department of Rheumatology and Immunology, XiAn Jiaotong University, XiAn; 7Department of Rheumatology and Immunology, The first Affiliated Hospital of Henan University of Science and Technology, Luoyang; 8Department of Rheumatology, The First Affiliated Hospital of Bengbu Medical College, Bengbu; 9Medical Department, Shanghai Goethe Internet Technology Co., Ltd., Shanghai, China

Background: There are more than 5 million RA patients in China, but only 5,000 rheumatologists. Treat-to-Target (T2T) strategy are critical for the treatment of RA, but the Chinese rheumatologists can hardly provide patients with a complete assessment in the clinic due to limited time. The SSDM includes interfaces of both physicians’ and patients’ application. After entering the data of lab test records, treatment regiments, and executing DAS28 assessment by patients themselves, all data can be synchronized automatically to the authorized physicians’ mobile tool. The rheumatologists can rationally adjust treatment for RA patients can achieve better T2T result. SSDM can assist rheumatologist to improve disease activity.

Methods: A total of 74 patients, diagnosed according to the modified New York criteria for AS, were enrolled. Patients were assessed to measure disease activity using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). Fear of movement was assessed with the Tampa Scale for Kinesiophobia [TSK]. To calculate NSAID intake and the type of NSAID, percentage of days with intake were recorded, along with DMARD therapy, age, body mass index (BMI), and disease duration. The BASDAI equivalent scoring was calculated according to recommendations from longitudinal clinical studies. The drug therapy groups were compared using the Kruskal-Wallis test and the Chi-square test. Correlation analysis was evaluated by Spearman's correlation coefficient.

Results: Seventy-four patients (36 women, 38 men; mean age: 43.8±10.18 years; mean disease duration: 9.89±8.50 years; BMI: 28.20±5.07) treated with 4 types of DMARDS (adalimumab-golimumab=17; infliximab=19; etanercept=13; sulfasalazine=25) were included. There were no drug group differences in terms of age (p=0.586), sex (p=0.886), or BMI (p=0.821). BASDAI scores (mean: 3.9±2.4) and NSAID intake (mean: 68.1±76.1; p=0.003) were significantly higher in the sulfasalazine therapy (ST) group compared to other drug groups. BASDAI scores were not correlated with age (p=0.103), disease duration (p=0.131), BMI (p=0.641) or the TSK scores (p=0.376). Different NSAID intake groups (p=0.089) had similar TSK scores.

Conclusions: Patients with AS had fear of movement independent of age, BMI or disease duration, even when they experienced positive results from drug therapies and concomitant therapy with a single oral dose of NSAID or oral corticosteroids in stable dosages.

SAT0760-HPR

PSYCHOLOGICAL VARIABLES PREDICTIVE OF DISORDERS OF SLEEP IN PATIENTS WITH SPONDYLARTHRITIS AND PSORIATIC ARTHRITIS. PRELIMINARY MULTICENTER STUDY

L. Cano García1, M.D. Hernandez-Sanchez2, R. Segura-Ruiz3, C. Domínguez-Quesada4, M.J. Peña-Vallejo4, N. Mena-Vázquez5, E. Vichuez-Ocaña6, A. Fernandez-Nebro7, R. Rheumatology, Hospital Regional Universitario de Málaga, Málaga; 2Rheumatology, Complejo Hospitalario de Jaén, Jaén; 3Rheumatology, Hospital Reina Sofia, Córdoba; 4Rheumatology, Hospital Virgen Macarena, Sevilla, Spain

Objectives: To study the psychological variables associated with the severity of insomnia and hypersomnia according to the Oviedo sleep questionnaire (COS) in patients with spondylarthritids (SPA) and psoriatic arthritis (PA), including the disease activity BASDAI and DAS28.

Methods: Design. Cross-sectional descriptive study. Patients: Patients with consecutive SPA or PA were selected by consecutive sampling in follow-up in rheumatology units of 4 Spanish hospitals. Inclusion criteria: Adults (age >16 years) with SPA (ASAS criteria) or PA (CASPAR criteria) capable of understanding and willing to perform questionnaires. Exclusion criteria: other rheumatic diseases, age <16 years. Protocol: Upon arriving at the consultation, he was offered to participate in the study, he was explained and the patient was given the battery of questionnaires; His physician performed the evaluation of disease activity and recorded the comorbidities and current medication. Main outcomes: the 3 dimensions of COS: (1) Subjective satisfaction with sleep, (2) Insomnia and (3) Hyperinsomnia. The COS is a semi-structured interview to aid the diagnosis of insomnia and hypersomnia according to the diagnostic criteria ICD-10 and DSM-IV. Other variables: current medication for SPA or PA, comorbidities, use of sleeping pills and/or CPAP according to COS questionnaire (insomnia was divided into mild <15 and moderate-severe >15), disease activity: ADAS and PsA (DAS28); Health-related quality of life (HRQL) using SF-36; Pain perception (Brief Pain Inventory BPI questionnaire), SPA (BASDAI) and PA (DAS28, BASDAI) and FACIT fatigue, TMMS emotional intelligence. Resilience with resilience questionnaire, anxiety and depression screening using HADs. Statistical analysis: descriptive, bivariate analysis using T-Student, Mann-Whitney and χ2; Followed by binary logistic regression (BLR) (Vd. moderate/severe insomnia).

Results: A total of 126 patients participated: 65 patients with SPA (33.8% women, 42% <40.92 years) and 61 patients with PA (60.7% women, 49.4±5.5 years) with an average of 8.4±6.8 years of disease. They used biological therapy SPA 29 (23%) and PA 28 (45.9%). The most common comorbidity were in SPA and PA: disc disease 33 (50.8%) and 18 (29.5%), 16 (24.6%), Both patients with SPA and PA were dissatisfied with their sleep (3.4±1.39). We did not find correlation of the COS variables with the HRQoL, the fatigue or the pain. There were no differences in COS scale according to biological treatment and/or FAME. Logistic regression analysis demonstrated an association between insomnia and TMMS repair, resilience and anxiety in PA. Insomnia in SPA showed an association with depression and BASDAI.

Conclusions: Insomnia is a common health problem in these diseases. Moderate-intense insomnia in patients with SPA was associated with an increase in BASDAI and depression. Also in patients with PA, the insomnia was associated with TMMS repair, resilience and anxiety. The patient assumes the sleep disorder as part of this chronic illness, this justifies the good evaluations of resilience and emotional intelligence of the evaluated patients.

SAT0761-HPR

IDENTIFICATION OF FACTORS THAT CONTRIBUTE TO SUCCESSFUL ONLINE MONITORING OF DISEASE ACTIVITY: EXPERIENCES FROM PATIENTS WITH RHEUMATOID ARTHRITIS

L. Renskers1, S.A.A. Rongen1,2, A.M.P. Huis1, M.E.J.L. Hulscher1, P.L.C.M. van Riel1,2, TQ Healthcare, Radboud Institute for Health Sciences, Radboud university medical center, Nijmegen; 2Rheumatology, Bernhoven, Uden, Netherlands

Background: In order to encourage patients to take an active role in their disease management and to enhance the dialogue between patients and healthcare providers, iMonitor was developed. iMonitor is a Software Medical Device developed and funded by Pfizer. Patients can complete patient-reported outcome measures (PROMs) in this online system. This allows for monitoring of disease activity in between visits, identification of patients who need medical attention in between visits, and it may lead to reduction of consultations for patients with stable disease activity. Moreover, completion of a PROM might help a patient to prepare for his or her consultation and might improve the communication between physician and patient.

Objectives: This study aims to identify factors that contribute to adequate online monitoring of disease activity, by collecting experiences from patients with RA with iMonitor.

Methods: Patients were recruited at Bernhoven (Uden, the Netherlands) by an announcement of the study on the hospital website, leaflets and by specific meetings. Four instruction classes were organised in which two researchers gave live instructions about the programme. Patients received log-in codes and chose their PROM-preference(s) and PROM-frequency. After nine months a focus group interview was performed and three telephone interviews were held. Questions were semi-structured using a topic list based on Flottorp. Data will be transcribed, coded and grouped.

Results: Currently 33 patients with RA are using iMonitor. Of these patients 17 (52%) attended the instruction classes and six patients (18%) attended the focus group discussion. Preliminary results reveal six themes (Technological aspects, Patient factors, Need for feedback, Incentives and resources, Reduction of consultations and Security aspects). The Flottorp domain “Patient factors” provided most rich information. Most patients said they developed more knowledge about their disease activity and that they felt more aware about their disease activity. Additionally, iMonitor supported them in taking actions such as adjustments in lifestyle and becoming more prudent when noticing a flare. Some patients felt more prepared for a consultation and less dependent from their rheumatologist. With regard to the domain “Capacity for organisational change”, patients were confident that iMonitor could contribute to reduction of consultations, but contacting the outpatient clinic when feeling worried should be required.

Conclusions: Patients’ experiences with an online remote monitoring system were mainly positive. Instruction classes helped patients to get familiar with the programme. Patients experienced to have more control over their disease and to have developed more knowledge. This may result in enhanced self-management, which is important with regard to retain control over disease.

SAT0762-HPR

THE ACCESSIBILITY AND USABILITY OF AN AUSTRALIAN WEB-BASED SELF-MANAGEMENT PROGRAM (MYJOINTPAIN) FOR PEOPLE WITH LOWER HEALTH LITERACY AND JOINT PAIN IN THE UK

L.B. Parsons1, J. Adams1,2, 1Faculty of Health Sciences; 2Arthritis Research UK Centre for Sport Exercise and Osteoarthritis, University of Southampton, Southampton, United Kingdom

Background: Osteoarthritis (OA) is disproportionately prevalent in people from lower socio economic groups (1). People from lower socio economic groups are also more likely to have lower health literacy. Health literacy influences people’s capacity to understand, acquire, appraise and use health information. Currently, health professionals over estimate patients’ health literacy (2), potentially reducing the impact of OA self-management interventions that rely on educational approaches (3). As internet usage increases, online OA self-management resources are an option for delivering patient education. Currently, there is no evidence as to whether online education resources are suitable and accessible for people with joint pain and lower health literacy.

Objectives: To identify facilitators and barriers experienced by people with joint pain and low health literacy to access and utilise information available on the MyJointPain website. (https://www.myjointpain.org.au).

Results: Currently 33 patients with RA are using iMonitor. Of these patients 17 (52%) attended the instruction classes and six patients (18%) attended the focus group discussion. Preliminary results reveal six themes (Technological aspects, Patient factors, Need for feedback, Incentives and resources, Reduction of consultations and Security aspects). The Flottorp domain “Patient factors” provided most rich information. Most patients said they developed more knowledge about their disease activity and that they felt more aware about their disease activity. Additionally, iMonitor supported them in taking actions such as adjustments in lifestyle and becoming more prudent when noticing a flare. Some patients felt more prepared for a consultation and less dependent from their rheumatologist. With regard to the domain “Capacity for organisational change”, patients were confident that iMonitor could contribute to reduction of consultations, but contacting the outpatient clinic when feeling worried should be required.

Conclusions: Patients’ experiences with an online remote monitoring system were mainly positive. Instruction classes helped patients to get familiar with the programme. Patients experienced to have more control over their disease and to have developed more knowledge. This may result in enhanced self-management, which is important with regard to retain control over disease.

Disclosure of Interest: L. Renskers Grant/research support from: Pfizer, S. Rongen: None declared, A. Huis: None declared, M. Hulscher: None declared, P. van Riel Grant/research support from: Pfizer DOI: 10.1136/annrheumdis-2017-eular.2294
Methods: A qualitative interview study was conducted. Participants were invited to use the website for two weeks and then participated in semi-structured interviews. The interview topic guide had been developed in line with current literature. The interviews were audio recorded and transcribed verbatim. Thematic analysis was used by the main researcher (with independent verification) to interrogate the data and identify themes.

Results: Six people with low health literacy (S-TOFHLA 17±3) were recruited from community groups from an inner-city area with a high index for social deprivation. Four key themes were identified. 1) Dealing with technical issues, where participants demonstrated that they could persevere with technical problems in using online resources. 2) Information over provision, here participants found there was too much complex health information provided, that hindered usability; 3) Motivation for information seeking, where participants discussed that it was pain that encouraged resource use but motivation to self-manage was influenced by personal beliefs; 4) Specialist professional insights: some participants whilst willing to use and engage with the website recalled that they also want to have access to a health professional and felt the website could supplement but not replace this contact.

“I think you have it from the health care where the healthcare are telling you and explaining to you”. 

Conclusions: Digital online OA self-management presented by MyJointPain showed potential for use by people with joint pain and lower health literacy levels. This is important as outcomes for this group are poor (1). Text volume, detail and image use should be carefully considered when designing new online resources and involvement of people with lower health literacy when designing websites will help to ensure inclusion and useful content is accessible to all OA patients. Clinicians should consider their patients’ health literacy levels, computer literacy and readiness to change behaviour before prescribing web based self-management tools.

SAT0763-HPR FUNCTIONAL OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS ON THE BACKGROUND CORRECTION OF PROGESTERONE INSUFFICIENCY M. Salokhiddinov 1, T.G. Woodworth1, F. Guillemin2, D.E. Furst1, J. Brook1, S. Kafaja1, 3Rheumatology, Saudi German hospital, Jeddah, 2Rheumatology, Saudi German hospital, Medinah; 3Rheumatology, Saudi German hospital, Riyadh, Saudi Arabia; 4Rheumatology, Thumbay Hospital, Dubai, United Arab Emirates

Background: Chronic pain is a common condition that affects one-third of the population, accounting for a large number of medical consultations and a significant proportion of health care costs. Evidence suggests that anxiety and depression are associated with increased pain sensitivity and pain-related disability, co-morbid conditions that are more disabling than either condition alone (1). Pain management in OA patients is complicated in the setting of chronic pain and depression, and the effect of OA management on these co-morbid conditions is not well understood.

Objectives: The objective of this study was to determine the prevalence of anxiety, depression, and sleep disorders, painful musculoskeletal conditions in a sample of adults with disabilities.

Methods: This cross-sectional study analyzed data of 1692 adults aged 18 or older who have disabilities over 10 years (2005 to 2014). We examined the following chronic conditions, in which pain is a key symptom and forms part of the diagnostic process, and organized them into 3 groups. Group 1 consisted of (rheumatic diseases), arthritis, osteoarthritis, rheumatoid arthritis, and ankylosing spondylitis; group 2 consisted of muscular dystrophy; and group 3 consisted of neck or back pain. The prevalence (95% confidence interval) of painful musculoskeletal conditions was determined according to the diagnosis. Factors associated with these painful conditions were analyzed separately for men and women by using a logistic regression model.

Results: The prevalence of painful musculoskeletal conditions was 66.9% (95% CI, 66.0%–67.7%). Factors associated with these conditions in both men and women included older age, a sleep disorder, and comorbid chronic anxiety and/or depression was 23.5% (95% CI, 22.5%–24%), all of which were higher in women than in men. Of the 1692 adults with disability included in the study, 65% were women. The average age was 50.5 (standard deviation, 12.5 y), and 65% of participants were 50.5 or older. In addition, 48% of participants were married. Of the participants, 16% had been diagnosed with chronic anxiety and 22% with chronic depression; and 32% with sleep disorder (sleeping 6 hours or less per day. Prevalence of Painful Conditions in Adults with Disabilities, by Group of Conditions was developed to facilitate and standardize detection and measurement of RA flares in an American English version of the FLARE questionnaire to detect and measure RA flares in rheumatoid arthritis.

CITERI ON AND CONCORDANCE VALIDITY OF THE AMERICAN-ENGLISH VERSION OF THE FLARE QUESTIONNAIRE TO DETECT AND MEASURE FLARES IN RHEUMATOID ARTHRITIS N. Barros1, T.G. Woodworth1, F. Guillemin2, D.E. Furst1, J. Brook1, S. Kafaja1, N. Borazan1, D.A. Elashoff1, B.J. Fautrel3, V.K. Ranganath1, 1Rheumatology, Saudi German hospital, Jeddah, 2Medicine, UCLA, Los Angeles, United States; 3Université de Lorraine, Paris Descartes University, APEMAC, EA 4360; 4Pitié Salpêtrière Hospital, Paris, France

Background: Despite advances in rheumatoid arthritis (RA) therapeutic agents, difficulty in managing RA flares persists, and remission or the persistent absence of inflammation remains challenging to achieve. The French FLARE (F-FLARE) was developed to facilitate and standardize detection and measurement of RA flares between clinic visits. Here we report validation of the American English version of FLARE (Am-E FLARE-RA).

Objectives: To assess whether the Am-E FLARE questionnaire performs comparably to the French version of FLARE in detecting RA flare in an American English-speaking clinic population.

References:

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2017-eular.1067
Methods: We enrolled patients attending UCLA rheumatology clinics. After informed consent, patients completed a questionnaire to collect demographics, Am-E FLARE, RAPID3, patient global visual analog scale (VAS), and self-reported flare at time of visit or between visits (yes/no). Questions were provided to patients without specific instruction. From the electronic medical records, we extracted MD global, VAS, MD-reported flare, seropositivity, disease duration, swollen/tender joint counts (SJC/TJC), and calculated the clinical disease activity index (CDAI). Analyses included Wilcoxon rank sum tests and Spearman correlations to assess criterion and concurrent construct validity.

Results: Eighty-five RA patients diagnosed by the 1987 American College of Rheumatology (ACR) criteria enrolled in our study. For the study population as a whole, mean age was about 50 years and most were female. Mean disease duration was about 10 years and about 65% were seropositive. (see Table). Am-E FLARE scores were significantly higher in patients' self-reporting flare compared to those without (p = 0.008), and to patients who did not report flare compared to those without flare (p = 0.008) (see Table). Interestingly, there were no significant differences in SJC (p = 0.82) and physician global (p = 0.19) between patients who self-reported flare versus those who reported no flare. In addition, the Am-E FLARE scores correlated moderately with both CDAI (corr=0.46) and RAPID3 (corr=0.57).

Conclusions: The Am-E FLARE is feasible for use in clinic, and shows good criterion validity, with scores significantly higher in patients who self-report flare. In addition, Am-E FLARE shows good discriminant validity, distinguishing patients who are flaring according to MD or patient self-report from those who are not. Finally, Am-E FLARE demonstrates construct validity comparable to that of the original French version of FLARE.

Objective measures of cognitive impairment and the importance of considering cognitive dysfunction. Findings emphasize the gap between subjective and objective measures of cognitive impairment in persons with chronic disease. 

Background: There is an increased appreciation of the burden of cognitive impairment in persons with rheumatoid arthritis (RA). Research shows a gap between subjective and objective measures of cognitive impairment in persons with chronic disease.

Objectives: This study explored the relationship between subjective cognitive dysfunction and computerized neuropsychological performance in Korean older adults with RA.

Methods: Individuals with RA were recruited by their rheumatologists during follow-up visits at a university hospital in Korea. After getting signed consents, a trained research nurse assessed participants with a range of physical, psychosocial, and biological metrics. Subjective cognitive dysfunction was assessed using the Perceived Deficits Questionnaire (PDQ; range 0–20, higher score=greater impairment). Objective cognitive impairment was assessed using a set of 6 computerized neuropsychological tests yielding 18 indices covering a range of cognitive domains. Subjects were classified as “impaired” if they performed 1 SD below age-based population norms on each test [1]. A total cognitive impairment score was calculated by summing the transformed scores (range: 0–18, higher score=greater impairment). Multiple regression analysis controlling for education, disease severity, and depression was conducted to identify the relationship between objective and subjective cognitive measures.

Results: Fifty four subjects with a mean (±SD) age of 63.6 (±10.5) years were included in the final analyses. 85% were female and 87% were married. Mean education level was 10.2 (±4.9) years and mean depression (SE) was 8.9 (±8.5) years. 25.9% had depression and 55.6% had sleep difficulty. Mean PDQ score was 11.8 (±4.5, range 5–25) and mean total cognitive impairment score was 11.0 (±4.1, range 2–18). 92% were classified as cognitively impaired on five or more test indices. There was no significant correlation between PDQ score and total cognitive function score (r=0.26, p=0.086). However, psychological factors including depression (r=0.18, p=0.001) and sleep problem (r=0.577, p=0.001) were significantly correlated with PDQ score. In the multivariate analysis, there was no significant relationship between PDQ score and total cognitive impairment score. However, functional limitations and depression (r=0.317, p=0.048; r=0.334, p=0.019) were significantly associated with the PDQ score.

Conclusions: There was no significant relationship between subjective cognitive dysfunction and computerized neuropsychological performance in this cohort. Functional limitations and depression were significantly associated with perceived cognitive dysfunction. Findings emphasize the gap between subjective and objective measures of cognitive impairment and the importance of considering psychological factors in the context of cognitive complaints in clinical settings.

HPR measuring health (development and measurement properties of PROs, tests, devices) __

**AB1195-HPR**  
**PSORIATIC ARTHRITIS PATIENTS INITIATED ON APREMILAST: A RETROSPECTIVE ANALYSIS OF PATIENT OUTCOMES FROM A WEST LONDON TEACHING HOSPITAL**

C. Anthury, Pharmacy, Imperial College NHS Healthcare Trust, London, United Kingdom

**Background:** Apremilast is an oral phosphodiesterase 4 (PDE-4) inhibitor that reduces disease activity in psoriatic arthritis (PsA) by modulating the expression of inflammatory cytokines. In December 2015, apremilast received a negative National Institute of Clinical Excellence (NICE) appraisal for its use in PsA, owing to a lack of robust evidence on its long-term impact on patient outcomes and efficacy in improving radiographic progression (TA372).

The role of the drug in the PsA treatment pathway remains uncertain. We present a retrospective analysis of the use of apremilast in 14 patients with PsA within our hospital trust.

**Methods:** Pharmacy funding applications and medication dispensing records were used to identify patients. All patients commenced on apremilast at Imperial College NHS Healthcare Trust (ICH) for PsA were included in the analysis.

**Results:** A total of 14 patients were initiated on apremilast between June 2015 and September 2016 (Table 1). Of these patients, 9 (64%) achieved an adequate response to treatment, defined by NICE as an improvement in at least 2 of the 4 PsA response criteria (PsARC) scores, with no worsening in any of the four criteria. Of the 5 patients not achieving response, 3 patients discontinued treatment prior to assessment due to intolerable side effects, whilst 2 further patients did not achieve the appropriate therapeutic response (primary failure).

From the 9 patients that achieved an adequate response only 5 are currently taking therapy, with intolerable side effects causing discontinuation in a further 4. This gives an overall discontinuation rate of 65% (9 out of 14). In the 5 patients remaining on therapy, one patient needed to reduce the drug dose due to side effects, whilst one continued treatment despite tolerable side effects. Of our 14 remaining patients only 3 remained on treatment in the absence of any side effects. The most common side effects causing discontinuation were nausea and vomiting (Spaltins, 21%) and mood changes (2 patients, 14%).

Conclusions: Apremilast was poorly tolerated in our population with only 3 patients continuing the drug with response and without ongoing side effects. Discontinuation rates within ICHT were found to be much higher than those in the original trial data (65% versus 15%). Patients who have continued the medication and tolerated side effects, however have shown a good response to treatment.

**A COMPARISON OF PATIENT PREFERENCE AND USABILITY BETWEEN TWO ELECTRONIC GONIOMETRIC GLOVES IN THE MEASUREMENT OF JOINT MOVEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS**

D. Small 1, P.V. Gardiner 1, J. Connolly 2, J. Condell 2, K. Curran 2, A. O’Neill 1, R. Friel 1. 1 Rheumatology, WHSCT; 2 School of Computing, Ulster University, Londonderry, United Kingdom

**Background:** Patients with Rheumatoid arthritis suffer from pain, stiffness and reduced mobility of their finger joints. Instrumented electronic goniometric gloves have been developed which can enable dynamic measurements to be made with accuracy and efficiency [1]. This technology could be employed in assessing patients with rheumatoid arthritis and could also be used as an aid to rehabilitation. However, pain and swelling in the joints might limit the applicability of these measurement devices as to date they have not been tested in this patient group.

**Objectives:** The purpose of this pilot study was to establish the usability of two different electronic gloves in patients with mild to moderate Rheumatoid arthritis. We wished to establish if patients experienced difficulty donning or doffing either glove or if carrying out a series of measurements with the gloves on caused a change in pain and stiffness. We also investigated differences in the usability and preference between the two Datagloves.

**Methods:** We compared a commercially available electronic glove (the 5DT dataglove 14 Ultra) with a bespoke IMU based electronic glove produced to our specifications by Tyndall National Institute, University College Cork (Figure). We developed a programming interface for both devices to facilitate calibration and detailed evaluation of joint movement. Nine patients with mild to moderate rheumatoid arthritis who were experiencing significant but not severe pain and early morning stiffness in their hands were recruited. After calibration, the patients worked through a protocol of finger flexion and extension movements, which were repeated for each glove and again to test repeatability. The patients completed questionnaires before and after using the gloves on their pain and stiffness levels and at the end of the session on glove donning and doffing usability and preference between the two gloves.

**Results:** All nine patients were able to don and doff the IMU glove without any difficulty compared to 4/9 for the 5DT glove. Seven of 9 patients expressed a preference for the IMU glove or if carrying out a series of measurements with the gloves on caused a change in pain and stiffness. We also investigated differences in the usability and preference between the two Datagloves.

**Conclusions:** Electrogoniometric gloves are usable in patients with rheumatoid arthritis.
arthritis, but patients cannot tolerate longer protocols without an increase in discomfort.

**VALIDITY AND RELIABILITY OF A SMARTPHONE GONIOMETER APPLICATION FOR MEASURING HIP RANGE OF MOTION IN PATIENTS WITH HIP OSTEOARTHRITIS: A PILOT STUDY**

D.C. Sarac1, G. Yalcinkaya2, B. Unver2, 1 Division of Physiotherapy and Rehabilitation, Katip Celebi University; 2 School of Physical Therapy and Rehabilitation, Dokuz Eylul University, Izmir, Turkey

**Background:** Osteoarthritis (OA) of the hip affects the entire joint structure and function and leads joint capsule changes which result limitation in range of motion (ROM). Therefore, measuring ROM is an essential part of the hip assessment. Various measurement tools are available for determining the ROM such as universal goniometers (UG), digital inclinometers, motion analysis systems. Recently, smartphones equipped with suitable applications are able to measure ROM.

**Objectives:** The aim of this study was to determine the inter-rater and intra-rater reliability of a smartphone application “PT Goniometer®” 2015 Mark Busman (PTG) and investigate the agreement within PTG versus UG for active hip ROMs in patients with OA.

**Methods:** This study included eight people who were diagnosed with hip OA. Two physiotherapists performed the ROM measurements on affected hips by using PTG and UG. UG was employed as the reference standard. Hip ROM tests were performed in the following order: flexion, abduction, internal and external rotation. Inter-rater correlation coefficient were used to determine the inter-rater and intra-rater reliability. The Spearman correlation coefficients were used to establish validity of PTG.

**Results:** The PTG smartphone application demonstrated good to excellent inter-rater and intra-rater reliability (ICCs > 0.75) for all measured hip movements in patients with hip OA. ICC scores, minimum detectable change (MDC95) and standard error of measurement (SEM) values were indicated in Table 1 and Table 2. Additionally, UG and PTG application methods demonstrated positive correlations for all hip movements (p < 0.05).

**Conclusions:** Results showed the application potential of PTG in clinical practice. PTG might be a valid and a reliable method for measuring hip ROM in patients with hip OA and smartphone applications can be used in clinical settings. Studies with larger population are required for further investigation of smartphones psychometric properties on measuring hip ROM.

**IMPROVING TRIAGE TO APPROPRIATE TREATMENT LEVEL BY USING A COMBINATION OF SCREENING TOOLS IN PATIENTS AT RISK OF DEVELOPING CHRONIC BACK PAIN**

E. Halgund1,2, C. Olsson3, A. Bremander1,2,4, S. Bergman2,3,4, 1 School of Business, Engineering and Science, Halmstad University; 2 Spenshult Research and Development Center, Halmstad; 3 Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, University of Gothenburg, Gothenburg, Sweden; 4 Department of clinical sciences, Lund, Section of rheumatology, Lund University, Lund, Sweden

**Background:** The screening instrument STaR (Subgroups for Targeted Treatment) Back Screening Tool (SBST) identify patients at risk of developing chronic back pain in order to facilitate triage to appropriate treatment level. The SBST takes into account known risk factors such as activity limitations, kinesiophobia and psychological health. However, SBST does not consider pain distribution which is a known predictor of chronic widespread pain (CWP). According to evidenced clinical practice patients with CWP should be referred to multidimensional rehabilitation (1).

**Objectives:** The purpose of the study was to compare screening by SBST with screening of multisite chronic widespread pain (MS-CWP) in a group of patients with back pain and to analyze to what extent the two screening methods identify the same patients at higher risk.

**Methods:** 73 individuals with a report of chronic back pain (>3 months during last year) age 40–70 years responded to both screening tools. The SBST stratifies patients into low, medium or high risk groups. A pain mannequin was used to categorize patients into no chronic pain (NCP), chronic regional pain (CRP) or chronic widespread pain (CWP) and number of painful areas (0–18). A presence of ≥ 7 painful areas was stratified as MS-CWP. The outcome of the different screening tools was analyzed by cross tabulations. The Roland-Morris Disability Questionnaire (RMDQ, 0–24), health related quality of life (EQ5D, 0–1), Fear-Avoidance Beliefs Questionnaire about physical activity (FABQ-PA, 0–24) and work (FABQ-Work, 0–42), Hospital Anxiety (HAD-A, 0–21) and Depression scale (HAD-D, 0–21) were used to describe physical function, health related quality of life, kinesiophobia and mental health.

**PRESENTATION OF A NEW SCALE ASSESSING THE BIOPSYCHOSOCIAL ASPECTS OF HEALING PROPERTIES IN RHEUMATIC PATIENTS**

E. Ünal1, P. Kisacik1, G. Arin1, E. Karabulut2, D. Gökşülük2, N. Vardar Yalğı1, A. Aydın Özcan1, U. Berberoğlu1, N.B. Karaca1, A. Akdoğan3, Ö. Karadağ3, 1 Department of Internal Medicine, Rheumatology Subdivision, Hacettepe University, Ankara, Turkey

**Background:** Exercise programs have been providing in Hacettepe University for 12 years. The group exercises were transformed into a book named as "Bilisel Egzersiz Terapi Yaklaşımı (BETY)" (1) in 2014 and were registered as a trademark by the Turkish Patent Institute in 2015. This approach includes cognitive processes in pain management, clinical pilates exercises and awareness of mood state during patients therapy (2).When rheumatic patients participating in BETY sessions, they are evaluated with appropriate scales for their diseases and it is stated that these scales do not express enough the healing properties they feel with BETY.

**Objectives:** The aim was to develop a new scale assessing the biopsychosocial aspects of healing properties in rheumatic patients.

**Methods:** After 12 years of treatment, cognitive beliefs about health perceptions were gathered from the patients who participates in the BETY group for at least 5 years, with the open-ended question “What kind of changes did you make in this group? What kind of methodology did you apply?”. After that, 51 rheumatologists, 2 and physiatrists for expert opinion. 15 rheumatologists and 1 physiatrist were returned. When the survey items were examined on a question-based basis, the acceptance rate of all questions was 78.83%. According to this result, the scale was finalized. Structural validity of the created draft will be investigated in the subheadings of functional activity, pain, sexual life, fear of movement, and psychological health.

**Conclusions:** As a result, an original scale which will assess the biopsychosocial aspects of healing properties in rheumatic patients is developed. Our future purpose is to investigate the validation of this scale in different rheumatic diseases.

DOI: 10.1136/annrheumdis-2017-eular.6283
Results: The mean (SD) age was 59 (8) years, 63% were women. Self-reports of physical function (RMDQ) were 4.5 (4.8), health related quality of life (EQ5D) 0.71 (0.21), kinesiophobia (FABO-PA and FABO-Work) 8.3 (5.9) and 14.7 (11.1), and mental health (HAD-A and HAD-B) 8.8 (2.0) and 4.5 (1.7). Comparing the different screening methods, 5 patients (7%) were at high risk as captured by SBST while using the pain mannequin 38 (52%) patients had CWP and 22 (30%) had MS-CWP. No patients in the SBST high risk group had NCP, but 31 (50%) in the SBST low risk group reported CWP, and 16 (26%) reported MS-CWP. In the medium risk group 3 reported CWP, and 3 were also categorized as MS-CWP.

Conclusions: SBST and the pain mannequin as screening tools partly capture different patients at high risk of developing chronic back pain. Using a combination of the two instruments may improve the ability to triage to appropriate treatment level.

THE RELIABILITY OF ROMANIAN MORRIS DISABILITY QUESTIONNAIRE IN PEOPLE WITH LOW BACK PAIN: A PRELIMINARY STUDY

E. Iliu, L. Rusu. Faculty of Physical Education, Department of Sports Medicine and Kinesiology, University of Craiova, Craiova, Romania

Background: Patient reported assessments are widely recommended by the clinical guidelines and an important part of a comprehensive assessment. Patient-reported questionnaires should be translated into local language accordingly and validated in the translated language (1). The clinicians in Romania suffer from lack of validated questionnaires in Romanian language. The Roland Morris Disability Questionnaire is one of the most recommended questionnaires evaluating low back pain. Although, the Romanian translation was performed before, there is no effort regarding to its validation in Romanian language until now.

Objectives: To investigate the test-retest reliability Romanian version of the Roland Morris Disability Questionnaire (RMDQ-Ro) in people low back pain.

Methods: The permission to conduct such a study was asked to the original author Prof. Martin Roland, before starting to the study. The Romanian translated form of Roland Morris Disability Questionnaire which is provided on the web site “http://www.rmdq.org/” was used in the study. A total of 100 people with low back pain filled the RMDQ-Ro as well as Numeric Rating Scales for rest (NRS-R) and activity (NRS-A). Due to the lack of other validated measures such the Oswestry Disability Index in Romanian, these additional assessments (VAS-R and VAS-A) were performed for investigating convergent validity. For test-retest reliability 30 people filled the RMDQ-Ro after 3–14 days later as recommended. Test-retest reliability was assessed with intra-class coefficient correlation (ICC). Non-parametric tests were employed due to the heterogeneity of the data. Therefore, the Spearman correlation test was used for determining the relationship between RMDQ-Ro and VAS-R and VAS-A.

Results: The characteristics of the participants were shown at Table 1. The test-retest reliability of RMDQ-Ro was found at an excellent level (ICC: 0.95). Moderate positive correlations were determined between RMDQ-Ro and NRS-R (rho: 0.518, p<0.001), and NRS-A (rho: 0.484, p<0.001).

Table 1. Characteristics of the Participants

</tr>
</tbody>
</table>

Conclusions: RMDQ-Ro was found reliable regarding test-retest reliability. This questionnaire can be performed in the repeated measures for evaluating low-back pain patients. However, more psychometric characteristics of RMDQ-Ro such as internal consistency and construct validity should be investigated in further studies.

THE VALIDITY AND TEST-RETEST RELIABILITY OF THE TURKISH PATIENT SPECIFIC FUNCTIONAL SCALE IN CHRONIC NECK PAIN PATIENTS. A PRELIMINARY REPORT

G. Yalçinkaya 1, B. Kara 1, M.N. Arda 2, "School of Physical Therapy and Rehabilitation; 2Department of Neurosurgery, Dokuz Eylul University, Izmir, Turkey.

Background: Current clinical guidelines recommend to use both clinical and self-reported measurements for evaluation of chronic neck pain. Among the self-reported outcomes, Neck Disability Index (NDI) and Patient Specific Functional Scale (PSFS) are the most widely used and recommended instruments. Although, NDI was validated in Turkish language before, no validation study related to the PSFS was detected in the literature.

Objectives: The aims of this study were to translate PSFS in Turkish language and to establish the test-retest reliability and validity of the PSFS-T in chronic neck pain patients.

Methods: The PSFS was translated into Turkish by using the “translation-backward translation” method as recommended in the guidelines. The demographic information, PSFS-T and NDI were recorded at the first visit of the patients. Thirty patients were called by phone for the retest evaluation of PSFS-T. The construct validity of PSFS-T was determined by investigating the correlation between NDI and PSFS-T scores. The Cronbach’s alpha was used for the internal consistency. Intra-class coefficient (ICC) was employed to determine the test-retest reliability.

Results: The final form was completed by 42 chronic neck pain patients (18 F) until now. The mean age was 42±14. The internal consistency was found as good (Cronbach’s alpha:0.9). A positive moderate correlation was determined between NDI and PSFS-T scores (p<0.05; r=0.5). The ICC for test-retest reliability was determined in high level (ICC: 0.88).

Conclusions: The PSFS-T is a reliable and valid instrument for chronic neck pain patients. However, the preliminary results should be confirmed by completing the study.

RELATIONSHIP OF WORK DISABILITY BETWEEN THE DISEASE ACTIVITY, DEPRESSION AND QUALITY OF LIFE IN HOUSEWIFE AND WORKING PATIENTS WITH RHEUMATOID ARTHRITIS

S. Sağ, K. Nas, M.S. Sağ, I. Tekeoğlu, A. Kamarlı. Department of Physical Medicine and Rehabilitation, Rheumatology, Faculty of Medicine, Sakarya University, Sakarya, Turkey, sakarya, Turkey.

Background: The aim of this study was to determine the work status in patients with rheumatoid arthritis (RA) while also defining the factors related to work disability.

Objectives: In this study, our objective was to determine the work productivity, work disability and quality of life in time-off daily activities of the housewife and working patients with rheumatoid arthritis (RA) and to investigate the relation of the parameters with disease activity, anxiety, depression and quality of life.

Methods: 82 patients with the diagnosis of RA (26 males, 56 females) and 29 healthy control subjects (5 males, 24 females) were included in the study. In patients with RA, DAS28 was used to evaluate the disease activity. Duruöz hand index was used to determine the functional status. In addition, HAQ (Health Assessment Quality) and The Short Form (SF-36) Health Survey was used to evaluate the health status, Hospital Anxiety and Depression Scale (HADS) was used for the evaluation of depression and anxiety and Work Productivity and Activity Impairment Questionnaire: Specific Health Problem v2.0 (WPAI-SHP) was used to evaluate the work productivity.

Results: Demographic characteristics such as age and gender, were comparable in both patient and control groups (p>0.05). The difficulty in the time off daily activities were worse in the patient group compared with the control group (p<0.05). Anxiety, were significantly higher in housewife RA group (p<0.05). Difficulty in time-off daily activities was correlated with VAS-fatigue and DAS28,HAQ,Duruöz hand index was correlated. (p<0.05).

Conclusions: Even if they are not working in housewives, we have found that...
as much as the least active RA patients, it is difficult for activities in daily life, that the quality of life associated with the illness is low, and that depression and anxiety are similar to employees. As a result, disease activity, quality of life and functional status control in RA patients are as important as those who are working as housewives. Particularly in increasing productivity and participation in everyday activities, the mood is influential and it is must examine the patients in this regard. There is a need for more extensive cohort studies on this topic.

AB1023-HPR COMPARISON OF QUALITY OF LIFE OF PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIARTHSITIS AND ANKILOSING SPONDYLITIS WITH TREATMENT OR PULSATION WITH BIOLOGIC DRUGS: RESULTS FROM THE CARA STUDY

L. Sinigaglia 1, L. Scalone 2,3, P. Sarzi-Puttini 4, C.M. Montecucco 5, R. Giacomelli 5, G. Lapadula 1, I. Oliveri 1, A. Giardino 1, G. Didoni 9, P. Cortesi 2,3, L.G. Mantovani 2,3, M. Mecchia 9 on behalf of CARA study working group. 1Rheumatology Unit, G. Pini Hospital; 2CHARTA Foundation, Milano; 3University of Milano Bicocca, Monza; 4Rheumatology Unit, L. Sacco University Hospital, Milano; 5University of Pavia School of Medicine, IRCCS Policlinico San Matteo Foundation, Pavia; 6Rheumatology Unit School of Medicine, University of L’Aquila, L’Aquila; 7Rheumatology Unit, University of Bari, Bari; 8San Carlo Hospital of Potenza and Madonna delle Grazie Hospital of Matera, and the Basilicata Ricerca Biomedica (BRB) Foundation, Italy, Potenza and Matera; 9MSD Italia, Roma, Italy

Background: Chronic rheumatic conditions such as rheumatoid arthritis (RA), ankyllosing spondylitis (AS), and psoriatic arthritis (PsA) are associated with severe morbidity and significant impairment of patients’ health related quality of life (HRQoL). Several treatments are available but not all the patients respond positively to them. Biologic therapies such as anti-TNFs agents are shown to benefit who fail or have partial responses to standard DMARD therapy.

Objectives: Within a multicenter stated preferances study (CARA Study), we assessed HRQoL in patients with RA, AS and PsA, and estimated relationship of HRQoL with the different diagnoses, clinical characteristics and biological treatment experience.

Methods: Patients with RA, AS, or PsA, who at the time of enrollment were following a treatment (experienced) or received a first prescription (naïve) of biological drugs were enrolled. Together with preferences data, clinical and HRQoL information was reported. HRQoL was assessed with the recently developed and successfully validated version of the EQ-5D-5L, which allows to obtain a description of health (in 5 domains and 5 levels of severity each), a measure (EQ-VAS) and a valuation (utility) of health. Multiple linear regression analyses were conducted to assess the association between EQ-5D VAS score, EQ-5D utility with age, sex, diagnosis, treatment experience, years from symptoms onset and years from diagnosis.

Results: 513 patients were enrolled (mean±SD = 50±13.6, 42.5% female). As regards the diagnosis, 33.9% had RA, 34.9% PsA and 31.2% AS. The mean±SD time from the symptoms onset was 10.8±5.4 and from the diagnosis was 6.0±6.2 years. Almost half of the patients (47.4%) were naïve to biological treatment. Patients reporting severe or extreme problems were: 7.1% in mobility, 3.6% in self-care, 10.3% in usual activities, 18.6% in pain/discomfort, 5.5% in anxiety/depression. The mean±SD of the VAS was 60±22.5 and of the utility was 0.77±0.11. From the regression model the VAS and utility are significantly (p<0.05) associated with age, sex and disease activity, treatment experience, years from symptoms onset and years from diagnosis.

Conclusions: Patients naïve to biological treatment have significant lower levels of HRQoL, suggesting that their current situation is not satisfactory and need to start with a more effective treatment.

DOI: 10.1136/annrheumdis-2017-eular.4904

AB1204-HPR EVALUATION OF CARBOHYDRATE METABOLISM IN RHEUMATOLOGIC PATIENTS AFTER PULSE THERAPY WITH GLUCOCORTICOIDS

M. Salikhidinov, A. Tulaev, Rheumatology, Tashkent Medical Academy, Tashkent, Uzbekistan

Background: Chronic inflammation – the crucial pathogenic mechanism of rheumatoid arthritis is the main cause of accelerated atherosclerosis, insulin resistance and well-known consequences related to it. The conservative treatment of rheumatoid arthritis may provide a significant influence on glucose metabolism. When the duration of rheumatic diseases of administration and dosage of glucocorticoids (GC) are significant predictors of the development of impaired glucose tolerance and diabetes mellitus.

Objectives: To study the effect of pulse-therapy (PT) of the GC on the violation of carbohydrate metabolism in rheumatologic patients.

Methods: The study included 35 patients (7 men, 18 women) with a variety of rheumatic diseases (systemic lupus erythematosus - 23, systemic vasculitis - 12) between the ages of 18 to 68 years (mean age 42.3±14.3 years) and duration of disease from 6 months to 12 years (mean 3.55±3.36 years). Pulse-therapy of GC included intravenous prednisolone 600–1000 mg per day for 3 consecutive days (course dose of 1800–3000 mg). Oral glucose tolerance test (OGTT) was performed after the course. The first group included patients with a normal result of OGTT (glucose concentration of <7.8 mmol/L at 2 hours after taking 75 g of glucose). There were 23 patients in this first group at the age of 30–54 years and 8±0.2±1.6 days (p<0.05) at the age of 52±6±4 years. The second group had OGTT was >7.8 mmol/L. This group included 12 people aged from 44 to 61 years (mean age 52±6±4 years).

All patients underwent the measurement of blood glucose levels prior to PT, 2, 4, 6, 10, 24, 48 and 72 hours and after the PT.

Results: All patients included in the study, after the PT session there was an increase in blood glucose levels with a peak at 4 hours after the start of administration - 12±0.82 in the first group, in the second to 21.95±0.25 mmol/L (p<0.05). Normalization of glucose levels in the first group of patients occurred within 1.75±0.18 days (1 to 3), whereas in the second - for 5.0±1.0 (3 to 5; p<0.05). During the OGTT the mean fasting blood glucose levels in patients with the first group was 4.49±0.12 mmol/L, and the second - 5.85±0.35 (p<0.05), after 2 hours - 6.0±0.21 and 10.0±1.5 mmol/L, respectively (p<0.05).

Conclusions: Application PT of GC in rheumatologic patients causes blood glucose levels to change values, indicating the development of impaired glucose tolerance. Predictors of disorders of carbohydrate metabolism in these patients are high levels of glycemia during the PT more continuous glucose normalization indices after the course PT GC.

AB1205-HPR THE EFFECTS OF KINESIOTAPING ON JOINT POSITION SENSE AND POSTURAL STABILITY FOLLOWING FATIGUE PROTOCOL

O. Aydogdu, Z. San, U.S. Yurdalan. Physiotherapy and Rehabilitation, Marmara University, Health Sciences Faculty, Istanbul, Turkey

Background: Muscle fatigue is common in sports activities and has been shown to adversely alter proprioception, impair neuromuscular control, and increase the risk of injury. Kinesiotaping has recently gained popularity among sports professionals for its assumed injury prevention and performance enhancement (1). Two studies have reported conflicting findings with respect to the effects of KT on proprioception. Halseth et al reported that KT produced no significant change in the absolute error in ankle joint position sense (2). However, Chang et al reported that KT decreased the force sense error in grip strength measurements among 21 healthy college athletes (3). Thus, the current literature does not provide clear information about the effects of KT on proprioception. Although there are published articles about investigating KT on joint position sense and postural stability, the effects of KT is still unknown after muscle fatigue, to our knowledge.

Objectives: There is a lack of literature examining the KT on joint position sense and postural stability following fatigue protocol. Therefore, the aim of this study was to investigate the effects of KT on knee joint position sense and postural stability after muscle fatigue. It was hypothesized that KT applied on quadriceps femoris muscle would partially compensate for the proprioceptive and postural stability losses caused by muscle fatigue.

Methods: Thirty – six healthy subjects were evaluated in the study. Knee joint position sense was assessed by Biodex System Pro 4 during active repositioning tests at the target angles of 30°, 50° and 70° of knee flexion in sagittal plane. Postural stability was assessed by Pedalo Sensamove® System in antero –
posterior and medio – lateral plane. Joint position sense and postural stability were assessed three times: during rest, following the fatigue protocol, and following the taping. The subjects were received a clinically-used fatigue protocol on a cycle ergometer. The Modified Borg’s Rate of Perceived Exertion Scale has been used for fatigue determination. 

Regarding position sense and postural stability were significantly decreased following fatigue compared to the condition during rest (p < 0.05). However, no significant difference was found in terms of joint position sense and postural stability after taping compared to the condition following fatigue (p > 0.05).

Conclusions: The hypothesis of this study, that KT could partially compensate for the proprioceptive and balance-related deficits induced by muscle fatigue, was not supported. According to the results of our study, we concluded that the subjects do not benefit from the use of KT for compensating joint position sense and postural stability in condition following fatigue.

ADAPTATION INTO SPANISH OF THE SCLERODERMA HEALTH ASSESSMENT QUESTIONNAIRE (S-HAQ)

P. Quevedo 1, M.A. Rivero 1, N. Perez 2, H. Laborde 2, G. Earsman 1, M. Mayer 1, S. Papasidero 1, S. Julia 3, C. Zaffarana 4, R. Maldonado 5, M. Khury 1, M. Lara 1, C. Castel 1, A. Curti 1, J.C. Barreira 1, V. Steen 5.

1British Hospital; 2Hospital de Clínicas José de San Martín; 3Torun Hospital; 4Psychophysical Rehabilitation Institute (Rep.), Buenos Aires; 5Padilla Hospital, TUCUMAN.

Statistics, British Hospital, Buenos Aires; 6Luis Lagomaggiore Hospital, MENDOZA, Argentina; 7Georgetown University, Washington, United States

Background: The Health Assessment Questionnaire (HAQ) is an instrument administered to patients to self-report functional status originally in rheumatoid arthritis (RA). In Argentina, it has been translated and validated for RA in 2004.

For diffuse SSC, HAQ has been associated to morbidity and mortality.

Objectives: To adapt S-HAQ into Spanish and to assess its validity in SSC patients in Argentina.

Methods: S-HAQ was translated following a forward-backward translation procedure of the original English version, and transcultural adaptation was performed by a comprehension test reaching the final Spanish version. SSC patients that fulfilled ACR 80 criteria and early Systemic Sclerosis according to Le Roy and Medsger criteria were included. Patients with overlap were excluded. Cronbach’s alpha and item-total correlation were used to assess internal consistency.

Construction validity was analyzed through factor analysis with Varimax rotation. Construct validity was compared by t-test, Mann-Whitney or Kruskal-Wallis test, and categorical variables by chi-square or Fisher’s test. A value of p < 0.05 was considered significant.

Results: 19 an adapted Argentine-Spanish version of S-HAQ was developed. One hundred patients were surveyed; 84% were female, mean age 54±12.8 years and disease duration 8.8±1.9 years. Limited SSC was more frequent (63%), followed by diffuse SSC (36%). Serologically, 89% were ANA positive, 27% had anti Scl 70 and 41% had anti centromere antibodies. Median Rodnan score (mRSS) was 9.8 (±4.05) and median activity measured by EUSTAR was 1.25 (0–6). Median S-HAQ was 0.62 (0–2.5), Cronbach’s alpha 0.89, and when removing questions one by one the coefficient decreased. Median VAS (visual analogue scale) was 0.57 (0–2.8). Factor analysis identified two factors for the S-HAQ: factor 1: dressing (0.61), arising (0.68), reaching (0.63), and personal hygiene (0.70); factor 2: reaching (0.49), usual activities (0.68). For questions, these factors were identified through VAS: factor 1: overall disease severity (0.63) and gastro-intestinal symptoms (0.57); factor 2: Raynaud’s (0.66), digital ulcers (0.56); factor 3: respiratory symptoms (0.43). There was a statistically significant association between higher values of S-HAQ and higher values of mRSS (1.1±0.74 vs. 0.64±0.5 p=0.002) and also with seropositivity for anti-Scl 70 (p=0.003). Higher values of total VAS were associated to female gender (0.75±0.5 vs. 0.49±0.71, p=0.01). There was a significant association between S-HAQ and MEDSGER (p=0.04) and EUSTAR (p=0.03) scores; likewise, between VAS and MEDSGER (p=0.09) and EUSTAR (p=0.03) scores.

Conclusions: A Spanish version of S-HAQ was developed, showing an acceptable reliability and validity.

AB1207-HPR

PATIENT SATISFACTION IN A RHEUMATOID ARTHRITIS SPECIALIZED CENTER

S. Henao 1, F. Rodriguez 2, P. Santos-Moreno 3, L. Villareal 3, M. Cabrera 3, A. Malpica 6, D. Buitrago-Garcia 6, 1Patient service; 2Program Patient; 3Rheumatology; 4Psychology and processes; 5Engineer and processes; 6Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia

Background: According to the Beryl Institute’s, patient experience (PX) is “the sum of all interactions, shaped by an organization’s culture, that influence patient perceptions across the continuum of care”. Nowadays patient satisfaction is considered as one of the quality for performance in health systems [1]. In order to provide a multidisciplinary quality care to patients with RA in centers of excellence (CoEs) under the coordination of a rheumatologist, provide comprehensive management of patients with this pathology, ensuring a probability to medical appointments and treatment, in order to get better clinical outcomes and improve patient safety and satisfaction of the health services provided.

Objectives: To measure levels of satisfaction of RA patients treated at a specialized center and to evaluate patient service.

Methods: In a RA specialized center during a 24 month period we performed a satisfaction survey in order to evaluate the health services provided. We evaluated the timing on appointment, appointment assignment, information provided, the treatment received by the healthcare team, facilities among others. Patients evaluated the services provided in a scale from 1 to 4, were 1 was very bad, 2 regular, 3 good and 4 excellent. Descriptive epidemiology was performed for each variable presented.

Results: We collected 1125 surveys during 2015 and 2016, 45% considered to have a timely care, the mean of waiting time for an appointment was 9 min ± 8; regarding the appointment assignment 96% of the patients evaluated it as good or excellent (mean 3.5±0.7), 80% considered that the information provided was clear and useful, 90% reported to receive a kind and friendly treatment and to considered the facilities as good or excellent. When we evaluated the satisfaction regarding the health care team 50% of patients evaluated the rheumatologist, nurse, nutritionist, physical therapist, psychologist and physiatrist as good and 40% as excellent.

Conclusions: Although we found that our patients are highly satisfied, there is a large opportunity to improve our services. Also, this evidence can support further research projects in order to increase the patient’s satisfaction.

PSORIASIS INDUCED BY TNF ANTAGONIST THERAPY. ANALYSIS OF 13 CASES

A. Martínez-Ferrer 1, A. Mateu Puchades 2, C. Verryang Dangond 3, M. Aguilar Zamora 1, L. Montielo 1, S. Santos 2, E. Valls Pascual 1, D. Ybañez García 1, J.J. Alegre Sancho 1.

1Rheumatology; 2Dermatology, Hospital Dr Peset, Valencia, Spain

Background: Tumor necrosis factor (TNF) antagonist drugs have been shown to be effective in different inflammatory arthropathies and autoimmune pathologies, including psoriasis. However, an unexpected side effect has been observed: the new occurrence or worsening of psoriasis in patients treated with TNF antagonist therapy in our center.

Objectives: The aim of this study is to describe the cases of induction or worsening of psoriasis in patients treated with TNF antagonist therapy in our center.

Methods: Retrospective observational study, review of cases of new or worsening psoriasis in patients with TNF antagonist at the University Hospital Dr. Peset from October 2008 to November 2016. A total of 13 cases were obtained.

Results: Thirteen patients, 8 females and 5 males with mean age 46 years (±16), 38% of patients received treatment for Crohn’s disease, 31% for rheumatoid arthritis (RA), 31% for psoriatic arthritis (PsA), 8% for ankylosing spondylitis (AS) and another 8% for psoriasis. Two patients were diagnosed of more than one pathology: Crohn’s disease associated with PsA and Crohn’s disease associated with RA. Sixty one percent had no known personal history of psoriasis, in one of these patients the family history of psoriasis was recorded. Infliximab was used in 38% of cases, followed by adalimumab and golimumab in 23% each and etanercept in 15.4%. The mean latency time since drug introduction was 9.3 months (2–26). There were 12 cases of psoriasis and 1 case of pityriasis lichenoides (histologically confirmed). Lesion morphology included pustular psoriasis in 91%, scalp psoriasis in 8%, and guttate lesions in 25%, plaques psoriasis in 8%, and inverse psoriasis in 8%; 58% experienced lesions of more than one type. There were no cases of nail, mucosal or erythrodemic psoriasis. The psoriasisform lesions resolved without interruption of TNF antagonist therapy in 53.85%. Of the 6 patients who required discontinuation, 3 patients were switched to another anti-TNF drug (adalimumab,
golimumab and certolizumab) and all 3 had recurrence of the lesions, in 2 patients the anti-TNF was replaced by a non-anti-TNF biological. Topical treatment was used in all cases, one patient also required systemic treatment with methotrexate.

Conclusions: TNF antagonist induced psoriasis is a well-described adverse event. Pustular psoriasis is the most frequent presentation. In most cases there is no personal or family history of psoriasis. Topical therapy may be effective but some patients require discontinuation of the drug. Skin lesions can reappear when switching to another anti-TNF drug.

AB1210-HPR  THE PREVALENCE OF DENTAL AND SINUS INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS BEFORE BIologic THERAPY INITIATION: USEFULNESS OF A SYSTEMATIC SCREENING?

C. Tewli 1, E. Descamps, M. Forien, A. Gardette, E. Palazzo, S. Ottaviani, P. Dieude. Rheumatology Department, Bichat Hospital, Paris, France

Background: Introduction of the biologic therapies has dramatically improved the outcome of severe rheumatoid arthritis (RA). Biologic therapies play a central role in the control of synovial inflammation. However they also decrease host defenses leading to an increased rate of infection. Because of their adverse effects, a careful assessment is needed before their initiation. A systematic assessment of dental and sinus infections before a biologic therapy is not required.

Objectives: The aim of our study was to assess the prevalence and the usefulness of a systematic screening of oral (dental and/or sinus) infection of RA patients before biologic therapy initiation.

Methods: This was a monocentric retrospective study. We included RA (ACR/EULAR 2010 criteria) patients with active disease despite disease-modifying anti-rheumatic drugs (DMARDs) and requiring biologic therapy initiation between 2010 and 2016. The following parameters were collected: demographic and disease characteristics, disease activity (CRP, disease activity score (DAS) 28), current therapies (DMARDs, corticosteroids). Dental infections were assessed by stomatologist after clinical and panoramic dental X-ray evaluation. Sinusitis was defined on sinus computed tomography as partial or complete opacification of one or more sinuses cavities. Factors associated with oral infections were analyzed in uni- and multivariate models.

Results: We included 223 RA patients (79.4% of female, mean ± SD disease duration of 8.9±8.6 years). The mean age was 54±10.9 years, 70.3% rheumatoid factor (RF) positive, 64.4% anti–citrullinated protein antibody (ACPA) positive and 68.1% had radiographic damages. The mean DAS 28 was 5.5±2.6; 71% of patients received corticosteroids (mean 7mg per day of equivalent prednisone) and 63% methotrexate (mean 17.8mg per week). No patient had pain or other sinus or dental symptoms. Before biologic agent initiation, systematic dental and sinus screening revealed an oral infection in 31.5% of patients (dental: 20.2% and sinus: 14.8%). In univariate analysis, active smoking was associated with a higher risk of oral infection (OR=2.16 [1.02–4.57], p=0.038) and methotrexate with a lower rate (OR=0.43 [0.23–0.81], p=0.006). Corticosteroid, disease duration, DAS 28, RF, ACPA and structural damages were not associated with oral infection. No significant association was confirmed with oral infection using multivariate analysis.

Conclusions: In our study, one third of RA patients requiring biologic agents had asymptomatic oral infection. The high prevalence of oral infection in RA patients suggests the usefulness of systematic dental and sinus screening before biologic therapy initiation.

AB1211-HPR  THE USE OF SUBCUTANEOUS METHOTREXATE IN POLISH PATIENTS WITH RHEUMATOID ARTHRITIS

M. Przygodzka 1, K. Sikorska-Siudek 1, R. Radomska 2, S. Bojanowski 2

1Mazovian Centre of Rheumatology and Osteoporosis; 2EHR.eu, Warsaw, Poland

Background: Methotrexate (Mtx) should be the drug of the first choice in rheumatoid arthritis (RA) if there are no contraindications to use it. The efficacy of Mtx is measured by remission or low disease activity and depends on the dose taken. Higher doses (25–30 mg/week) are more effective, but intolerance is the main cause of discontinuation of oral treatment. Subcutaneous Mtx is efficient alternative in those cases.

Objectives: The aim of this study was to evaluate subcutaneous Mtx use frequency in Polish patients and change oral form for subcutaneous as well.

Methods: The disease activity was assessed by Disease Activity Score 28 (DAS 28) during the first visit (V1) and after 3 months therapy (V2) and compliance with therapy as well.

Results: There were 194 RA patients diagnosed by the ACR and 1997 and/or ACR/EULAR 2010 criteria. 144 patients were treated by oral Mtx (group A) and 50 patients (group B) by subcutaneous Mtx at the time of study enrolment (V1). 37 patients of group A (28%) required changes in therapy during V2. 24 (17%) were switched to subcutaneous Mtx (group A1). 6 patients of group B (12%) required change of treatment during V2, including 2 patients (4%) with subcutaneous Mtx, who were switched to oral Mtx. The main cause of changing therapy from oral to subcutaneous was gastrointestinal intolerance of high dose of Mtx. 69 patients (12%) of group A required additional steroid therapy compared to 18 (36%) of group B. Average DAS 28 decreased by 0.58 in group A1 in oral treatment and during the subcutaneous treatment time decreased by next 0.23, in group A1 during oral treatment 14 (58%) patients used 25 mg/week and 20 patients (83%) used 25 mg/week during subcutaneous treatment time.

Conclusions: Patients treatment by oral Mtx often require modification of therapy in comparison to patients treated by subcutaneous Mtx, including more frequent use of steroids.

The main cause of oral intolerance are ailments of the digestive system. Change of oral to subcutaneous therapy allows administration of higher doses of Mtx and results in decrease of DAS28 in comparison to the patients continuing their oral treatment.

AB1212-HPR  DYNAMICS OF ARTICULAR SYNDROME IN RHEUMATOID ARTHRITIS AGAINST CORRECTION OF PROGESTERONE INSUFFICIENCY

M. Salokhiddinov, A. Ahmadov. Rheumatology and Osteopathy, Tashkent Medical Academy, Tashkent, Uzbekistan

Background: According to the literature, sex hormones manifest themselves as immune modulators that inhibit the ones and stimulate other immune functions. Studies have shown that patients with RA, decrease of estradiol and particularly
progesterone in the blood serum is found in the women of reproductive age. According to the literature, progesterone has a close relationship with T-cell immunity. A value of T-cell deficiency plays an important role in the cause of the autoimmune process.

**Objectives:** To study of progesterone correction in RA patients. The aim of this study was to evaluate the effectiveness of progesterone deficiency correction in patients with rheumatoid arthritis based on the analysis of articular syndrome

**Methods:** The study involved 40 patients with a documented diagnosis of RA, women of reproductive age. The study group consisted of 30 patients who had correction of progesterone deficiency background in the pathogenic therapy. The control group consisted of 10 female patients who are on the pathogenic therapy. We used the following criteria: disease activity and severity of the articular syndrome with determining of the number of tender and swollen joints, indices of DAS and HAQ. Statistical analysis of the results of research used the method of parametrics of Student criterion

**Results:** Among the patients studied disease duration ranged from 3 months to 19 years (mean age 10±7.2 years), 20 patients (50%), from 5 to 10 years – 15 (37.5%), and more than 10 years – 5 patients (12.5%). X-ray picture of joint damage in the majority of patients corresponded to stage 2–3 – 87.5% (35 patients). Less common muscular disorders (7.5%), mainly in patients taking long-term GC, myalgia and muscle malnutrition were detected in 7.5% and 25% of patients, respectively. In addition to the articular syndrome, the most frequent complaints of general weakness (75%), irritability, sleep disorders and attention (50%), anxiety and anxiety (75%), low-grade temperature (10%).

**Conclusions:** Progesterone deficiency correction in RA patients against pathogenic therapy has improved performance of articular syndrome and improves quality of life, such as vitality, general health and social function as well as it contributes to the positive dynamics of mental health.

A NATIONAL RHEUMATOID ARTHRITIS REGISTRY SUPPORTED BY A PUBLIC POLICY AS A STRATEGY FOR DISEASE CONTROL AND RISK MANAGEMENT IN COLOMBIA

**Background:** Rheumatoid arthritis (RA) is a chronic disease that implies high direct and indirect costs for the health system (1.2). According to the needs of the health care system, the clinical interests and the national regulatory framework, it was developed a national registry information of RA patients (3).

**Objectives:** To show how a registry of information that would meet the RA situation was developed and to present the results obtained from the analysis of the Registry on this first year.

**Methods:** A national RA Registry was created after a comprehensive literature review to identify the relevant variables to determine monitoring indicators used by health insurers and health services providers in the attention of patients with RA. Variables were selected and defined by an agreement with clinical experts, rheumatic and methodological experts and were evaluated by the Ministry of Health in order to review and approve the structure to gather the information.

**Results:** A structure of 89 variables contained was defined. All entities must report annually to the Registry all the patients with a diagnosis of RA, their clinical and demographic characteristics, and the process of care and costs (3). On its first year the Registry provided a baseline of the disease situation of 68.357 patients with RA. Prevalence, incidence, state of disease and drugs including synthetic and biologic DMARDs were analyzed (Table 1). Most important results were: mean age 57 years; relation women: men 5.2:1; age at onset of disease: 36 years; mean evolution time of disease-7 years; population with DAS 28 measured 45.6%; mean DAS-28 2.8; percentage of the patient with DMARD therapy 78.9% and bDMARD 16.5%.

**Conclusions:** A national Registry supported by an official policy, with data from the real world provided for healthcare insurers gives an opportunity to obtain a global vision and to identify failures and strengths in the attention process of RA, and to develop indicators to obtain better outcomes. In the future, through continuous efforts towards improving the quality of care provided, these will allow to monitoring and decreasing the burden of RA in the country and may serve as a model to other countries.

**SPINAL BRUCELLOSIS: A RETROSPECTIVE STUDY OF 30 CASES**

**Rheumatology, la Rabta, Tunis, Tunisia**

**Background:** Brucellosis is a major health problem in Mediterranean countries including Tunisia. The clinical presentation of this zoonosis varies considerably but osteoarticular involvement and spinal brucellosis particularly is the commonest complication.

**Methods:** This study was carried out between 2000 and 2015. One hundred and six patients with infectious spondylodiscitis hospitalized in the department of rheumatology were analyzed. All patients were thoroughly interrogated subjected to a rigorous clinical examination aned, battery of investigations including: complete blood count, urine analysis, blood culture, erythrocyte sedimentation rate, C - reactive protein (CRP) and serology for brucellosis. The imaging of spine ordered including: X-ray, bone scan and magnetic resonance imaging (MRI) with contrast enhancement.

**Results:** Thirty of the 106 patients (28%) proved to have spinal brucellosis. The mean age of these patients was 53 years (range 15–68 years) and female/men ratio at 1.5. The mean delay of diagnosis was 8 months. The following symptoms were observed: fever in 14 patients and back pain in all of patients. Other symptoms were less frequent observed, such as splenomegaly (2 patients), peripheral adenopathy (5 patients) and diarrhea (2 patients). Laboratory exams showed elevated erythrocyte sedimentation rate in 13 patients, high levels of CRP in all patients and leukocytosis in 11 cases. Wright serology was positive in 21 of the patients. Brucella melitensis was isolated in blood cultures in 2 cases. Standard X-rays were performed in all patients. They showed signs of spondylodiscitis in the lumbar spine in 20 cases, cervical in 2 cases and dorsal in 8 cases. Ct-scan and MRI confirms the diagnosis and showed associated epiduritis in 2 cases or abscess in 6 cases. Bone biopsy with histopathological examination was performed in 7 cases. A combination of rifampicin and doxycycline was given to all patients. The duration of therapy was between 6 and 8 weeks.

**Conclusions:** Brucellosis is present with various clinical signs in endemic areas and may simulate many diseases. The need for prompt diagnosis and treatment of spinal brucellosis is of utmost importance to prevent serious bone destruction and severe neurological Sequelae.

**EFFECTS OF BEETROOT JUICE SUPPLEMENTATION N ENDOXILATION FUNCTION AND MARKERS OF INFLAMMATION AMONG PATIENTS WITH RHEUMATOID ARTHRITIS**

A. Stavropoulos 1, E. Manthou 2, T. Nakopoulou3, K. Georgakouli 2, A. Jamurtas 2. 1Carnegie School of Sport, Leeds Beckett University, Leeds, United Kingdom; 2School of Physical Education and Sports Science, University of Thessaly; 3Radiology, General Hospital of Trikala, Trikala, Greece

**Background:** Nitric oxide (NO) is central in the process of vasodilatation (1). Limited bioavailability of NO often associates with endothelial dysfunction, a precursor to atherosclerosis (1). Such dysfunction is often observed in patients with chronic conditions such as Rheumatoid Arthritis (RA) (2) and Chronic Obstructive Pulmonary Disease (COPD) (3). Common therapies for this include the administration of nitrate-rich medication. However, in the general population beetroot juice supplementation has been shown to increase NO bioavailability (4). It could therefore have beneficial effects on endothelial function of these patients as well.
AB1216-HPR
THE EFFECTS OF APPLICATION OF IONTOPHORESIS AND PHONOPHORESIS IN PATIENTS WITH SUBACROMIAL IMPINGEMENT SYNDROME
A. Yıldız ¹, E. Kusan².
¹Physiotherapy and Rehabilitation, Marmara University Health Sciences Faculty; ²Physiotherapy and Rehabilitation, Kosyolu Medipol Hospital, Istanbul, Turkey

Background: Subacromial impingement syndrome (SIS) is defined as the mechanical compression of subacromial structures between the coraco-acromial arch and the humerus during active elevation of the arm above shoulder height. Objectives: The aim of this study was to investigate the effects of applications of iontophoresis and phonophoresis, which has been used in addition to physiotherapy program on pain and disability level in patients with SIS.

Methods: The study was conducted with subjects (n=43) diagnosed with SIS. The subjects were divided into two groups randomly as iontophoresis group (IG) and phonophoresis group (PG). Diclofenac sodium iontophoresis was applied to the first group (n=22), diclofenac sodium phonophoresis was applied to the second group (n=21). In addition all of groups therapy program includes superficial heat, transcutaneous electrical nerve stimulation and exercise. The groups were evaluated before and after treatment in terms of pain and scores of shoulder disability. Visual analog scale was used to assess of pain (night pain, rest pain, pain with motion and pain in functional use), Shoulder Disability Questionnaire (SDQ) and Disabilities of the Arm Shoulder and Hand (DASH) were used to assess of shoulder disability.

Results: 43 patients with age range of 18 to 65 years were recruited in this study. After treatments pain severity (night pain and pain in functional use) was decreased in both groups (p<0.05) and in the scores of disability of shoulder (p<0.05) in both groups. Pain relief was similar in groups. SDQ and DASH scores remained relatively unaffected by blackcurrant consumption (Overall: 3.9% [0 – 5.1] vs 4.2% [2.3 – 6.1]; p=0.26).

Conclusions: A two week consumption of beetroot juice seems to be able to significantly improve endothelial function both in RA and COPD. A two week consumption of beetroot juice is a safe supplement for both patients’ groups (RA: 2.6% [0.9 – 6.2] vs 10.7% [6.2 – 11.7], p=0.013; COPD: 3.4% [1.2 – 4.8] vs 7.8% [3.6 – 10.2], p=0.034).

IG: Iontophoresis group, PG: Phonophoresis group. *p<0.001.

DASH scores were improved in two groups after treatments. But there was no difference between the groups in terms of functionality and disability scores. Conclusions: This study shows that diclofenac sodium iontophoresis and phonophoresis that are used in patients with subacromial impingement syndrome have similar positive therapeutic effects on shoulder functions.
EFFECTIVENESS OF PLATELET-RICH PLASMA ON FUNCTION AND PERFORMANCE IN PATIENTS WITH KNEE OSTEOARTHRITIS: PRELIMINARY RESULTS

D.C. Sara1, B. Uner2, S. Cekmekte3, M. Erduran1, 1Division of Physiotherapy and Rehabilitation, Faculty of Health Sciences, Izmir Katip Celebi University; 2School of Physiotherapy and Rehabilitation; 3School of Medicine, Department of Orthopaedics, Dokuz Eylul University, Izmir, Turkey

Background: Osteoarthritis is one of the most painful conditions and the most frequent cause of functional limitation and disability. There are variety of methods used in osteoarthritis (OA) treatment, including, physical therapy, exercise, intraarticular injections, surgery, etc. Platelet-rich plasma (PRP) is a relatively new autologous biologic treatment that is used for stimulating cartilage healing process and improving the symptoms. Although the effects of PRP injection on pain and function investigated before, as to our knowledge there are no studies related to performance.

Objectives: Aim of this study was to investigate effectiveness of PRP on improving function and performance in patients with knee osteoarthritis.

Methods: This study included 28 patients (16 F, 12 M) who were affected by grade 1–3 bilateral knee OA according to Kellgren-Lawrence Scale. Patients received three injections of PRP that were performed at monthly intervals by the same doctor. All patients were evaluated before and six months after the first injection. Primary outcome measures were: Stair Climbing Test (SCT), 50-Foot Walk Test (50 FWT), 30-sec Chair Stand Test (30 CST) and Timed Up and Go Test (TUG). IOWA Score. Additionally, Hospital for Special Surgery Score (HSS) was also recorded as a secondary outcome measure. Wilcoxon signed-rank test is used for interpreting the differences between before and after the injections.

Results: All patients completed the study with no adverse effects. The mean age of the patients was 67.6 years (range 29–83). Improvements were determined for all outcome measures after 6 months regard to baseline results (p<0.01) (Table 1).

EXPERIENCES OF SWEDISH “PAIN SCHOOL - COMPETENCE FOR LIFE” OF PATIENTS WITH CHRONIC WIDESPREAD PAIN - A QUALITATIVE INTERVIEW STUDY

G. Goksör1,2, A. Bergenheim1,3, K. Mannertorp1. 1Neuroscience and Physiology, Gothenburg University, Sahlgrenska Academy; 2Nårhälsan Frölunda Rehab, Gothenburg; 3Nårhälsan Uddevalla Rehab, Uddevalla, Sweden

Background: Chronic pain is generally associated with low activity level, low work capability, and negative health consequences (1). Education and exercise have shown effective results for patients with chronic pain (2), and is according to EULAR 2016 recommendations first line interventions for patients with fibromyalgia (3). This educational program “Pain school - Competence for life” for patients with chronic pain was developed by the Swedish Rheumatoid Association together with health care professionals for use in primary health care, but is not used in clinical practice. The aim of the study was to describe the participants’ experiences of the educational program, was held 10 weeks after completion of four educational group sessions. Interviews were conducted by two authors and transcribed verbatim.

Methods: One theme and four categories were identified. An overarching theme, increased understanding and support to patients.

Results: We found optimal adherence in 52% of patients: the average (SD) adherence rate was 71.1±9.42. We didn’t find any significant differences between adherent and nonadherent patients regarding patient age, gender, the diagnosis of rheumatic disease and disease duration time, however, patients with higher education level (at least graduate level) were more compliant than those without any formal education (p<0.006). In addition there was no association between adherence and the type of medication (csDMARD, bDMARD) (p=0.39). Patient data are presented in the table 1.

COMPARISON OF DMARD THERAPIES ON NSAID INTAKE, DISEASE ACTIVITY, FEAR OF MOVEMENT, AND QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

G.I. Kinikli1, S. Karahan2, A. Ates3, M. Turgut4, G. Kinikli3. 1Dept. of Physiotherapy and Rehabilitation, Hacettepe University Faculty of Health Sciences; 2Dept. of Biostatistics, Hacettepe University Faculty of Medicine; 3Dept. of Rheumatology, Ankara University Faculty of Medicine, Ankara, Turkey

Background: Ankylosing Spondylitis (AS) may result in loss of mobility and function; therefore, patients can experience pain and stiffness with a loss of physical function in addition to severe impairment in their quality of life. Standard treatment of AS consists of nonsteroidal anti-inflammatory drugs (NSAIDs) and physical therapy.

They expressed new strategies relating to managing pain, physical activity, and everyday life. Both individual and social value of participation was described, such as increased well-being, decreased anxiety and improved relationships. Group dynamics, structure of education and former knowledge was described to predispose change in perception of pain and lifestyle.

Conclusions: The results provide deeper knowledge about patients’ experiences of the educational program Pain School Competence for life. The educational program appears to provide a meaningful and well-functioning structure for education for patients with chronic widespread pain in primary health care. Further, this can contribute to improve education and rehabilitation for patients with CWP provided by physiotherapists and occupational therapists in primary health care.

References:

Disclosure of Interest: None declared

Objectives: The aim of this study was to compare the effectiveness of DMARD therapies on requirements for NSAIDs, disease activity, fear of movement, and quality of life in AS patients.

Methods: A total of 74 patients diagnosed according to the modified New York criteria for AS were enrolled. To calculate NSAID intake, the type of NSAID, dose, and percentage of days with intake were recorded in conjunction with DMARD therapy, age, body mass index (BMI), and disease duration. Patients were assessed to measure several parameters: 1) disease activity using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI); 2) fear of movement as assessed by the Tampa Scale for Kinesiophobia (TSK); and 3) quality of life using the Ankylosing Spondylitis Quality of Life Scale (ASQoL) from the patient’s perspective.

Results: Seventy-four patients (36 women, 38 men; mean age: 43.8±10.18 years; mean disease duration: 9.8±5.50 years; BMI: 28.20±5.07) treated with different DMARDs (ADA+GO=17; Infliximab [INF/X]=19; Etanercept [ETA]=13; Sulphasalazine [ST]=25) were included. NSAID intake was significantly lower in the INF/X group compared to the ADA+GO (mean: 28.1±81.5) compared to the ADA+GO (mean: 33.3±76.0), ETA (mean: 33.5±58.2), and ST therapy groups (mean: 68.1±76.1) (p=0.003). BASDAI scores (mean: 3.9±2.4), NSAID intake (mean: 68.1±76.1; p=0.003), and ASQoL scores (mean:10.2±7.4) were significantly higher in the ST group compared to the other drug groups. TSK scores were also similar between different NSAID intake groups (p=0.089).

Conclusions: According to our results, ST was not effective enough even with concomitant therapy consisting of a single oral dose of NSAID or standard doses of concomitant drugs in terms of disease activity, fear of movement, and quality of life in AS patients.

EXERGAMES VERSUS SELF-REGULATED EXERCISES WITH INSTRUCTION LEAFLETS TO IMPROVE ADHERENCE IN GERIATRIC REHABILITATION: A RANDOMIZED CONTROLLED TRIAL

J. Kool1, P. Oesch1, L. Fernandez-Luque2, E. Brox3, G. Evertsen3, A. Civit4, R. Hilfiker2, S. Bachmann5,6, Department of Physical Therapy, Klinikum Valens, Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, University of Genova, Savona, Italy; 4Department of Geriatrics, Inselspital, Bern University Hospital, University of Bern, Bern; 5Department of Rheumatology, Klinikum Valens, Valens, Switzerland

Background: Improving mobility in elderly persons is a primary goal in geriatric rehabilitation (Bachmann 2010). Self-regulated exercises with instruction leaflets are used to increase training volume but adherence is often low. Exergames may improve adherence. This study therefore compared exergames with self-regulated exercise using instruction leaflets.

Objectives: To evaluate short-term effects of exergames versus self-regulated exercise using instruction leaflets. Primary outcome was adherence. Secondary outcomes were enjoyment, motivation and balance.

Methods: Design: single center parallel group non-blinded randomized controlled trial with central stratified randomization (Hasselmann 2015). Setting: center for geriatric inpatient rehabilitation. Included were patients over 65 with mobility restrictions who were able to perform self-regulated exercise. Patients were assigned to self-regulated exercise using a) exergames on Windows Kinect® (exergame group EG) or b) instruction leaflets (conventional group CG). Physical therapists instructed self-regulated exercise to be conducted twice daily during thirty minutes during ten working days. Patients reported adherence (primary outcome), enjoyment and motivation daily. Balance during walking was measured blind with an accelerometer. Analysis was by intention to treat. Repeated measures mixed models and Cohen’s d effect sizes (ES, moderate if >0.5, large if >0.8) were used for between-group effects and effect sizes over time.

Results: We evaluated 217 patients and included and 54, 26 in the EG and 28 in the CG. Adverse effects were observed in two patients in the EG who stopped because of pain during exercising. Adherence was comparable at day one (38 min. in the EG and 42 min. in the CG) and significantly higher in the CG at day 10 (54 min. in the CG while decreasing to 28 min. in the EG, p=0.007, ES (0.94, 0.39–0.151). Benefits favoring the CG were also observed for enjoyment (p=0.001, ES 0.88, 0.32 – 1.44) and motivation (p=0.046, ES 0.59, 0.05–1.14). There was no between-group effect in balance during walking.

Conclusions: Self-regulated exercise using instruction leaflets is superior to exergames regarding adherence, enjoyment and motivation in a geriatric inpatient rehabilitation setting. Effects were moderate to large. There was no between group difference in balance during walking.

BELIEFS AND ATTITUDES OF ITALIAN NURSES TOWARDS PLACEBO AND NOCEBO RESPONSES INDUCED BY CONTEXTUAL FACTORS IN CLINICAL PRACTICE

M. Testa1, G. Rossetti1, T. Geri1, A. Viceconti1, L. Colloca2,3, A. Palese4,5

1Department of Neurosciences, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health, University of Genova, Savona, Italy; 2Department of Pain Translational Symptom Science, School of Nursing; 3Department of Anesthesiology, School of Medicine, University of Maryland, Baltimore, United States; 4Department of Medical and Biological Sciences, University of Udine, Udine, Italy

Background: Placebo and nocebo represent psycho-neuro-immuno-endocrinological responses commonly encountered in nursing care (1,2). A new paradigm proposed the contextual factors (CF) as mediators and moderators of these responses (3). To date, the knowledge about the awareness of CF and their use in nursing is scant.

Objectives: The goal of this study was to examine frequency of use, beliefs and attitudes of Italian specialised nurses regarding the contextual factors.

Methods: In December 2016, through SurveyMonkey Software®, an online survey was conducted by sending a questionnaire to the members of four Italian Nursing Association, grouping nurses specialized in Neuroscience, Medical, Geriatric and Diabetic care. Behaviours, beliefs and attitudes of nurses about the implementation of CF in clinical practice were assessed by a 17 items questionnaire and resulting data were analysed by descriptive statistic.

Results: Of the 1441 members of the involved Nursing Associations invited to participate to the survey 425 responded (30.1%). An high number of respondent nurses adopts CF often in their practice (42%). They believe that CF can positively influence acute pain (47.5%), chronic pain (61%) and rheumatologic disorders (42%), 34% of responders consider the use of CF, if it can determine beneficial psychological effects, as ethically acceptable. 15.5% responders oppose to the adoption of CF when based on deception or if they undermines trust between nurses and patients. A relevant number of nurses (24%) do not communicate the use of CF to their patients and 19% implement CF as addition to other nursing interventions to optimize clinical responses. Nurses explain the power of CF through patient’s expectation and psychological mechanism (11%).
Conclusions: The Italian specialised nurses use CF quite frequently and believe that their use has the capacity of positively influencing the clinical outcome. Larger surveys are needed to understand the proportion of use of CF by nurses in common clinical practice in Italy.

COULD WE USE THE LAY REFERRAL SYSTEM TO IMPROVE THE EARLY ARTHRITIS CLINIC EFFICIENCY?
M. Dobroiu1, M. Trandafir1, C. Ioan1, D. Vasile1, D. Predeteanu2, R. Ionescu 2

Background: The professional’s monopoly on knowledge about disease and its treatment is something gone now, in the era of internet and patient consumerism. In addition, the interest of rheumatologists (and the interest of the society, too) shifted toward early recognition of the disease and early arthritis clinics. Education is definitely one of the solutions to increase the awareness of potential patients regarding rheumatic disease. However, most of rheumatic diseases are not very frequent in the population that raise the problem of cost efficiency of the education process. Per Eliot Freidson’s view, the members of every community of whatever kind share some cultural understandings about disease, treatment, and cure. The lay community network could be considered an instrument for dissemination of proper knowledge regarding health and could help to earlier recognition of a sign of disease related to early arthritis.

Objectives: To identify the opportunity of using lay network for early arthritis referral. In addition, we intended to identify the most suitable vectors from this network to be used for education and dissemination of medical knowledge.

Methods: 48 rheumatic patients (mean age (SD): 50.8 (14.7)) consecutively declared between first sign of disease and professional examination, 71.7% use the professional’s referral. In addition, we intended to identify the most suitable vectors from this network to be used for education and dissemination of medical knowledge.

Results: In 28.3% cases the first sign of disease was noticed not by the patient but by somebody else, for 36.7% a delay of several months to one year was declared between first sign of disease and professional examination, 71.7% use to discuss bout health problems with their lay network (often and very often), 76.1% consider them able to give pertinent advices regarding the disease they suffer from, 45.7% are ready to act as an education vector and 41.3% are ready to participate in additional education programs. They interest in such activity is not related to gender, education level or work status.

Conclusions: Lay network referral could be a powerful instrument to reduce the duration between onset of rheumatic symptoms and medical visit, to increase the awareness regarding rheumatic disease, to reduce the cost of health education. Health professionals should understand how to use these networks.

A PROGRAM BASED ON PSYCHOEDUCATION FOR RHEUMATOID ARTHRITIS PATIENTS
P. Orquía1, L. Villarreal2, P. Santos-Moreno3, D. Buitrago-García4, G. Cajado5, A.M. Orozco6, Psychology and processes: 1Rheumatology; 2Epidemiology, Biobam, Center for Rheumatoid Arthritis, Bogota; 3Psychology, El Bosque University, Bogota, Colombia

Background: The National Institute of Arthritis and Musculoskeletal and Skin Diseases defines rheumatoid arthritis (RA) as a chronic disease that affects the joints, causing pain, swelling, stiffness, reduced mobility and affection of internal organs. In order to learn to accept and integrate the disease as a part of their daily life, it is important that they have enough information and knowledge about their health condition. The strategy of psychoeducation is important because it involves the patient actively and seeks to have specialist who provide relevant, clear, and comprehensive information. In this way, a change is generated at level of beliefs and myths on the disease, and suggests suggestions for coping with situations for the management of the disease's impact on the patient’s life.

Objectives: To determine the effect of a psychoeducation program on the quality of life and commitment to the treatment of patients diagnosed with RA from a specialized center in Bogotá.

Methods: We conducted a quasi-experimental study with two independent groups, one experimental and one for control. The Inclusion Criteria was: patients with RA over 30 years old that knew how to write and read with mobility resources. We excluded patients with emotional stress, stroke, and diagnosed cognitive deficit or with patients with consumption of psychotropic substance. We applied the Arthritis Visual Scale (EVA), a Quality of Life Questionnaire - Specific for patients with Rheumatoid Arthritis (QOL-RA). Data Analysis: when performing the normality test, the QOL-RA results were parametric and the analysis was performed with Student’s t test for independent measurements. On the other hand, the results of the EVA and QOR were non-parametric, for that reason we worked with the Mann Whitney U test.

Results: We included 36 patients, men (4) and women (32), aged between 35 and 75 years, with diagnosis of RA, which belong to the integral model of RA specialized center. The subjects that patients preferred were: Disease recognition, changes in lifestyle, training educational resources for self-care among others. Statistical analysis showed that, when we evaluated quality of life T-student test did not show any statistical differences between pre and post test results in both groups. The Man Whitney test showed statistical differences between groups (u=70,500, z=241,500, p<.004) regarding the compromise with the RA treatment, but it did not showed differences in regards of pain intensity between groups.

Conclusions: We recommend a strategy to facilitate the process of data collection in pre-test and post-test. For the next application of the program, it is suggested that the sample of patients must be increased, to increase the duration of each session and the number of sessions of the program. In order to achieve the patients’ attendance at the program, maintain permanent telephone contact (may be by telephone). To have printed or recorded material (Brochures, guides, CDs, etc.) is recommended with more relevant to each session of the program.

AB1226-HPR

VACCINATION COMPLIANCE IN AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES (AIRDs): ROLE OF SPECIALIST NURSE

Background: The patients with autoimmune inflammatory rheumatic diseases (AIRDs) have double the risk of infections as compared to the general population. This may be due to highly inflammatory nature of the disease, the drug used, and the co-morbidities. In recent years, the efficacy of vaccinations has been proven in decreasing morbidity and mortality among these patients, hence, it reduces the cost of the treatment and improves the quality of life of the patients. However, low vaccination compliance is a global problem. Therefore, in this study, we tried to assess the effect of nursing counselling on vaccinations compliance.

Objectives: To assess the efficacy of counseling by the specialist rheumatology nurses in vaccination compliance among AIRDs patients.

Methods: All the adult patients (>18yrs), suffering from AIRDs, were advised vaccinations between January to December 2016 were enrolled in this study. The basic demographic and disease-related data captured with details of vaccinations such as date of advice of vaccination and reasons for non-compliance were recorded. The patients were counselled by specialist nurses about the importance and needs of vaccination, clarifying their doubts. Reinforcement of the same was carried out in the follow-up visits.

Results: A total of 506 patients (374 female, 73.9.2% and 132 male, 26%), with mean age 48 years, of which 87.5% had rheumatoid arthritis, 76% (74.75%), Spondyloarthropathy: 80 (15.81%) other autoimmune rheumatic disease 48 (9.48%), Co-morbidities status: 309 (61%) having multiple co-morbidities and 197 (38.9%) have no co-morbidities. The vaccination compliance outcome is shown in table.

Conclusions: The compliance rate of all vaccinations was highest on the same day when it was prescribed. This was despite the fact that the patients that they had their own vaccinations without any third party payment. However, the compliance decreases with increase in the period when it was prescribed with the passage of time. This suggests that intensive counselling, availability of vaccines at premises (pharmacy) and administration of vaccination free of cost are a few of the important factors which can boost the compliance of the vaccination among patients with AIRDs.

Background: Osteomalacia is caused by a deficiency of vitamin D and can be corrected by changes in diet, lifestyle and supplementation. Consequently, it is a condition where education has a primary role in prevention.

Objectives: If educational interventions are to be developed and evaluated, then an instrument for measuring knowledge is required. This has led us to develop a novel Osteomalacia Knowledge Questionnaire (OKQ).

Methods: Based on nominal group technique, a steering group of people who are knowledgeable about osteomalacia, educational theory and questionnaire development was convened. The group decided to use true and false questions. Important areas of knowledge of osteomalacia were first determined by the group and then relevant statements which were true or false were written and grouped into 8 sections of 5 questions, each covering the different areas of knowledge. This resulted in a knowledge instrument with 40 questions in all. The questions were tested for utility and ambiguity in the group and modified and replaced accordingly.

The questionnaire was then trialled in 37 people of South Asian origin (an osteomalacia susceptible population), in three groups. Participants were initially administered the OKQ and then received an educational intervention comprising a practitioner led education session on osteomalacia, including a presentation and written or electronic material. Participants were re-tested with the OKQ after 6 weeks.

Although there is no “gold standard” for measuring knowledge about osteomalacia, if effective, increased knowledge should lead to an increase in vitamin D (Vit D) levels and a decrease in parathormone (Pth) levels. Vitamin D and Parathormone levels were measured alongside the OKQ in 2 of the groups before and after the educational intervention.

Results: Baseline knowledge about osteomalacia was low pre education averaging only 12.7 out of 40 (range 0–29) (n=27).

A total of 30 participants (81%) attended for the follow up test. They averaged a score of 13.9 at baseline and 23.4 at follow up. This was statistically significant (p=0.002 Mann Whitney) and demonstrated sensitivity to change of the OKQ.

Knowledge at baseline was correlated with vit D and Pth blood levels for two of the groups (n=27). This showed correlation coefficients of 0.128 and -0.407 respectively. For change of knowledge and change of parathormone (n=21) the r value was -0.324 suggesting a relationship between knowledge and Pth that is worthy of confirmation through further studies.

Conclusions: A novel questionnaire has been developed that has face validity and can be corrected by changes in diet, lifestyle and supplementation. Consequently, it is a condition where education has a primary role in prevention. Reduced in diet K in RA group was more pronounced for women. All patients tested normokalemic (mean serum K: 4.37 mEq/l). No meaningful correlation between diet components and disease measures (data not shown). Food avoidance patterns identified a-priori did not seem to impact disease measures (data not shown). 44% RA and 77% controls consumed vegetarian diet (excluding eggs). Patient dependence for diet recall and measure was the important limitation.

Conclusions: The diet of RA patients seemed adequate except for an intriguingly low K. We speculate that patients eat less vegetables and fruits that source K. K sub serves several physiological functions that may be deranged in RA and contribute to disease progression. This would need further investigation.

Acknowledgements: In contrary to our expectations and reassuringly, the diet of RA patients seemed adequate except for an intriguingly low potassium which should be investigated. We speculate that patients eat less vegetables and fruits that source K potassium.

EVALUATION OF RHEUMATOLOGY NURSE-LED CLINIC IN MANAGING PATIENTS WITH RHEUMATOID ARTHRITIS: A RETROSPECTIVE STUDY

Y.M.E. Leung1, K.Y. Wong2, L.S. Tam1, 1Department of Medicine and Therapeutics, Prince of Wales Hospital; 2School of Nursing, Hong Kong Polytechnic University, Hong Kong, Hong Kong

Background: Rheumatoid arthritis (RA) is a chronic, systemic, autoimmune disease characterized by inflammation of the synovial joints. Management of RA patients is usually provided by rheumatologists only. Enhanced care provided by rheumatology nurses between rheumatologist consultations may have beneficial effects in terms of symptom control. In Hong Kong, whether rheumatology nurse care model can favor to patient outcomes remained uncertain.

Objectives: The aim of the study was to examine the clinical effectiveness of rheumatology nurse clinic in controlling disease activity as expressed in change of Disease Activity Score in 28 joints in RA patients compared with usual care led by rheumatologists only.

Methods: This was a retrospective study. Two historical groups of RA patients (30 patients at each group) were identified from attendance records between 1/1/2015 and 20/7/2015 at the rheumatology outpatient clinics. Group 1 comprised of patients who attended rheumatology nurse clinic in between the doctor clinic and nurse clinic.

Results: The mean follow up duration for the study cohort was 20 weeks (median: 22.5 weeks). Patient global assessment and DAS 28 were similar for both groups at baseline. At follow-up, patient global assessment and in the nurse group (Group 1) decreased from mean ± SD: 42±24.7 at baseline to 28.7±24.8 at follow-up, and DAS28 decreased from mean ± SD: 3.7±15. With regards to DAS28, there was a 8.2% decrease (absolute change: -0.38±1.14) in DAS28 in group 1 suggesting a trend of improvement (p=0.081).

Conclusions: This study demonstrates the short-term benefit of a nurse-led program on RA disease management. Future multi-center studies with a randomized controlled design and a larger sample will be required to confirm our findings.
Background: Inflammatory arthritis strongly correlates with work disability. Treatment guidelines recommend work support but data are lacking on rheumatology clinicians’ perspectives on work referral and extent of work support within current rheumatology services for this population.

Objectives: To scope the need for and patterns of work referral, and examine the extent and type of work support currently available in Irish rheumatology services for people with inflammatory arthritis. To identify factors that help or hinder employment-related service provision. To explore the role of occupational therapy in addressing work with this population from the perspectives of the other members of the rheumatology team and current practices and challenges.

Methods: A questionnaire concerning work support provision was distributed via online survey to doctors, nurses and physiotherapists working in clinical rheumatology in Ireland.

Results: Response rate of 22% was achieved and total sample of 73 analysed. Respondents indicated that 71% of service users were of working age and the majority of respondents (85%) agreed that addressing employment-related service provision was within the remit of rheumatology services. Over half of respondent (55%) of respondents estimated that 25–49% of their caseload had work needs. Work was usually addressed if clients raised work concerns (94%), client reports work absenteeism (83%), client’s work involved manual component (75%). Barriers to addressing work included limited time in clinical setting (92%); unfamiliarity with best practice for work support (91%); lack of perceived competency to address work included limited time in clinical setting (92%); unfamiliarity with best practice for work support (91%); lack of perceived competency to address work; client’s work involved manual component (75%).

Conclusions: Work support provision was distributed via online survey to doctors, nurses and physiotherapists working in clinical rheumatology in Ireland.

DOI: 10.1136/annrheumdis-2017-eular.6236
hematoma formation increase following surgery. Therefore, propioprocitave acuity decrease after TKR surgery (1). Drainage is a common procedure in TKR, but its effectiveness is controversial. Some studies have claimed that drainage decreases the risk of articular effusion and hematoma formation. However, some studies have demonstrated that drainage increases postoperative blood loss and does not improve the surgical result (2). Several studies have examined the effects of using drainage, but they have not involved improvement in proprioception for patients who had drains compared with those who did not after TKR.

Objectives: The aim of this study was to compare the effect of the drainage on proprioception acuity impairments with total knee prosthesis.

Methods: The study group consisted of 34 patients (35 knees), 15
two TKR because of arthrosis were consecutively allocated to a drainage group (n=26 (41 knees), with median age; 66.23±8.63 years), and were allocated to a non-drainage group (n=14 (54 knees), with median age; 63.97±9.99 years).

Patients were evaluated regarding knee proprioception (in knee joint angle 15°, 30° and 60°), knee function score (Hospital for Special Surgery (HSS) score), pain (Numeric Pain Rating Scale (NPRS)), knee circumference, knee range of motion. Functional activities were evaluated using the Iowa Level of Assistance Scale and walking speed was evaluated using the Iowa Ambulation Velocity Scale. Patients were evaluated preoperatively and at discharge. All patients underwent the same rehabilitation program.

Results: At baseline, demographic and anthropometric characteristics were similar in groups and there was no statistically difference between groups (p>0.05). When knee proprioceptive acuity measurements (in knee joint angle 15°, 30° and 60°) were compared before and after surgery there was no statistical differences in proprioceptive acuity between groups (p>0.05). It was determined that; the drainage group had better results in terms of reduction of pain severity after surgery (p<0.001). When the HSS knee scores were compared there was statistically difference between groups (p<0.001) and the knee joint angles were lower in non-drainage group after surgery. There were no statistical differences in knee circumference, knee range of motion, the IOWA help level score and IOWA walking speed score between groups after TKR (p>0.05).

Conclusions: According to our results, the use of drainage did not improve the knee proprioceptive acuity impairments with TKR. But, it is suggested that using drainage decreases pain severity and improves the HSS knee score. Also the use of drains has no effect on patients’ outcomes after TKR, in terms of improvements knee range of motion, knee circumference, functional activities and walking speed.

AB1223-HPR COGNITIVE COMPLAINTS IN PATIENTS WITH ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS AND PAST NEUROPSYCHIATRIC SYMPTOMS

D. Ushva 1, D. Ivanova 2, J. Petrova 1, 1MU Sofia, Sofia, Bulgaria; 2Rheumatology, MU Sofia; 3Neurology, University Hospital Alexandria, Sofia, Bulgaria

Objectives: Cognitive complaints are common in patients with systemic lupus erythematosus (SLE). Their association with disease and non-disease related factors have been inconsistently reported. We studied their relation to disease related factors including disease activity, neuropsychiatric history and non-disease related factors such as anxiety or depression.

Methods: We used cognitive symptoms inventory (CSI) for measuring cognitive impairment at 3 time-points 12 months apart/2015–2016/ and Hospital Anxiety and Depression Scale (HADS)-HADS-A and D.Disease activity was measured by SLAM.

Results: 93 SLE patients were recruited at baseline (T0). Among them 59 had first re-evaluation (T1) and 34 had second re-evaluation (T2) at 12-month interval. Majority (72%, 24/34) of patients had stable CSI whereas 5.5% (2/34) of patients worsened CSI over 12 months. At T0, multivariate analysis revealed that higher CSI was associated with history of NPSLE (p=0.001), depression (p=0.04), higher HADS-A (p<0.001) and HADS-D (p=0.001) scores. CSI of active patients (SLEDAI–6) was not different from inactive patients. It did not change despite regression of disease activity in 12 months. There was no difference in CSI between T0 and T1 regardless of history of NPSLE, change in anxiety and depression at T1 (HADS-D≥11 as cutoff).Multivariate linear regression analysis revealed change in HADS-A as the only significant predictive factor of change in CSI over time (p=0.774, 95% CI 0.43 –1.12, p<0.001).

Conclusions: 11.5% of SLE patients reported persistent cognitive symptoms.CSI had worsened in patients with NPSLE and psychiatric illness, anxiety or depression.

AB1234-HPR PHYSOTHERAPY EFFECTS ON GAIT SPEED AND PAIN IN PATIENTS WITH KNEE OSTEOARTHRITIS THREE DAYS AFTER APPLYING KINESIOTAPE

K. Tani 1, I. Kola 2, F. Dhamaj 2, E. Qalliaj 1, K. Zallari 2. 1University of Medicine, Tirana, Albania; 2Faculty of Technical Medical Sciences, University of Medicine, Tirana, Albania

Background: Knee osteoarthritis is a chronic degenerative disease, known as the most common cause of difficulty walking in older adults and subsequently is associated with slow walking, also one of the most main symptoms is a degenerative and mechanical type of pain. Pain is very noticeable while walking in rugged terrain, during ascent and descent of stairs, when changing from sitting to standing position as well as staying in one position for a long time. Many studies have shown that the strength of the quadriceps femoris muscle can affect gait, by improving or weakening it. Kinesiotape is a physiotherapeutic technique, which reduces pain and increases muscular strength by irritating the skin receptors.

Objectives: The aims of this study was firstly to verify if the application of Kinesiotape on quadriceps femoris muscle increases gait speed in patients with knee osteoarthritis and secondly if applying Kinesiotape on quadriceps femoris muscle reduces pain while walking.

Methods: 73 patients with primary knee osteoarthritis, aged 50–73 years, participated in this study. Firstly we observed the change of gait speed, while walking for 10 meters at normal speed for each patient, before and three days after the application of Kinesiotape on quadriceps femoris muscle, with the help of the 10-meter walk test. Secondly we observed the change of the pain, while walking for 10 meters at normal speed for each patient, before and three days after the application, with the help of Numerical Pain Rating Scale-NRS.

Results: Our results indicated that there was a significant increase of gait speed while walking for 10 meters one day and also three days after application of Kinesiotape, also there was a significant change of pain. Before applying Kinesiotape on quadriceps muscle was shown that 41.1% chose score 6, 30.1% chose score 7 and 28.8% chose score 8 of the numerical pain rating scale. Three days after the application 15.1% chose score 2, 37% chose score 3 and 47.9% chose score 4 of numerical pain rating scale.

Conclusions: Our results indicated that there was a significant decrease of pain and increase of gait speed while walking for 10 meters. Kinesio-Tape can be used in patients with knee osteoarthritis, especially when changing walking stereotypes is a long term goal of the treatment.

AB1235-HPR SEXUAL DISTURBANCES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND IT'S RELATION WITH DISEASE ACTIVITY

L. Villarreal 1, S. Henao 2, D. Buitrago-Garcia 3, P. Santos-Moreno 4, 1Psychology and processes; 2Patient service; 3Epidemiology; 4Rheumatology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia

Background: Sexuality is an important dimension of personality and human body, therefore any involvement in this area should be considered as important. Sexual disturbances in rheumatoid arthritis (RA) patients are poorly described in literature. In other chronic conditions studies had shown that sexual disturbances can be common problem in but, sexual dysfunction has a high risk of under treatment because providers frequently do not initiate the conversation with the patient.

Objectives: The purpose of this study was to describe sexual disturbances in
a meaningful relationship between functional ability and disease activity in a specialized rheumatology center.

**Methods:** A descriptive cross-sectional study was performed in a specialized clinic dedicated to care patients with rheumatoid arthritis (RA). Data was collected during a two year period at a psychology consultation, through semi-structured interviews. Descriptive epidemiology was applied for continuous variables, using measures of central tendency and dispersion for categorical and qualitative variables by averages and percentages. We analyzed bivariate association with Pearson’s X².

**Results:** We included 1398 patients attending to our psychology consultation. Mean age was 55 years ± 8; 80% were female and 20% male. Mean DAS28 was 2.6±1.3, mean HAQ was 1.6±1.6; patients had the disease for an average of 12 years ± 8; 41% of patients had comorbidities associated with non-autoimmune disease, 14% comorbidities related to autoimmune disease; 35% of our patients did not report any specific comorbidities. Most of patients were married 50%, followed by divorced 19%, single 14% and widowed 7%. Regarding occupation 33% were employees, 25% were housekeepers or retired due to age, 12% were retired due to disabilities, and 3% unemployed. Of the total population 45% had elementary school, 32% high school, 8% college education, 7% graduate education and 7% were illiterate. Concerning sexual disorders, 38% reported no to have any sexual activity, 32% reported to have a satisfactory sexual life, 11% dyspareunia, 9% had an unsatisfactory sexual life, 5% loss of desire, 3% premature ejaculation and 2% orgasmic decrease. Regarding predisposing factors of sexual disorders 63% of our population did not present any, 11% had insecurity related to the sexual role, 10% inadequate information related to sexuality; 10% infidelity and 6% physical and biological predisposing factors. Regarding precipitant factors of sexual disorders 63% report no to have any, 19% had biological or physical factors, 12% infidelity, 3% inadequate information and 3% insecurity related to the sexual role. There was no statistical association between disease activity and predisposing or precipitant factors.

**Conclusions:** We found that a third of patients with RA have sexual disorders and a high percentage reported not having any sexual activity. Also, it is important to have a multidisciplinary care team for the patient with RA, including a psychologist and a sexologist for managing this kind of illness in order to improve the life quality of patients.

Respondents of our study described their functional ability good by the average of the entire sample 2.06. This value shows us a relatively good functional ability of patients most days or very often. Patients had some problems with function of hand and wrist in particular by opening jars (43%) and on area walking and bending with intensive activity (42%). Correlation between functional ability and socio-demographic data show us some statistical deviation in age group 41 to 50 year (p=0.94), in patients with higher education level (p=0.09) and in group of patients who monthly earns more than 900 € (p=0.96). But we didn’t find any statistically significant difference in the entire sample including patients treated with biological drugs (functional ability patients and control: results of a cross-sectional pilot study. **CONNEXION BETWEEN FUNCTIONAL ABILITY AND SOCIO-DEMOGRAPHIC DATA IN PATIENTS WITH RA IN SLOVENIA**

M. Pavic Nikolic, S. Kosir Jost. Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia

**Background:** Rheumatoid arthritis (RA) is the most common chronic inflammatory arthritis, characterized by progressive, destructive course when left untreated, resulting in severe patient disability and significantly reduced quality of life. RA has an important impact on work ability and economic status of patients.

**Objectives:** In our study we focused on specific consequences of arthritis in terms of functional ability and we were looking for correlation with socio-demographic data.

**Methods:** The study was conducted between January 2016 and May 2016 at the Department of Rheumatology, UMC Ljubljana and included patients with RA. Data were collected using Arthritis Impact Measurement Scales 2 (AIMS2) questionnaire.

**Results:** One hundred RA patients (76% women, mean age (SD) of 61.1±15.29 years) participated in the study. Disease duration was ± 5.6 year. Most of our patients were married, retired with elementary education and lower incomes (Table1).

**Conclusions:** We found fairly good functional ability of patients; which might be explained by relatively short duration of RA. The most important functional-related issues from patient perspective were identified. Despite that we not find a statistically significant relationship between socio-demographic data and functional ability of patients, it is very important that we pay attention on socially unprivileged patients and we offer our support in managing disease.

**POSTURAL STABILITY AND ANKLE PROPRIOPCEPTION IN DIFFERENT SUBGROUPS OF SUBJECTS WITH HALLUX VALGUS**

O. Aydoğdu, Z. San, G.M. Polat. Physiotherapy and Rehabilitation, Marmara University, Health Sciences Faculty, Istanbul, Turkey

**Background:** Hallux valgus (HV) is lateral deviation of the great toe towards the second with subluxation of the first metatarsophalangeal joint and medial deviation of the second metatarsophalangeal joint. Increasing HV severity has been shown to negatively impact on health-related quality of life and self-reported function, and HV has been linked to increased falls risk in older adults (2). HV, in particular, is associated with poorer performance during postural stability and functional testing in older adults (3).

**Objectives:** Despite the findings of impaired postural stability in older adults with hallux valgus, the links between functional status and postural stability, ankle proprioception are not well established in HV. One of clinical significance of this study was to determine whether impaired postural stability was caused by deficits in ankle proprioception and impaired functional status in HV subjects. Our purpose of this study was to assess postural stability and ankle proprioception in different subgroups of HV. In this study, we hypothesized that subjects with severe deformity would exhibit poorer postural stability and ankle proprioception performance compared to subjects with mild and moderate deformity in HV.

**Methods:** Thirty-five adults diagnosed with unilateral HV according to the Manchester Oxford Foot Questionnaire deformation grade 2 and on were participated in the study. They were distributed among three groups: Mild (grade 2), moderate (grade 3), and severe deformity (grade 4). Functional status was measured with a disease specific score (the hallux valgus scale of the American Orthopaedic Foot and Ankle Society). While postural stability was measured with Pedalo Sensamove® System, ankle proprioception was measured with Biodex Balance System Pro 4.

**Results:** Subjects in HV with severe deformity group showed poorer postural stability performance than groups in HV mild (p=0.024) and moderate (p=0.039) deformity groups. However, there was no significant difference between the groups in ankle proprioception. There was a significant correlation between postural stability and functional status (p<0.05, r=0.771) in all subjects with HV. In addition, it was found that ankle proprioception was not correlated to functional status and postural stability (p>0.05).

**Conclusions:** It has been concluded that HV with severe deformity affects postural stability according to the results of our study. On the other hand, ankle proprioception is not as an important predictor as postural stability for rehabilitation in different subgroups of HV. Therefore subjects in HV with severe deformity should be focused on stability exercises, in particular, in addition to home – based exercise programs, foot orthoses, footwear recommendations, and patient education in their rehabilitation.

**PEOPLE’S PERCEPTIONS OF THEIR PHONE CALL WITH RHEUMA DIRECTLY, A RHEUMATIC DISEASES HELPLINE**

S. Arvidsson 1, 2, M. Nylander 1, S. Bergman 1, 2, 3.

1School of Health and Welfare, Halmstads Universitet, 2Spenshult Research and Development Centre, Halmstad; 3The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

**Background:** Information on rheumatic diseases is often complex to understand or scary, and additional support is often necessary. Rheuma Directly (RD) is a helpline with working nurses on rheumatic diseases, funded by the Swedish Rheumatism Association and Spenshult Research and Development Centre. Little is known of how people calling a helpline perceive the contact.

**Objectives:** To describe the variation in how people perceive the contact with the helpline RD.

**Methods:** The study had a descriptive, qualitative design with a phenomenographic approach and was carried out by means of 27 semi-structured telephone interviews. The informants were 22 female and 5 men, and their ages ranged from 22 to 69 years (mean 54 years).

**Results:** The informants called RD when they had problems getting answers

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2017-eular.2524
to their questions through the Internet or from healthcare professionals. Three different description categories emerged: Specific competence, Constructive dialogue, and Applicability. The informants’ perceived specific competence when the nurses were knowledgeable, the call was complementary to previously received information and when the informants had greater knowledge after the consultation. It was considered that it was worth to continue to have Constructive dialogue when they got someone to discuss with, a “sounding board”, and perceived emotional support, felt reassured and were satisfied with the answer. The informants perceived Applicability because RD was available and they could make different choices according to their own desire, before (how and when they would contact RD), during (what to tell and when the question they would ask) and after (how and what they would do after the contact with RD).

Conclusions: People calling RD perceived that the telephone call with the nurses meant meeting specific competence, gaining constructive dialogue and that the helpline was applicable. This knowledge ad to a fuller understanding of factors that from a callers perspective, are important when calling a helpline with specially trained nurses on rheumatic diseases.

FATIGUE AT DIAGNOSIS OF INFLAMMATORY JOINT DISEASES - A PREDICTOR OF FATIGUE DURING THE COURSE OF DISEASE DESPITE OF LOW DISEASE ACTIVITY

S.H. Jakobsen, A. Esmaili, S.M.J. Hansen. Rheumatology, OUH, Svendborg Hospital, Svendborg, Denmark

Background: Fatigue is a common symptom in patients suffering from inflammatory rheumatic diseases. Several patients still present with fatigue, although they are well treated with anti-TNF-therapy (1).

Objectives: To investigate disease-related aspects of fatigue in patients with inflammatory rheumatic diseases using the Functional Assessment of Chronic Illness Therapy-Fatigue (FACT-F) with the aim later to develop methods to improve the patients quality of life in a more specific way.

Methods: All patients with inflammatory diseases including Rheumatoid Arthritis (38) and Spondyloarthropathy (15) and Psoriatic arthritis (2) treated with Intravenous biologic from 15.10 until 31.12.16 were invited to fill out the FACT-F questionnaire during intravenous (IV) infusion of the drugs in the rheumatology outpatient clinic. Furthermore hemoglobin and disease activity score were extracted from patients electronic records.

Results: Of 72 patients, 53 patients completed the questionnaire. 5 patients did not want to participate. In 11 patients treatment was discontinued during the study and 3 patients were not able to answer the questions.

Patients with a fatigue score of >30 had few problems with any of the subgroups within the FACT-F questionnaire (A-E), whereas more than 30% of patients with a fatigue score of >30 had challenges in one of the FACT-F subgroups (somewhat, quite a bit and very much) A. Physical well-being: lack of energy and troubles with meeting the needs of their family because of their physical condition. B. Social/family well-being: patients were not feeling close to their friends, not getting enough emotional support from their family and not satisfied with the emotional support they received. C. Emotional well-being: patients worry if their conditions might get worse. D. Functional well-being: patients feel they are partly unable to work, not satisfied with their performance at work and they have sleeping and quality of life problems. E. Additional concerns: patients had problems with fatigue, weakness, tiredness, starting and finishing things because of tiredness, not having energy, not being able to do usual activities, frustration by being too tired to do the things they want to do as well as they want to limit social activities because of tiredness and they need to sleep during the day. Furthermore, there was a moderate correlation between fatigue at diagnosis and fatigue at time of data extraction (r =0.53). The fatigue was not correlated with anaemia or high disease activity.

Conclusions: Our results demonstrated that patients with a fatigue score of >30 had different challenges mentioned in the fatigue questionnaire. In addition, patients who experience fatigue at time of diagnosis, they often remain fatigue, proving fatigue is not correlated with inflammatory joint disease. Maybe more explorative questions about fatigue at the consultation could be a part of improving the patients’ quality of life.

PATIENTS’ DOGMA, NUMBER OF SWOLLEN JOINTS AND PHYSICIANS’ AND PATIENTS’ AGE PREDICT NON-ADHERENCE TO MEDICATIONS AND NON-PHARMACOLOGICAL INTERVENTIONS IN RHEUMATOID ARTHRITIS – A MIXED METHODS STUDY

V. Ritschl1, A. Lackner2, C. Boström3, M. Kundi4, P. Studenic5, J. Smolen3, T. Slamm3,1. Institute of Outcomes Research, Center for Medical Statistics, Informatics, and Intelligent Systems, Medical University of Vienna, Vienna; 2Department of Rheumatology, Medical University of Graz, Graz, Austria; 3Department of Neurobiology, Karolinska Institute, Huddinge, Sweden; 4Institute of Environmental Health, Center for Public Health; 5Division of Rheumatology, Department of Medicine 3, Medical University of Vienna, Vienna, Austria

Background: In rheumatoid arthritis (RA), up to 80% of patients were found to be non-adherent to prescribed medication and non-pharmacological recommendations. These patients do not achieve an optimal clinical outcome.

Objectives: In the present study, we therefore explored predictors that may lead to non-adherence to both medicines and/or non-pharmacological recommendations. Methods: In a mixed methods study, retrospective observational data from patients meeting the ACR/EULAR criteria for RA who were non-attenders/missed the routine check up visits for at least 9 months to the rheumatology clinic and had had an initial DMARD therapy were queried of the databases of two rheumatology centers in Austria (Graz, Vienna). Subsequently, we invited all patients to take part in a qualitative semi-structured interview study with a meaning condensation data analysis. In the interviews, patients were assigned to the subgroups “adherent” (e.g. having regular rheumatology visits in another clinic) or “non-adherent” (e.g. having stopped taking the prescribed medication). Possible predictors derived from the qualitative analysis and the retrospective observational data were then tested in a logistic regression model.

Results: In total, data of 459 patients (346 [75.4%] females; mean age 63.0 [SD ± 14.8]) were extracted out of the databases. 131 patients (109 [83.2%] females; mean age 64.8 [SD ± 14.1]) participated in the qualitative interviews. In addition to already known themes, new topics arose from the analysis: (i) patient’s disease inhibited adherent behavior, in that patients felt that pain was an important part of life and attributed to having had a high manual workload during life of which patients were proud; (ii) patients had less trust in physicians when they were seeking support from other physicians, because they appeared to be “young or inexperienced”; (iii) Some patients did not feel properly understood if physicians only prescribed medication without giving advice on non-pharmacological aspects of treatment.

Two clinical variables were found to be predictors for non-adherent behavior (table 1): swollen joint count (patients with higher numbers of swollen joints were less adherent) and age (younger patients were less adherent).

Table 1. Logistic regression models. Odds ratios of relevant factors for non-adherent behavior in RA: results of the logistic regression analysis

<table>
<thead>

Conclusions: In order to achieve a good clinical outcome, it is important to provide evidence based treatment recommendations, but also to ensure adherence to these. The predictors found in our study could be used to enhance patient adherence and therefore improve clinical outcome.

EVALUATION OF PATIENT COMPLIANCE WITH LONG TERM PRESCRIBED RHEUMATIC MEDICATION AT LOCAL LONDON HOSPITAL RHEUMATOLOGY UNIT

V. Sodhi, C.B. Coelho, M. Hoffman, J. Kirk on behalf of Central Middlesex Hospital Rheumatology (Patient) Support Group. LNWHT, London, United Kingdom

Background: Non-Compliance with Long term medication is reported as high 60% [1]. Health belief model suggests four elements contribute to this problem. The Beliefs About Medicines Questionnaire (BMQ) is a tool for evaluating people’s beliefs about medicines (1).

Objectives: A Service Evaluation of compliance with prescribed medication for Long Term Rheumatologic Conditions at Central Middlesex Hospital. This was conducted to assess any relationship between compliance with medicines and beliefs or concerns of patient’s ethnicity.

Methods: The design was a voluntary self-reported, cross-sectional paper based questionnaire survey of people with Rheumatic Conditions. Twelve questions were grouped within three categories (healthcare utilisation, necessity beliefs and concern beliefs) to capture compliance behaviour for later analysis and comparison.

The Beliefs about Medicines Questionnaire was adapted from ref (1) to distinguish patients beliefs of ‘necessity’ or ‘concerns’. In line with principles of PPH, the questionnaire was discussed prior to the audit with a sample focus group of 5
patients who contributed to the wording and the simplification of the questions re: ethnicity.

Questionnaires were offered to all patients attending the CMH Rheumatology Unit. The evaluation was discontinued when a target of 100 was reached (n=102). No questionnaires were excluded. And up to 5% of questions were unanswered. Data was collected on a voluntary basis.

Results: The Number of questionnaires returned for this service evaluation was 102.

- Most respondents (94%) showed compliance with rheumatic medication as prescribed.
- More than half the respondents (66%) agreed or strongly agreed that their arthritis medications are necessary for their health.
- 54% were concerned about potential adverse consequences.
- The overall necessity score (19.32 S.D. 3.17) was higher than the concerns score (13.48 S.D. 3.35).1, 61.57, P =0.001.
- Concerns about the long-term effect of rheumatic conditions correlate positively with perceptions of health in the future P < 0.01 level (2-tailed Pearson).
- No significant correlation was found between compliance and patient's ethnicity/individual demographics.

Conclusions: Most people with Rheumatic conditions have positive beliefs about the necessity of their medication. However, levels of concern are high, especially towards the long-term effects of the medication. This concurs with a similar study in Rheumatoid Arthritis.(2). The service evaluation using the Beliefs about Medicines Questionnaire has helped to identify people at risk of poor compliance locally. This illustrates a need to discuss patients' beliefs and concerns in targeted drug counseling sessions with specialist nurses. A post study patient focus group recognised the high level of compliance yet recommended a fixed weekly walk in session with a nurse and pharmacist to sustain this high quality outcome. Further methods of continued patient re-education will be explored.

HPR service developments, innovation and economics in healthcare

Ab1242-HPR NUMERICAL PREDICTION OF THE OPTIMUM SHEET METAL THICKNESS Implanted as the JOINT CARTILAGE

M. Moayedfar, A.M. Rani, H. Hanaei. Mechanical Engineering, Universiti Teknologi Petronas, Bandar Seri Iskandar, Malaysia.

Background: The combination of computer-aided-design (CAD), digital image processing techniques and finite element method (FEM) has been successfully employed to create the customized distal condyle implants in human joints during arthroplasty surgery when the manufacturing method is incremental sheet forming (ISF) technique. However, due to the high time of process in the FEM analysing of human joints, finding the optimum material thickness with respect to the joint cartilage has been neglected.

Objectives: To apply a numerical investigation based on the FEM to predict and propose the sheet metal thickness for joint cartilage in the ISF process in a timely method for the human knee as a case study.

Methods: To reduce the expense of experiments and save the time of production, a numerical investigation method based on FEM is designed for the ISF. The user subroutine is employed to navigate the tool motion and material behaviour for reducing the time of simulation in the analysing tool. Hence, the sequence of FEM process was as follows: 1) Create the geometric model of the clamping system and sheet metal. 2) Choosing associated nodes together with Shell elements to increase the accuracy of the simulation and simplify the process. 3) Applying the specifications of every element. 4) Assign and render the material properties for sheet metal. 5) Apply the initial boundary conditions. 6) Assigning the asymmetric boundary conditions using the subroutine for time reduction purpose. 7) Apply the loads related to the complete FEM. Consequently, the proper thickness from MRI based on the previous study is sent to the CAD system for the mechanical and anatomical modification.

Sheet metal thickness and also material selection were based on the joint mechanical properties, shape and size. Therefore, by using the optimum pressure profile, the FEM can be performed to predict the sheet stretch and also shear failure to illuminate the optimum sheet thickness used in customized medical implants.

Results: The result of this study is based on the validation of predicted sheet thickness with the real patient cartilage thickness. This result showed a good agreement with the hospital data (for cartilage thickness of −2.20mm) and simulation result (~2.23mm for sheet thickness). It was not possible to divide the model into some sections and only analyse one particular part as a sample.

Therefore, the time of calculation was 23 hours for FEM when a high-performance computer was used. Regarding the same issue, the mesh was not uniform distributed so the time of analysing for each particular location was not the similar and predictable. The shear failure happens on the edge of design and also some locations that a turning point existed.

Conclusions: A numerical simulation is required to predict the material thickness replaced with the joint cartilage. Thus, the mathematical solution is investigated to predict the sheet thickness in the customized production process. Therefore, the result showed 98.5% similarity thickness of sheet metal with cartilage.

[2] B. Huzjan, Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia

Background: The use of information and communication technology (ICT) in occupational therapy should allow management of chronic diseases by providing support programs in education including the use of multimedia services.

Objectives: In order to determine the presence of information and communication technologies use in the options of telerehabilitation, a survey was conducted 224 newly diagnosed patients with rheumatoid arthritis (RA).

Methods: The quantitative research approach was used with the newly created patients with RA treated on Department of Rheumatology at the University Medical Centre Ljubljana. The questionnaire included basic demographic information and questions about the use extent and possibilities for using ICT. The population also accounted for patients with RA diagnosed between 1 January 2014 and 31 December 2015. The data obtained was statistically analysed with the SPSS program IMB 20. The total of 64 survey questionnaires were completed, which represents 28% of the selected population.

Results: 23.4% RA patients don’t use internet. 48.4% RA patients use personal computers (PC), and 51.6% patients use smart phones. 35.3% of patients that use PC use it for e-mailing, searching health information (35.4%), video calls (13.3%) and sending messages (15%). Patients who use smart phones use them for calls (31.9%), texting and calls (26.7%), e-mailing (25%), searching health information (12.9%), and video calls (3.4%). There is a positive correlation between the use of modern ICT and the opinion that the interviewed patients would use telerehabilitation services during their rehabilitation. Pearson correlation coefficients are statistically significant with all the ICT. With using a PC (r =0.602) and smartphones (r =0.542) there is a medium strong positive correlation Positive coefficients indicate that the surveyed patients who are increasingly using ICT think they could help themselves with telerehabilitation. Increased frequency of ICT usage is associated with potentially greater possibility of using telerehabilitation.

Conclusions: The need for rapid access and exchange of information is the main reason for the use of information and communication technologies in healthcare, and is conditional for the development of e-health. Research provided answers questions about the possibilities of using information and communication technology and rehabilitation services at a distance – telerehabilitation in occupational therapy.

Ab1243-HPR USING INFORMATION-COMMUNICATION TECHNOLOGIES AND OPPORTUNITIES FOR TELEREHABILITATION IN OCCUPATIONAL THERAPY

E. Fjerstad 1, R.H. Moe 2, 3, S. Nymo 4, T. Berge 5

1. Enhet för psykiske helsetjenester i somatikken, Diakonhjemmet Hospital, Oslo, Norway; 2. Rheumatology, NKRR, Diakonhjemmet Hospital, Oslo, Norway; 3. RHEUMATOLGY, NKBRR, Diakonhjemmet Hospital, Oslo, Norway; 4. Drammen Hospital, Drammengata 28, 3004 Drammen, Drammen; 5. Enhet för psykiske helsetjenester somatikken, Diakonhjemmet Hospital, Oslo, Norway

Background: Fatigue is reported to be a common symptom in people with inflammatory rheumatic diseases. It is a complex symptom, characterized by an individual interplay of biopsychosocial factors that has been associated with different factors such as: pain, sleep problems, depression, fatigue. Pain and psychosocial factors like depression.

Objectives: The main objective was to contribute to improved coping and quality of life in people with inflammatory rheumatic disease and fatigue. Cognitive therapy is one of the common psychological interventions used in the rehabilitation...
of people with rheumatic diseases and fatigue. The current intervention was developed as a supplement to medical treatment to strengthen coping and quality of life, and reducing fatigue, depression and pain.

Methods: People with inflammatory rheumatic diseases and fatigue were recruited for 6–9 sessions of cognitive therapy sessions, in addition to treatment as usual at a rheumatology outpatient clinic in Norway. The intervention aimed at reducing fatigue, depression and pain, consisted of four main elements: understanding fatigue, assessment and activity planning, mental and cognitive self-help skills.

Results: This pilot project recruited 40 people with inflammatory rheumatic disease from a rheumatologic outpatient clinic in Norway. Participants had a disease duration of mean 14 years, they were mainly women (n=36) with a mean age of 45 (Standard Deviation =10) years (Table 1). Repeated ANOVA analyses and Paired t-tests showed promising statistically significant changes on a group level for fatigue and depression, not for pain (Table 2).

Conclusions: This pilot project supports the idea of conducting a trial on the effectiveness of a brief cognitive therapy intervention for people with inflammatory rheumatic diseases and fatigue. ANOVA analyses and Paired t-tests showed promising statistically significant changes on a group level for fatigue and depression, but not for pain, whether these changes are clinically meaningful, and if there is a difference, compared to treatment as usual remains to be explored.

Acknowledgements: This project would not have been possible without the support from the national patient organization, through a grant from the Norwegian ExtraFoundation for Health and Rehabilitation. We acknowledge patients who contributed to this project and the staff at the rheumatological outpatient clinic at Diakonhjemmet Hospital.

AB1245-HPR NEW HEALTH TECHNOLOGIES AND LIFESTYLE MANAGEMENT FOR PATIENTS WITH OSTEARTHRITIS

M. Loiskandl1, H. Ritschl2, T. Stamm1, G. Steiner1, J. Smolen1, D. Aletaha1.
1Rheumatology, Medical University of Vienna, Vienna; 2Joanneum, University of Applied Sciences, Graz, Austria

Background: Osteoarthritis (OA) is one of the most common chronic diseases of the elderly worldwide. It represents significant impairments in terms of quality of life [1]. It notably affects self-care-tasks, body-image, self-esteem, well-being, social-activities and relationships. A wide-ranged field of therapy concepts exist. Medication is often one part, but it cannot solve other existing problems due to OA [2]. The demographic trends combined with the growth of mobile devices among the older population suggest that using digital devices, as a platform for health care services, is a promising option. OA patients and (B) to evaluate existing health applications. The demographic trends combined with the growth of mobile devices among the older population suggest that using digital devices, as a platform for health care services, is a promising option.

Methods: The areas most commonly found were disease- and treatment information (n=23), social support regarding the level of patient empowerment [4], self-management, social-activities and relationships. A wide-ranged field of therapy concepts exist.

Results: This study included 40 people with inflammatory rheumatic disease from a rheumatologic outpatient clinic in Norway. The intervention aimed at reducing fatigue, depression and pain, consisted of four main elements: understanding fatigue, assessment and activity planning, mental and cognitive self-help skills. The project was developed, and data collected at the rheumatology outpatient clinic at Diakonhjemmet Hospital in 2014–2016.

Conclusions: The areas most commonly found were disease- and treatment information (n=23), social support regarding the level of patient empowerment [4], self-management, social-activities and relationships. A wide-ranged field of therapy concepts exist.

HPR professional education, training and competencies

AB1247-HPR AN INTEGRATED APPROACH TO CUSTOMIZED MEDICAL FEMORAL COMPONENT PRODUCTION TO MINIMIZE THE CONDYLERT CUT OFF DURING THE TKA

M. Moayedtalar, A. M. Abdul Rani, Mechanical Engineering, Universiti Teknologi Petronas, Bandar Seri Iskandar, Malaysia

Background: To prepare the femoral component during the Total knee arthroplasty (TKA), it is needed to cut off the damaged condyle to a dimension matched with one of the available implant sizes in the market. Since there is a variety of humans’ knee size and shape, therefore, some parts of the distal femoral are over cut. This problem is to customisation of the implants via a cohesive procedure specifically designed for medical orthopaedic implant production. Objectives: This research aims to provide a fully integrated system of digital image processing of Magnetic Resonance Imaging (MRI) data and Finite Element Method (FEM) for testing and analysing prior to manufacturing of customized medical femoral component. Methods: An automatic algorithm to segment MR images from end-of-femur condyle is developed and employed for 3D reconstruction followed by computer-aided design (CAD) system, FEM and incremental sheet forming (ISF) process. In femur segmentation, multi-resolution edge detection is applied that extracts all the edges at bone surfaces. The edge detection process followed by the selection and extraction of strong edges with enhanced active contour technique that results in separation between femur and tibia components. Morphological processing is applied for creating a solid part and solid body. The Proper femoral component is designed using region growing technique then exported to FEM system to calculate the best metal thickness and angles, regarding the normal cartilage, to bear the maximum load with the lighter material. The process of ISF that involves machining and sheet forming parameters is using to manufacture customized medical metal femoral component but in low surface quality which increases the risk of ion release at in vivo condition. Therefore, during this technique, optimum parameters using Design of Experiment method are applied to modify and enhance the sheet stretching of final parts. Results: The integrated system demonstrates a cohesive user-friendly system for creation of patients specific implants while it showed a substantial reduction in implant production time compares to the current manufacturing method. In ISF process optimum parameters are used to increase the rate of stretching together with the best sheet thickness ~2.5 mm based on validated sheet stretching simulation. The results of this study also show that the high surface quality for femoral component up to ~Ra 2.527 is achievable using this newly developed method. Conclusions: An integrated system that combines computational method, CAD, FEM and ISF procedure is developed that shows its potential for manufacturing of customized medical femoral component. Flexibility in size and shape make this system prominent. The best sheet thickness with respect to the cartilage thickness is calculated and obtained with the optimum process parameters for manufacturing section.

Acknowledgments: The authors are thankful to the Ministry of Higher Education, Malaysia for supporting this research via FRGS/1/2014/TK01/UTP/02/8 research grant.

AB1249-HPR THE EFFECT OF TASK ORIENTED TRAINING ON FUNCTIONALITY, DEXTERITY AND ADL PERFORMANCE IN RHEUMATOID ARTHRITIS

O.F. Özçepel 1, E.I. Üstün 2, Z.C. Algun 3, 1 Prosthetics Orthotics Research Center, Istanbul Medipol University; 2Physical Therapy and Rehabilitation, Bağcılar Education and Research Hospital; 3Orthotics and Prosthetics, Istanbul Medipol University, Istanbul, Turkey

Background: Rheumatoid arthritis is the most common and most serious of the inflammatory arthropitides, and it dominates clinical rheumatological practice (1). This inflammation leads gradually to a destruction of bone and cartilage, responsible for loss of function (2). The main goals of treatment for RA are to prevent or control joint damage, prevent loss of function, and decrease pain (3).

Objectives: The purpose of the study is to investigate the effect of task oriented training on functionality, dexterity and ADL performance in rheumatic hands. Also the other goal of this study is to bring a new perspective to RA rehabilitation.

Methods: Thirty seven women (16 patients in control group and 17 patients in study group) performed therapy programme. Control group received hand exercise therapy (MCP, DIP,PIP mobilization, range of motion exercise, isometric exercise), and study group received both hand exercise therapy and task oriented training (fork use, drinking water with a glass, face washing, sit up-stand up and t-shirt wearing) twice a week for 5 weeks. Every therapy sessions took 40–45 minutes for study group and 20–25 minutes for control group. According to the patient’s condition, the rest interval was given and it was said that the exercises should be done too three times a day. The results were evaluated with therapy programme with Jamar Hand Dynamometer, Nine Hole Peg Test, Health Assessment Questionnaire and Duruöz Hand Index.

Results: Age distribution of participants was 49, 57 (p<0.005) and were found to be homogeneously dispersed (p<0.15). Hand grip strength was not statistically
significant, although it increased in both groups except left hand grip strength which was decreased after the program (control group: $r=0.552$ (right hand), $p=0.066$ (left hand)/study group: $p=0.136$ (right hand), $p=0.723$ (left hand)). The NHP showed a decrease in the duration of the test within both groups, but this decrease was not statistically significant (control group: $p=0.113$ (right hand), $p=0.265$ (left hand)/study group: $p=0.215$ (right hand), $p=0.291$ (left hand). The HAQ showed a statistically significant decrease in both groups (control group: $p=0.001$/study group: $p=0.01$). Although DHI decreased in both groups, the decrease in the study group was not statistically significant (control group: $p=0.003$/study group: $p=0.440$). Treatment efficacy between groups after treatment was evaluated by Independent-t test and change in parameters other than HAQ and DHI was not statistically significant.

**Conclusions:** Hand exercise program and task oriented training are safe methods that can be used to increase the grip strengths of patients with rheumatoid arthritis, daily life activities and hand skills. The statistical significance of the results may be due to the low number of patients. We assume that this study can be done in a larger sample, the effect of task-oriented training on patients with rheumatoid arthritis will be better.

**GROWING STRONGER TOGETHER: IMPLEMENTING EULAR YOUNG PARE’S STRATEGY**

J. Andersen1,2,3, P. Balazova1,4,5, P. Boyd1,6, W. C. Olsen1,7, S. Ostuzzi1,8, T. Wilhelmer1,12, L. Van Nieuwkoop7, N. Caeyers4,13, F. Klett14.

1EULAR Young PARE, Zurich, Switzerland; 2Lupus Europe, London, United Kingdom; 3State University of Novi Pazar, Novi Pazar, Serbia; 4Clinical Health Centre, Vranje, Serbia; 5Faculty of Medical Science, University of Novi Pazar, Vranje, Serbia; 6Oxford NIHR Biomedical Research Centre, Oxford, United Kingdom; 7University of Leeds, Leeds, United Kingdom; 8ANMAR Y oung, Rome, Italy; 9EULAR Standing Committee of PARE, Zurich, Switzerland; 10Slovak League Against Rheumatism, Bratislava, Slovakia; 11Arthritis Ireland, Dublin, Ireland; 12Youth-R-Well.com, Lisse, Netherlands; 13ANMAR Young, Rome, Italy; 14Fibromyalgia Action UK, Paisley, Renfrewshire, United Kingdom; 15University of Leeds, Leeds, United Kingdom; 16Österreichische Rheumagila, Salzburg, Austria; 17ReumaNet Jong & Reuma, Bresserdiuk, Belgium; 18EULAR, Zurich, Switzerland

**Background:** In a recent European youth survey, 53% reported that rheumatic and musculoskeletal diseases (RMDs) affected their ability to work, while 75% reported that RMDs interrupted their education. Therefore, in 2017 and 2018, while continuing to achieve the objectives reached in 2015 and 2016, EULAR Young PARE will focus on two key points from EULAR Young PARE’s strategic objectives: work and education.

**Objectives:** In 2017, in line with EULAR’s efforts to raise awareness of the needs of people with RMDs among employers and other stakeholders, the specific and still unmet needs of young people with RMDs will be highlighted, so that employers and other stakeholders will be more aware of the needs of young people with RMDs and young people will receive better support to find a suitable job. In 2018, education for young people with RMDs will be in focus, so that educational institutions across Europe will be more flexible and assistive in supporting high quality education for young people with RMDs.

**Methods:** In 2017, we will support EULAR’s lobbying activities by raising awareness among employers and other stakeholders about the needs of young people with RMDs, and young people will receive better support to find a suitable job.

**Results:** In 2017, we will support EULAR’s lobbying activities by raising awareness among employers and other stakeholders about the needs of young people with RMDs. In 2018, education for young people with RMDs will be in focus, so that educational institutions across Europe will be more flexible and assistive in providing high quality education for young people with RMDs by offering training and support to national youth leaders.

**Conclusions:** The objectives reached by EULAR Young PARE in 2015 and 2016 are closely related to its future aims and achievements, allowing EULAR Young PARE to grow stronger and continue its work by the side of young people with RMDs, in order to improve their quality of life.

**CELEBRATING TEN YEARS OF SUCCESSFUL PATIENT INVOLVEMENT IN RESEARCH OF INFLAMMATORY CONDITIONS**

A. Higginbottom1, S. Blackburn1, L. Campbell2, C. Rhodes1, R. Taylor1, A. Macin1, S. Hider2, E. Roby2, C.A. Chew-Graham1, K. Dziedzic1.

1Research Institute of Primary Care and Health Sciences, Keele University, Keele; 2Haywood Academic Rheumatology Centre, Staffordshire and Stoke-on-Trent Partnership Trust, Stoke-On-Trent, United Kingdom

**Background:** In 2016, the Research Institute (RI), Primary Care and Health Sciences, Keele University, UK, celebrated 10 years of Patient and Public Involvement and Engagement (PPIE) in research of musculoskeletal and other long term conditions. Our Research User Group (RUG) with over 90 members with a range of long-term conditions, actively work with research teams on studies. Many of whom have been involved in ten studies of different inflammatory conditions. We provide two case studies: 1) CONTACT: a trial comparing the effectiveness and side-effects of two commonly-used drugs (Naproxen and low-dose Colchicine) to treat acute gout in primary care; 2) A qualitative interview study with people with rheumatoid arthritis (RA) who had attended a nurse-led review clinic, which included identifying people at risk of anxiety and depression.

**Objectives:** To describe how PPIE helped shape the design and delivery of the CONTACT and qualitative interview studies.

**Methods:** 1) For the CONTACT trial, two RUG members with experience of gout joined the Trial Steering Committee. Another seven RUG members formed an advisory group to provide the patient perspective on trial procedures.

2) For the qualitative interview study, a group of eight people with RA from a local rheumatology centre (Haywood User Group) commented on the documents for the ethics application and met to discuss data analysis and dissemination.

**Results:** 1) In the CONTACT trial, RUG members made a difference by:

- Helping to produce clear and user-friendly information sheets for participants in the trial.
- Providing practical advice regarding how participants were recruited.
- Future RUG involvement will include helping to interpret the trial findings planning further dissemination and discussing future research studies.

2) In the qualitative interview study, the PPIE group:

- Contributed to the development of readable patient questionnaires for use in the clinic.
- Offered their perspectives on the interpretation of the qualitative data.
- Helped develop a leaflet to inform patients about mood problems related to rheumatoid arthritis and where help could be sought.
- Contributed to the establishment of an RA annual review clinic at the local hospital.

**Conclusions:** Both studies demonstrated the wide-ranging benefits of PPIE input throughout the research cycle of identification, designing, managing and disseminating research. The RI will continue to involve patients with long-term conditions in studies for the benefit of the wider patient community.

**Acknowledgements:** We thank all of our Research User Group members for their valuable time and contribution to the RI’s research. CONTACT was funded by the NIHR School for Primary Care Research. The RA qualitative study was funded by the NIHR School for Primary Care Research. The RA qualitative study was funded by the Scientific Foundation Board of the Royal College of General Practitioners and the Haywood Foundation. KD is part-funded by a NIHR Knowledge Mobilisation Research Fellowship (KMF-2014–03–002). CCG is part funded by the NIHR Collaborations for Leadership in Applied Research and Care West Midlands.

**THURSDAY, 15 JUNE TO SATURDAY, 17 JUNE 2017 Work and rehabilitation**

**ASSESSMENT OF PAIN AND IMPORTANCE OF EXERCISE IN HIP OSTEOARTHRITIS**

A. Jurisse Skiven1, V. Grbovic2, A. Divjak3, A. Tomic Lucic1, M. Veselinovic1, D. Pavlovic3, J. Jurdovic1, Faculty of Medical Science; 2Clinical Health Centre, Vranje, Serbia; 3Faculty of Medicine, University of Novi Pazar, Vranje, Serbia

**Background:** Osteoarthritis (OA) of the hip is a common condition which affects men and women of all ages. The cartilage becomes damaged. Stiffness and reduced range of movement are common. The pain experienced from OA of the hip may be felt in your lower back, buttocks and groin. You may also feel pain from your hip in your leg and down into your knee. This is called referred pain. The goals of OA treatment include alleviation of pain and improvement of functional status. Optimally, patients should receive a combination of nonpharmacologic and pharmacologic treatment. A physiatrist may help in formulating a nonpharmacologic management plan for the patient with OA.
Guidelines from Osteoarthritis Research Society International (OARSI) advise that nonpharmacologic treatment of hip and knee OA include the following: patient education; heat and cold; weight loss; exercise; physical therapy; occupational therapy; unloading in certain joints (eg, knee, hip).

Objectives: The aim of this study was to investigate the importance of exercise and TENS (transcutaneous electrical nerve stimulation) therapy in patients with OA of the hip on the pain and functional status.

Methods: This was a prospective clinical study involving 20 patients with primary hip OA treated at stationary at the Center for Physical Medicine and Rehabilitation during 2016. On receipt of all the respondents filled out the social survey, questionnaire; Direct telephone questionnaire. Patients were asked the same questions: 1. Describe the best you feel at present following the exercise programme; 2. Did you feel the programme was too long, just right or too short? 3. Do you feel the programme was worthwhile? 4. Did you feel the programme was worthwhile.

Results: There was 100% of women, mean age 64.15±0.06 years. The most represented were retired, 60%, followed by workers and unemployed 10% and 30%. BMI was 27.3±2.22 kg/m². After a month there was a statistically significant reduction in pain measured by VAS (at the beginning it was 6.7; at the end 3.2; p<0.001). At the end of the study there was a statistically significant increasing range of motion for active flexion (p<0.05) and active abduction (p<0.05), while there was no statistically significant increasing for active extension, adduction, internal and external rotation in the hip joint (p>0.05).

Conclusions: The ER strongly recommends the following nonpharmacologic measures for patients with knee or hip OA: cardiovascular or resistance land-based exercise, aquatic exercise, weight loss, for overweight patients. TENS may have a role in reducing pain measured by VAS (at the beginning it was 6,7; and it is a huge burden on primary care (Peat, McCarnyn, & Croft, 2001). The knee joint is one of the most affected in elderly, influencing directly physical function and affecting psychological and social parameters. Therefore, it is imperative to develop strategies that help individuals to change the way they affect their lives. International recommendations reinforce educational and exercise programs as the core of non-pharmacological approaches to enhance physical functional and relieve pain and others osteoarthritis symptoms.

Objectives: The purpose was to assess the effectiveness of a three months educational program for older adults with knee osteoarthritis (KOA).

Methods: Participants recruitment was done in the community using various marketing strategies. Forty individuals with 60 years or more, bilateral or unilateral KOA diagnosed according to clinical and radiological criteria of the ACR [1] and independently mobile and literate participated in the program. Educational sessions regarding exercise and joint protection strategies were offered. Telephone calls were done 15 days after each educational session. Patients received a book (2), with a core exercise section. Patients in the first attendance session were taught to do registration in an exercise training diary. Self-reported measures were used for other symptoms, activities of daily living (ADL), and quality of life assessed by Knee Injury and Osteoarthritis Outcome Score (KOOS) questionnaire (3). Patient Global Impression of Change Scale (PGICS).

Results: Final sample included 32 adults (age: 67.8±5.3 years; bilateral KOA: 93.8%; female, 59.4%; BMI: 30.1±5.3 kg/m²). Eight participants did not complete the program (3 due to health problems and 5 for personal reasons). KOOS pain improved 10% (p<0.042), and other symptoms 8%. Improvement in KOOS ADL (6.7±13.6) and quality of life (8.2±11.8) were also observed. 47% of the participants reported significant changes (scores 5–7) after intervention and a decrease in medication use of 31%.

Conclusions: The educational program can be an effective and suitable way for osteoarthritis management and to improve pain and health-related quality of life, leading individuals with KOA to better control their pathology and consequently better living.
Objectives:  
- Mapping beliefs of researchers and PRs about the potential value of patient involvement in basic research.  
- To document experiences of both patient representatives and researchers of a pilot project of PRs participating in basic research.

Method:  
A mixed-method study with a participatory action research has been used. This is a research approach that emphasizes both participation and action [2]. In this case two working groups were involved. The coordinator participated in meetings of the working groups, made notes during these meetings about the nature and degree of participation, evaluated the meetings with the participants and kept a diary. At the start and at the end of the pilot 6 researchers of the working groups were interviewed by the coordinator. The findings of the interviews were categorized and summarized. During 6 months, 5 PRs were invited to attend once a month, in one of the working group meetings. In the first meeting expectations of both researchers and PRs were exchanged. In the following meetings one researcher presented a lay version summary of his/her work. There was room for PRs to ask questions.

Results:  
Prior to the pilot, some researchers had doubts about the added value of PRs, others were more positive and even curious. All PRs were open minded about the pilot, although none of them had experience with involvement in basic research.

At the end of the pilot, researchers expressed positive statements, such as: “(very) nice, good initiative and interesting discussions.” Positive experiences included: exercise in explaining their work to lay persons; stimulation in developing a more holistic (helicopter) view of their research, and getting a better insight in problems in daily life that patients encounter.

The PRs experienced the atmosphere during meetings as open and pleasant; they felt that the degree of participation was limited, but worthwhile. The coordinator observed that interaction between the researchers and PRs mainly consisted of asking questions for clarification. Besides, the coordinator observed after presentations exchanges between PRs and about research-related issues such as the availability of human tissues for research and conversations about personal experiences.

Critical comments were made about the difficulty in understanding the complex matter for PRs and the chosen method (researchers present, PRs listen) that does not encourage interaction.

Conclusions:  
There is a potential value of patient involvement in basic research. A first result is that junior researchers develop a more holistic view of their research subject.

An open atmosphere and low expectations may contribute to success. Continuation of this pilot with modifications, including more research groups and PRs, are needed to find ways to increase patient involvement in basic research.

PARE0007  
HOPES AND FEARS OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS IN SPAIN. THE VALUE OF PATIENT OPINION: RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbraa 1,2, P. Plazuelo-Ramos 2, A. Costa 3, O. Brace 1, J. Chacón-García 1, D. Gálvez-Ruiz 1, 1Universidad de Sevilla, Seville; 2CEADE, Madrid; 3Novartis, Seville, Spain

Background:  
Not much attention has been paid to listening to the opinions of patients in most scientific studies on Spondyloarthritis, despite their opinions playing an increasingly important role in decision-making alongside clinical and public health criteria.

Objectives:  
To assess the opinions of patients with Axial Spondyloarthritis (axSpA) using qualitative information.

Methods:  
A sample of 680 patients diagnosed with axSpA was interviewed during a pilot as part of the Spanish Atlas, which aims to promote early referral and improve healthcare and the use of effective treatments in patients with axSpA. The Atlas is a CEADE initiative (Spanish Coordinator of Patients with axSpA in Spain) developed by the University of Seville and Max Weber Institute in collaboration with GRESSER (Spanish Rheumatology Society spondyloarthropathy study group). Responses to qualitative items about patients’ hopes and fears for their disease and their personal aims regarding their treatment were analysed.

Results:  
53% were females, mean age 46 years and 77.1% were HLA-B27+.

The five main hopes of patients are: stopping the disease, dream of a cure, elimination of pain, improve their quality of life and live without limitations. Additionally, patients has expectations on the medical research outcomes. Thus, 81% of patients hope that the research will make possible to find the cause and a cure for axSpA, developing more efficient biologic therapies (11%), and finding new techniques or medication (8%).

The following stand out among drug treatment-related concerns: having more effective treatments (32%), sustaining the results of biologic therapies (29%), being able to start on biologics (8%), the public health system funding non-drug treatments for AS (8%), eliminating secondary effects (15%), reducing prices (4%), and correct use (4%).

With respect to their fears, patients stated that their main concern was mobility loss (31%), followed by loss of independence (23%), disability (22%), stiffness (12%), structural damage (3%), organ damage (3%), other illnesses and diseases related (3%), physical decline (3%), and sight loss (1%).

Patients who expressed fear regarding their disease listed their greatest concern related to the disease (12%), structural damage (3%), organ damage (3%), other illnesses and diseases (3%), physical decline (3%), and sight loss (1%).

Patients who expressed fear regarding their disease listed their greatest concern related to the disease (12%), structural damage (3%), organ damage (3%), other illnesses and diseases (3%), physical decline (3%), and sight loss (1%).

With respect to patients’ personal objectives in terms of their treatments, they highlighted the wish that their treatment would, first, help them to reduce and eliminate pain, increasing in mobility, improved quality of life, the avoidance of structural damage and the disease eventually being cured.

Conclusions:  
Analysis of patient opinion using qualitative information has enabled the identification of important concerns for patients such as discovering the cause of the disease, reducing pain and structural damage, loss of self-sufficiency and disability.

A TAXONOMY OF DISEASE EXPERIENCES OF WOMEN WITH SJÖGREN’S SYNDROME FROM THE PERSPECTIVE OF THE PATIENT

M.Y. Visser-Noordegraaf 1, V. Hierons 2, G. Rojas-Alcayaga 3, R. Geenen 2

1NVSP, National Association Sjögren Patients, Maarssen; 2Psychology, Utrecht University, Utrecht, Netherlands; 3Faculty of Dentistry, Universidad de Chile, Santiago, Chile

Background: In earlier studies of experiences of patients with Sjögren’s Syndrome (SS), professionals interpreted the data and drew conclusions and implications. In the current study, patients had a major share in the interpretation and structuring of experiences, and a patient research partner was part of the research group in all phases of the study: planning, collecting data, organizing, analyzing, and reporting.

Objectives: The aim of this study was to examine the full spectrum of life experiences of women with SS in an integrated, hierarchical model, and to examine the degree to which the research participants experienced the sorted experiences themselves.

Methods: Patients structured and interpreted the data using a concept mapping technique. In a card-sorting task, 52 patients with SS from the Netherlands grouped 75 experiences in piles. These experiences came from previous in-depth interviews with Chilean patients [1]. Hierarchical cluster analysis yielded an integrated, hierarchical model of these sortings. The 52 patients indicated on a Likert scale whether they had had these experiences themselves: agree, agree a little, disagree a little, disagree.

Results: Hierarchical cluster analyses showed a main 6-category clustering of experiences with primary symptoms, emotional processing, social interaction, self-management, ignorance, and physicians. Four of these categories showed underlying clusters of experiences (see Figure). Patients generally agreed to have common experiences of “primary symptoms”, “role functioning barriers”, and “diagnosis” and they commonly disagreed with the “psychologizing” symptoms, while they differed in the degree to which they had individually experienced the other experiences.

Conclusions: Life experiences of women with SS were summarized in an integrated, hierarchical model consisting of 14 clusters in 6 overarching categories. The results may be colored by the cultural background of the participants. This year this concept mapping study will be extended to patients from Chile, which will increase the generalizability of the findings and allow cross-cultural comparison. The final hierarchical overview with life experiences from the patient’s view can be used to improve screening in clinical consults, develop a questionnaire, give direction to future research, and enhance education and self-management support [cf. 2]. The method gives ample room to really incorporate the patient perspective in research.

SIGNIFICANCE OF FOOT PROBLEMS FOR PATIENTS WITH RHEUMATOID ARTHRITIS: A PATIENT-LED QUALITATIVE STUDY

S. de Souza, H. Lempo. Academic Rheumatology, King’s College London, London, United Kingdom

Background: Patients with rheumatoid arthritis (RA) commonly report problems with their feet. It is known that foot joint involvement begins early in the course of RA and even patients on biologic therapy and/or with low disease activity can still experience high levels of foot pain. Current UK guidance states that “All people with RA and foot problems should have access to a podiatrist for assessment and periodic review of their foot health needs.”

Objectives: To understand how foot health problems affect patients with RA.

Methods: Adult patients, with a diagnosis of rheumatoid arthritis and ability to converse in English, were recruited by clinicians based at a London hospital rheumatology outpatient clinic to participate in two focus groups on foot health. These were conducted by the lead patient researcher and comprised 8 females and 1 male of diverse ethnicities, aged 27-68 years old with 4-46 years disease duration. The focus groups were audio-recorded and transcribed verbatim. Transcripts were verified for authenticity by a random sample of 4 participants, and were systematically coded with the assistance of qualitative data analysis computer software. Themes were generated and cross-checked by the co-researcher to negate any potential bias by the lead patient researcher.

Results: Four interlinked themes were identified: 1) dependence on feet, e.g. for standing and walking; 2) physical impact e.g. pain, swelling and deformities; 3) social impact e.g. hard to keep appointments and participate in leisure activities; 4) psychological impact e.g. low self-esteem, worry and using humour to cope. The sole male participant was unaffected by theme 4. One patient in the group had not experienced foot problems since diagnosis. No differences were identified across age, ethnicity or disease duration.

Conclusions: Foot problems can significantly lower quality of life for patients with RA. It is therefore essential that foot health is adequately addressed during rheumatology outpatient consultations with onward referral to podiatry services as necessary.

EDUCATING YOUNG CHILDREN, PARENTS AND DOCTORS THROUGH THE MEDIUM OF AN ILLUSTRATED CHILDREN’S BOOK

T. Egert1, Y. Egert2, R. Vitman1, W. Costello1, 14682, Efrat, Israel; 2Net zach Tefillahayim 8, 4682, Efrat, Israel; 34882, Dublin, Ireland

Background: Chronic illness in a child is a complex reality for all involved. The child often feels confused and afraid. He doesn’t understand why he is sick and in pain, he worries about the doctor and hospital visits, as well as the medications and shots to which he is subjected. Parents are unsure how the illness will affect their child, and how to best prepare him for future challenges. Both parent and child are not always sure how to communicate to the Doctor their needs and concerns. Communication, however, between parent, doctor, child and health professionals is critical for effective treatment of the disease.

Objectives: This book attempts to open lines of communication between parent and child, to educate, give coping tools, and a voice to the young patient in a fun and optimistic manner. The book targets many of the children’s challenges through identifying with Kipo, the young monkey who also has JIA. The objectives are: 1. To give the child strength and tools to deal with his illness. 2. Improve compliance through a better understanding of treatment.

Methods: A list of challenges young children with JIA face was compiled through meetings with parents, doctors and children. Next, a list of coping strategies was produced based on discussions with parents and health professionals. The book addresses the challenges and methods of dealing with them in a fun and optimistic manner through young Kipo’s routine. Included are also messages addressed to the parent and doctor. To keep the child an active part of the story, thus allowing him to voice his concerns and discover coping skills, the story line requires active participation through “reading the pictures” which accompany the text. (The book includes a “how to read” guide). The back page includes a brief description of the illness, as well as other useful web addresses: parents associations, PRINTO, etc.

Results: Working jointly with the illustrator an illustrated children’s book in 3 different languages (Hebrew, English and Arabic) was published. The book addresses the challenges and difficulties of a young child with JIA through the story of Kipo the monkey who is also ill. Included are a visit to the doctor, getting an injection, going to the physiotherapist, etc. The book is distributed free of charge through the paediatric rheumatologists to the families, and is received very enthusiastically by parents, children and doctors. The children read and reread the book sharing it with family, friends and kindergarten classrooms. They use the terminology introduced in the book to describe their own physical and emotional feelings, and adopt coping strategies used by Kipo.

Conclusions: The success of the book motivated us to allow for a more international distribution. The illustrations and the text are available allowing it to be used by any national group.

Patient information and education

PARE0012

EXPLORING THE ADDED VALUE OF A BOOSTER SESSION AFTER COMPLETING THE DUTCH SELF-MANAGEMENT TRAINING “CHALLENGING ARTHRITIS”

M. Vos1, R. Van den Brink2, S. de Jong3, J. Amsterdam3, 1 Expert, 2Patient, 3Psychologist; Purmerend, 1Dutch Arthritis Foundation, Amsterdam; 2Rheumatology & Clinical Immunology, University Medical Centre Utrecht, Utrecht, Netherlands

Background: In the Netherlands, the peer-guided self-management training “Challenging Arthritis” exists for over 15 years and is being organized by the Dutch Arthritis Foundation and the University Medical Center Utrecht. The training is based on the “Arthritis Self-Management Program”1 but has recently gone through several updates, improvements and extensions2. The goal of the training is to improve self-management skills of patients and thereby improving their physical and emotional health and quality of life. Evaluations show that participants highly appreciate the training, but some of them have suggested that they would like to have an extra moment of training, (i.e., a booster session) after the ending of the regular program. Research shows that self-management programs are effective but mostly in the short term3. The effects of “Challenging Arthritis” may be enhanced and prolonged by organizing booster sessions.

Objectives: Aim of this research is to make recommendations about organizing booster sessions based on 1) a literature search and 2) a needs assessment among former participants and peer trainers.

Methods: A literature search was performed in databases like Google Scholar, PubMed and Science Direct, focusing on articles about the use of boosters in self-management interventions. Up to the year 2016. Next to that, a needs assessment was conducted among participants and trainers on needs and preferences, using two separate online surveys. The survey for the participants, who followed a live training between 2012 and 2015, included items on the need for a booster, reasons and on preferences regarding its form, content and frequency. The survey for peer trainers addressed the perceived usefulness and the trainers’ willingness to provide booster sessions. The resulting data were analyzed using SPSS and thematic analysis.

Results: The literature search yielded 27 articles describing health interventions with aspects of self-management, including one or more booster sessions. From a theoretical perspective, boosters are a way to maintain new behavior over an extended period of time. As of yet, there is little evidence that the use of boosters lead to better outcomes in terms of health or health behavior, but it has been suggested that tailoring may lead to better results4.5. Regarding the needs assessment, 124 participants and 34 trainers completed the survey. Results showed that almost half of the participants (47.5%) expressed a need for a booster, while the other half (52.5%) expressed little or no need. Participants who prefer a booster want to share experiences, learn how to stay active with self-management and hold on to skills they have already achieved without the experiences of the users. We presented the support of Donna Saunders, NRAS Member & Volunteer, on hand to comment and ensure authenticity of how the actress moved and dealt with every day activities. The final scene shows the character of Jane attending her clinic appointment with her rheumatologist and even then putting on a brave face and hiding behind the smile of the typical response “I’m fine”. In addition, Donna who lives with RA, was filmed giving her personal comments on the awareness film and insights into her personal struggles. Finally, Prof. Iain McInnes, was filmed giving the clinicians perspective and offering advice as to how health care professionals need to keep at the forefront of their minds that patients are people and to be truly effective as physicians they should always make the time to open the dialogue on how the individual is truly “feeling”.

Results: The films were released on World Arthritis Day 2016 via Lilly and NRAS social media channels in the UK. To date the “Jane” clip has been viewed in access of 200,000 times. The feedback from patients has been overwhelmingly that it has truly captured their “story”. Physicians and industry staff have been left speechless and moved by the emotive film. NRAS and Lilly continue to utilise the films at health care professional training, staff and patient events.

Conclusions: Plans for 2017 is to develop more similar awareness raising videos as it is evident that using social media with video has impact and reach.

Acknowledgements: Acknowledge the support of Lilly Pharmaceuticals for the funding to develop these resources. The invaluable support of Prof. Iain McInnes and patient Donna Saunders

PARE0014

BEHIND THE SMILE - RA AWARENESS VIDEOS - RAISING AWARENESS OF THE HIDDEN IMPACT OF RHEUMATOID ARTHRITIS

C.B. Jacklin, D. Saunders. External Affairs, National Rheumatoid Arthritis Society, Maidenhead, United Kingdom

Background: NRAS was approached by Lilly Pharmaceuticals to contribute to the design and production of a series of videos to raise awareness of the hidden impact of rheumatoid arthritis. As this clearly met the charity’s own objectives of raising awareness to a variety of audiences NRAS gladly collaborated on this project.

Objectives: The key aim of developing these resources to be utilised in European countries was to raise awareness of the impact of RA on daily life to 1) the general public, 2) clinicians, 3) payers, 4) industry and 5) people living with RA and their families. The challenge was to capture, in a two minute video, key messages that would resonate with all these stakeholders.

Methods: NRAS worked with a PR agency to develop an appropriate script for the main Behind the Smile resource. The main character, Jane, who lives with RA, was to be in her mid 30s – to represent that RA is not associated with ageing; a school teacher – to represent that RA hits people of all ages. She is a valued contributor to society; and a daughter, wife and mother – to represent how many other people depend on her and that she has commitments to. We filmed with the support of Donna Saunders, NRAS Member & Volunteer, on hand to comment and ensure authenticity of how the actress moved and dealt with every day activities. The final scene shows the character of Jane attending her clinic appointment with her rheumatologist and even then putting on a brave face and hiding behind the smile of the typical response “I’m fine”. In addition, Donna who lives with RA, was filmed giving her personal comments on the awareness film and insights into her personal struggles. Finally, Prof. Iain McInnes, was filmed giving the clinicians perspective and offering advice as to how health care professionals need to keep at the forefront of their minds that patients are people and to be truly effective as physicians they should always make the time to open the dialogue on how the individual is truly “feeling”.

Results: The films were released on World Arthritis Day 2016 via Lilly and NRAS social media channels in the UK. To date the “Jane” clip has been viewed in access of 200,000 times. The feedback from patients has been overwhelmingly that it has truly captured their “story”. Physicians and industry staff have been left speechless and moved by the emotive film. NRAS and Lilly continue to utilise the films at health care professional training, staff and patient events.

Conclusions: Plans for 2017 is to develop more similar awareness raising videos as it is evident that using social media with video has impact and reach.
part of the participants expresses the need for a booster and trainers are highly motivated to provide it. Therefore, we think it’s worthwhile to start experimenting with organizing booster sessions on a small scale and, depending on the outcomes, consider further implementation.

THE IMPORTANCE OF FACE-TO-FACE NETWORKS: FINDINGS FROM THE 2ND EULAR YOUNG PARE CONFERENCE, “CHANGE THE FUTURE”

J. Andersen 1,2, P. Balazova 3,4, W. Olisier 5, S. Ostuzzi 6, D. Papastavrou 7,8, S. Stones 6,8, T. Wilhelmer 10, P. Boyd 11 on behalf of EULAR YOUNG PARE.

1. Sele/Lupus Ung Dk, Gigvetorenjen, Gentofte, Denmark, Gentofte, Denmark;
2. Lupus Europe, Essex, United Kingdom, Essex, United Kingdom;
3. Slovak League Against Rheumatism, Piestany, Slovakia, Piestany, Slovakia;
4. EULAR Standing Committee of PARE, Zurich, Switzerland, Zurich, Switzerland;
5. Youth-H-Well.com, Lisse, The Netherlands, Lisse, Netherlands;
6. ANMAR Young, Rome, Italy, Rome, Italy; 7. ELEANA Hellenic League Against Presentation; each liaison had the opportunity to share recent work in their
8. School of Healthcare, University of Leeds, Leeds, United Kingdom, Leeds;
9. Fibromyalgia Action UK, Paisley, Renfrewshire, United Kingdom, Paisley, United Kingdom;
10. Österreichische Rheumaliga, Salzburg, Austria, Salzburg, Austria;
11. Arthritis Ireland, Dublin, Ireland, Dublin, Ireland.

Background: EULAR YOUNG PARE’s strategy for 2020 is to establish and strengthen liaisons for young people with rheumatic and musculoskeletal diseases (RMDs) across Europe, by developing a collaborative network. We aim to empower young leaders to ensure the voice of young people with RMDs is heard. To facilitate this, the 2nd EULAR YOUNG PARE Conference was held in Retie, Belgium in October.

Objectives: To empower and educate EULAR YOUNG PARE youth liaisons, focusing on developing academic and interpersonal skills to best support young people across Europe living with RMDs. This was achieved through a series of practical, skills-based workshops and plenary sessions.

Methods: The EULAR YOUNG PARE working group reflected on the conference during a debrief meeting. A post-conference evaluation was completed by liaisons. A five-point Likert scale (1= very bad, 5= very good) was used alongside open questions. In addition, there was an informal meeting to generate discussions and receive input from participants regarding the future direction and focus of EULAR YOUNG PARE in 2017 and 2018.

Results: The conference was attended by 22 youth liaisons from 20 organisations. The programme was well received with the face-to-face interactions favoured over digital. A five-point Likert scale (1= very bad, 5= very good) was used alongside open questions. In addition, there was an informal meeting to generate discussions and receive input from participants regarding the future direction and focus of EULAR YOUNG PARE in 2017 and 2018.

Conclusions: The ‘Change the Future’ conference was a successful meeting of youth liaisons from across Europe, who were highly satisfied with the programme and mechanism of delivery. Meeting in person facilitated the growth and continued involvement within the EULAR YOUNG PARE network. The activities of EULAR, and specifically the Standing Committee of PARE, were shared with liaisons, encouraging liaisons to become involved in a wider number of EULAR activities. The method is based on the capacity of a motivated patient to positively influence others also worried by their health situation by sharing their experiences. The campaign spread online, allowing ANMAR YOUNG to gather different experiences, expand its network, contribute in the process of empowerment and engagement of Italian young rheumatic patients.

EMPOWERING PATIENTS WITH OSTEARTHROSIS WITH NON-PHARMACOLOGICAL MEASURES

J. Vergés 1, J. Monfort 2, M. Bibas 1, M.T. Vergés 1.

1. Osteoarthritis Foundation International-‘Hospital del Mar, Barcelona, Spain.

Background: Osteoarthritis (OA) and other joint pains are generally seen as ailments that affect people with age. With the increase in life expectancy over recent decades, the prevalence of people with OA is drastically growing. Estimates suggest that there are 242M people with OA in the world 1; 30M live in Europe 2. The most commonly affected joint at the present time is the knee, followed by hips and shoulders.

Objectives: To run an educational program that will provide elderly people with tools to tackle their problems of joints so that they can improve their quality of life by adopting non-pharmacological measures. A well-informed patient knows how to address their disease. Thus, they can improve their quality of life.

Methods: The method is based on the capacity of a motivated patient to positively influence others also worried by their health situation by sharing their experiences and awareness of the disease.

Stage I. Preparatory actions:
1. Elaboration of contents: An expert team (psychologist, nurse, rheumatologist, family doctor, physiotherapist and rehabilitator) elaborates the content: Knowledge, Weight control, Doing the right exercise, Dealing with the disease.
2. Engagement of the target group: “La Caixa” Banking Foundation is supporting this study by giving access to its 63 senior centers in Catalonia (Spain)
3. Selection of senior centers: The educational program is planned to be run in 6 centers. Currently, 20 centers are conducting initial presentations to evaluate interest and ensure the selection of 6 final centers
4. Enrollment of smart seniors: 12 people will be selected (2 per center), called hereafter as “smart patients” through a survey so we can assess interest of enrolling and quality of the presentation.

Stage II. Training and implementation:
5. Training of smart patients: Train selected smart patients during 9 sessions, 90 minutes each
6. Test of groups of patients: Every smart patient will train 2 groups of 10 people also interested in joint health. A nurse will be in every session, giving support only if necessary
7. Evaluation and follow-up: Improvement of participants in the course will be assessed (anticipated sample size 240 people) by surveying level of satisfaction
Conclusions: Based on results to date, after the 20 sessions the team expects to collect 763 surveys and identify 190 potential smart patients and 483 people willing to participate in the program. There is a clear interest or concern for OA disease in elderly people and they want to take more responsibility for their disease and age with quality of life.

WE DO THE IMPOSSIBLE, BECAUSE THE POSSIBLE EVERYONE CAN DO WAD AWARENESS CAMPAIGN

H. Bankova, B. Iykov, S. Bozhinova, B. Boteva. BOPRD, Sofia, Bulgaria

Background: One of the main priorities that Bulgarian organization for people with rheumatic diseases follows is dissemination of knowledge and information about RMD’S and their impact on people’s life and to the society. The WAD awareness campaign is the culmination of the organization’s activities during the whole year.

Objectives: The main goal of the 2016 WAD awareness campaign was to:
- To inform the society and BOPRD’s members about the social importance of RMD’s.
- To inform BOPRD’s members what are their rights as people with long term chronic condition.
- To inform the society about RMD’s and the challenges that people with RMD’s face.
- To challenge the people with RMD's to look into their inner world and to define what are their strengths and weaknesses.
- To make the informing process more attractive, by visualizing the key features of life with an RMD.

Methods: In 2016 BOPRD organized an awareness campaign - "We do the impossible, because the possible everyone can do”.

The start of our campaign was on 1st of October and lasted for more than two weeks till the World arthritis day and ended on 16th of October. Informative and motivating pictures, with information about different RMD’s, were published every day on the official BOPRD’s Facebook page and were shared in the closed group for people with rheumatic diseases as well.

A social experiment among the members of the organization was made. They were asked to explain what the disease means to them, like they are telling the story to a person who do not know anything about it. The aim of this experiment was to identify the meaning and significance which people with rheumatic diseases give to their condition, as well as the basic problems result from the illness.

Based on the social experiment and analysis of 33 small biographical narratives 17 basic characteristics of the rheumatic diseases are identified. These characteristics form the problematic areas for people with RMD’s and bases for their study.

The main characteristics are life with chronic pain, the process of disabling, life in continuous compliance with the environment and the high degree of uncertainty and ambiguity, imposed by chronic illness.

An e-booklet, containing the results of the social experiment was published on BOPRD’s Facebook page and website on 12th October. On the same day we published the WAD video, of the PARE WAD campaign: "The future is in your hands". At the end of the awareness campaign we published an online booklet, which contained translated articles about RMD’s and the different aspects of life with a chronic condition.

Results:
- The total number of all publications is 22.
- The publications were seen from over 3 000 people.
- The WAD video was seen by 1000 people.
- The results of the social experiment were seen by 1500 people.
- The most popular were those pictures that managed to touch people’s feelings.

Conclusions: Main common characteristics of rheumatic diseases were identified and can help patients in getting the right diagnosis. The most popular were the posts that were related to emotions and experience of life with a chronic condition.

By publishing the results of the social experiment we managed to help those who read the narratives get the feeling that they are not alone.

The results of the social experiment will be used as a basis in developing a manual for the main symptoms of RMD’s (the patient perspective).

PARE0018 ADHERENCE TO THERAPY: A COMPARISON BETWEEN THREE PATIENT POPULATIONS WITH AUTOIMMUNE INFLAMMATORY DISEASES

U.G. Viora1, R. Giannelli2, M.G. Pisu3, G. Voltan4 on behalf of ANMAR Italia.
1Anmar Italia, Torino; 2Anmar Italia, Firenze; 3Anmar Italia, Milano; 4Anmar Italia, Roma, Italy

Background: Non-adherence to therapy is one of the main obstacles achieving the goals of care in chronic autoimmune inflammatory diseases, including Rheumatic diseases (RMDs). In the “ MOSAICO” study, ANMAR along with two other associations of Italian patients (AMICI chronic inflammatory bowel diseases (IBD) and ANAP - psoriasis (PSO) and chronic dermatological diseases) wanted to compare the adherence to therapies for IBD, RMDs and PSO and identify key problems that can affect it positively or negatively. This paper presents the results related to adherence to treatment, the obstacles that are disadvantageous and to the factors that, conversely, favor adherence and persistence.

Objectives: to fix the degree of adherence to therapy - with DMARDs and biological indifferently - in the three different pathologies; to identify obstacles and factors predisposing good adherence and persistence by patients; to compare the different populations, highlighting similarities and significant differences.

Methods: A 72 questions questionnaire - about 50% of which were dedicated to adherence and persistence to therapy and the predisposing factors and impediments - prepared in collaboration with Doxapharma was administered to patients with RMDs, IBD, PSO via web and by volunteers of the three associations.

The evaluation of adherence to therapy (“degree in which a person’s behavior in taking medication, following a diet and/or change the lifestyle, corresponds to the specific recommendations made in agreement with the Medical”) was assessed by Morisky Medication Adherence Scale - 8 items (MMAS-8).

Results: 1.017 patients - 233 with RMDs (AR e SA), 449 with IBD (Crohn and ulcerative colitis), 273 with PSO and 62 APs – answered to the questionnaire useful for the purpose of the study.

Non-adherence varies in a range from 50% of dermatological patients, to 44% of them with IBDs, to 40% of patients with APs, to 36% of them with RMDs. Only 74.8% of adherent people is persistent (83% in biologic therapy; 76% in DMARDS) and non-persistent patients does not ask and/or inform their doctors.

Patients with Psoriasis take therapies more discontinuously and inaccurately then patients with RMDs, IBDs and APs. The most popular were the posts that were related to emotions and experience of life with a chronic condition.

Conclusions: Our study shows that patients who enjoy a better health state, both physically and psychologically, are more likely to follow the treatment prescribed by their doctor, according to the mode and the specified time, especially if properly informed and well supported in choices, shared by medical and health professional staff.

25 YEARS OF PATIENTS’ ASSOCIATIONS OF ANKYLOSING SPONDYLITIS IN SPAIN: ACEADE

J. L. Garrido-Castro 1, C. Gonzalez-Navas 2, J. De La Haza 1, P. Plazuelo 2, E. Collantes-Estevez 2, ACEADE, AS Patient Association of Cordoba; 2CEADE, National Coordinator of AS Patient Associations, Cordoba; 3CEADE, Coordinator of AS Patient Associations, Madrid; 4Reina Sofia University Hospital, Cordoba, Spain

Background: Patients’ associations can provide to the ankylosing spondylitis (AS) patient all the information and support that his/her rheumatologist cannot give and that is necessary to fight against the disease having a greater quality of life. The knowledge about AS is fundamental and Patients’ associations play an important role in education on disease (2). In 1991, the first association dedicated to AS in Spain, was born: ACEADE (Asociacion Cordobesa de Enfermos Afectados de Espondilitis). The Rheumatologist, Dr Eduardo Collantes, after having spent some years in several countries, brings together several patients affected by this disease, in the city of Cordoba, to create the first Patients Association dedicated to this disease in Spain. There were some associations of this kind in the UK and France, and they decided to create their own association to promote the knowledge about AS and to help the AS patient. More than 25 years later, there are many AS patient associations in Spain that were created following the example of ACEADE, and with the help of this pioneering association.

Objectives: The aims of ACEADE during these 25 years has been:
1) Disseminate the knowledge of the disease.
2) Collaborate with medical researchers.
3) Improve the quality of life of the AS patient.
4) Organize and participate in scientific meetings, congresses and specialized courses.
5) Nativise the patients in socio-labor aspects.
6) Inform associates of the advances related to the disease.

Methods: Several activities are being carried out in the Association, some of them were exposed previously (3): educational seminars, rehabilitation courses, patient guides, social events, legal advice, employment bureau, newsletter, web page, ... In order to develop these activities, we have several sources for fundraising, donations, local and regional governments, pharmaceuticals, foundations, ...

Results: ACEADE is formed by 415 members distributed in the province of Cordoba (Spain), although some of them are from outside this city (11%), 67% of them are men and the average age of the members is 53 years. Of these, 32% have a recognized legal disability. After ACEADE, up to 18 patient associations have been created in Spain. There is also a national organization of AS patient associations: CEADE.

Conclusions: ACEADE was the pioneering AS Association in Spain and has been the mother of others that have been appearing. Today there are associations of AS in virtually all territories of Spain, helping patients to have a better quality of life. The next 25 years appear, for our association, full of illusions, ideas and a lot of work ahead, to help in the fight against AS.

PUBLIC AND PATIENT INVOLVEMENT AT ARTHRITIS RESEARCH UK: ENSURING BENEFIT FOR ALL

C. Macdonald, Arthritis Research UK, London, United Kingdom

Background: Since 2008, Arthritis Research UK have utilised the valuable experience and perspective of people with arthritis to review and evaluate the research applications we receive, through the USER stakeholder committee. The world of public and patient involvement (PPI) has developed and progressed hugely in that time. So too has Arthritis Research UK, becoming an insight-led charity that can now genuinely say that people with arthritis are at the centre of everything we do, helping those people to be in control, independent and recognised. As such, our approach to PPI must not only meet the high new standards of meaningful PPI set by the research community but also serve to anchor our research activities and the work that we fund in genuine relevance and patient benefit.

Objectives: To present our new approach to involving people with arthritis in the decision-making processes of research and the wider charity.

Methods: We carried out a UK-wide scope exercise, consisting of questionnaires and one-to-one interviews, of key stakeholder groups and PPI leaders. This included: our funded researchers and centres of excellence; medical research charities; and people with arthritis including ex- and current USER members. The findings were written up in to a report.

Results: The findings of the report highlighted to us that we need to 1) scale up our PPI activities in order to ensure that insight of people with arthritis can be integrated at all stages of the research cycle 2) improve the quality of our PPI ensuring that all the things we do are carried out with clear purpose, that they are meaningful and add mutual value to all involved 3) increase the numbers of people with arthritis in our PPI processes. To help realise this vision, whilst improving our support, training and guidance processes for those people 4) recognise and support the already excellent PPI activities going on in the musculoskeletal community, and providing resources and training for those also wishing to start or develop similar activities.

Conclusions: After implementing this new approach for over a 18 months, we are now confident that our research activities and the research we fund have the utmost relevance and potential benefit to people with arthritis.

LOVE YOUR HEART – AN INTERACTIVE ON-LINE EDUCATION PROGRAMME TO ENABLE PEOPLE WITH RHEUMATOID ARTHRITIS TO ASSESS THEIR CARDIOVASCULAR RISK AND SET PERSONAL GOALS TO IMPROVE THEIR CARDIOVASCULAR HEALTH

H. John 1, A. Bosworth 2, 1Rheumatology, The Dudley Group NHS Foundation Trust, Dudley, 2CEO, National Rheumatoid Arthritis Society, Maidenhead, United Kingdom

Background: Rheumatoid arthritis (RA) is associated with an increased risk of cardiovascular disease, akin to type 2 diabetes. However, screening for, management of, and education about co-morbidities is not always adequate and as a result, the co-morbid risks may be overlooked by the general public, some health professionals and policymakers alike. Dr. John originally developed and piloted a programme in group format in Dudley to educate RA patients about their cardiovascular risk and help them change their lifestyle to improve their health; it achieved promising results. The format however limited the number of people who could access it and NRAS wanted to make it as widely available as possible. The sad reality is that it is not unusual to meet someone with RA who does not realise that they are at an increased risk of heart disease, so they are far less likely to address factors such as smoking, weight and diet which are firmly within their control.

Objectives: Our aim was to create an engaging and interactive online programme to educate people with RA about heart disease and atherosclerosis. This programme should; explain in simple terms why they are at increased risk; include the opportunity to determine individual risk factors thereby allowing a QRisk2 score to be performed; provide a cognitive-behavioural framework to empower people to change their behaviours and achieve a healthier lifestyle, thereby reducing risk of premature death from heart disease.

Methods: The participant manual created for the group programme and working closely with Dr. John and other health professionals in Dudley (exercise physiologist, smoking cessation nurse, dietician, health psychologist) and patients who had attended the programme, we explored with our creative film production team the best way to adapt this to create a really engaging on-line experience which would allow participants to undertake the programme over time whilst working through the behaviour change goal-setting process. Two days of filming were done in Dudley and Maidenhead followed by a period of editing, additional recording and review. Beta testing of the programme will be conducted in February, piloting in March and launch anticipated for April 2017.

Results: Evaluation of both the programme and the potential to change health behaviours will be measured on completion of the programme and actual behaviour change will be measured at 6 months.

Quote from a patient who participated in the face to face programme: “Before I did this programme I thought that I was doing pretty well in terms of diet and exercise but it showed me that there was a lot I wasn’t aware of, that my knowledge of lifestyle factors wasn’t adequate and I needed to do more to help myself. I found it a valuable and life-changing experience to do this programme.”

Conclusions: We are very excited about the launch of this programme as it is an important new resource addressing the major co-morbidity which shortens the lives of those with RA. It is unique in that not only does it provide patient education, but it also provides a structure through which patient can change their behaviour. Furthermore, it also illustrates what can be achieved when patient-led charity organisations work alongside healthcare professionals; we are hugely excited about its potential.

THE NEEDS AND PRIORITIES OF YOUNG PEOPLE LIVING WITH RHEUMATIC AND MUSCULOSKELETAL DISEASES IN ITALY: A SUB-ANALYSIS OF THE PARE YOUTH RESEARCH PROJECT

U.G. Viora 1, S. Ostuzzi 2, A. Alunno 3, 1on behalf of ANMAR Italia - ANMAR Young - EULAR Young PARE, 2ANMAR Italia, Torino, 3ANMAR Young, Anmar Italia, Rome, 1Rheumatology unit -dept. of Medicine, University of Perugia, Perugia, Italy; 2Eular Young Pare, Zurich, Switzerland

Background: In 2014 EULAR Young PARE conducted a research (PARE Youth Research) to gather information about how young people (aged 18–35) living with rheumatic and musculoskeletal diseases (RMDs) are organized in different European countries and to explore their specific needs, obstacles, preferences and priorities. The research was developed through a survey launched in countries with EULAR members organizations and a total of 2,339 validated responses from the target population were obtained. In 2015 ANMAR Young, Italian National Association for people with RMDs (ANMAR) youth group, was born aimed to create a network of young people with RMDs living in this country.

Objectives: Taken the socio-economical and cultural differences across countries, as well as the need to tailor interventions, activities and projects of national youth groups accordingly, the purpose of this study was to map out specific insights about Italian young people living with RMDs.

Methods: Data from Italian responders to the survey of the PARE Youth Research Project survey were extrapolated and answers were encoded to be analyzed using SPSS 21.0 software. Descriptive statistics were calculated in the whole group as well in subgroups of subjects as needed.

Results: 81 young Italian people living with RMDs responded to the survey: 75 females and 6 males. The conditions reported most often are rheumatoid arthritis (38%), juvenile idiopathic arthritis (23%), ankylosing spondylitis (15%). The work on PARE Youth Research’s Italian data shows some important insights, among which the most significant are the following: 84% report a delay in their studies due to the rheumatic condition, 92% report that the condition has affected their ability to work; 90% report the impact of RMD on social life, 70% report an impact on sexual life and 83% on mental health. Focusing on mental health issues, we highlight that 69% express the need for psychological support while only 43% have the possibility to access psychological support. Although all patients reported that after being diagnosed with an RMD they have access to a rheumatologist for regular follow-up visits, an average 3-year diagnostic delay is reported.

Conclusions: The results from the analysis of Italian responders to the survey represent a crucial starting point to put in light the unmet needs of Italian young people living with RMDs. These findings will be of great help to develop a fruitful national network of young people with RMDs on one hand and a focused collaboration with patient representatives, physicians, and health professionals (HPs) on the other. We believe that the awareness of physicians and HPs working in the field of rheumatology about the needs and priorities of young people with RMDs will ensure a better management of the disease and therefore lead to the reduction of the RMD burden in this subgroup of patients.

TO RAISE AWARENESS OF RHEUMATIC AND MUSCULOSKELETAL DISEASES AND TO PROVIDE THE OPPORTUNITY TO THE FINANCIALLY LESS ABLE TO RECEIVE TIMELY DIAGNOSIS AND INTERVENTION IN RMDs

Background: The timely and accurate diagnosis in most rheumatic diseases is still a big issue for patients as the choice of the appropriate doctor’s specialty is still at the discretion of the patient, mainly due to the poor organized health care services. Furthermore, the success of our campaign two years ago, when we gave the opportunity to people who might suffer from an RMD but who could not afford a rheumatologist to be examined for free, prompted our organization to offer not only free consultations but free lab tests as well.

Objectives: To raise awareness of RMDs and at the same time to enable people of lower income who may have the early warning signs of rheumatic diseases to be examined by a rheumatologist and have lab tests done at no cost.

Methods: Firstly, we found a sponsor who embraced our initiative and was willing to cover the cost of the whole campaign. Secondly, we contacted various medical laboratories to give us low estimates on the RMD tests and then we chose to collaborate with the ones offering us the lowest prices. Then we came into contact with all the rheumatologists in all the prefectures of the island and asked them to offer consultations free of charge according to their availability. On WAD, 12 October, we erected four stands in four central locations of our island with our logo, a banner, informative leaflets and a large number of well-informed volunteers to answer questions. From WAD we had to work in the mass and social media. A lot of people visited our stands, told us their problem and their signs and we wrote down the names and phone numbers of those we deemed needed a rheumatologist. As last time, there were people who had already been seeing a rheumatologist who wanted to take advantage
of this opportunity; we had to reject them as this was only available to people who had not been diagnosed previously. The following two days our office made an appointment for these people with a rheumatologist in their area. The doctors prescribed the necessary laboratory tests and gave a free voucher for the tests to those that needed them. The cost of the lab tests was covered by our association. Our office received a large number of calls from people who wanted to be tested and unfortunately, we could not accommodate all of them as our budget was limited.

Results: More than 267 people visited our stands and 209 people phoned our office asking to be tested. We made appointments for 123 people of whom 111 showed up for their appointments. The rheumatologists gave vouchers and prescribed lab tests for 89 of them. 12 rheumatologists volunteered their services gratis and more than 40 volunteers took part in the campaign.

Conclusions: People's awareness of RMDs is growing but there are still undiagnosed people due to financial constraints, inadequate health insurance coverage and lack of information. Since the demand for free testing is very high we will make every effort to be able to provide this opportunity to undiagnosed people again in the future!

AB1253-PARE

KID'S GET ARTHRITIS TOO - EXPANSION OF TARGET GROUPS

M. Ekroth, The Finnish Rheumatism Association, Helsinki, Finland

Background: The Finnish Rheumatism Association is generally perceived as a very strong alliance of older people. However in Finland there are more than 2000 children and youth suffering JIA and around 250 new ones get diagnosis yearly. Children will have their whole lives ahead with rheumatic disease, so they and their families also need information, support and friends.

Objectives: Support children and families living with JIA in different ways

Get in touch with families, understand what their needs are, provide them with the correct information and promote their interests

Bring new energy into the families' challenging lives affected by illness

Build a supporting network for the families and increase mental well-being

Rejuvenate the brand of our association

Methods: Ordered international top photographer to photograph the JIA children and families. Created an entirely new high-quality imagery and expression to all Rheumatism Association children communications.

Created the “Puppana” bunny soft toy and the mascot costume.

Have the rheumatism-week campaign: Kids Get Arthritis Too: one week nation wide big radio campaign with a child’s voice, a poster campaign in hospitals, our local associations and public spaces.

First aid packet with information of JIA, some toys, and the Puppana mascot. Packets were delivered to all Finnish hospitals, juvenile rheumatoid arthritis units. The rheumatologist gives a packet for a child who receives a diagnosis.

Introduced the action program of two annual nationwide large children’s events Joy of Life.

New juvenile rheumatoid arthritis sites for children and families on our new website.

Support the activities of local associations directed for children and families.

Create a new web portal support activities “Reumanakanssa.fi”. International Trials Organisation) in co-operation. Translated into Finnish and added to the new website where we built ABC for JIA.

Results: The brand of the Finnish Rheumatism Association has become more modern and wider.

People have experienced an eye opening campaign, the children suffer from rheumatism–arthritis can be a disease at all ages

Families with children have been reached more, they have joined our social media groups, the event attracted more than 250 children and their families, new families with children have joined the association, some of the local association has begun to organize groups of juvenile rheumatoid arthritis

Fund-raising, it was very easy to find sponsors for children activities and it also helped in common fundraising.

Children suffering from rheumatoid have experienced a positive campaign, it feels better when people’s attitudes change, and no longer think that they’re suffering from “a disease of the elderly”.

Cooperation with arthritis professionals has intensified and improved. Their want to do more co-operation and they guide patients to more actively explore the Finnish Rheumatism Association activities.

Conclusions: Operation for JIA children and their families are needed.

Children’s powerful vision of the activities have a positive impact on the brand and fundraising organization.

The positivity of this type of cooperation with arthritis professionals to approximate intervals and supported by more co-operation

It’s relatively easy to receive sponsor funds for the development of children’s activities

Children and families inclusion will bring new energy and confidence in the future among local associations
